Get the Most from JMP®

Whether you are a first-time or a long-time user, there is always something to learn about JMP.

Visit JMP.com to find the following:

- live and recorded webcasts about how to get started with JMP
- video demos and webcasts of new features and advanced techniques
- details on registering for JMP training
- schedules for seminars being held in your area
- success stories showing how others use JMP
- a blog with tips, tricks, and stories from JMP staff
- a forum to discuss JMP with other users

JSL Syntax Reference

Chapter **1**

Learn about JMP

Documentation and Additional Resources

This chapter includes details about JMP documentation, such as book conventions, descriptions of each JMP book, the Help system, and where to find other support.

Contents

Formatting Conventions

The following conventions help you relate written material to information that you see on your screen:

- Sample data table names, column names, pathnames, filenames, file extensions, and folders appear in Helvetica font.

- Code appears in Lucida Sans Typewriter font.

- Code output appears in *Lucida Sans Typewriter* italic font and is indented farther than the preceding code.

- **Helvetica bold** formatting indicates items that you select to complete a task:
  - buttons
  - check boxes
  - commands
  - list names that are selectable
  - menus
  - options
  - tab names
  - text boxes

- The following items appear in italics:
  - words or phrases that are important or have definitions specific to JMP
  - book titles
  - variables

- Features that are for JMP Pro only are noted with the JMP Pro icon **JMP PRO**. For an overview of JMP Pro features, visit https://www.jmp.com/software/pro/.

Note: Special information and limitations appear within a Note.

Tip: Helpful information appears within a Tip.

JMP Documentation

JMP offers documentation in various formats, from print books and Portable Document Format (PDF) to electronic books (e-books).

- Open the PDF versions from the **Help > Books** menu.

- All books are also combined into one PDF file, called *JMP Documentation Library*, for convenient searching. Open the *JMP Documentation Library* PDF file from the **Help > Books** menu.

- You can also purchase printed documentation and e-books on the SAS website:

  https://www.sas.com/store/search.ep?keyWords=JMP

JMP Documentation Library

The following table describes the purpose and content of each book in the JMP library.

Document Title	Document Purpose	Document Content
Discovering JMP	If you are not familiar with JMP, start here.	Introduces you to JMP and gets you started creating and analyzing data. Also learn how to share your results.
Using JMP	Learn about JMP data tables and how to perform basic operations.	Covers general JMP concepts and features that span across all of JMP, including importing data, modifying columns properties, sorting data, and connecting to SAS.

Document Title	Document Purpose	Document Content
Basic Analysis	Perform basic analysis using this document.	Describes these Analyze menu platforms: • Distribution • Fit Y by X • Tabulate • Text Explorer Covers how to perform bivariate, one-way ANOVA, and contingency analyses through Analyze > Fit Y by X. How to approximate sampling distributions using bootstrapping and how to perform parametric resampling with the Simulate platform are also included.
Essential Graphing	Find the ideal graph for your data.	Describes these Graph menu platforms: • Graph Builder • Scatterplot 3D • Contour Plot • Bubble Plot • Parallel Plot • Cell Plot • Scatterplot Matrix • Ternary Plot • Treemap • Chart • Overlay Plot The book also covers how to create background and custom maps.
Profilers	Learn how to use interactive profiling tools, which enable you to view cross-sections of any response surface.	Covers all profilers listed in the Graph menu. Analyzing noise factors is included along with running simulations using random inputs.

Document Title	Document Purpose	Document Content
Design of Experiments Guide	Learn how to design experiments and determine appropriate sample sizes.	Covers all topics in the DOE menu and the Specialized DOE Models menu item in the Analyze > Specialized Modeling menu.
Fitting Linear Models	Learn about Fit Model platform and many of its personalities.	Describes these personalities, all available within the Analyze menu Fit Model platform: - Standard Least Squares - Stepwise - Generalized Regression - Mixed Model - MANOVA - Loglinear Variance - Nominal Logistic - Ordinal Logistic - Generalized Linear Model

Document Title	Document Purpose	Document Content
Predictive and Specialized Modeling	Learn about additional modeling techniques.	Describes these Analyze > Predictive Modeling menu platforms:

Describes these Analyze > Predictive Modeling menu platforms:

- Modeling Utilities
- Neural
- Partition
- Bootstrap Forest
- Boosted Tree
- K Nearest Neighbors
- Naive Bayes
- Model Comparison
- Formula Depot

Describes these Analyze > Specialized Modeling menu platforms:

- Fit Curve
- Nonlinear
- Functional Data Explorer
- Gaussian Process
- Time Series
- Matched Pairs

Describes these Analyze > Screening menu platforms:

- Response Screening
- Process Screening
- Predictor Screening
- Association Analysis
- Process History Explorer

The platforms in the Analyze > Specialized Modeling > Specialized DOE Models menu are described in *Design of Experiments Guide*.

Document Title	Document Purpose	Document Content
Multivariate Methods	Read about techniques for analyzing several variables simultaneously.	Describes these Analyze > Multivariate Methods menu platforms: • Multivariate • Principal Components • Discriminant • Partial Least Squares • Multiple Correspondence Analysis • Factor Analysis • Multidimensional Scaling • Item Analysis Describes these Analyze > Clustering menu platforms: • Hierarchical Cluster • K Means Cluster • Normal Mixtures • Latent Class Analysis • Cluster Variables
Quality and Process Methods	Read about tools for evaluating and improving processes.	Describes these Analyze > Quality and Process menu platforms: • Control Chart Builder and individual control charts • Measurement Systems Analysis • Variability / Attribute Gauge Charts • Process Capability • Pareto Plot • Diagram • Manage Spec Limits

Document Title	Document Purpose	Document Content
Reliability and Survival Methods	Learn to evaluate and improve reliability in a product or system and analyze survival data for people and products.	Describes these Analyze > Reliability and Survival menu platforms: • Life Distribution • Fit Life by X • Cumulative Damage • Recurrence Analysis • Degradation and Destructive Degradation • Reliability Forecast • Reliability Growth • Reliability Block Diagram • Repairable Systems Simulation • Survival • Fit Parametric Survival • Fit Proportional Hazards
Consumer Research	Learn about methods for studying consumer preferences and using that insight to create better products and services.	Describes these Analyze > Consumer Research menu platforms: • Categorical • Choice • MaxDiff • Uplift • Multiple Factor Analysis
Scripting Guide	Learn about taking advantage of the powerful JMP Scripting Language (JSL).	Covers a variety of topics, such as writing and debugging scripts, manipulating data tables, constructing display boxes, and creating JMP applications.
JSL Syntax Reference	Read about many JSL functions on functions and their arguments, and messages that you send to objects and display boxes.	Includes syntax, examples, and notes for JSL commands.

Note: The **Books** menu also contains two reference cards that can be printed: The *Menu Card* describes JMP menus, and the *Quick Reference* describes JMP keyboard shortcuts.

JMP Help

JMP Help is an abbreviated version of the documentation library that provides targeted information. You can open JMP Help in several ways:

- On Windows, press the F1 key to open the Help system window.

- Get help on a specific part of a data table or report window. Select the Help tool ❓ from the **Tools** menu and then click anywhere in a data table or report window to see the Help for that area.

- Within a JMP window, click the **Help** button.

- Search and view JMP Help on Windows using the **Help > Help Contents**, **Search Help**, and **Help Index** options. On Mac, select **Help > JMP Help**.

- Search the Help at https://jmp.com/support/help/ (English only).

Additional Resources for Learning JMP

In addition to JMP documentation and JMP Help, you can also learn about JMP using the following resources:

- "Tutorials"
- "Sample Data Tables"
- "Learn about Statistical and JSL Terms"
- "Learn JMP Tips and Tricks"
- "Tooltips"
- "JMP User Community"
- "JMP Books by Users"
- "The JMP Starter Window"

Tutorials

You can access JMP tutorials by selecting **Help > Tutorials**. The first item on the **Tutorials** menu is **Tutorials Directory**. This opens a new window with all the tutorials grouped by category.

If you are not familiar with JMP, then start with the **Beginners Tutorial**. It steps you through the JMP interface and explains the basics of using JMP.

The rest of the tutorials help you with specific aspects of JMP, such as designing an experiment and comparing a sample mean to a constant.

Sample Data Tables

All of the examples in the JMP documentation suite use sample data. Select **Help > Sample Data Library** to open the sample data directory.

To view an alphabetized list of sample data tables or view sample data within categories, select **Help > Sample Data**.

Sample data tables are installed in the following directory:

On Windows: C:\Program Files\SAS\JMP\14\Samples\Data

On Macintosh: \Library\Application Support\JMP\14\Samples\Data

In JMP Pro, sample data is installed in the JMPPRO (rather than JMP) directory. In JMP Shrinkwrap, sample data is installed in the JMPSW directory.

To view examples using sample data, select **Help > Sample Data** and navigate to the Teaching Resources section. To learn more about the teaching resources, visit http://jmp.com/tools.

Learn about Statistical and JSL Terms

The **Help** menu contains the following indexes:

Statistics Index   Provides definitions of statistical terms.

Scripting Index   Lets you search for information about JSL functions, objects, and display boxes. You can also edit and run sample scripts from the Scripting Index.

Learn JMP Tips and Tricks

When you first start JMP, you see the Tip of the Day window. This window provides tips for using JMP.

To turn off the Tip of the Day, clear the **Show tips at startup** check box. To view it again, select **Help > Tip of the Day**. Or, you can turn it off using the Preferences window.

Tooltips

JMP provides descriptive tooltips when you place your cursor over items, such as the following:

• Menu or toolbar options

- Labels in graphs

- Text results in the report window (move your cursor in a circle to reveal)

- Files or windows in the Home Window

- Code in the Script Editor

Tip: On Windows, you can hide tooltips in the JMP Preferences. Select **File > Preferences > General** and then deselect **Show menu tips**. This option is not available on Macintosh.

JMP User Community

The JMP User Community provides a range of options to help you learn more about JMP and connect with other JMP users. The learning library of one-page guides, tutorials, and demos is a good place to start. And you can continue your education by registering for a variety of JMP training courses.

Other resources include a discussion forum, sample data and script file exchange, webcasts, and social networking groups.

To access JMP resources on the website, select **Help > JMP User Community** or visit https://community.jmp.com/.

JMP Books by Users

Additional books about using JMP that are written by JMP users are available on the JMP website:

https://www.jmp.com/en_us/software/books.html

The JMP Starter Window

The JMP Starter window is a good place to begin if you are not familiar with JMP or data analysis. Options are categorized and described, and you launch them by clicking a button. The JMP Starter window covers many of the options found in the Analyze, Graph, Tables, and File menus. The window also lists JMP Pro features and platforms.

- To open the JMP Starter window, select **View** (**Window** on the Macintosh) **> JMP Starter**.

- To display the JMP Starter automatically when you open JMP on Windows, select **File > Preferences > General**, and then select **JMP Starter** from the Initial JMP Window list. On Macintosh, select **JMP > Preferences > Initial JMP Starter Window**.

Technical Support

JMP technical support is provided by statisticians and engineers educated in SAS and JMP, many of whom have graduate degrees in statistics or other technical disciplines.

Many technical support options are provided at https://www.jmp.com/support, including the technical support phone number.

Chapter **2**

JSL Functions
Summary of Functions, Operators, and Messages

This topic provides abbreviated descriptions for many of JMP's functions, operators, and general object messages. For complete information about functions, see the JMP Scripting Index. In JMP, select **Help > Scripting Index**.

For information about platform messages, see the Scripting Platforms chapter in the *Scripting Guide*.

Contents

Assignment Functions

JSL also provides operators for in-place arithmetic, or *assignment operators*. These operations are all done in place, meaning that the result of the operation is assigned to the first argument. The most basic assignment operator is the = operator (or the equivalent function `Assign`). For example, if *a* is 3 and you do a+=4, then *a* becomes 7.

The first argument to an assignment function must be something capable of being assigned (an *L-value*). You cannot do something like 3+=4, because 3 is just a value and cannot be reassigned. However, you can do something like a+=4, because *a* is a variable whose value you can set.

`Add To(a, b)`

a+=b

Description

Adds *a* and *b* and places the sum into *a*.

Returns

The sum.

Arguments

a   Must be a variable.

b   Can be a variable, number, or matrix.

Notes

The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.

For `Add To()`: Only two arguments are permitted. If one or no argument is specified, `Add To()` returns a missing value. Any arguments after the first two are ignored.

For a+=b: More than two arguments can be strung together. JMP evaluates pairs from right to left, and each sum is placed in the left-hand variable. All arguments except the last must be a variable.

Example

a+=b+=c

JMP adds *b* and *c* and places the sum into *b*. Then JMP adds *a* and *b* and places the sum into *a*.

See Also

The Data Structures chapter in the *Scripting Guide*.

Assign(a, b)

a=b

Description

Places the value of *b* into *a*.

Returns

The new value of *a*.

Arguments

a   Must be a variable.

b   Can be a variable, number, or matrix.

Notes

a must be a variable, because it must be able to accept a value change. A number as the first argument produces an error. If *b* is some sort of expression, it's evaluated first and the result is placed into *a*.

Divide To(a, b)

a/=b

Description

Divides *a* by *b* and places the result into *a*.

Returns

The quotient.

Arguments

a   Must be a variable.

b   Can be a variable, number, or matrix.

See Also

The Data Structures chapter in the *Scripting Guide*.

Multiply To(a, b)

a*=b

Description

Multiplies *a* and *b* and places the product into *a*.

Returns

The product.

Arguments

a   Must be a variable.

b   Can be a variable, number, or matrix.

Notes

The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.

For `Multiply To()`: Only two arguments are permitted. If one or no argument is specified, `Multiply To()` returns a missing value. Any arguments after the first two are ignored.

For `a*=b`: More than two arguments can be strung together. JMP evaluates pairs from right to left, and each product is placed in the left-hand variable. All arguments except the last must be a variable.

Example

```
a*=b*=c
```

JMP multiplies *b* and *c* and places the product into *b*. Then JMP multiplies *a* and *b* and places the product into *a*.

See Also

The Data Structures chapter in the *Scripting Guide*.

PostDecrement(a)

a--

Description

Post-decrement. Subtracts 1 from *a* and places the difference into *a*.

Returns

a-1

Argument

a   Must be a variable.

Notes

If `a--` or `Post Decrement(a)` is inside another expression, the expression is evaluated first, and then the decrement operation is performed. This expression is mostly used for loop control.

PostIncrement(a)

a++

Description

Post-increment. Adds 1 to *a* and places the sum into *a*.

Returns

a+1

Argument

a   Must be a variable.

Notes

If `a++` or `PostIncrement(a)` is inside another expression, the expression is evaluated first, and then the increment operation is performed. Mostly used for loop control.

```
Subtract To(a, b)
```

`a-=b`

Description

Subtracts *b* from *a* and places the difference into *a*.

Returns

The difference.

Arguments

a   Must be a variable.

b   Can be a variable, number, or matrix.

Notes

The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.

For `SubtractTo()`: Only two arguments are permitted. If fewer than two or more than two arguments is specified, `SubtractTo()` returns a missing value.

For `a-=b`: More than two arguments can be strung together. JMP evaluates pairs from right to left, and each difference is placed in the left-hand variable. All arguments except the last must be a variable.

Example

```
 a-=b-=c
```

JMP subtracts *c* from *b* and places the difference into *b*. Then JMP subtracts *b* from *a* and places the difference into *a*.

See Also

The Data Structures chapter in the *Scripting Guide*.

Character Functions

Most character functions take character arguments and return character strings, although some take numeric arguments or return numeric data. Arguments that are literal character strings must be enclosed in quotation marks.

The Types of Data chapter in the *Scripting Guide* provides more details about some of the functions.

Blob To Char(blob, <"encoding">)

Description

Reinterpret binary data as a Unicode string.

Returns

A string.

Arguments

blob a binary large object.

encoding Optional quoted string that specifies an encoding. The default encoding for the character string is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and euc-jp are also supported.

Notes

The optional argument *ascii* is intended to make conversions of blobs containing normal ASCII data simpler when the data might contain CR, LF, or TAB characters (for example) and those characters do not need any special attention.

Blob To Matrix(blob, "type", bytes, "endian", <nCols>)

Description

Creates a matrix by converting each byte in the blob to numbers.

Returns

A matrix that represents the blob.

Arguments

blob A blob or reference to a blob.

type A quoted string that contains the named type of number. The options are int, uint, or float.

bytes Byte size of the data in the blob. Options are 1, 2, 4, or 8.

endian A quoted string that contains a named type that indicates whether the first byte is the most significant. Options are as follows:

– "big" indicates that the first byte is the most significant.

– "little" indicates that the first byte is the least significant.

– "native" indicates that the machine's native format should be used.

nCols Optional. Specify the number of columns in the matrix. The default value is 1.

Char(x, <width>, <decimal>)

Description

Converts an expression or numeric value into a character string.

Returns

A string.

Arguments

x   an expression or a numeric value. An expression must be quoted with `Expr()`.
Otherwise, its evaluated value is converted to a string.

width   optional number that sets the maximum number of characters in the string.

decimal   optional number that sets the maximum number of places after the decimal that
is included in the string.

Note

The *width* argument overrides the *decimal* argument.

Example

```
Char( Pi(), 10, 4)
    "3.1416"

Char( Pi(), 3, 4)
    "3.1"
```

Char To Blob(string, <"encoding">)

Description

Converts a string of characters into a binary (blob).

Returns

A binary object.

Arguments

string   Quoted string or a reference to a string.

encoding   Optional quoted string that specifies an encoding. The default encoding for the
blob is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and
euc-jp are also supported.

Notes

Converting BLOBS into printable format escapes \ (in addition to ~ " ! and characters
outside of the printable ASCII range) into hex notation (~5C for the backslash character).

```
x = Char To Blob( "abc\def\!n" );
y = Blob To Char( x, encoding = "ASCII~HEX" );
If(
    y == "abc~5Cdef~0A", "JMP 12.2 and later behavior",
    y == "abc\def~0A", "Pre-JMP 12.2 behavior"
);
    "JMP 12.2 and later behavior" // output
```

```
Char To Hex(value, <"integer" | "encoding">)
```

```
Hex(value, <"integer" | "encoding">)
```

Description

Converts the given value and encoding into its hexadecimal representation.

Returns

A hexadecimal string.

Arguments

`value` Any number, quoted string, or blob.

`integer` Switch that causes the value to be interpreted as an integer.

`encoding` Optional quoted string that specifies an encoding. The default encoding is `utf-8`. `utf-16le`, `utf-16be`, `us-ascii`, `iso-8859-1`, `ascii~hex`, `shift-jis`, and `euc-jp` are also supported.

```
Collapse Whitespace("text")
```

Description

Trims leading and trailing whitespace and replaces interior whitespace with a single space. That is, if more than one white space character is present, the `Collapse Whitespace` function replaces the two spaces with one space.

Returns

A quoted string.

Arguments

`text` A quoted string.

```
Concat(a, b)
```

```
Concat(A, B)
```

```
a||b
```

```
A||B
```

Description

For strings: Appends the string *b* to the string *a*. Neither argument is changed.

For lists: Appends the list *b* to the list *a*. Neither argument is changed.

For matrices: Horizontal concatenation of two matrices, A and B.

Returns

For strings: A string composed of the string *a* directly followed by the string *b*.

For lists: A list composed of the list *a* directly followed by the list *b*.

For matrices: A matrix.

Arguments

Two or more strings, string variables, lists, or matrices.

Notes

More than two arguments can be strung together. Each additional string is appended to the end, in left to right order. Each additional matrix is appended in left to right order.

Example

```
a = "Hello"; b = " "; c = "World"; a || b || c;
  "Hello World"
d = {"apples", "bananas"}; e = {"peaches", "pears"}; Concat( d, e );
  {"apples", "bananas", "peaches", "pears"}
A = [1 2 3]; B = [4 5 6]; Concat( A, B );
  [1 2 3 4 5 6]
```

Concat Items

See "Concat Items({string1, string2, ...}, <delimiter>})" on page 156.

Concat To(a, b)

Concat To(a, b)

a||=b

A||=B

Description

For strings: Appends the string *b* to the string *a* and places the new concatenated string into *a*.

For matrices: Appends the matrix *b* to the matrix *a* and places the new concatenated matrix into *a*.

For lists: Appends the list *b* to the list and places the new concatenated list into *a*.

Returns

For strings: A string composed of the string *a* directly followed by the string *b*.

For matrices: A matrix.

For lists: A list composed of the list *a* directly followed by the list *b*.

Arguments

Two or more strings, string variables, matrices, or lists. The first variable must be a variable whose value can be changed.

Notes

More than two arguments can be strung together. Each additional string, matrix, or list is appended to the end, in left to right order.

Example

```
a = "Hello"; b = " "; c = "World"; Concat To( a, b, c ); Show( a );
  a = "Hello World"
A = [1 2 3]; B = [4 5 6]; Concat To( A, B ); Show( A );
  A = [1 2 3 4 5 6];
d = {"apples", "bananas"}; e = {"peaches", "pears"}; Concat to(d,e); Show( d
  );
  d = {"apples", "bananas", "peaches", "pears"};
```

Contains(whole, part, <start>)

Description

Determines whether *part* is contained within *whole*.

Returns

If *part* is found: For lists, strings, and namespaces, the numeric position where the first occurrence of *part* is located. For associative arrays, 1.

If *part* is not found, 0 is returned in all cases.

Arguments

whole A string, list, namespace, or associative array.

part For a string or namespace, a string that can be part of the string *whole*. For a list, an item that can be an item in the list *whole*. For an associative array, a key that can be one of the keys in the map *whole*.

start An optional numeric argument that specifies a starting point. within *whole*. If *start* is negative, contains searches *whole* for *part* backwards, beginning with the position specified by the length of *whole* – *start*. Note that *start* is meaningless for associative arrays and is ignored.

Example

```
nameList={"Katie", "Louise", "Jane", "Jaclyn"};
r = Contains(nameList, "Katie");
```

The example returns a 1 because "Katie" is the first item in the list.

Contains Item(x, <item | list | pattern>, <delimiter>)

Description

Identifies multiple responses by searching for the specified item, list, pattern, or delimiter. The function can be used on columns with the Multiple Response modeling type or column property.

Returns

Returns a Boolean that indicates whether the word (item), one of a list of words (list), or pattern (pattern) matches one of the words in the text represented by *x*. Words are delimited by the characters in the optional delimiter (delimiter) string. A comma, ",",

character is the default delimiter. Blanks are trimmed from the ends of each extracted word
from the input text string (*x*).

Example

The following example searches for *"pots"* followed by a comma and then outputs the
result.

```
x = "Franklin Garden Supply is a leading online store featuring garden decor,
   statues, pots, shovels, benches, and much more.";
b = Contains Item( x, "pots", "," );
If( b,
   Write( "The specified items were found." ), Write( "No match." )
);
    The specified items were found.
```

Ends With(string, substring)

Description

Determines whether substring appears at the end of string.

Returns

1 if string ends with substring, otherwise 0.

Arguments

string A quoted string or a string variable. Can also be a list.

substring A quoted string or a string variable. Can also be a list.

Equivalent Expression

```
Right(string, Length(substring)) == substring
```

Hex(value, <"integer" | encoding="enc")

See

Hex To Blob(string)

Description

Converts the quoted hexadecimal *string* (including whitespace characters) to a blob
(binary large object).

Example

```
Hex To Blob( "4A4D50" );
    Char To Blob("JMP", "ascii~hex")
```

Hex To Char(string, <encoding>)

Description

Converts the quoted hexadecimal *string* to its character equivalent.

Example

Hex To Char("30") results in "0".

Notes

The default encoding for character string is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and euc-jp are also supported.

Hex To Number(string)

Description

Converts the quoted hexadecimal *string* to its integer or its floating number equivalent.

Example

```
Hex To Number( "80" );
    128
```

Note

16-digit hexadecimal numbers are converted as IEEE 754 64-bit floating point numbers.

Whitespace between bytes (or pairs of digits) and in the middle of bytes is permitted (for example, FF 1919 and F F1919).

Insert

See "Insert(source, item, <position>)" on page 157.

Insert Into

See "Insert Into(source, item, <position>)" on page 158.

Item(n, string, <delimiters>)

Description

Extracts the nth word from a quoted *string* according to the quoted string *delimiters* given. The default delimiter is space. If you include a third argument, any and all characters in that argument are taken to be delimiters.

Note

Item() is the same as Word() except that Item() treats each delimiter character as a separate delimiter, and Word() treats several adjacent delimiters as a single delimiter.

```
Item( 4,"the  quick, brown fox", ", " ); // notice two spaces before "quick"
    "brown"
Word( 4,"the  quick, brown fox", ", " );
    "fox"
```

```
Left(string, n, <filler>)
```

```
Left(list, n, <filler>)
```

Description

Returns a truncated or padded version of the original *string* or *list*. The result contains the left *n* characters or list items, padded with any *filler* on the right if the length of *string* is less than *n*.

```
Length(string)
```

Description

Calculates the number of characters (length) of the quoted *string*.

```
Lowercase(string)
```

Description

Converts any upper case character found in quoted *string* to the equivalent lowercase character.

```
Munger(string, offset, find|length)
```

```
Munger(string, offset, find, replace)
```

Description

Computes new character strings from the quoted *string* by inserting or deleting characters. It can also produce substrings, calculate indexes, and perform other tasks depending on how you specify its arguments.

Offset is a numeric expression indicating the starting position to search in the string. If the *offset* is greater than the position of the first instance of the find argument, the first instance is disregarded. If the *offset* is greater than the search string's length, Munger uses the string's length as the *offset*.

```
Num(string)
```

Description

Converts a character string into a number.

```
Regex("source", "pattern", (<replacementString>, <GLOBALREPLACE>),
<format>, <IGNORECASE>)
```

Description

Searches for the *pattern* within the *source* string.

Returns

The matched text as a string or numeric missing if there was no match.

Arguments

`source` A quoted string.

`pattern` A quoted regular expression.

`format` Optional. A backreference to the capturing group. The default is /0, which is the entire matched string. /n returns the nth match.

`IGNORECASE` Optional. The search is case sensitive, unless you specify `IGNORECASE`.

`GLOBALREPLACE` Optional with a replacement string. Applies the regular expression to the source string repeatedly until all matches are found.

Remove

See "Remove(source, position, <n>)" on page 159.

Remove From

See "Remove From(source, position, <n>)" on page 159.

Repeat(source, a)

Repeat(matrix, a, b)

Description

Returns a copy of *source* concatenated with itself *a* times. Or returns a matrix composed of *a* row repeats and *b* column repeats. The *source* can be text, a matrix, or a list.

Reverse

See "Reverse(source)" on page 159.

Reverse Into

See "Reverse Into(source)" on page 160.

Right(string, n, <filler>)

Right(list, n, <filler>)

Description

Returns a truncated or padded version of the original *string* or *list*. The result contains the right *n* characters or list items, padded with any *filler* on the left if the length of *string* is less than *n*.

Shift

See "Shift(source, <n>)" on page 160.

Shift Into

See "Shift Into(source, <n>)" on page 160.

Starts With(string, substring)

Description

Determines whether substring appears at the start of *string*.

Returns

1 if *string* starts with *substring,* otherwise 0.

Arguments

string A quoted string or a reference to one. Can also be a list.

substring A quoted string or a reference to one. Can also be a list.

Equivalent Expression

Left(string, Length(substring)) = = substring

Substitute

See "Substitute(string, substring, replacementString, ...)" on page 161.

Substitute Into

See "Substitute Into(string, substring, replacementString, ...)" on page 161.

Substr(string, start, length)

Description

Extracts the characters that are the portion of the first argument beginning at the position given by the second argument and ending based on the number of characters specified in the third argument. The first argument can be a character column or value, or an expression evaluating to same. The starting argument and the length argument can be numbers or expressions that evaluate to numbers.

Example

This example extracts the first name:

```
Substr( "Katie Layman", 1, 5 );
```

The function starts at position 1, reads through position 5, and ignores the remaining characters, which yields "Katie."

Titlecase("text")

Description

Converts the string to title case, that is, each word in the string has an initial uppercase character and subsequent lowercase characters.

Returns

A quoted string.

Arguments

`text` A quoted string.

Example

For example, the following function:

```
Titlecase( "veronica layman " )
```

returns the following string:

```
"Veronica Layman"
```

Trim("text",<left|right|both>)

Trim Whitespace("text",<left|right|both>)

Description

Removes leading and trailing whitespace.

Results

A quoted string.

Arguments

`text` A quoted string.

`left|right|both` The second argument determines if whitespace is removed from the left, the right, or both ends of the string. If no second argument is used, whitespace is removed from both ends.

Example

For example, the following command:

```
Trim( "  John     ", both )
```

returns the following string:

```
"John"
```

Uppercase(string)

Description

Converts any lower case character found in the quoted *string* to the equivalent uppercase character.

Word(n, "text", <"delimiters">)

Description

Extracts the nth word from a character string according to the delimiters given. The default delimiter is space. If you include a third argument, any and all characters in that argument are taken to be delimiters.

Examples

This example returns the last name:

```
Word( 2, "Katie Layman" );
```

Note

Word() is the same as Item(), except that Item() treats each delimiter character as a separate delimiter, and Word() treats several adjacent delimiters as a single delimiter.

```
Item( 4,"the  quick brown fox" ); // notice two spaces before "quick"
    "fox"
Word( 4,"the  quick brown fox" );
    "brown
```

Words

See "Words("text", <"delimiters">)" on page 162.

XPath Query(xml, "xpath_expression")

Description

Runs an XPath expression on an XML document.

Returns

A list.

Arguments

xml A valid XML document.

xpath_expression A quoted XPath 1.0 expression.

Example

Suppose that you created a report of test results in JMP and exported important details to an XML document. The test results are enclosed in <result> tags.

The following example stores the XML document in a variable. The XPath Query expression parses the XML to find the text nodes inside the <result> tags. The results are returned in a list.

```
rpt =
"\[<?xml version="1.0" encoding="utf-8"?>
<JMP><report><title>Production Report</title>
<result>November 21st: Pass</result>
<result>November 22nd: Fail</result>
```

```
<note>Tests ran at 3:00 a.m.</note></report>
</JMP> ]\";
results = XPath Query( rpt, "//result/text()" );
    {"November 21st: Pass", "November 22nd: Fail"}
```

Character Pattern Functions

See the Types of Data chapter in the *Scripting Guide* book for more detailed information on constructing and using pattern matching expressions.

Pat Abort()

Description

Constructs a pattern that immediately stops the pattern match. The matcher does not back up and retry any alternatives. Conditional assignments are *not* made. Immediate assignments that were already made are kept.

Returns

0 when a match is stopped.

Argument

Pat Altern(pattern1, <pattern 2, ...>)

Description

Constructs a pattern that matches any one of the pattern arguments.

Returns

A pattern.

Argument

One or more patterns.

Pat Any("string")

Description

Constructs a pattern that matches a single character in the argument.

Returns

A pattern.

Argument

string a string.

Pat Arb()

Description

Constructs a pattern that matches an arbitrary string. It initially matches the null string. It then matches one additional character each time the pattern matcher backs into it.

Returns

A pattern.

Argument

Example

```
p = "the beginning" + Pat Arb() >? stuffInTheMiddle + "the end";
Pat Match( "in the beginning of the story, and not near the end, there are
    three bears", p );
Show( stuffInTheMiddle );
    stuffInTheMiddle = " of the story, and not near "
```

Pat Arb No(pattern)

Description

Constructs a pattern that matches zero or more copies of *pattern*.

Returns

A pattern.

Argument

pattern   a pattern to match against.

Example

```
adjectives = "large" | "medium" | "small" | "warm" | "cold" | "hot" | "sweet";
rc = Pat Match( "I would like a medium hot, sweet tea please",
                Pat Arbno( adjectives | Pat Any(", ") ) >> adj +
                ("tea" | "coffee" | "milk") );
Show( rc, adj );
    rc = 1;
    adj = " medium hot, sweet ";
```

Pat At(varName)

Description

Constructs a pattern that matches the null string and stores the current position in the source string into the specified JSL variable (*varName*). The assignment is immediate, and the variable can be used with expr() to affect the remainder of the match.

Returns

A pattern.

Argument

varName the name of a variable to store the result in.

Example

```
p = ":" + Pat At( listStart ) + Expr(
  If( listStart == 1,
     Pat Immediate( Pat Len( 3 ), early ),
     Pat Immediate( Pat Len( 2 ), late )
  )
);
early = "";
late = "";
Pat Match( ":123456789", p );
Show( early, late );
early = "";
late = "";
Pat Match( "    :123456789", p );
Show( early, late );
```

First this is produced:

```
early = "123"
late = ""
```

and later this:

```
early = ""
late = "12"
```

Pat Break("string")

Description

Constructs a pattern that matches zero or more characters that are not in its argument; it stops or breaks on a character in its argument. It fails if a character in its argument is not found (in particular, it fails to match if it finds the end of the source string without finding a break character).

Returns

A pattern.

Argument

string a string.

Pat Concat(pattern1, pattern2 <pattern 3, ...>)

Pattern1 + Pattern2 + ...

Description

Constructs a pattern that matches each pattern argument in turn.

Returns

A pattern.

Argument

Two or more patterns.

Pat Conditional(pattern, varName)

Description

Saves the result of the pattern match, if it succeeds, to a variable named as the second argument (*varName*) after the match is finished.

Returns

A pattern.

Arguments

pattern a pattern to match against.

varName the name of a variable to store the result in.

Example

```
type = "undefined";
rc = Pat Match(
    "green apples",
    Pat Conditional( "red" | "green", type ) + " apples"
);
Show( rc, type );
    rc = 1;
    type = "green";
```

Pat Fail()

Description

Constructs a pattern that fails whenever the matcher attempts to move forward through it. The matcher backs up and tries different alternatives. If and when there are no alternatives left, the match fails and Pat Match returns 0.

Returns

0 when a match fails.

Argument

Pat Fence()

Description

Constructs a pattern that succeeds and matches the null string when the matcher moves forward through it, but fails when the matcher tries to back up through it. It is a one-way trap door that can be used to optimize some matches.

Returns

1 when the match succeeds, 0 otherwise.

Argument

Pat Immediate(pattern, varName)

Description

Saves the result of the pattern match to a variable named as the second argument (*varName*) immediately.

Returns

A pattern.

Arguments

pattern a pattern to match against.

varName the name of a variable to store the result in.

Example

```
type = "undefined";
rc = Pat Match(
    "green apples",
    ("red" | "green") >> type + " pears"
);
Show( rc, type );
    rc = 0
    type = "green"
```

Even though the match failed, the immediate assignment was made.

Pat Len(int)

Description

Constructs a pattern that matches n characters.

Returns

A pattern.

Argument

int an integer that specifies the number of characters.

```
Pat Match(SourceText, Pattern, <ReplacementText>, <NULL>, <ANCHOR>,
<MATCHCASE>, <FULLSCAN>)
```

Description

Pat Match executes the *Pattern* against the *SourceText*. The pattern must be constructed first, either inline or by assigning it to a JSL variable elsewhere.

Returns

1 if the pattern is found, 0 otherwise.

Arguments

SourceText A string or string variable that contains the text to be searched.

Pattern A pattern or pattern variable that contains the text to be searched for.

ReplacementText Optional string that defines text to replace the pattern in the source text.

NULL A placeholder for the third argument if ANCHOR, MATCHCASE, or FULLSCAN are necessary *and* there is no replacement text.

ANCHOR Optional command to start the pattern match to the beginning of the string. The following match fails because the pattern, "cream", is not found at the beginning of the string:

```
Pat Match( "coffee with cream and sugar", "cream", NULL, ANCHOR );
```

MATCHCASE Optional command to consider capitalization in the match. By default, Pat Match() is case insensitive.

FULLSCAN Optional command to force Pat Match to try all alternatives, which uses more memory as the match expands. By default, Pat Match() does not use FULLSCAN, and makes some assumptions that allow the recursion to stop and the match to succeed.

```
Pat Not Any("string")
```

Description

Constructs a pattern that matches a single character that is not in the argument.

Returns

A pattern.

Argument

string a string.

```
Pat Pos(int)
```

Description

Constructs patterns that match the null string if the current position is *int* from the left end of the string, and fail otherwise.

Returns

A pattern.

Argument

`int` an integer that specifies a position in a string.

`Pat R Pos(int)`

Description

Constructs patterns that match the null string if the current position is *int* from the right end of the string, and fails otherwise.

Returns

A pattern.

Argument

`int` an integer that specifies a position in a string.

`Pat R Tab(int)`

Description

Constructs a pattern that matches up to position n from the end of the string. It can match 0 or more characters. It fails if it would have to move backwards or beyond the end of the string.

Returns

A pattern.

Argument

`int` an integer that specifies a position in a string.

`Pat Regex(string)`

Description

Constructs a pattern that matches the regular expression in the quoted *string* argument.

Returns

A pattern.

Argument

`string` a string.

`Pat Rem()`

Description

Constructs a pattern that matches the remainder of the string. It is equivalent to `Pat R Tab(0)`.

Returns

A pattern.

Argument

Pat Repeat(pattern, minimum, maximum, GREEDY|RELUCTANT)

Description

Matches *pattern* between *minimum* and *maximum* times.

Returns

A pattern.

Arguments

pattern a pattern to match against.

minimum An integer that must be smaller than maximum.

maximum An integer that must be greater than minimum.

GREEDY|RELUCTANT If GREEDY is specified, it tries the maximum first and works back to the minimum. If RELUCTANT is specified, it tries the minimum first and works up to the maximum.

Notes

Pat Arbno(p) is the same as Pat Repeat(p, 0, infinity, RELUCTANT)

Pat Repeat(p) is the same as Pat Repeat(p, 1, infinity, GREEDY)

Pat Repeat(p, n) is the same as Pat Repeat(p, n, infinity, GREEDY)

Pat Repeat(p, n, m) is the same as Pat Repeat(p, n, m, GREEDY)

Pat Span("string")

Description

Constructs a pattern that matches one or more (not zero) occurrences of characters in its argument. It is greedy; it always matches the longest possible string. It fails rather than matching zero characters.

Returns

A pattern.

Argument

string a string.

Pat String("string")

Description

Constructs a pattern that matches its string argument.

Returns

A pattern.

Argument

`string` a string.

Pat Succeed()

Description

Constructs a pattern that always succeeds, even when the matcher backs into it. It matches the null string.

Returns

1 when the match succeeds.

Argument

Pat Tab(int)

Description

Constructs a pattern that matches forward to position *int* in the source string. It can match 0 or more characters. It fails if it would have to move backwards or beyond the end of the string.

Returns

A pattern.

Argument

`int` an integer that specifies a position in a string.

Pat Test(expr)

Description

Constructs a pattern that succeeds and matches the null string if *expr* is not zero and fails otherwise.

Returns

A pattern.

Argument

`expr` An expression.

Note

Usually the argument is wrapped with `expr()` because the test needs to be made on the current value of variables set by `Pat Immediate`, `Pat Conditional`, and `Pat At`. Without `expr`, the test is based on values that were known when the pattern was constructed, which

means the test always succeeds or always fails at pattern execution time, which is probably not what you want.

Example

```
nCats = 0;
whichCat = 3;
string = "catch a catnapping cat in a catsup factory";
rc = Pat Match(
   string,
   "cat" + Pat Test(
      Expr(
         nCats = nCats + 1;
         nCats == whichCat;
      )
   ),
   "dog"
);
Show( rc, string, nCats );
   rc = 1
   string = "catch a catnapping dog in a catsup factory"
   nCats = 3
```

Regex Match(source, pattern, <MATCHCASE>)

Description

Executes the pattern match in *pattern* against the quoted *source* string.

Returns

A pattern.

Argument

source a string.

pattern a pattern.

MATCHCASE Optional. The search is case insensitive unless you specify MATCHCASE.

Comment Functions

// comment

Description

Comments to end of line.

Notes

Everything after the // is ignored when running the script.

/* comment */

Description

A comment that can appear in the middle of a line of script.

Notes

Anything between the beginning tag /* and the end tag */ is ignored when running the script. This comment style can be used almost anywhere, even inside lists of arguments. If you place a comment inside a double-quoted string, the comment is treated merely as part of the string and not a comment. You cannot place comments in the middle of operators.

Examples

```
+/*comment*/=
:/*comment*/name
```

are invalid and produce errors. The first comment interrupts += and the second interrupts :name.

```
sums = {(a+b /*comment*/), /*comment*/ (c^2)}
```

is valid JSL; the comments are both ignored.

//!

Description

If placed on the first line of a script, this comment line causes the script to be run when opened in JMP without opening into the script editor window.

Notes

You can over-ride this comment when opening the file. Select **File > Open**. Hold the Ctrl key while you select the JSL file and click **Open**. Or right-click the file in the Home Window Recent Files list and select **Edit Script**. The script opens into a script window instead of being executed.

/*debug step*/

/*debug run*/

Description

If placed on the first line of a script, the script is opened into the debugger when it is run.

Notes

All letters must be lower case. There must be one space between debug and step or run, and there must be no other spaces present. Only one of these lines can be used, and it must be the first line of the script; a first line that is blank followed by this comment negates the debug command.

Comparison Functions

The comparison operators (<, <=, >, >=) work for numbers, strings, and matrices. For matrices, they produce a matrix of results. If you compare mixed arguments, such as strings with numbers or matrices, the result is a missing value. Comparisons involving lists are not allowed and also return missing values.

The equality operators (== and !=) work for numbers, strings, matrices, and lists. For matrices, they produce a matrix of results; for lists, they produce a single result. If you *test equality* of mixed results (for example. strings with numbers or matrices) the result is 0 or unequal.

Range check operators let you check whether something falls between two specified values:

```
a = 1;
Show( 1 <= a < 3 );
b = 2;
Show( 2 < b <= 3 );
   1 <= a < 3 = 1;
   2 < b <= 3 = 0;
```

Expressions with comparison operators are evaluated all at once, not in sequence

All the comparison operators are *eliding operators*. That means JMP treats arguments joined by comparison operators as one big clause, as opposed to the way most expressions are evaluated one operator at a time. Evaluating as a single clause produces different results than the more usual method of evaluating in pieces. For example, the following two statements are different:

```
12 < a < 13;
(12 < a) < 13;
```

The first statement checks whether *a* is between 12 and 13, because all three arguments and both operators are read and evaluated together. The second statement uses parentheses to regroup the operations explicitly to evaluate from left to right, which would be the normal way to evaluate most expressions. Thus it first checks whether 12 is less than *a*, returning 1 if true or 0 if false. Then it checks whether the result is less than 13, which is always true because 0 and 1 are both less than 13.

All the comparison operators are elided when they are used in matched pairs or in the unmatched pairs <... <= and <=... <. What this means is that if you want a comparison statement to be evaluated one comparison operator at a time, you should use parentheses ( ) to control the order of operations explicitly.

Equal(a, b, ...)

a==b==...

Description

Compares all the listed values and tests if they are all equal to each other.

Returns

1 (true) if all arguments evaluate to the same value.

0 (false) otherwise.

Arguments

Two or more variables, references, matrices, or numbers.

Notes

If more than two arguments are specified, a 1 is returned only if all arguments are exactly the same. This is typically used in conditional statements and to control loops.

The comparison is case-sensitive for string comparisons.

Greater(a, b, ...)

a>b>...

Description

Compares all the list values and tests if, in each pair, the left value is greater than the right.

Returns

1 (true) if *a* evaluates strictly greater than *b* (and *b* evaluates strictly greater than *c*, and so on).

0 (false) otherwise.

Arguments

Two or more variables, references, matrices, or numbers.

Notes

If more than two arguments are specified, a 1 is returned only if each argument is greater than the one that follows it. This is typically used in conditional statements and to control loops.

Greater, Less, GreaterOrEqual, and LessOrEqual can also be strung together. If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.

`Greater or Equal(a, b, ...)`

`a>=b>=...`

Description

Compares all the list values and tests if, in each pair, the left value is greater than or equal to the right.

Returns

1 (true) if *a* evaluates strictly greater than or equal to *b* (and *b* evaluates strictly greater than or equal to *c*, and so on).

0 (false) otherwise.

Arguments

Two or more variables, references, matrices, or numbers.

Notes

If more than two arguments are specified, a 1 is returned only if each argument is greater than or equal to the one that follows it. This is typically used in conditional statements and to control loops.

`Greater`, `Less`, `GreaterOrEqual`, and `LessOrEqual` can also be strung together. If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.

`Is Missing(expr)`

Description

Returns 1 if the expression yields a missing value and 0 otherwise.

`Less(a, b, ...)`

`a<b<...`

Description

Compares all the list values and tests if, in each pair, the left value is less than the right.

Returns

1 (true) if *a* evaluates strictly less than *b* (and *b* evaluates strictly less than *c*, and so on).

0 (false) otherwise.

Arguments

Two or more variables, references, matrices, or numbers.

Notes

If more than two arguments are specified, a 1 is returned only if each argument is less than the one that follows it. This is typically used in conditional statements and to control loops.

Greater, Less, GreaterOrEqual, and LessOrEqual can also be strung together. If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.

Less LessEqual(a, b, c, ...)

a<b<=c<=...

Description

Range check, exclusive below and inclusive above.

Returns

1 (true) if *b* is greater than *a* and less than or equal to *c*.

0 (false) otherwise.

Arguments

a, b, c variables, references, matrices, or numbers.

Notes

Returns 1 when two conditions are met: the first argument is less than the second argument, and each remaining argument is less than or equal to its argument on the right. This is typically used in conditional statements and to control loops.

Less or Equal(a, b, ...)

a<=b<=...

Description

Compares all the list values and tests if, in each pair, the left value is less than or equal to the right.

Returns

1 (true) if *a* evaluates strictly less than or equal to *b* (and *b* evaluates strictly less than or equal to *c*, and so on).

0 (false) otherwise.

Arguments

Two or more variables, references, matrices, or numbers.

Notes

If more than two arguments are specified, a 1 is returned only if each argument is less than or equal to the one that follows it. This is typically used in conditional statements and to control loops.

Greater, Less, GreaterOrEqual, and LessOrEqual can also be strung together. If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.

```
LessEqual Less(a, b, c, ...)
```

a<=b<c<...

Description

Range check, inclusive below and exclusive above.

Returns

1 (true) if *b* is greater than or equal to *a* and less than *c*.

0 (false) otherwise.

Arguments

`a, b, c` variables, references, matrices, or numbers.

Notes

Returns 1 when two conditions are met: the first argument is less than or equal to the second argument, and each remaining argument is less than its argument on the right. This is typically used in conditional statements and to control loops.

```
Not Equal(a, b)
```

a!=b

Description

Compares a and b and tests if they are equal.

Returns

0 (false) if *a* and *b* evaluate to the same value.

1 (true) otherwise.

Argument

`a, b` Any variable or number.

Notes

Mostly used for conditional statements and loop control.

Conditional and Logical Functions

```
And(a, b)
```

a&b

Description

Logical And.

Returns

1 (true) if both *a* and *b* are true.

0 (false) if either *a* or *b* is false or if both *a* and *b* are false.

Missing if either *a* or *b* is a missing value or if both *a* and *b* are missing values.

Arguments

Two or more variables or expressions.

Notes

More than two arguments can be strung together. a&b returns 1 (true) only if all arguments evaluate to true.

AndMZ(a, b)

AndV3(a, b)

a:&b

Description

Logical And with JMP 3 behavior, which treats missing values as 0.

Returns

1 (true) if both *a* and *b* are true.

0 (false) if either *a* or *b* is false or if both *a* and *b* are false.

0 (false) if either *a* or *b* is a missing value or if both *a* and *b* are missing values.

Arguments

Two or more variables or expressions.

Notes

More than two arguments can be strung together. a:&b returns 1 (true) only if all arguments evaluate to true. When opening a JMP 3 data table, this function is automatically used for any And function.

Break()

Description

Stops execution of a loop completely and continues to the statement following the loop.

Note

Break works with For and While loops, and also with For Each Row.

Choose(expr, r1, r2, r3, ..., rElse)

Description

Evaluates *expr*. If the value of *expr* is 1, *r1* is returned; if 2, the value of *r2* is returned, and so on. If no matches are found, the last argument (*rElse*) is returned.

Returns

The value whose index in the list of arguments matches *expr,* or the value of the last argument.

Arguments

`expr` an expression or a value.

`r1, r2, r3, ...` an expression or a value.

Continue()

Description

Ends the current iteration of a loop and begins the loop at the next iteration.

Note

`Continue` works with `For` and `While` loops, and also with `For Each Row`.

For(init, while, increment, body)

Description

Repeats the statement(s) in the *body* as long as the *while* condition is true. *Init* and *increment* control iterations.

Returns

Null.

Arguments

`init` Initialization of loop control counter.

`while` Condition for loop to continue or end. As long as the conditional statement while is true, the loop is iterated one more time. As soon as while is false, the loop is exited.

`increment` Increments (or decrements) the loop counter after while is evaluated every time the loop is executed.

`body` Any number of valid JSL expressions, glued together if there are more than one.

Example

```
mysum = 0; myprod = 1;
For( i = 1, i <= 10, i++, mysum += i; myprod *= i; );
Show( mysum, myprod );
   mysum = 55;
   myprod = 3628800;
```

For Each Row(<dt,> script)

Description

Repeats the *script* on each row of the data table.

Returns

Null.

Argument

dt Optional positional argument: a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.

script Any valid JSL expressions.

Example

The following example creates data table references and then iterates over each row in Big Class.jmp. If the value of age in a row is greater than 15, the age is printed to the log.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( dt, If( :age > 15, Show( :age ) ) );
```

If(condition, result, condition, ..., <elseResult>)

Description

Returns *result* when *condition* evaluates true. Otherwise returns next *result* when that *condition* evaluates as true. The optional *elseResult* is used if none of the preceding conditions are true. If no *elseResult* is given, and none of the conditions are true, then nothing happens.

IfMax(expr1, result1, expr2, result2, ... <all missing result>)

Description

Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the maximum of the expressions. If more than one expression is the maximum, the first maximum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.

Returns

The result expression associated with the maximum of the expressions

---

IfMin(expr1, result1, expr2, result2, ... <all missing result>)

Description

Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the minimum of the expressions. If more than one expression is the minimum, the first minimum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.

Returns

The result expression associated with the minimum of the expressions

---

`IfMZ(condition, result, condition, ..., <elseResult>)`

`IfV3(condition, result, condition, ..., <elseResult>)`

Description

Logical `If` with version 3.x behavior, which treats missing values as 0; used automatically when opening v3 data tables.

`Interpolate(x, x1, y1, x2, y2)`

`Interpolate(x, xmatrix, ymatrix)`

Description

Linearly interpolates the *y*-value corresponding to a given *x*-value between two points (*x1, y1*), and (*x2, y2*) or by matrices *xmatrix* and *ymatrix*. The points must be in ascending order.

`Is Associative Array(name)`

Description

Returns 1 if the evaluated argument is an associative array, or 0 otherwise.

`Is Empty(global)`

`Is Empty(dt)`

`Is Empty(col)`

Description

Returns 1 if the *global* variable, data table, or data column is undefined or holds the Empty() value, or 0 otherwise.

`Is Expr(x)`

Description

Returns 1 if the evaluated argument is an expression, or 0 otherwise.

`Is List`

See

`Is Name(x)`

Description

Returns 1 if the evaluated argument is a name, or 0 otherwise.

`Is Namespace(namespace)`

Description

Returns 1 if the namespace argument is a namespace; returns 0 otherwise.

`Is Number(x)`

Description

Returns 1 if the evaluated argument is a number or missing numeric value, or 0 otherwise.

`Is Scriptable(x)`

Description

Returns 1 if the evaluated argument is a scriptable object, or 0 otherwise.

`Is String(x)`

Description

Returns 1 if the evaluated argument is a string, or 0 otherwise.

`Match(a, value1, result1, value2, result2, ...)`

Description

If *a* is equal to *value1,* then *result1* is returned. If *a* is equal to *value2, result2* is returned, and so on.

Note

The `Match()` function explicitly checks to see if the compare expression *x* is missing and if the value of *value1* is missing, then it returns the value of `result1`; otherwise it continues to compare the expression *x* to each *valueN* value in each *valueN/resultN* pair, ignoring any missing values. If the expression *x* is equal to any of the *valueN* value, then the corresponding *resultN* value is returned. If no matching *valueN* value is found, then the *resultElse* value is returned.

```
MatchMZ(a, value1, result1, value2, result2, ...)
```

```
MatchV3(a, value1, result1, value2, result2, ...)
```

Description

Match with version 3.x behavior, which treats missing values as 0; used automatically when opening v3 data tables.

Note

The MatchMZ() function explicitly checks to see if the compare expression *x* is missing and if the value of *value1* is missing, then it returns the value of result1; otherwise it continues to compare the expression *x* to each *valueN* value in each *valueN/resultN* pair, ignoring any missing values. If the expression *x* is equal to any of the *valueN* value, then the corresponding *resultN* value is returned. If no matching *valueN* value is found, then the *resultElse* value is returned.

```
Not(a)
```

```
!a
```

Description

Logical Not.

Returns

0 (false) if *a*>0.

1 (true) if *a*<=0.

Missing value if *a* is missing.

Argument

a Any variable or number. The variable must have a numeric or matrix value.

Notes

Mostly used for conditional statements and loop control.

```
Or(a, b)
```

```
a|b
```

Description

Logical Or.

Returns

1 (true) if either of or both *a* and *b* are true.

0 (false) otherwise.

Missing if either are missing.

Arguments

a, b Any variable or number.

Notes

Mostly used for conditional statements and loop control.

OrMZ(a, b)

OrV3(a, b)

a :| b

Description

Logical Or with version 3.x behavior, which treats missing values as 0.

Returns

1 (true) if either of or both *a* and *b* are true.

0 (false) otherwise.

Arguments

a, b Any variable or number.

Notes

Mostly used for conditional statements and loop control. When opening a JMP 3 data table, this function is automatically used for any Or function.

Or() returns missing if any evaluated argument is missing. OrMZ() returns 0 if any evaluated argument is missing.

Return(<Expr1>, <Expr2>, ..., <ExprN>)

Description

Returns an expression value from a user-defined function.

Example

This example returns the evaluation of both expressions in the Return() function as a list. The Return() function can have more than one argument. If only one is present, then the value of the expression is returned. If more than one is present, then the values of all the expressions is returned in a list.

```
f = Function( {a, b},
   Return( a - b, a + b )
);
{lo, hi} = f( 10, 1 );
Show( lo, hi );
Show( f( 7, 15 ) );
   lo = 9;
   hi = 11;
   f(7, 15) = {-8, 22};
```

Note

> `Return()` not enclosed by a function, method, or recursive function call causes an error.

`Step(x0, x1, y1, x2, y2, ...)`

`Step(x0, [x1, x2, ...], [y1, y2, ...])`

Description

Returns the *y* argument corresponding to the largest *x* argument that is less than or equal to *x0*. The *x* points must be specified in ascending order.

`Stop()`

Description

Immediately stops a script that is running.

`While(expr, body)`

Description

Repeatedly tests the *expr* condition and executes the *body* until the *expr* condition is no longer true.

`Zero Or Missing(expr)`

Description

Returns 1 if *expr* yields a missing value or zero, 0 otherwise.

Constant Functions

JMP provides functions for two useful constant functions.

Note: These functions do not take an argument, but the parentheses are required.

`e()`

Description

Returns the constant *e*, which is 2.7182818284590451...

`Pi( )`

Description

Returns the constant π, which is 3.1415926535897931...

Date and Time Functions

Datetime values are handled internally as numbers of seconds since midnight, January 1, 1904.

The expression x=01Jan1904 sets *x* to zero, since the indicated date is the base date or "zero date" in JMP. If you examine the values of dates, they should be appropriately large numbers. For example 5oct1998 is 2990390400.

Abbrev Date(date)

Description

Converts the provided *date* to a string.

Returns

A string representation of the date.

Argument

date Can be the number of seconds since the base date (midnight, January 1, 1904), or any date-time operator.

Example

```
Abbrev Date( 29Feb2004 );
    02/29/2004
```

See Also

The Types of Data chapter in the *Scripting Guide*.

As Date(x)

Description

Formats the number or expression *x* so that it shows as a date or duration when displayed in a text window. Values that represent one year or more are returned as dates. Values that represent less than a year are returned as durations.

Returns

A date that is calculated from the number or expression provided.

Argument

x Number or expression.

See Also

The Types of Data chapter in the *Scripting Guide*.

Date Difference(datetime1, datetime2, "interval_name", <"alignment">)

Description

Returns the difference in intervals of two date-time values.

Returns

A number.

Arguments

datetime1, datetime2 Datetime values.

interval_name A quoted string that contains a date-time interval, such as "Month", "Day", or "Hour".

alignment An optional string. Options are as follows:

- "start" includes full or partial intervals.

- "actual" counts only whole intervals.

- "fractional" returns fractional differences using averages for "Year", "Quarter", and "Month" intervals.

Date DMY(day, month, year)

Description

Constructs a date value from the arguments.

Returns

The specified date, expressed as the number of seconds since midnight, 1 January 1904.

Arguments

day number, day of month, 1-31. Note that there is no error-checking, so you can enter February 31.

month number of month, 1-12.

year number of year.

Date Increment(datetime, "interval_name", <increment>, <"alignment">)

Description

Adds 1 or more intervals to a starting datetime value.

Returns

Returns the new datetime value.

Arguments

datetime The starting datetime value.

interval_name A quoted string that contains the name of a datetime interval. "Year", "Quarter", "Month", "Week", "Day", "Hour", "Minute", and "Second" are supported.

increment An optional number that specifies the number of intervals. The default value is
1.

alignment An optional quoted string that contains a keyword:

- "start" truncates the date to the nearest interval prior to adding the increment. For
  example, it removes the time and outputs the date. "start" is the default value.

- "actual" retains the full input datetime value.

- "fractional" allows fractional incremental values using averages for the duration of
  "Year", "Quarter", and "Month" intervals.

Date MDY(month, day, year)

Description

Constructs a date value from the arguments.

Returns

The specified date, expressed as the number of seconds since midnight, 1 January 1904.

Arguments

month number of month, 1-12.

day number, day of month, 1-31. Note that there is no error-checking, so you can enter
February 31.

year number of year.

Day(datetime)

Description

Determine the day of the month supplied by the *datetime* argument.

Returns

Returns an integer representation for the day of the month of the date supplied.

Arguments

datetime Number of seconds since midnight, 1 January 1904. This can also be an
expression.

Example

```
d1 = Date DMY( 12, 2, 2003 );
  3127852800

Day( 3127852800 );
  12
Day( d1 );
  12
```

Day Of Week(datetime)

Description

Determine the day of the week supplied by the *datetime* argument.

Returns

Returns an integer representation for the day of the week of the date supplied.

Arguments

datetime Number of seconds since midnight, 1 January 1904. This can also be an expression.

Day Of Year(datetime)

Description

Determine the day of the year supplied by the *datetime* argument.

Returns

Returns an integer representation for the day of the year of the date supplied.

Arguments

datetime Number of seconds since midnight, 1 January 1904. This can also be an expression.

```
Format(x, width|<width, decimal places>, <"Use thousands separator">)
```

```
Format(x, "Best", <width>, <"Use thousands separator">)
```

```
Format(x, ("Fixed Dec"|"Percent"), width|<width, decimal places>, <"Use
thousands separator">)
```

```
Format(x, "Pvalue", <width>)
```

```
Format(x, ("Scientific"|"Engineering"|"Engineering SI"), <width>|<width,
decimal places>)
```

```
Format(x,"Precision", width|<width, decimal places>, <"Use thousands
separator">, <"Keep trailing zeroes">, <"Keep all whole digits">)
```

```
Format(x, "Currency", <"currency code">, <width>|<width, decimal places>,
<"Use thousands separator">, < <<Use Locale(0|1) >)
```

```
Format(x, "datetime", <width>)
```

```
Format(x, ("Latitude DDD"|"Latitude DDM"|"Latitude DMS"|"Longitude
DDD"|"Longitude DDM"|"Longitude DDM"), width|<width, decimal places>,
("PUN"|"DIR"|"PUNDIR"))
```

```
Format(x, "Custom", Formula(), <width>)
```

Description

Converts the value *x* into the "*format*" that you specify in the subsequent arguments.

Returns

Returns the text that corresponds to the number in the specified format.

Arguments

See The Column Info Window chapter in the *Using JMP* book for details about the arguments. The arguments are also shown in the data table Column Info window.

Examples

```
Format( x, 10, 2, "Use thousands separator" );
Format( x, "Currency", "EUR", 20, <<Use Locale(0)); // ignores computer locale
Format( x, "m/d/y", 10 );
Format( x, "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole digits"
  );
Format( x, "Latitude DDD", "PUNDIR"); // "PUN" for punctuation, "DIR" for
  direction, PUNDIR for both
Format( x, "Custom", Formula( Abs( value ) ), 15 );
```

Notes

- For details about formatting currency, see the Types of Data chapter in the *Scripting Guide*.

- You must always precede the number of decimal places with the width.

Format Date(x, "datetime", <width>)

Description

Converts the value of *x* into the "*format*" that you specify in the second argument. Format choices are those shown in the data table column properties.

Returns

Returns the number in the specified format.

Arguments

See The Column Info Window chapter in the *Using JMP* book for details about the arguments.

Example

```
Format Date( Today(), "yyyQq" );
```

Hour(datetime, <12|24>)

Description

Determines the hour supplied by the *datetime* argument.

Returns

Returns an integer representation for the hour part of the date-time value supplied.

Arguments

datetime Number of seconds since midnight, 1 January 1904. This can also be an expression.

12|24 Changes the mode to 12 hours (with am and pm). The default is 24-hour mode.

HP Time()

Description

Returns a high precision time value (in microseconds). This function is only useful relative to another HP Time() value. The time value represents the number of microseconds since the start of the JMP session.

Note

For less precise time values use Tick Seconds().

In Days(n)

Description

Returns the number of seconds per *n* days. Divide by this function to express seconds as days.

```
Informat(string, "format")
```

```
Parse Date(string, "format")
```

Description

Parses a *string* of a given *"format"* and returns a date/time value. The value is expressed as if surrounded by the As Date() function, returning the date in "*ddMonyyyy*" format.

Example

```
Informat( "07152000", "MMDDYYYY" );
    15Jul2000
```

Notes

- To see the format options, open the Column Info window in a data table, select a date/time value for the format, and view the Input Format list.

- See the Types of Data chapter in the *Scripting Guide* for more examples.

- See "As Date(x)" on page 71.

```
In Hours(n)
```

Description

Returns the number of seconds per *n* hours. Divide by this function to express seconds as hours.

```
In Minutes(n)
```

Description

Returns the number of seconds per *n* minutes. Divide by this function to express seconds as minutes.

```
In Weeks(n)
```

Description

Returns the number of seconds per *n* weeks. Divide by this function to express seconds as weeks.

```
In Years(n)
```

Description

Returns the number of seconds per *n* years. Divide by this function to express seconds as years.

Long Date(date)

Description

Returns a locale-specific string representation for the *date* supplied, formatted like
`"Sunday, February 29, 2004" or "Wednesday, November 9, 2011"`.

MDYHMS(date)

Description

Returns a string representation for the *date* supplied, formatted like `"2/29/04 00:02:20"`.

Minute(datetime)

Description

Determines the minute supplied by the *datetime* argument, 0-59.

Returns

Returns an integer representation for the minute part of the date-time value supplied.

Month(date)

Description

Returns an integer representation for the month of the *date* supplied.

Parse Date()

See

Quarter(datetime)

Description

Returns the annual quarter of a *datetime* value as an integer 1-4.

Second(datetime)

Description

Determines the second supplied by the *datetime* argument.

Returns

Returns an integer representation for the second part of the date-time value supplied.

Argument

datetime Number of seconds since midnight, 1 January 1904. This can also be an
expression.

Short Date(date)

Description

Returns a string representation for the *date* supplied, in the format mm/dd/yy. For example, **"2/29/04"** for the next Leap Day.

Tick Seconds()

Description

Measures the time taken for a script to run, measured down to the 60th of a second.

Note

For higher time value resolution (for example, microseconds) use the `HP Time()` function.

Time Of Day(datetime)

Description

Returns an integer representation for the time of day of the *datetime* supplied.

Today()

Description

Returns the current date and time expressed as the number of seconds since midnight, 1 January 1904. No arguments are available, but the parentheses are still necessary.

Week Of Year(date, <rule_*n*>)

Description

Returns the week of the year that contains a date-time value. Three rules determine when the first week of the year begins.

– With rule 1 (the default), weeks start on Sunday, with the first Sunday of the year being week 2. Week 1 is a partial week or empty.

– With rule 2, the first Sunday begins with week 1, with previous days being week 0.

– With rule 3, the ISO-8601 week number is returned. Weeks start on Monday. Week 1 is the first week of the year with four days in that year. It is possible for the first or last three days of the year to belong to the neighboring year's week number.

Year(date)

Description

Returns an integer representation for the year of *date*.

Discrete Probability Functions

Beta Binomial Distribution(k, p, n, delta)

Description

Returns the probability that a beta binomially distributed random variable is less than or equal to *k*.

Beta Binomial Probability(k, p, n, delta)

Description

Returns the probability that a beta binomially distributed random variable is equal to *k*.

Beta Binomial Quantile(p, n, delta, cumprob)

Description

Returns the smallest integer quantile for which the cumulative probability of the Beta Binomial(p, n, delta) distribution is larger than or equal to *cumprob*.

Binomial Distribution(p, n, k)

Description

The probability that a binomially distributed random variable is less than or equal to *k*.

Returns

The cdf for the binomial distribution with *n* trials, probability *p* of success for each trial, and *k* successes.

Arguments

p probability of success for each trial

n number of trials

k number of successes

Binomial Probability(p, n, k)

Description

The probability that a binomially distributed random variable is equal to *k*.

Returns

The probability of getting *k* successes out of *n* trials if the probability is *p*.

Arguments

p probability of success for each trial

n number of trials

k   number of successes

Binomial Quantile(p, n, cumprob)

Description

The quantile function of binomial distribution.

Returns

The smallest integer quantile for which the cumulative probability of the Binomial(p, n) distribution is larger than or equal to *cumprob*.

Arguments

p   probability of success for each trial

n   number of trials

cumprob   cumulative probability

Gamma Poisson Distribution(k, lambda, sigma)

Description

Returns the probability that a gamma-Poisson distributed random variable is less than or equal to *k*.

Arguments

k   The count of interest.

lambda   The mean argument.

sigma   The overdispersion argument.

Gamma Poisson Probability(k, lambda, sigma)

Description

Returns the probability that a gamma-Poisson distributed random variable is equal to *k*.

Arguments

k   The count of interest.

lambda   The mean argument.

sigma   The overdispersion argument.

Gamma Poisson Quantile(lambda, sigma, cumprob)

Description

Returns the smallest integer quantile for which the cumulative probability of the Gamma Poisson(lambda, sigma) distribution is larger than or equal to *cumprob*.

Hypergeometric Distribution(N, K, n, x, <r>)

Description

Returns the cumulative distribution function at *x* for the hypergeometric distribution with population size *N*, *K* items in the category of interest, sample size *n*, count of interest *x*, and optional odds ratio *r*.

Hypergeometric Probability(N, k, n, x, <r>)

Description

Returns the probability that a hypergeometrically distributed random variable is equal to *x*.

Arguments

N Population size.

k The Number of items in the category of interest.

n Sample size.

x Count of interest.

r Optional odds ratio.

Neg Binomial Distribution(p, n, k)

Description

Returns the probability that a negative binomially distributed random variable is less than or equal to *k*, where the probability of success is *p* and the number of successes is *n*.

Neg Binomial Probability(p, n, k)

Description

Returns the probability that a negative binomially distributed random variable is equal to *k*, where the probability of success is *p* and the number of successes is *n*.

Poisson Distribution(lambda, k)

Description

Returns the cumulative distribution function at *k* for the Poisson distribution with mean *lambda*.

Poisson Probability(lambda, k)

Description

Returns the probability that a Poisson distributed random variable with mean *lambda* is equal to *k*.

```
Poisson Quantile(lambda, cumprob)
```

Description

Returns the smallest integer quantile for which the cumulative probability of the Poisson(lambda) distribution is larger than or equal to *cumprob*.

Display Functions

```
Alpha Shape(Triangulation)
```

Description

Returns the alpha shape for the given triangulation.

```
Border Box(<Left(pix)>, <Right(pix)>, <Top(Pix)>, <Bottom(Pix)>,
<Sides(0)>, db)
```

Description

Constructs a bordered display box that contains another display box. Optional arguments (Left, Right, Top, Bottom) add space between the border box and what it contains. The other optional argument (Sides) draws borders around the border box on any single side or combination of sides; draws the border in black or the highlight color; makes the background transparent or white or erases the background of a display box that contains it.

Returns

The display box.

Arguments

Left An integer that measures pixels.

Right An integer that measures pixels.

Top An integer that measures pixels.

Bottom An integer that measures pixels.

Sides An integer that maps to settings for the display box.

db a display box object (for example, a text box or another border box).

Notes

The formula for deriving the integer for Sides is: 1*top + 2*left + 4*bottom + 8*right + 16*highlightcolor + 32*whitebackground + 64*erase. Thus, if you want to just draw a black border on the top and bottom, 1+4 = 5. If you want that same box with a white background, 5+32 = 37.

```
Box Plot Seg(<data>, <frequency>, <weight>, <vertical(Boolean)>
```

Description

Returns a display seg that represents a box plot based on the passed x and y values.

Returns

The display box (a box plot).

Optional Arguments

data The data values within the box plot.

frequency The frequency values within the box plot.

weight The weights for observations on continuous Ys.

vertical(Boolean) A vertical (1) or horizontal(0) box plot.

Example

```
win = New Window( "Box Plot Seg Example",
Graph Box(
    Frame Size( 40, 180 ),
    Y Scale( 0, 100 ),
    Box Plot Seg(
        [20, 30, 40], // data
        [1, 1, 3], // frequencies
        [1, 1, 1], // weights
        1 // vertical
        )
    )
);
```

```
Busy Light(< <<Automatic(Boolean), <Size(x, y)>, < <<Disable>)
```

Description

Creates a rotating image to indicate a busy process.

Returns

A rotating image.

Arguments

<<Automatic(Boolean) Rotates the image.

Size(x, y) Specifies the size of the image.

<<Disable Hides the image.

Example

```
win = New Window( "Example",
    blb = Busy Light( <<Automatic( 1 ), Size( 50, 50 ) ) );
```

```
Button Box("title", <<Set Icon("path"), "script" <<Set Icon Location("left,
"right")
```

Description

Constructs a button with the text *title* that executes *script* when clicked.

Returns

The display box (button box).

Arguments

`title` A quoted string or a string variable.

`script` A quoted string or a reference to a string where the string is a valid JSL script.

`<<Set Icon("path")` Displays the image in the pathname on the button. Most common graphic formats are supported, such as GIF, JPG, PNG, BMP, TIF. Since the title argument is optional, you can create a button with only a text title, with only an icon, or with both a text title and an icon. In the last case, the icon is placed next to the text title.

`<<Set Icon Location("right" or "left")` Allows the position of the icon on a button to be either left or right of the text.

Notes

Line-break characters are ignored in button boxes.

Example

The following example shows a simple button box. When the user clicks the button box, `"Pressed"` is printed to the log.

```
win = New Window( "Simple Example",
   ex = Button Box( "Press me" )
);
ex << Set Script( Print( "Pressed" ) );
```

```
Calendar Box("title", < <<Date, <<Min Date, <<Max Date, <<Show Time>)
```

Description

Constructs a pop-up calendar with selectable days and time.

Returns

The display box (calendar box).

Arguments

`title` A quoted string or a string variable.

`<<Date` The currently selected date.

`<<Min Date` The earliest date that can be selected.

`<<Max Date` The latest date that can be selected.

`<<Show Time` The time that can be specified.

Example

The following example creates a calendar with October 5, 1989 initially selected. The minimum date and maximum date are specified, so the user can select only dates in that range.

```
New Window( "Calendar Box Example", cal = Calendar Box() );
date = Date MDY (10, 5, 1989);
cal << Date( date );
cal << Show Time( 0 ); // omit the time

cal << Min Date( Date Increment(date, "Day", -60, "start" ) );
// earliest date that can be selected is 60 days before 10/5/1989
// "start" truncates the value so the time is not included

cal << Max Date( Date Increment(date, "Day",  60, "start" ) );
// latest date that can be selected is 60 days after 10/5/1989

cal << Set Function( Function( {this}, Print( Abbrev Date(this << Get Date())
  ) ) );
// print the abbreviated date to the log
```

Check Box(list, <script>)

Description

Constructs a display box to show one or more check boxes.

Returns

The display box (Check Box).

Arguments

list a list of quoted strings or a reference to a list of strings.

script an optional JSL script.

Messages

<<Get(n) Returns 1 if the check box item specified by *n* is selected, or 0 otherwise.

<<Set(n, 0|1) Sets the check box item specified by *n* as either selected (1) or cleared (0).

<<Get Selected Returns a list of strings that contain the names of the check box items that are selected.

<<Enable Item(n, 0|1) Sets the check box item specified by *n* as either enabled (1) or disabled (0). The state of a disabled check box cannot be changed.

<<Item Enabled(check box item) Returns 0 or 1 depending on whether the specific check box item is enabled.

Example

Create three check boxes labeled "one", "two", and "three". The first check box is selected.

```
New Window( "Example", Check Box( {"one", "two", "three"}, <<Set( 1, 1 ) ) );
```

```
Col Box(title, display boxes)
```

Description

Returns a column box made up of the specified display boxes.

Arguments

title The title of the column.

display boxes Display boxes that hold content within the column box.

Example

```
win = New Window( "Example",
    exx = 1;
    exy = 4;
    exz = 8;
    Table Box(
        String Col Box( "strings", {"x", "y", "z"} ),
        Col Box(
            "boxes",
            Slider Box( 0, 10, exx, Show( exx ) ),
            Slider Box( 0, 10, exy, Show( exy ) ),
            Slider Box( 0, 10, exz, Show( exz ) )
        )
    );
);
```

```
Col List Box(<Data Table ("name" )>, <"all"|"character"|"numeric">,
<width(pixels)>, <grouped>, <maxSelected(n)>, <nlines(n)>, <MaxItems(n)>,
<MinItems(n)>, <On Change(expr)>, < <<Set Analysis
Type("Any"|"Continuous"|"Ordinal"|"Nominal"|Multiple
Response"|"Unstructured Text"|"Vector"|"None"|"Row State") >, < << Set Data
Type(Any|Numeric|Character)>, <script>)
```

Description

Constructs a display box to show a list box that allows selection of data table columns.

Returns

The display box (Col List Box).

Arguments

name The name of the data table.

all | character | numeric an optional command that adds all columns of the current
data table into the list. Omitting "all" results in an empty collistbox with the "optional"
label. To display "optional character", specify "character". To display "optional
numeric", specify "numeric".

width(pixels) an optional command that sets the width of the list box to pixels. Pixels
is a number that measures pixels.

grouped An optional command that displays grouped columns in the box.

maxSelected(n) an optional command that sets whether only one item can be selected. For *n*>1, *n* is ignored.

nlines(n) an optional command that sets the length of the list box to n number of lines. *n* is an integer.

script an optional script.

MaxItems(n) An optional number that only allows *n* columns to be added to the list.

MinItems(n) An optional number that only requires at least *n* columns for the list. If *n*=2, the top two slots in the Col List Box an initial display of "required numeric" (or whatever you set the data type to be).

On Change(expression) An optional command that evaluates the expression when the selection in the list changes. Dragging between two column list boxes that have this argument results in both expressions being evaluated. The expression for the target being dragged is evaluated first, then the expression for the source is evaluated.

Messages

<<Set Tips ({"Tip text 1", "Tip text 2", ...}) Sets tool tips for items in the list box. A null string or an empty list results in no tips. A list shorter that the list of items in the list box will use the last tip text for the remaining items in the list and the list box.

<<Set Tip ("Tip text") Overrides any tool tips set using Set Tips() function. If there is a tip set for the box, you cannot set tips for each individual item.

Using Set Tip() with no arguments clears the list box tip and allows the individual item tool tips to be displayed.

Notes

– The maxSelected argument only affects whether one or more than one item can be selected. It does not enforce a limit greater than 1.

– Specialty modeling types can be used only in a role (determined by the platform) that explicitly accepts columns of the same type.

Col Span Box(title, display box args)

Description

Creates spanned columns headers inside a table box. The top column header spans two child column headers.

Returns

The display box (a Col Span Box).

Arguments

title The title that appears in the box.

display box args Display boxes.

Example

```
win = New Window( "Col Span Box",
   <<Modal,
   Table Box(
      Col Span Box(
         "Confidence Limits",
         neb = Number Col Edit Box( "Upper limits", [0, 0] ),
         Number Col Edit Box( "Lower limits", [0, 0] )
      )
   )
);
```

Column Dialog(ColList("rolename"), specifications)

Description

Draws a dialog box for column role assignments.

Returns

A list of commands that were sent and the button that was clicked.

Arguments

ColList Specifies the name of at list one list to add variables to.

specifications Any additional Dialog items (for example, Max Col, Datatype).

Combo Box(list, <script>)

Description

Constructs a display box to show a combo box with a menu.

Returns

The display box (ComboBox).

Arguments

list a list of quoted strings or a reference to a list of strings.

script an optional JSL script.

Context Box(displayBox, ...)

Description

Defines a scoped evaluation context. Each Context Box is executed independently of each other.

Returns

A display box.

Arguments

Any number of display boxes.

```
Contour Seg( Triangulation, [levels], <zColor([colors], <Cycle
Colors|Interpolate Colors>)>, <Fill|Fill Between|Fill Below|Fill Above>, <
Transparency([]|t)>
```

Description

Returns a display seg that represents contours of a Triangulation.

Arguments

`Triangulation` The columns to include in the Triangulation.

`[levels]`

`zColor([colors]` Optional. Colors for each level, specified as a matrix or list.

`Cycle Colors|Interpolate Colors` Optional.

`Fill|Fill Between|Fill Below|Fill Above` Optional.

`Transparency([]|t)` Optional. The transparency specified as a number or matrix.

Example

```
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
tri = Triangulation( X( :X, :Y ), Y( :POP ) );
{xx, yy} = tri << Get Points();
win = New Window( "Contour Seg Example",
  g = Graph Box(
    X Scale( Min( xx ) - .1, Max( xx ) + .1 ),
    Y Scale( Min( yy ) - .1, Max( yy ) + .1 ),
    Contour Seg(
      tri,
      [0, 400, 1000, 2000, 9000],
      zColor( 5 + [64 32 0 16 48] ),
      Transparency( [1, 1, 1, 1, 1] )
    )
  )
);
```

Current Journal()

Description

Gets the display box at the top of the current (topmost) journal.

Returns

Returns a reference to the display box at the top of the current journal.

Current Report()

Description

Gets the display box at the top of the current (topmost) report window.

Returns

Returns a reference to the display box at the top of the current report window.

Current Window()

Description

Returns a reference to the current window.

Data Filter Context Box(display box)

Description

Returns a display box that defines the extent of the local data filters that a display tree contains. Data filters and Data Filter Context Boxes can be arranged in a hierarchy and shared among platforms or boxes that the Data Filter Context Boxes contain.

Notes

See the Display Trees chapter in the *Scripting Guide* for details and examples.

Data Filter Source Box(display box)

Description

Defines which graph is the "source" of the selection filter. Selected rows in reports that are within the Data Filter Source box are included for analysis in the other reports that are within a common Data Filter Context Box.

Notes

See the Display Trees chapter in the *Scripting Guide* for details and examples.

Data Table Box(data table)

Description

Returns a table box the represents the specified data table.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Example", Data Table Box( dt ) );
```

Data Table Col Box(col)

Description

Returns a column box that corresponds to the specified data table column.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Example",
  Table Box( Data Table Col Box( :name ), Data Table Col Box( :height ) ) )
```

```
    );
```

Dialog(contents)

Dialog is deprecated. Use New Window() with the Modal argument instead. See the Display
Trees chapter in the *Scripting Guide* for details.

Excerpt Box(report, subscripts)

Description

Returns a display box containing the excerpt designated by the report held at number
report and the list of display subscripts *subscripts*. The subscripts reflect the current state
of the report, after previous excerpts have been removed.

Expr As Picture(expr(...), <width(pixels)>)

Description

Converts expr() to a picture as it would appear in the Formula Editor.

Returns

Reference to the picture.

Argument

expr(...) Place any valid JSL expression that can be displayed as a picture inside expr().

width(pixels) an optional command that sets the width of the box to pix. pix is a
number that measures pixels.

Filter Col Selector(<data table(name)>, <width(pixels)>, <Nlines(n)>, <script>, <OnChange(expr)>)

Description

Returns a display box that contains a list of items. Control allows column filtering.

Get Project(title|index|display box|window)

Description

Returns a single project.

Examples

The following examples show how to get the window title of various projects.

```
 Get Project( 1 ) << Get Window Title
 // first open project
 Get Project( "My Project" ) << Get Window Title
 // first project named "My Project"
 Get Project( display box ) << Get Window Title
 // parent project of the specified display box
```

Get Project List()

Description

Returns a list of all open projects.

Example

```
Get Project List() << Get Window Title
// list of all open projects
```

Get Window(<Project(title|index|display box|window),> <Type(string),>, title|index|display box)

Description

Returns a reference to a specific open window by title, index, or display box. By default, `Get Window()` returns windows from the current project (or no project when you're not running the script from a project).

Optional Arguments

`Project` Specifies the title, index, display box, or window from another project.

`Type` To limit the search to particular types of windows, use the `Type ()` argument and one of these strings: "Data Tables", "Journals", "Reports", or "Dialogs".

Examples

The following examples show how to get the window title of various windows.

```
Get Window( 1 ) << Get Window Title
// first window in the current project

Get Window( "Big Class" ) << Get Window Title
// Big Class window in the current project

Get Window( ob ) << Get Window Title
// parent window of specified display box in the current project

Get Window( Project(), 1 ) << Get Window Title
// first window, no project (global scope)

Get Window( Project( myProject ), "Big Class" << Get Window Title
// Big Class window in the specified project
```

Get Window List(<Project(title|index|display box),><Type (string)>)

Description

Returns a list of currently open windows. By default, `Get Window List()` returns a list of currently open windows in the current project. You can return an open window list from something other than the current project by using the `Project()` argument. To limit the

search to particular types of windows, use the `Type ()` argument and one of these strings: `"Data Tables"`, `"Journals"`, `"Reports"`, or `"Dialogs"`.

Optional Arguments

`Project` Specifies the title, index, display box, or window from another project.

`Type` To limit the search to particular types of windows, use the `Type ()` argument and one of these strings: `"Data Tables"`, `"Journals"`, `"Reports"`, or `"Dialogs"`.

Examples

```
Get Window List() << Get Window Title
// list of open windows in the current project
Get Window List( Type( "Reports" ) ) << Get Window Title;
// list of open reports in the current project
Get Window List( Project( 0 ), Type( "Reports" ) ); // positional arguments
// list of open reports outside of a project
Get Window List( 2 );
// second window list
```

Global Box(global)

Description

Constructs a box for editing *global* value directly.

Graph()

See "Graph Box(properties, script)" on page 94.

Graph 3D Box(properties)

Description

Constructs a display box with 3-D content.

Returns

The display box.

Arguments

Properties can include: `framesize(x, y)`, `Xname("title")`, `Yname("title")`, `Zname("title")`.

Note

This display box constructor is experimental.

Graph Box(properties, script)

Graph(properties, script)

Description

Constructs a graph with axes.

Returns

The display box (Graph Box).

Arguments

`properties` Named property arguments: `title("title")`, `XScale(low, high)`,
`YScale(low, high)`, `FrameSize(h, v)`, `XName("x")`, `YName("y")`, `SuppressAxes`.

`script` Any script to be run on the graph box.

H Center Box(display box)

Description

Returns a display box with the display box argument centered horizontally with respect to
all other sibling display boxes.

H List Box(<Align("center"|"bottom")>, display box, <arguments>)

Description

Creates a display box that contains other display boxes and displays them horizontally.

Arguments

`Align` Specify bottom or center alignment of the contents in the list box. The contents are
bottom aligned by default.

`display box` Any number of display box arguments can be contained in the list box.

H Sheet Box(<<Hold(report), display boxes)

Description

Returns a display box that arranges the display boxes provided by the arguments in a
horizontal layout. The `<<Hold()` message tells the sheet to own the report(s) that is
excerpted.

H Splitter Box(<size(*h*,*v*)>, display box, <arguments>)

Description

Returns a display box that arranges the display boxes provided by the arguments in a
horizontal layout (or panel). The splitter enables the user to interactively resize the panel.

Arguments

`display box` Any number of display box arguments can be contained in the splitter box.

Optional Arguments

`size(*h*,*v*)` Specifies the size of the splitter box in pixels. This size is for the outer splitter
box. Inner display boxes are proportionately sized according to the width and height of
the outer splitter box.

<<Size(*n*) Specifies the proportions of the last panel. <<Size(.25) resizes the last panel to 25% the splitter box height (or width, for vertical splitter boxes).

<<Set Sizes({*n*,*n*}) Specifies the proportions of each panel. db<<Set Sizes({.75, .25}) sizes the first panel to 75% and the second panel to 25% of the splitter box height (or width, for vertical splitter boxes).

<<Close Panel(*n*, *<Boolean>*) Closes the panel that you specify. <<Close Panel(2) closes the second panel. With three or more panels, you must include the second Boolean value. That value indicates which panel expands to fill the space left by the closed panel.

– <<Close Panel(2,0) closes the second panel; the following sibling takes the extra space.

– <<Close Panel(2,1) closes the second panel; the preceding sibling takes the extra space.

<<Open Panel(*n*, *<Boolean>)* Opens the panel that you specify. With three or more panels, you must include the second Boolean value. Works similar to <<Close Panel described above. The panels are initially opened. You use <<Open Panel only after using <<Close Panel.

<<Get Sizes() Returns the proportions of each panel as a list.

Hier Box("text", Hier Box(...), ...)

Description

Constructs a node of a tree (similar to Diagram output) containing text. Hier Box can contain additional Hier Boxes, allowing you to create a tree. The text can be a Text Edit Box.

Hist Seg([data], <[freq data]>, <[weight data]>, <vertical(Boolean)>, <Row States()>

Description

Returns a histogram seg.

Arguments

Icon Box("name")

Description

Constructs a display box containing an icon, where the argument is a name such as Popup ▾, Locked 🔒, Labeled 🏷, Sub ▾, Excluded 🚫, Hidden 👓, Continuous ◢, Nominal ▮▮, or Ordinal ▮. The argument can also be a path to an image.

Argument

name Quoted string that is the name of a JMP icon or the path to an icon.

Example

Icon Box("Nominal") constructs a display box that contains the Nominal icon.

Icon Box("$SAMPLE_IMAGES/pi.gif") inserts the pi.gif sample image.

See Also

Appendix B, "JMP Icon Names" specifies the icon names.

If Box(Boolean, display boxes)

Description

Constructs a display box whose contents are conditionally displayed.

Arguments

Boolean 1 displays the display boxes inside the If Box; if 0, does not display them.

display boxes Any display box tree.

If Seg(<state(Boolean)>)

Description

Returns a display seg that shows or hides display seg children.

Arguments

state

Example

```
lines = [30 20 80 70, 10 90 90 10, 40 20 60 30];
win = New Window( "Lines Seg Example",
   g = Graph Box( If Seg( true, <<Append( Lines Seg( lines ) ) ) ) )
);
```

Journal Box("Journal Text")

Description

Constructs a display box that displays the quoted string *journal box*. We recommend that you do not generate the journal text by hand.

Line Seg(x, y, <Row States(dt | dt, [rows] | dt, {{rows}, ...} | {states}) >, <Sizes(s)>)

Description

Creates a display seg of connected line segments. The optional third argument enables row state assignments from either a data table or independently.

`Lineup Box(<NCol(n)>, <Spacing(pixels, <vspace>), display boxes, ...)`

Description

Constructs a display box to show an alignment of boxes in *n* columns.

`List Box({"item", ...}, <width(pixels)>, <maxSelected(n)>, <nLines(n)>, <script>)`

Description

Creates a display box to show a list box of selection items. The argument can be a list of two-item lists containing the item name and a string that specifies the modeling type or sorting order. Item names are case sensitive by default. The icon appears next to the corresponding item in the list box.

`Marker Seg(x, y, <Row States(dt | dt, [rows] | dt, {{rows}, ...}| {states} ) >, <Sizes(s)>)`

Description

Creates a display seg with markers for all of the x and y values. The optional third argument enables row state assignments from either a data table or independently.

`Matrix Box(matrix)`

Description

Displays the *matrix* given in the usual array form.

`Mouse Box(displayBoxArgs, messages)`

Description

Returns a box that can make JSL callbacks for dragging and dropping, marking, or clicking and tracking mouse actions.

Arguments

`displayBoxArgs` Specifies the object that the user interacts with, such as a `Text Box` or `Button Box`. See the Scripting Index in the Help menu for details.

`Move to Project(<source(project)|destination(project)>, <windows({list of windows to move})>)`

Description

Moves one or more windows into a project or out of a project, or between projects.

Arguments

`source(project)` The project containing the windows that you want to move.

`destination(project)` The project to which you want to move the windows.

windows({list of windows to move}) A list of windows to move to the project. If
    omitted, all windows will be moved. Note that the data table and all of its dependent
    reports will be moved. However, you need to specify only the data table name or report
    name in the windows argument to move it.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
report = dt << Run Script( "Bivariate" );
project = New Project();
// move the report and data table to a new project
Move to Project( destination( project ), windows( {report} ) );
```

New Image()

New Image(width, height)

New Image("filepath")

New Image (open ("url"))

New Image(picture)

New Image(matrix)

New Image("rgb"|"r"|"rgba", {matrix, ...})

Description

Creates a new image which can then be edited using JSL. The following file types are
supported: PNG, JPG, GIF, BMP, or TIF.

Returns

An image.

Arguments

All argument sets are optional, but all arguments within each set are required.

width, height Sets the width and height of the image in pixels.

"filepath" A filepath to an image.

open "url" Opens the image at the specified URL path.

picture A JSL picture object.

matrix The image as a matrix of JSL color pixels.

"rgb"|"r"|"rgba", {matrix, ...} Specify the channels (rgb, r, or rgba) and provide a
    matrix of values (0.0-1.0) for each channel. Examples:
```
New Image( "r", [r matrix] );
New Image( "rgb", {[r matrix], [g matrix], [b matrix]} );
New Image( "rgba", {[r matrix], [g matrix], [b matrix], [a matrix]} );
```

`New Project(arguments)`

Description

Creates a project using the specified script.

Arguments

`<<Add Bookmarks({<File(path)>, <Folder(path, Expanded(Boolean)>)>, <Group(name, <Expanded(Boolean)>, {contents}>)` Creates bookmarks for frequently used files in the project. Existing bookmarks are retained. The argument is a list of bookmark items, each of which is specified using `File()`, `Folder()`, or `Group()`. `Group()` accepts `File()`, `Folder()`, and `Group()` as children. See the Creating Projects chapter in the *Scripting Guide* for an example of how to construct the arguments.

`<<Get Bookmarks` Returns the list of bookmarks in the project. The format of the returned list is the same as is used by `Add Bookmarks` and `Set Bookmarks`.

`<<Get Layout` Returns the window layout of the project. The format is the same as is used for `Set Layout`.

`<<Reset Layout` Sets the project to use the default layout.

`<<Run Script` Specifies the data tables and reports that appear in the project.

`<<Save(<path>)` Saves the project. Include a path and file name to save the project to a specific location. If the project has already been saved, this argument is optional. `Save As` is an alias.

`<<Set Bookmarks({<File(path)>, <Folder(path, Expanded(Boolean)>)>, <Group(name, <Expanded(Boolean)>, {contents}>)` Sets the bookmarks for the project. Unlike `Add Bookmarks`, existing bookmarks are removed. The argument is a list of bookmark items, each of which is specified using `File()`, `Folder()`, or `Group()`. `Group()` accepts `File()`, `Folder()`, and `Group()` as children.

`<<Set Layout` Sets the window layout of the project.

`<<Show Bookmarks` Shows or hides the bookmarks.

`<<Show Log` Shows or hides the log.

`<<Show Window List` Shows or hides the Window List.

Example

The following example creates a project from BigClass.jmp and two reports.

```
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
);
```

See Also

the Creating Projects chapter in the *Scripting Guide*.

New Window("title", <arguments>, displayBox)

Description

Makes a new window with the indicated title (a required argument) and a display box tree.

Additional Arguments

<<Script(<"script">) Creates a new script window. The optional quoted string *script* is placed inside the script window.

<<Journal Creates an empty journal.

<<Modal Makes the new window a modal window, which prevents any other actions in JMP until the window is closed. If you do not include an **OK** or **Cancel** button, one is added automatically for you. **Note:** If used, this argument must be the second argument, directly after the window title. Available modal window arguments are:

– <<On Open(expr) runs expr when the window is created.

Note: In data tables, On Open (or OnOpen) scripts that execute other programs are never run. Set the Evaluate OnOpen Scripts preference to control when the script is run.

– <<On Close (expr) runs expr when the window is closed. Returns 0 if the window fails to close.

– <<On Validate (expr) runs expr when the **OK** button is pressed. If it returns True, the window is closed otherwise the window remains open.

– <<Return Result changes the window's return value when it closes to match that of the deprecated Dialog() function.

Show Toolbars(0|1) Show or hide the toolbar. The default value is 1. (Windows only.)

Show Menu(0|1) Show or hide the menu bar. The default value is 1. (Windows only.)

Suppress AutoHide Suppress or use the auto-hide feature for menus and toolbars. The default value is 1. (Windows only).

Notes

Dialog() was deprecated in JMP 10. Use New Window() with the Modal argument instead. See the Display Trees chapter in the *Scripting Guide* for details about using New Window().

Number Col Box("title", numbers)

Description

Creates a column named *title* with numeric entries given in list or matrix form.

Number Col Edit Box("title", numbers)

Description

Creates a column named *title* with numeric entries given in list or matrix form. The numbers can be edited.

Number Edit Box(initValue, <width>)

Description

Creates an editable number box that initially contains the *initValue* argument.

Returns

The display box object.

Argument

initValue Any number to use as the initial value. If you use a date or time format, a date and time selector window is created.

<width> Value to set the width of the box in characters.

Outline Box("title", display box, ...)

Description

Creates a new outline named *title* containing the listed display boxes.

Page Break Box()

Description

Creates a display box that forces a page break when the window is printed.

Panel Box("title", display box)

Description

Creates a display box labeled with the quoted string *title* that contains the listed display boxes.

Picture Box(Open(picture), format)

Description

Creates a display box that contains a graphics picture object.

Returns

A reference to the display box.

Argument

Open Opens the directory that contains the picture.

picture The pathname for the picture to include.

format The graphic file format. Specifying the format opens the picture in JMP. If you omit this argument, the picture opens in the default graphics program.

Example

```
New Window( "Example",
    Picture Box( Open( "$SAMPLE_IMAGES/pi.gif", gif ) ) );
```

Platform(data table, script)

Description

Evaluates the specified script in the context of the specified data table.

Returns

The resulting display box for embedding in a display tree.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Platform example",
    H List Box(
        Platform(
            dt,
            Bubble Plot(
                X( :weight ),
                Y( :height ),
                Sizes( :age ),
                Title Position( 0, 0 )
            )
        ),
        Platform(
            dt,
            Bubble Plot(
                X( :weight ),
                Y( :age ),
                Sizes( :height ),
                Title Position( 0, 0 )
            )
        )
    )
);
```

Plot Col Box("title", numbers)

Description

Returns a display box labeled with the quoted string *title* to graph the *numbers*. The numbers can be either a list or a matrix.

Poly Seg(x values, y values)

Description

Returns a display seg that represents a polygon with vertices based on the x and y values.

Example

```
x = [10, 50, 90];
y = [10, 90, 10];
```

```
win = New Window( "Poly Seg Example",
g = Graph Box( Poly Seg( x, y ) ) );
frame = g[FrameBox( 1 )];
seg = (frame << Find Seg( "Poly Seg" ));
```

Popup Box({"command1", script1, "command2", script2, ...})

Description

Creates a red triangle menu. The single argument is an expression yielding a list of an even number of items alternating between the command string and the expression that you want evaluated when the command is selected. If the command is an empty string, a separator line is inserted. **Note:** Pressing ALT and right-clicking the red triangle menu opens a window with check boxes for the commands. See the JMP Reports chapter in the *Using JMP* book for details.

Radio Box({"item", ...}, <script>)

Description

Constructs a display box to show a set of radio buttons. The optional script is run every time a radio button is selected.

Range Slider Box(minValue, maxValue, lowVariable, highVariable, script)

Description

Range Slider Box() returns a display box that shows a range slider control that ranges from minValue to maxValue. As the two sliders' positions change, their values are placed into lowVariable and highVariable, and the script is run.

Returns

The display box (RangeSliderBox).

Arguments

minValue, maxValue Numbers that set the minimum and maximum value the slider represents.

lowVariable The variable whose value is set and changed by the lower slider.

highVariable The variable whose value is set and changed by the upper slider.

script Any valid JSL commands that are run as the slider is moved.

Report(obj)

Description

Returns the display tree of a platform *obj*. This can also be sent as a message to a platform:
 obj<<Report

Scene Box(x size, y size)

Description

Creates an *x* by *y*-sized scene box for 3-D graphics.

Scene Display List

Description

Returns a display list for 3-D graphics.

Example

```
ex = Scene Display List();
ex << Color( .9, .9, .9 );
ex << Text( center, middle, .3, "Hello World" );
exScene = Scene Box( 600, 600 );
exScene << Background Color( 0 );
exScene << Show Arcball( always );
New Window( "See HelloWorld.jsl in sample scripts", exScene );
exScene << Perspective( 45, .2, 20 );
exScene << Translate( 0.0, 0.0, -4.5 );
exScene << Arcball( ex, 1.5 );
exScene << Update;
```

Script Box(<"script">, <width>, <height>)

Description

Constructs an editable box that contains the quoted string *script*. The editable box is a script window and can both be edited and run as JSL.

Arguments

script An optional quoted string that appears in the script box.

width An optional integer that sets the width of the script box.

height An optional integer that sets the height of the script box.

Scroll Box(<size(*h*,*v*)>, <flexible(Boolean)>, display box, ...)

Description

Creates a display box that positions a larger child box using scroll bars.

Returns

A reference to the scroll box object.

Arguments

size(h,v) Optional. The *h* and *v* arguments specify the size of the box in pixels.

flexible(Boolean) Optional. True (1) sets the box to be resizable with the window. False (0) sets the box to remain the same size when the window is resized.

`display box` Any number of display box arguments can be contained in the scroll box.

Note

You can send a scroll box object a message to set the background color:

```
<<Set Background Color( {R, G, B} | <color> )
```

You can set the Boolean flags for horizontal (h) and vertical (v) scrolling to enable (1) or disable (0) the scroll bars. If scrolling is disabled in a given direction, the Scroll Box will behave as a regular container in that direction.

```
<<Set Scrollers (h, v)
```

To return the flags for scrolling, use the following message:

```
<<Get Scrollers
```

To set the horizontal (h) and vertical (v) positions (in pixels) for the scrollers on the scroll bar:

```
<<Set Scroll Position (h,v)
```

To return the flags for scroll position, use the following message:

```
<<Get Scroll Position
```

To return the maximum positions for horizontal and vertical scrolling, use the following message:

```
<<Get Scroll Extents
```

Example

The following example shows a window containing a scroll box with the specified settings.

```
win = New Window( "Example",
   sb = Scroll Box(
      Size( 150, 75 ),
      List Box(
         {"First Item", "Second Item",
         "Third Item", "Fourth Item",
         "Fifth Item"},
         width( 200 ),
         max selected( 2 ),
         nlines( 6 )
      )
   )
);
win << Set Window Size( 300, 200 );
sb << Set Scrollers( 1, 1 ); // enable both scroll bars
sb << Set Scroll Position( 0, 20 ); // position the scrollers on the scroll
   bar
```

```
Shape Seg( {Path(<path>), ...}, <Row States(dt|dt,[rows]|dt,{{rows},
...}|{states})>)
```

Description

Returns a display seg with a collection of shapes.

Arguments

Path Specifies the path with an Nx3 matrix or with a text representation. A path matrix has three columns for x, y, and flags for each point in the path. The flag values are 0 for control, 1 for move, 2 for a line segment, 3 for a cubic Bézier segment, and are negative if the point also closes the path. Path text supports SVG syntax.

states Specifies row states that are listed in the Help > Scripting Index Row State category.

Example

```
win = New Window( "Shape Seg Example",
  Graph Box(
    Shape Seg(
      {Path( [10 10 1, 10 70 0, 70 70 0, 70 10 -3] ),
      Path( "M20,20 C20,60 60,60 60,20 Z" )},
      Row States( {Selected State( 1 ), Color State( "red" )} )
    )
  )
);
```

```
Sheet Part("title", display box)
```

Description

Returns a display box containing the *display box* argument with the quoted string *title* as its title.

```
Slider Box(minValue, maxValue, variable, script, <set width(n)>, <rescale
slider(min, max)>)
```

Description

Creates an interactive slider control.

Returns

The display box (SliderBox).

Arguments

minValue, maxValue Numbers that set the minimum and maximum value the slider represents.

variable the variable whose value is set and changed by the slider box.

script Any valid JSL commands that is run as the slider box is moved.

set width(n) specify the width of the slider box in pixels.

rescale slider(l, u) resets the max and min values for the slider box.

Notes

You can send Set Width and Rescale Slider as commands to a slider object. For example:

```
ex = .6;
New Window( "Example", mybox = Slider Box( 0, 1, ex, Show( ex ) ) );
mybox << Set Width( 200 ) << Rescale Slider( 0, 5 );
```

Spacer Box(<size(*h*,*v*)>, <color(color)>)

Description

Creates a display box that can be used to maintain space between other display boxes, or to fill a cell in a LineUp Box.

Returns

A reference to the display box.

Arguments

size(h,v) Optional. The *h* and *v* arguments specify the size of the box in pixels.

color(color) Optional. Sets the color of the box to the JSL color argument.

Spin Box(script)

Description

Returns a display box that shows a button with up and down controls.

Argument

script Invoked with an argument that indicates the direction of the arrow clicked. Negative is down, and positive is up. A magnitude of 1 indicates a single click, while larger values may be used to indicate a repeating action.

Example

```
win = New Window( "Example",
  Lineup Box(
    2,
    nb = Number Edit Box( 3 ),
    sb = Spin Box( Function( {value}, nb << Increment( value ) ) )
  )
);
nb << Set Increment( 1 );
```

String Col Box("title", {"string", ...})

Description

Creates column in the table containing the *string* items listed.

```
String Col Edit Box("title", {"string", ...})
```

Description

Creates column in the table containing the *string* items listed. The string boxes are editable.

Note

To retrieve the data, use this message:

```
data = obj << Get;
```

```
Tab Box(Tab Page Box(Title("page title 1"), <options>, contents of page 1),
Tab Page Box(Title("page title 2"), <options>, contents of page 2), ...);
```

Description

(Previously called `Tab List Box`.) Creates a tabbed window pane. The arguments are an even number of items alternating between the name of a tab page and the contents of the tab page.

Note

Certain messages you can send to `Tab Page Box` have been renamed, as follows:

- `Set Title` to `Title`
- `Set Tip` to `Tip`
- `Set Icon` to `Icon`
- `Set Closeable` to `Closeable`

Example

```
New Window( "Example",
  Tab Box(
    t1 = Tab Page Box( Title( "alpha" ), Panel Box( "panel", Text Box( "text"
  ) ) ),
    t2 = Tab Page Box( Title( "beta" ), Popup Box( {"x", ex = 1, "y", ex = 2}
  ) ),
  )
);
```

```
Table Box(display box, ...)
```

Description

Creates a report table with the *display boxes* listed as columns.

```
Text Box("text", <arguments>)
```

Description

Constructs a box that contains the quoted string *text*.

Arguments

    `<<Justify Text("position")` Justifies the text left, center, or right as specified in quotes.

    `<<Set Wrap(pixels)` Sets the point at which text wraps.

Text Edit Box("text", <arguments>)

Description

Constructs an editable box that contains the quoted string *text*.

Arguments

    `<<Password Style(boolean)` Displays asterisks in the box rather than the password.

    `<<Set Script` Runs the specified script after the text is edited.

    `<<Set Width(pixesl)` Sets the point at which text wraps.

This Project()

Description

Gets the current project when a JSL script is run from that project.

Example

The following example gets the window title of the current project.

```
project = New Project();
project << Save( "$DOCUMENTS/Test Project.jmpprj" );
project << Run Script(
   New Window( "Project Title",
      Text Box(This Project() << Get Window Title())
   );
);
```

Tree Box(<{rootnodes}>, <size(*width*, *height*)>, <MultiSelect>)

Description

Constructs a box to show a hierarchical tree composed of Tree Nodes.

Arguments

    `{rootnodes}` Specifies the names for the root nodes created by `Tree Node()` which the box contains.

    `size(width, height)` Specifies the width and height (in pixels) of the box.

    `MultiSelect` Indicates that more than one item in the tree can be selected.

Tree Node(<data>)

Description

Creates a node for display in a Tree Box display. Tree Node is used for both parent and child nodes.

Note

If you send a root node that contains one or more nodes with the `Set Node Select Script` defining a collapse message, then Mac runs the script twice. Windows doesn't run the script. This behavior on Macintosh doesn't just affect increments. Any script runs twice. It will print to the log twice, create a column twice, try to delete something twice, and so on.

Triangulation(<dt>, X(col1, col1), <Y(Col)>)

Description

Returns an object containing the Delaunay triangulation of the given point set. The optional Y will be averaged for duplicate points, and all points in the output will be unique.

Examples

```
tri = Triangulation(
    X( [0 0 1 1], [0 1 0 1] ),
    Y( [0 1 2 3] )
);
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
tri = Triangulation( X( :X, :Y ), Y( :POP ) );
```

V Center Box(display box)

Description

Returns a display box with the display box argument centered vertically with respect to all other sibling display boxes.

V List Box(<Align("center"|"right")> display box, ...)

Description

Creates a display box that contains other display boxes and displays them vertically.

Arguments

`Align` Specify right or center alignment of the contents in the list box. The contents are center aligned by default.

`display box` Any number of display box arguments can be contained in the list box.

V Sheet Box(<<Hold(report), display boxes)

Description

Returns a display box that arranges the display boxes provided by the arguments in a vertical layout. The <<Hold() message tells the sheet to own the report(s) that is excerpted.

V Splitter Box(<size(*h*,*v*)>, display box, <arguments>)

Description

Returns a display box that arranges the display boxes provided by the arguments in a vertical layout (or panel). The splitter enables the user to interactively resize the panel.

Arguments

display box Any number of display box arguments can be contained in the splitter box.

Notes

For details about the optional arguments, see *"H Splitter Box(<size(h,v)>, display box, <arguments>)"* on page 95.

Web Browser Box("url")

Description

Creates a display box that contains a web page. Available only on Windows in Internet Explorer.

Returns

A reference to the web browser box object.

Argument

url A quoted string containing the URL to the web page to display.

Example

The following example creates a splitter box with the web browser box on the left and the bubble plot on the right.

```
dt = Open( "$SAMPLE_DATA/PopAgeGroup.jmp" );
New Window( "Example",
  H Splitter Box(
    Size( 800, 300 ),
    wb = Web Browser Box( "http://www.jmp.com" ),
    dt << Run Script( "Bubble Plot Region" )
  )
);
wb << Set Auto Stretching( 1, 1 ); // auto stretch horizontally and vertically
wb << Set Max Size( 10000, 10000 ); // maximum size in pixels
```

Notes

The <a href> target "_blank" opens the web page in a new Internet Explorer window. The <a href> target "_new" opens the web page in the active Internet Explorer tab.

Window(<string|int>)

Returns

Either a list of references to all open windows, or a reference to an explicitly named window.

Arguments

string A quoted string containing the name of a specific open window.

int the number of a specific open window.

Notes

If no argument is provided, a list of all open windows is returned.

If the argument (either a window name or number) does not exist, an empty list is returned.

Wrap List Box(display box, ...)

Description

Creates a list box that contains other display boxes and displays them horizontally, but wraps them when printing.

Arguments

display box Any number of display box arguments can be contained in the list box.

Expression Functions

Arg(expr, i)

Arg Expr(expr, i)

Description

Finds the argument numbered by *i* within the given expression.

Returns

The *i*th argument within the expression *expr*.

Empty() if that argument does not exist or is not specified.

Arguments

expr an expression defined previously in the JSL script.

i an integer denoting which argument to return.

Notes

Arg Expr() was deprecated in a previous release of JMP. Use Arg() instead.

Eval Expr(expr)

Description

Evaluates any expressions within *expr*, but leaves the outer expression unevaluated.

Returns

An expression with all the expressions inside *expr* evaluated.

Argument

expr Any JSL expression.

Expr(x)

Description

Returns the argument unevaluated (expression-quoting).

Returns

The argument, unevaluated.

Argument

x Any valid JSL expression.

Extract Expr(expr, pattern)

Description

Find *expr* matching *pattern*.

Returns

A pattern that matches the specified *pattern*.

Arguments

expr Any expression.

pattern Any pattern.

Head(exprArg)

Head Expr(exprArg)

Description

Returns the head of the evaluated expression, without its arguments.

Note

Head Expr() is deprecated. Use Head() instead.

```
Head Name(expr)
```

```
Head Name Expr(expr)
```

Description

Returns the head of the evaluated expression as a string.

Note

`Head Name Expr()` is deprecated. Use `Head Name()` instead.

```
N Arg(exprArg)
```

Description

Returns the number of arguments of the evaluated expression head.

```
N Arg Expr(exprArg)
```

Description

`N Arg Expr()` is deprecated. Use `N Arg()` instead.

Returns the number of arguments of the expression head.

```
Name Expr(x)
```

Description

Returns the unevaluated expression of *x* rather than the evaluation of *x*.

File Functions

```
Close(<dt|query>, <nosave|save("path")>)
```

Description

Closes a data table, query, or JSON file. If no arguments are specified, the current file is closed. If the file has been changed, it is automatically saved. All dependent windows are also closed (for example, report windows that are based on the data table).

Returns

Void.

Arguments

`dt` an optional reference to a data table, query, or JSON file.

`nosave|save("path")` An optional switch to either save the file to the specified path before closing or to close the file without saving it.

Close All(type, <invisible|private>, <noSave|save>)

Description

Closes all open resources of *type*.

Argument

type A named argument that defines the type of resources that you want to close. The allowable types are: Data Tables, Reports, and Journals.

invisible Optional. Specifies whether to close all invisible data tables.

private Optional. Specifies whether to close all private data tables.

noSave or Save An optional argument that specifies whether to save the specified types of windows before closing or to close without saving.

Close Database Connection(db connection handle)

Description

Closes a database connection returned from Create Database Connection.

Example

```
Close Database Connection(db connection handle)
```

Close Log(Boolean)

Description

Closes the log window.

Convert File Path(path, <"absolute"|"relative">, <"posix"|"windows">, <base(path)>)

Description

Converts a file path according to the arguments.

Returns

The converted path.

Arguments

path A pathname that can be either Windows or POSIX.

absolute|relative Optional quoted string, specifies whether the returned pathname is in absolute or relative terms. The default value is absolute.

posix|windows Optional quoted string, specifies whether the returned pathname is in Windows or POSIX style. The default is POSIX.

base(path) Optional, specifies the base pathname, useful if relative is specified. The default is the default directory.

Copy Directory("from path", "to path", <recursive=Boolean>)

Description

Copies files from one directory to another, optionally copying subdirectories. The directory name is created in the *to path* and should not be part of the *to path* argument.

Returns

Returns 1 if the directory is copied; otherwise, returns 0.

Arguments

from path Specifies the directory containing the files to copy to the new directory.

to path Specifies the path where the new directory should be created and to which the files are copied.

<recursive(Boolean)> Indicates whether to copy the *from path* subdirectory structure to the *to path*. On Windows operating systems released after Windows XP, copying is always done recursively.

Copy File("from path", "to path")

Description

Copies one file to a new file using the same or a different name.

Returns

Returns 1 if the file is copied; otherwise, returns 0.

Arguments

from path Specifies the path and file name to copy to the new file.

to path Specifies the path and file name for the new file.

Create Database Connection((string, <DriverPrompt(1)>) | "Connect Dialog");

Description

Creates a connection to the specified database or prompts the user to provide database log in information.

Returns

A handle to the database connection.

Arguments

string The server connection string that contains information such as the data source name and user name.

Driver Prompt An optional Boolean argument that enables the ODBC driver to prompt for the connection information if necessary.

"Connect Dialog" A string that opens the Select Data Source window, from which the
user selects the database.

Examples

Specify the data source name, user name, and password:

```
Create Database Connection( "dsn=Books;UID=johnsmith;password=Christmas" );
```

Request that the ODBC driver prompt the user to enter connection information, because the
connection string does not specify the password:

```
Create Database Connection( "dsn=Books;UID=johnsmith", Driver Prompt( 1 ) );
```

Enable the user to select the data source, specify "Connect Dialog":

```
Create Database Connection( "Connect Dialog" );
```

Create Directory("path")

Description

Creates a new directory at the specified path location.

Returns

Returns 1 if the directory is created; otherwise, returns 0.

Arguments

path Specifies the path where the new directory should be located.

Creation Date("path")

Description

Returns the creation date for the specified file or directory.

Returns

Creation date.

Arguments

path Specifies the directory or path and file name for the query.

Delete Directory("path", <Allow Undo(Boolean)>)

Description

Deletes the specified directory and its contents and any subdirectories.

Returns

Returns 1 if the directory is deleted; otherwise, returns 0.

Arguments

path Specifies the path and directory for deletion.

Allow Undo Allows undo operations, for example, moving to the Recycle Bin or Trash
Can.

Delete File("path", <Allow Undo(Boolean)>)

Description

Deletes the specified file.

Returns

Returns 1 if the file is deleted; otherwise, returns 0.

Arguments

path Specifies the path and file name for deletion.

Allow Undo Allows undo operations, for example, moving to the Recycle Bin or Trash Can.

Directory Exists("path")

Description

Verifies the specified directory exists.

Returns

Returns 1 if the directory exists; otherwise returns 0.

Arguments

path Specifies the path and directory for verification.

File Exists("path")

Description

Verifies the specified file name exists at the specified path.

Returns

Returns 1 if the file exists; otherwise returns 0.

Arguments

path Specifies the path and file name for verification.

File Size(path)

Description

Determines the size of the file within the specified path.

Example

```
File Size( "$SAMPLE_DATA/Big Class.jmp" );
```

Files In Directory(path, <"recursive">)

Description

Returns a list of filenames in the *path* given.

Returns

List of filenames. If `"recursive"` is not specified, directory names are included in the list.

Arguments

`path` A valid pathname.

`recursive` An optional quoted keyword that causes all folders in the path (and all folders that they contain, and so on) to be searched for files.

Find All(data tables|reports|journals, <invisible|private>)

Description

Finds all open files of the specified type.

Example

The following example finds all open data tables:

```
exdt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
exdt2 = Open( "$SAMPLE_DATA/Animals.jmp" );
windows = Find All( Data Tables );
For( i = 1, i <= N Items( windows ), i++,
   Write( Char( windows[i] << Get Window Title ) || "\!N" )
);
   Cities
   Big Class
   Animals
```

Get Default Directory()

Description

Retrieves the user's default directory. This path is used for subsequent relative paths.

If the default directory was set using `Set Default Directory()`, JMP returns the specified path as long as `Get Default Directory()` and `Set Default Directory()` are in the same script.

See "Set Default Directory("path")" on page 132.

Returns

The absolute pathname as a string.

Arguments

Get Excel Worksheets("absolute path")

Description

Retrieves a list of worksheets that are in the specified Microsoft Excel workbook. If no worksheets are found, an empty list is returned.

Notes

The function supports .xlsx and Excel 1997 or later workbooks.

Get File Search Path()

Description

Retrieves the current list of directories to search for opening files.

This list is configured using the Set File Search Path() function. See

Returns

A list of pathnames as strings.

Get Path Variable("name")

Description

Retrieves the value of name, a path variable.

Returns

The absolute pathname as a string.

Argument

name A quoted string that contains a path variable. (Examples: SAMPLE_DATA, SAMPLE_SCRIPTS)

Is Directory(path)

Description

Returns 1 if the path argument is a directory and 0 otherwise.

Is Directory Writable(path)

Description

Returns 1 if the directory specified in the path argument is writable and 0 otherwise.

Is File(path)

Description

Returns 1 if the path argument is a file and 0 otherwise.

Is File Writable(path)

Description

Returns 1 if the file specified in the path argument is writable and 0 otherwise.

```
Is Log Open()
```

Description

Returns a Boolean value that indicates whether the log window is open.

```
JSON to Data Table(JSON string)
```

Description

Converts JSON text to a data table.

Returns

A data table reference.

Example

```
dt = JSON to Data Table(
    "[ { \!"name\!": \!"KATIE\!", \!"age\!": 12, \!"sex\!": \!"F\!",
    \!"height\!": 59, \!"weight\!": 95 }, { \!"name\!": \!"LOUISE\!",
    \!"age\!": 12, \!"sex\!": \!"F\!", \!"height\!": 61, \!"weight\!": 123 }, {
    \!"name\!": \!"JANE\!", \!"age\!": 12, \!"sex\!": \!"F\!h", \!"height\!":
    55, \!"weight\!": 74 } ]"
);
```

```
JSON to List(JSON string)
```

Description

Converts JSON text to a JSL list that represents the structure specified by the JSON data.

Example

```
l = JSON To List(
    "[ { \!"name\!": \!"KATIE\!", \!"age\!": 12, \!"sex\!": \!"F\!",
    \!"height\!": 59, \!"weight\!": 95 }, { \!"name\!": \!"LOUISE\!",
    \!"age\!": 12, \!"sex\!": \!"F\!", \!"height\!": 61, \!"weight\!": 123 }, {
    \!"name\!": \!"JANE\!", \!"age\!": 12, \!"sex\!": \!"F\!", \!"height\!":
    55, \!"weight\!": 74 } ]"
);
Show( l );
```

```
JSON Literal(string)
```

Description

Returns a valid JSON Boolean or null constant based on the specification of the parameter.

```
Last Modification Date("path")
```

Description

Returns the last modification date of the specified file or directory.

Returns

Last modification date.

Arguments

`path` Specifies the directory or file name.

Load Text File(path, <arguments>)

Description

Reads the text file at *path* into a JSL variable.

Returns

A string.

Arguments

`path` A pathname that points to a text file. The path can be a URL.

`Charset` Optional argument that determines the character set. Arguments include the following:

– `"best guess"` attempts to detect the character set.

– `force("throw"|"alert"|"silent")` is an optional argument that determines what happens if the character set cannot be detected.

`Line Separator("character")` Optional argument that specifies the end-of-line character. For example, `"\!n"` specifies a line feed character. `"\!t"` specifies a tab.

`XMLParse` Optional argument that converts an XML file into JSL.

`SASODSXML` Optional argument that parses the text file as SAS ODS default XML.

`JSON` Optional argument that converts JSON into an expression tree.

`BLOB(<arguments>)` Optional argument that returns data from the file as a blob rather than a string. The following optional arguments are for reading parts of the file:

– `ReadOffsetFromBegin(`*n*`)` specifies the zero-based offset to begin reading from the beginning of the file.

– `ReadOffsetFromEnd(`*n*`)` specifies the zero-based offset to begin reading from the end of the file.

– `ReadLength(`*n*`)` specifies the number of bytes to read from the file, either from the beginning of the file or from one of the offset values.

– `Base64Compressed(0|1)` specifies how the blob is converted to a printable representation. 0, the default and recommended setting, uses JMP's ASCII~HEX representation. 1 means the blob is compressed and converted to base 64 when printed.

```
Method({arg1 = val1, ...}, < { local1 = val1, ... } >, expression)
```

Description

Creates a method within a class.

Arguments

`{ arg1 = val1, … }` The set of expected arguments and optional initialization expressions to be passed to the method when called.

`{ local1 = val1, ... }` The set of local variables to be used by the class method.

Returns

Initializes the Python integration interfaces.

```
Move Directory("from path", "to path")
```

Description

Moves a directory and its contents (including subdirectories) from the specified path to another specified path.

Returns

Returns 1 if the directory is moved; otherwise returns 0.

Arguments

`from path` Specifies the path and directory for relocation.

`to path` Specifies the destination path and directory.

```
Move File("from path", "to path")
```

Description

Moves a file from the specified path to another specified path with the same or different file name.

Returns

Returns 1 if the file is moved; otherwise returns 0.

Arguments

`from path` Specifies the path and file name for relocation.

`to path` Specifies the destination path and file name.

Notes

On Windows, when you move a file to a folder that does not exist, Windows creates the folder and returns 1. On Macintosh, the folder is not created, and an error is returned.

Open("path", <arguments>)

Description

Opens the data table or other JMP file or object created from a file named by the *path*. If no path is specified, the Open window appears. Also opens JSON and HDF5 files. Refer to the examples in the JMP Scripting Index for details about which arguments apply to specific file types.

Arguments

`Add to Recent Files(Boolean)` Determines whether the file is added to the Recent Files list in the Home Window.

`Charset("option")` The available character set options for importing text files are `Best Guess`, `utf-8`, `utf-16`, `us-ascii`, `windows-1252`, `x-max-roman`, `x-mac-japanese`, `shift-jis`, `euc-jp`, `utf-16be`, and `gb2312`.

`Column Names Start(n) | Column Names are on line(n)` Specifies the line number that column names start in the imported text file. If the text file uses returns between cells, column names could be on multiple lines.

`Columns(colName = colType(colWidth),...)` Specifies the columns by name in the text file to import into a data table where:

– `colName`: Specifies the column name used in the imported text file.

– `colType(Character | Numeric)`: Indicates whether the specified column contains character or numeric data.

– `colWidth(n)`: indicates the integer width of the specified column.

`Columns(<arguments>)` For ESRI shapefiles (.shp), this argument and its settings indicate the following:

– `Shape=numeric(n)`: Indicates the column number in the imported ESRI shapefile that contains the shape number.

– `Part=numeric(n)`: Indicates the column number in the imported ESRI shapefile that contains the part number.

– `X=numeric(n)`: Indicates the column number in the imported ESRI shapefile that contains the decimal degree for the longitude (range of ±180°).

– `Y=numeric(n)`: Indicates the column number in the imported ESRI shapefile that contains the decimal degree for the latitude (range of ±90°).

`Compress Allow List Check(Boolean)` Indicates that JMP can compress data table created from the imported text file.

`Compress Character Columns(Boolean)` Indicates that JMP should compress data table columns that contain character data from the imported text file.

`Compress Numeric Columns(Boolean)` Indicates that JMP should compress data table columns that contain numeric data from the imported text file.

Concatenate Worksheets(Boolean) Indicates that JMP should combine the imported Excel worksheets into one data table.

Create Concatenation Column(Boolean) Indicates that JMP should combine columns from an imported Excel file into one column.

Data Starts(n) | Data Starts on Line(n) Specifies the line number where data starts in the imported text file.

Debug JSL(Boolean) Opens the specified JSL script in the Debugger instead of opening it.

End Of Field(Tab|Space|Comma|Semicolon|Other|None) Specifies the character used to delimit the end of a field in the imported text file. To specify multiple characters, separate each character designation by a comma. If you use "Other", designate the delimiter with EOF Other() argument.

End Of Line(CRLF|CR|LF|Semicolon|Other) Specifies the character used to delimit the end of a line in the imported text file. To specify multiple characters, separate each character designation by a comma. If you use "Other", designate the delimiter with EOL Other() argument.

EOF Other("char") If the imported text file uses an end of field character other than the one specified by End of Field, this argument specifies the character used.

EOL Other("char") If the imported text file uses an end of line character other than the one specified by End of Line, this argument specifies the character used.

Excel Wizard Opens Microsoft Excel worksheets in the Excel Import Wizard. If you omit this argument, the worksheets open directly as a data table.

File Type An optional string that specifies the type of file that you are opening (for example, "text", "journal", "sas", "script", "png", and "jmp"). This can be useful if your file does not have a file extension, the file extension of the file does not match the contents of the file, or you want to import a JSL Blob. If you do not specify this string, the file opens in the default program for the file extension.

Note: The path argument should be used for a zip archive. The extension (.zip) is not required. See "Zip Archives" on page 465 in the "JSL Messages" chapter for the messages that you can send to a zip archive. The basic functionality is to get a list of files in the zip archive, to read a file in the zip archive into either a string or a blob, and to write files into the zip archive. Note that reading a zip archive temporarily puts the contents into memory. Reading very large zip archives can cause errors.

Force Refresh Closes the specified JMP (.jrn, .jsl, .jrp, or .jmpappsource) file without saving and tries to reopen the file from disk. This argument deletes any changes made since the last time the file was opened.

HTML Table(n, ColumnNames(n), DataStarts(n)) To import a table from an HTML web page, use the URL as the filepath. The optional *n* argument specifies which table number, *n*, on the web page to open. If you omit the value, only the first table on the

page is imported. The optional `ColumnNames(`*n*`)` specifies the row that contains column names. The optional `DataStarts(`*n*`)` specifies the row on which the data begins.

Tip: If the table you are importing contains images, they are first imported as text. To load the images in your JMP data table, run the automatically generated table script named Load Pictures. A new expression column containing the images is created. See The Column Info Window chapter in the *Using JMP* book for details about expression columns.

`Ignore Columns( "col", ... )` Indicates the column names in the JMP data table or other JMP file that should not be included in the data table.

`Invisible` Opens the file as invisible. This quoted keyword applies to the files: data table, JMP file, external, text, Excel, SAS, ESRI shapefile, or HTML. The data table appears only in the JMP Home Window and the Window menu.

`Labels(Boolean)` Indicates the imported text file contains labels or column headers as the first line in the file. The default value is `True`.

`Lines to Read(n)` Specifies the number of lines in the text file to import. JMP starts counting lines after column names are read.

`Number of Columns(n)` Specifies the number of columns contained in the imported text file.

`Run JSL(Boolean)` Runs the specified JSL file instead of opening it. Include a Boolean argument or an expression that contains a Boolean value. If the script begins with `//!`, which automatically runs the script, include the Boolean value `(0)` to open the script instead.

`Password("password")` Specifies the password for a password-protected SAS file to avoid entering it manually. The password is not encrypted. (Password-protected Microsoft Excel files cannot be imported.)

`Private` Opens the table as invisible and without showing it in the JMP Home Window or Window menu. For example, you might create a private data table to hold temporary data that the user does not need to see. This quoted keyword applies to the following files: data table, JMP file, external, text, Excel, SAS, ESRI shapefile, or HTML. Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

`Quarantine Action("Allow Scripts"|"Block Scripts"|"Do Not Open"|"Show Dialog")` Determines whether scripts run when you open downloaded data tables. Also provides an option to display a window that prompts users to examine or open the data table. If they select Examine, the scripts are disabled. See the Data Tables chapter in the *Scripting Guide* for examples.

`Scan Whole File(Boolean)` Specifies how long JMP scans the text file to determine data types for the columns. This is a Boolean value. The default value is true; the entire file is

scanned until the data type is determined. To import large files, consider setting the value to false, which scans the file for five seconds.

`Select Columns("col", ...)` Indicates the column names in the JMP data table or other JMP file that should be included in the data table.

`Strip Quotes | Strip Enclosing Quotes (Boolean)` If the fields in the text file are quoted, setting this to `True` removes the quotes, and setting it to `False` does not remove the quotes. The default value is `True`.

`Table Contains Column Headers (Boolean)` Indicates the imported text file contains labels or column headers as the first line in the file. The default value is `True`.

`Text Wizard` Opens the text file in the text import window, where you can select import options. Otherwise, the Text Data Files options in the JMP preferences apply, and the text file is automatically imported as a data table.

`Treat Empty Columns as Numeric(Boolean)` Indicates that JMP should import text file columns of missing data as numeric rather than character. Possible missing value indicators are a period, a Unicode dot, NaN, or a blank string. The default value is `False.`

`Use Apostrophe as Quotation Mark(Boolean)` Declares apostrophes as quotation marks in importing text files. This option is not recommended unless your data comes from a nonstandard source that places apostrophes around data fields rather than quotation marks. The default value is `False`.

`Use Labels for Var Names(Boolean)` For SAS data sets, this option specifies to use SAS labels as JMP columns names. The default value is `False`.

`Use for all sheets(Boolean)` Indicates that JMP should use the `Worksheets` settings for all worksheets in the Excel file to be opened as a data table.

`Worksheet Settings(Boolean, <options>)` Specifies options for importing an Excel file into a JMP data table. Available options are:

– `Has Column Headers(Boolean)` - Indicates the Excel file has column headers in the first row.

– `Number of Rows in Headers(n)` - Specifies the number of rows in the Excel file used as column headers.

– `Headers Start on Row(n)` - Specifies the row number in the Excel file where the column headers begin. Default is row 1.

– `Data Starts on Row(n)` - Specifies the row number in the Excel file where the data begins.

– `Data Starts on Column(n)` - Specifies the column number in the Excel file where the data begins.

– `Data Ends on Row(n)` - Specifies the row number in the Excel file where data ends.

- Data Ends on Column(n) - Specifies the column number in the Excel file where the data ends.
- Replicated Spanned Rows(Boolean) - Indicates the Excel file contains spanned columns that should be imported into JMP as spanned columns.
- Suppress Hidden Rows(Boolean) - Indicates that JMP should not import rows hidden in the Excel file.
- Suppress Hidden Columns(Boolean) - Indicates that JMP should not import columns hidden in the Excel file.
- Treat as Hierarchy(Boolean) - Indicates that JMP should treat multiple column headers (merged cells) as hierarchies when importing an Excel file. If True, the Excel file opens with the merged columns stacked (**Tables > Stacked**).

Worksheets ("sheet name"|{"sheet name", "sheet name",...}|"*n*") Opens the specified Excel file worksheet by name, all worksheets in a list of names, or the indexed number of the worksheet. If the worksheets are not specified, all worksheets in the spreadsheet open as separate data tables.

Year Rule | Two digit year rule
("1900-1999"|"1910-2009"|"1920-2019"|"1930-2029"|"1940-2039"|
"1950-2049"|"1960-2059"|"1970-2069"|"1980-2079"|"1990-2089"|"2000-2099")
Indicates the year format used in the imported text file. For example, if the earliest date is 1979, use "1970-2069".

```
Open Database(dataSourceName|"Connect Dialog", "SELECT
..."|"SQLFILE..."|tableName, <invisible|private>, <outputTableName">
```

Description

Opens the database indicated by *dataSourceName* (or opened by the user) with the *SELECT*, *SQLFILE,* or *tableName* arguments.

Returns

A data table named *outputTableName*.

Optional Arguments

invisible Creates an invisible data table that hides the table from view but lists it in the JMP Home Window and Window menu.

private Hides the data table completely. Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

outputTableName The name of the data table in JMP.

Example

```
Open Database(
    "DSN=dBASE Files;DBQ=C:/Program Files/SAS/JMPPRO/14/Samples/Import Data/;",
    // SQL statement
```

```
    "SELECT HEIGHT, WEIGHT FROM Bigclass", // selected columns
    "hw" // name of the output data table
);
```

Parse JSON(JSON string)

Description

Converts JSON text into an associative array or list based on the structure of the JSON data. Convert the result to a list if the parsed JSON object contains more than one member.

Example

The following example converts JSON into a list:

```
j = Parse JSON(
    "[ { \!"name\!": \!"KATIE\!", \!"age\!": 12, \!"sex\!": \!"F\!",
    \!"height\!": 59, \!"weight\!": 95 }, { \!"name\!": \!"LOUISE\!",
    \!"age\!": 12, \!"sex\!": \!"F\!", \!"height\!": 61, \!"weight\!": 123 }, {
    \!"name\!": \!"JANE\!", \!"age\!": 12, \!"sex\!": \!"F\!", \!"height\!":
    55, \!"weight\!": 74 } ]"
);
Show( j );
    j = {["age" => 12, "height" => 59, "name" => "KATIE", "sex" => "F", "weight"
        => 95], ["age" => 12, "height" => 61, "name" => "LOUISE", "sex" => "F",
        "weight" => 123], ["age" => 12, "height" => 55, "name" => "JANE", "sex"
        => "F", "weight" => 74]};
```

Pick Directory(<"prompt">, <path>, <Show Files>)

Description

Prompts the user for a directory, returning the directory path as a string.

Returns

The path for the directory that the user selects.

Arguments

prompt An optional quoted string. If provided, the string appears at the top of the Browse window (Windows) or below "Open" on the Finder window (Macintosh).

path An optional quoted string that specifies the initial directory that appears in the Pick Directory window.

Show Files (Boolean) Specify 1 to show files in the Pick Directory window, or zero to hide files. The default is zero.

Pick File(<"prompt">, <"initial directory">, <{filter list}>, <first filter>, <save flag>, <"default file">), <multiple>

Description

Prompts the user to select one or more files in the Open window.

Returns

The path of the file that the user selects.

Arguments

`prompt` An optional quoted string. If provided, that string appears at the top of the Open window.

`initial directory` An optional quoted string that is a valid filepath to a folder. If provided, it specifies where the Open window begins. If not provided, or if it's an empty string, the JMP Default Directory is used.

`filter list` An optional list of quoted strings that define the filetypes to show in the Open window. See the following example for syntax.

`first filter` An optional integer that specifies which of the filters in the filter list to use initially. If you use an integer that is too large or small for the list (for example, 4 for a list of 3), the first filter in the list is used.

`save flag` An optional Boolean that specifies whether the Open window or Save window is used. 0 lets the user select a file to open in JMP. 1 lets the user save a new, empty file of the selected type in the selected folder. The default value is 0.

`default file` The name of the file that appears in the window by default.

`multiple` An optional argument that lets the user select multiple files if the `save flag` is 0.

Notes

Although all arguments are optional, they are also positional. For example, you cannot specify a filter list without also specifying the caption and the initial directory.

The buffer size in the computer's physical memory affects the number of files the user can open.

Example

The following script assigns *Select JMP File* as the window title; shows the JMP Samples/Data directory; shows *JMP Files* and *All Files* in the File name list and selects *JMP Files*; displays the Open window; and shows the sample data file name Hollywood Movies.jmp.

```
Pick File(
    "Select JMP File",
    "$SAMPLE_DATA",
    {"JMP Files|jmp;jsl;jrn", "All Files|*"},
    1,
    0,
    "Hollywood Movies.jmp"
);
```

Rename Directory("old path name", "new directory name")

Description

Renames a directory without moving or copying it.

Returns

Returns 1 if the directory is renamed; otherwise, returns 0.

Arguments

old path name Specifies the path and old directory name.

new name Specifies the new directory name.

Notes

When you specify the *new directory name,* include only the directory name, not the entire path.

Rename File("old path name", "new name")

Description

Renames a file without moving or copying it.

Returns

Returns 1 if the file is renamed; otherwise, returns 0.

Arguments

old path name Specifies the path and old file name.

new name Specifies the new file name.

Notes

When you specify the *new name,* include only the file name, not the entire path.

Save Text File(path, text)

Description

Saves the JSL variable text into the file specified by path.

Set Default Directory("path")

Description

Sets the default directory, which is used for resolving relative paths.

See "Get Default Directory()" on page 120.

Set File Search Path({path or list of paths})

Description

Sets the current list of directories to search for opening files. Using {"."} as the path configures JMP to use the current directory.

See "Get File Search Path()" on page 121.

Example

```
Set File Search Path( {"C:/JMP/13/source", "C:/Program
    Files/SAS/JMPPRO/14/Samples"} );
```

Set Path Variable("name", <value>)

Description

Sets the path stored in the variable.

Arguments

`name` The name of the variable.

`value` The path.

TripleS Import("path", <arguments>)

Description

Imports the specified Triple-S Survey (SSS) file. The SSS format consists of a pair of files: .xml or .sss, and a .csv, .dat, or .asc file. Both sets of files must have the same root name and be in the same folder.

Arguments

`path` Quoted string that contains the full path to the .xml or .sss file.

`Invisible` Optional. Hides the table from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call `Close(dt)`, where *dt* is the data table reference returned by `TripleS Import`.

`Use Labels for Imported Column Names` Optional Boolean. Converts the label names to column headings. The default value is `true`.

Example

```
dt = TripleS Import( "C:/Data/airlines.sss", Invisible, Use Labels for
    Imported Column Names( 0 ) );
```

Financial Functions

Double Declining Balance(cost, salvage, life, period, <factor>)

Description

Returns the depreciation of an asset for a specified period of time. The function uses the double-declining balance method or some other depreciation factor.

Arguments

cost The initial cost.

salvage The value at the end of the depreciation.

life The number of periods in the depreciation cycle.

period The length of the period, in the same units as life.

factor An optional number that is the rate at which the balance declines. The default value is 2.

Note

This function is equivalent to the Excel function DDB.

Future Value(rate, nper, pmt, <pv>, <type>)

Description

Returns the future value of an investment that is based on periodic, constant payments and a constant interest rate.

Arguments

rate The interest rate.

nper The number of periods.

pmt The constant payment.

pv An optional number that is the present value. The default value is 0.

type An optional switch. 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Note

This function is equivalent to the Excel function FV.

Interest Payment(rate, per, nper, pv, <fv>, <type>)

Description

Returns the interest payment for a given period for an investment that is based on periodic, constant payments and a constant interest rate.

Arguments

   `rate` The interest rate.

   `per` The period for which you want the interest.

   `nper` The total number of periods.

   `pv` The present value.

   `fv` An optional number that is the future value. The default value is 0.

   `type` An optional switch. 0 specifies end-of-period payments, and 1 specifies
      beginning-of-period payments. The default value is 0.

Note

   This function is equivalent to the Excel function IPMT.

`Interest Rate(nper, pmt, pv, <fv>, <type>, <guess>)`

Description

   Returns the interest rate per period of an annuity.

Arguments

   `nper` The total number of periods.

   `pmt` The constant payment.

   `pv` The present value.

   `fv` An optional number that is the future value. The default value is 0.

   `type` An optional switch. 0 specifies end-of-period payments, and 1 specifies
      beginning-of-period payments. The default value is 0.

   `guess` An optional number that is what you think the rate will be. The default value is 0.1
      (10%).

Note

   This function is equivalent to the Excel function RATE.

`Internal Rate of Return(values, <guess>)`

`Internal Rate of Return(guess, value1, value2, ...)`

Description

   Returns the internal rate of return for a series of cash flows in the *values* argument.

Arguments

   `values` A one-dimensional matrix of values. If the second form of the function is used, list
      each value separately.

   `guess` The number that you think is near the result. The default value is 0.1 (10%).

Note

   This function is equivalent to the Excel function IRR.

`Modified Internal Rate of Return(values, finance rate, reinvest rate)`

`Modified Internal Rate of Return(finance rate, reinvest rate, value1, value2, ...)`

Description

Returns the modified internal rate of return for a series of periodic cash flows. The cost of investment and the interest received on reinvested cash is included.

Arguments

`values` A one-dimensional matrix of values. If the second form of the function is used, list each value separately.

`finance rate` The interest rate that you pay on the money in the cash flows.

`reinvest rate` The interest rate that you receive on the cash flows when you reinvest them.

Note

This function is equivalent to the Excel function MIRR.

`Net Present Value(rate, values)`

`Net Present Value(rate, value1, value2, ...)`

Description

Returns the net present value of an investment by using a discount rate and a series of future payments (negative values) and income (positive values).

Arguments

`rate` The discount rate.

`values` A one-dimensional matrix of values. If the second form of the function is used, list each value separately.

Note

This function is equivalent to the Excel function NPV.

`Number of Periods(rate, pmt, pv, <fv>, <rate>)`

Description

Returns the number of periods for an investment that is based on periodic, constant payments and a constant interest rate.

Arguments

`rate` The interest rate.

`pmt` The constant payment.

`pv` The present value.

`fv` An optional number that is the future value. The default value is 0.

    `type` An optional switch. 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Note

This function is equivalent to the Excel function NPER.

`Payment(rate, nper, pv, <fv>, <type>)`

Description

Returns the payment for a loan that is based on constant payments and a constant interest rate.

Arguments

    `rate` The interest rate.

    `nper` The total number of periods.

    `pv` The present value.

    `fv` An optional number that is the future value. The default value is 0.

    `type` An optional switch. 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Note

This function is equivalent to the Excel function PMT.

`Present Value(rate, nper, pmt, <fv>, <type>)`

Description

Returns the present value of an investment.

Arguments

    `rate` The interest rate per period.

    `nper` The total number of periods.

    `pmt` The constant payment.

    `fv` An optional number that is the future value. The default value is 0.

    `type` An optional switch. 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Note

This function is equivalent to the Excel function PV.

`Principal Payment(rate, per, nper, pv, <fv>, <type>)`

Description

Returns the payment on the principal for a given period for an investment that is based on periodic, constant payments and a constant interest rate.

Arguments

`rate` The interest rate per period.

`per` The period for which you want the interest.

`nper` The total number of periods.

`pv` The present value.

`fv` An optional number that is the future value. The default value is 0.

`type` An optional switch. 0 specifies end-of-period payments, and 1 specifies
beginning-of-period payments. The default value is 0.

Note

This function is equivalent to the Excel function PPMT.

`Straight Line Depreciation(cost, salvage, life)`

Description

Returns the straight-line depreciation of an asset for one period.

Arguments

`cost` The initial cost of the asset.

`salvage` The value at the end of the depreciation.

`life` The number of periods in the depreciation cycle.

Note

This function is equivalent to the Excel function SLN.

`Sum Of Years Digits Depreciation(cost, salvage, life, per)`

Description

Returns the sum-of-years' digits depreciation of an asset for a specified period.

Arguments

`cost` The initial cost of the asset.

`salvage` The value at the end of the depreciation.

`life` The number of periods in the depreciation cycle.

`per` The length of the period, in the same units as life.

Note

This function is equivalent to the Excel function SYD.

Graphics Functions

```
Add Color Theme({"name", <flags>, {color}, <{position}>)
```

Description

Creates a custom color theme that you can apply to components such as markers, data table rows, and treemaps. Add the color theme to the JMP Preferences by including `Add Color Theme(...)` inside `Preferences()`.

Returns

Null.

Arguments

`name` The name of the color theme.

`flags` An optional flag for the Continuous or Categorical color theme list and category of color.

```
Continuous, <Continuous>, Sequential
Continuous, <Continuous>, Diverging
Continuous, <Continuous>, Chromatic
Categorical, <Continuous>, Sequential
Categorical, <Continuous>, Diverging
Categorical, Qualitative
Categorical, <Continuous>, Chromatic
```

With the default JMP color themes, Sequential colors transition from left to right or right to left. Diverging colors are lighter in the middle. Chromatic colors consist of blocks or gradients of bright color. All categories except for Qualitative can be both continuous and categorical.

If you omit the flag, the color is shown in the Continuous, Sequential and Categorical, Sequential categories.

`color` Lists of RGB values. These values define the blocks in categorical color themes and the gradients in continuous color themes. Each list of RGB values corresponds to a slider in the preferences Color Themes window.

`position` An optional list of numbers between 0 and 1 with one position per color. Each position corresponds to a slider in the preferences Color Themes window. If you omit the position, the sliders are evenly spaced.

Examples

The following example creates a continuous color theme named Blue to Purple. The color is in the Diverging category. RGB values are defined in the four lists.

```
Add Color Theme(
  {"Blue to Purple", {"Continuous", "Diverging"}, {{0, 0, 255},
  {57, 108, 244}, "white", {128, 0, 100}}} );
```

Notes

Any style except for Qualitative can be Continuous and Categorical at the same time. For example, the Cool to Warm Diverging theme is in the Continuous and Categorical theme lists. In JMP, select **Preferences > Graphs** to see examples.

To delete a color theme, use `Remove Color Theme()`. See "Remove Color Theme("Name"|{"Name", <flags>, {color, ...}, <{position, ...}>}>" on page 153 for details.

Arc(x1, y1, x2, y2, startangle, endangle)

Description

Inscribes an arc in the rectangle described by the arguments.

Returns

Null.

Arguments

`x1, y1` The point at the top left of the rectangle

`x2, y2` The point at the bottom right of the rectangle

`startangle, endangle` The starting and ending angle in degrees, where 0 degrees is 12 o'clock and the arc or slice is drawn clockwise from *startangle* to *endangle*.

Arrow(<pixellength>, {x1, y1}, {x2, y2})

Description

Draws an arrow from the first point to the second point. The optional first argument specifies the length of the arrow's head lines (in pixels).

Returns

Null.

Arguments

`pixellength` Optional: specifies the length of the arrowhead in pixels.

`{x1, y1}, {x2, y2}` Two lists of two numbers that each specify a point in the graph.

Notes

The two points can also be enclosed in square brackets: `Arrow(<pixellength>, [x1, x2], [y1, y2])`.

Back Color("name")

Description

Sets the color used for filling the graph's background.

Returns

Null.

Argument

name A quoted color name or a color index (such as "red" or "3" for the color red).

Char To Path("path")

Description

Converts a path specification from a string to a matrix.

Returns

A matrix.

Arguments

path A string that contains the path specification.

Circle({x, y}, radius|PixelRadius(n), <...>, <"fill">)

Description

Draws a circle centered at {x, y} with the specified radius.

Returns

Null.

Arguments

{x, y} A number that describes a point in the graph

radius A number that describes the length of the circle's radius in relation to the vertical
axis. If the vertical axis is resized, the circle is also resized.

PixelRadius(n) A number that describes the length of the circle's radius in pixels. If the
vertical axis is resized, the circle is *not* resized.

"fill" Optional string. Indicates that all circles defined in the function are filled with the
current fill color. If "fill" is omitted, the circle is empty.

Note

The center point and the radius can be placed in any order. You can also add additional
center point and radius arguments and draw more than one circle in one statement. One
point and several radii results in a bull's-eye. Adding another point still draws all previous
circles, and then adds an additional circle with the last radius specified. This means that
this code:

```
graphbox(circle({20, 30}, 5, {50, 50}, 15))
```

results in three circles, not two. First, a circle with radius 5 is drawn at 20, 30. Second, a
circle with radius 5 is drawn at 50, 50. Third, a circle with radius 15 is drawn at 50, 50.

Color To HLS(color)

Description

Converts the *color* argument (including any JMP color) to a list of HLS values.

Returns

A list of the hue, lightness, and saturation components of *color*. The values range between 0 and 1.

Argument

`color` a number from the JMP color index.

Example

The output from `ColorToHLS()` can either be assigned to a single list variable or to a list of three scalar variables:

```
hls = Color To HLS( 8 );
{h, l, s} = Color To HLS( 8 );
Show( hls, h, l, s );
   hls = {0.778005464480874, 0.509803921568627, 0.976};
   h = 0.778005464480874;
   l = 0.509803921568627;
   s = 0.976;
```

Color To RGB(color)

Description

Converts the *color* argument (including any JMP color) to a list of RGB values.

Returns

A list of the red, green, and blue components of *color*. The values range between 0 and 1.

Argument

`color` a number from the JMP color index.

Example

The output from `ColorToRGB()` can either be assigned to a single list variable or to a list of three scalar variables:

```
rgb = Color To RGB( 8 );
{r, g, b} = Color To RGB( 8 );
Show( rgb, r, g, b );
   rgb = {0.670588235294118, 0.0313725490196078, 0.988235294117647};
   r = 0.670588235294118;
   g = 0.0313725490196078;
   b = 0.988235294117647;
```

Contour(xVector, yVector, zGridMatrix, zContour, <zColors>)

Description

Draws contours given a grid of values.

Returns

None.

Arguments

xVector The *n* values that describe zGridMatrix.

yVector The *m* values that describe zGridMatrix.

zGridMatrix An *n*x*m* matrix of values on some surface.

zContour Optional: Definition of values for the contour lines.

zColors Optional: Definition of colors to use for the contour lines.

Contour Function(expr, xName, yName, z, < <<XGrid(min, max, incr)>, <
<<YGrid(min, max, incr)>, < <<zColor(color)>, < <<zLabeled>, < <<Filled>, <
<<FillBetween>, < <<Ternary>, < <<Transparency(alpha|vector))

Description

Draws sets of contour lines of the expression, a function of the two symbols. The *z*
argument can be a single value or an index or matrix of values.

Returns

None.

Arguments

expr Any expression. For example, Sine(y)+Cosine(x).

xName, yName Values to use in the expression.

z A z-value or a matrix of z-values.

Optional Arguments

<<XGrid, <<YGrid Defines a box, beyond which the contour lines are not drawn.

<<zColor Defines the color in which to draw the contour lines. The argument can be either
a scalar or a matrix, but must evaluate to numeric.

<<zLabeled Labels the contours.

<<Filled Fills the contour levels using the current fill color.

<<FillBetween Fills only between adjacent contours using the current fill color. For nz
contours specified, this option fills nz-1 regions for the intervals between the nz values.
Using this option is recommended over using the <<Filled option.

<<Ternary Clips lines to be within the ternary coordinate system inside ternary plots.

<<Transparency sets the transparency level of the fill. A vector of numbers between 0 and
1 are sequenced through and cycled for the z contours. This option should be used only
in conjunction with the <<FillBetween option.

Drag Line(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

Description

Draws line segments between draggable vertices at the coordinates given by the matrix
arguments.

Returns

None.

Arguments

xMatrix A matrix of *x*-coordinates.

yMatrix A matrix of *y*-coordinates.

dragScript Any valid JSL script; it is run at drag.

mouseupScript Any valid JSL script; it is run at mouseup.

Drag Marker(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

Description

Draws draggable markers at the coordinates given by the matrix arguments.

Returns

None.

Arguments

xMatrix A matrix of *x*-coordinates.

yMatrix A matrix of *y*-coordinates.

dragScript Any valid JSL script; it is run at drag.

mouseupScript Any valid JSL script; it is run at mouseup.

Drag Polygon(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

Description

Draws a filled polygon with draggable vertices at the coordinates given by the matrix arguments.

Returns

None.

Arguments

xMatrix A matrix of *x*-coordinates.

yMatrix A matrix of *y*-coordinates.

dragScript Any valid JSL script; it is run at drag.

mouseupScript Any valid JSL script; it is run at mouseup.

Drag Rect(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

Description

Draws a filled rectangle with draggable vertices at the first two coordinates given by the matrix arguments.

Returns

None.

Arguments

xMatrix A matrix of 2 *x*-coordinates.

yMatrix A matrix of 2 *y*-coordinates.

dragScript Any valid JSL script; it is run at drag.

mouseupScript Any valid JSL script; it is run at mouseup.

Note

xMatrix and *yMatrix* should each contain exactly two values. The resulting coordinate pairs should follow the rules for drawing a rect(); the first point (given by the first value in *xMatrix* and the first value in *yMatrix*) must describe the top, left point in the rectangle, and the second point (given by the second value in *xMatrix* and the second value in *yMatrix*) must describe the bottom, right point in the rectangle.

Drag Text(xMatrix, yMatrix, "text", <dragScript>, <mouseupScript>)

Description

Draws the text (or all the items if a list is specified) at the coordinates given by the matrix arguments.

Returns

None.

Arguments

xMatrix A matrix of *x*-coordinates.

yMatrix A matrix of *y*-coordinates.

text A quoted string to be drawn in the graph.

dragScript Any valid JSL script; it is run at drag.

mouseupScript Any valid JSL script; it is run at mouseup.

Fill Color(n)

Description

Sets the color used for filling solid areas.

Returns

None.

Argument

n Index for a color or a quoted color name.

Fill Pattern()

Description

Sets the pattern for filled areas. See the Scripting Graphs chapter in the *Scripting Guide* for examples.

Get Color Theme Detail(name)

Description

Returns a script for the specified color theme.

Example

The following example returns the script for the JMP default color theme:

```
Get Color Theme Details( "JMP Default" );
    {"JMP Default", 9221, {{213, 72, 87}, {57, 177, 67}, {64, 111, 223}...}}
```

Get Color Theme Names(<kind>)

Description

Returns a list of all color theme names or color themes of the specified kind. The kinds include "continuous", "categorical", "sequential", "diverging", "qualitative", or "chromatic".

Example

The following example returns all color themes:

```
Get Color Theme Names();
    {"Green to Black to Red", "Green to White to Red", "White to Black"...}
```

The following example returns the diverging color themes:

```
Get Color Theme Names( "diverging" );
    {"Green to Black to Red", "Green to White to Red", "Blue to Gray to Red"...}
```

Gradient Function(zexpr, xname, yname, [zlow, zhigh], zcolor([colorlow, colorhigh]), < <<XGrid(min, max, incr)>, < <<YGrid(min, max, incr)> < <<Transparency(alpha|vector))

Description

Fills a set of rectangles on a grid according to a color determined by the expression value as it crosses a range corresponding to a range of colors.

Example

```
Gradient Function(Log(a * a + b * b),
a, b, [2 10],
Z Color([4, 6]));
```

Zepr is a function in terms of the two following variables (a and b), whose values range from *zlow* to *zhigh* (2 to 10). *Zcolor* defines the two colors that are blended together (4 is green, 6 is orange).

H Line(<x1, x2>, y)

Description

Draws a horizontal line at *y* across the graph. If you specify start and end points on the *x*-axis (*x1* and *x2*), the line is drawn horizontally at *y* from *x1* to *x2*. You can also draw multiple lines by using a matrix of values in the *y* argument.

H Size()

Description

Returns the horizontal size of the graphics frame in pixels.

Handle(a, b, dragScript, mouseupScript)

Description

Places draggable marker at coordinates given by *a, b*. The first script is executed at drag and the second at `mouseup`.

Heat Color(n, <"color theme">)

Description

Returns the JMP color that corresponds to *n* in the color "*theme*".

Returns

An integer that is a JMP color.

Arguments

n   A value between 0 and 1.

theme   Any quoted color theme that is supported by Cell Plot. The default value is "Blue to Gray to Red".

HLS Color(h, l, s)

HLS Color({h, l, s})

Description

Converts hue, lightness, and saturation values into a JMP color number.

Returns

An integer that is a JMP color number.

Arguments

Hue, lightness, and saturation, or a list containing the three HLS values. All values should be between 0 and 1.

In Path(x, y, path)

Description

Determines it the point described by *x* and *y* falls in *path*.

Returns

True (1) if the point (x, y) is in the given path, False(0) otherwise.

Arguments

x and y The coordinates of a point.

path Either a matrix or a string describing a path.

In Polygon(x, y, xx, yy)

In Polygon(x, y, xyPolygon)

Description

Returns 1 or 0, indicating whether the point (*x, y*) is inside the polygon that is defined by the *xx* and *yy* vector arguments.

The vector arguments (*xx, yy*) can also be combined into a 2-column matrix (*xyPolygon*), allowing you to use three arguments instead of four. Also, *x* and *y* can be conformable vectors, and then a vector of 0s and 1s are returned based on whether each (*x, y*) pair is inside the polygon.

Level Color(i, <n>, <"Color Theme">)

Description

Assigns a JMP color to categorical data in a graphic.

Returns

An integer that is a JMP color.

Arguments

i An integer that is greater than or equal to 1 and less than or equal to the number of categories specified by n.

n The number of categories.

"Color Theme" A color theme from the Value Color list of the Column Properties window. If not specified, the JMP Default color theme is applied.

Note

When the second argument is a character string and not *n*, then the second argument determines the color theme.

```
Line({x1, y1}, {x2, y2}, ...), <<ValueSpace(0|1)
```
```
Line([x1, x2, ...], [y1, y2, ...]), <<ValueSpace(0|1)
```

Description

Draws a line between points.

Arguments

{x1, y1}, {x2, y2} or [x1, x2, ...], [y1, y2, ...] Can be any number of lists
of two points, separated by commas; or a matrix of *x* values and a matrix of *y* values.

<<ValueSpace (Boolean) Draws lines that follow the projection when the line represents
a movement of the underlying data, such as a bubble trail in a bubble plot. The Boolean
value can be a constant or an expression.

```
Line Style(n)
```

Description

Sets the line style used to draw the graph.

Argument

n Can be either a style name or the style's number:

- – 0 or Solid
- – 1 or Dotted
- – 2 or Dashed
- – 3 or DashDot
- – 4 or DashDotDot

```
Marker(<markerState>, {x1, y1}, {x2, y2}, ...)
```
```
Marker(<markerState>, [x1, x2, ...], [y1, y2, ...})
```

Description

Draws one or more markers at the points described either by lists or matrices. The optional
markerState argument sets the type of marker.

```
Marker Size(n)
```

Description

Sets the size used for markers.

```
Mousetrap(dragscript, mouseupscript)
```

Description

Captures click coordinates to update graph properties. The first script is executed at drag and the second at mouseup.

```
Normal Contour(prob, meanMatrix, stdMatrix, corrMatrix, <colorsMatrix>,
<fill=x>)
```

Description

Draws normal probability contours for *k* populations and two variables.

Arguments

prob A scalar or matrix of probabilities.

meanMatrix A matrix of means of size *k* by 2.

stdMatrix A matrix of standard deviations of size *k* by 2.

corrMatrix A matrix of correlations of size *k* by 1.

colorsMatrix Optional. Specifies the color(s) for the k contour(s). The colors must be specified as JSL colors (either JSL color integer values or return values of JSL Color functions such as RGB Color or HLS Color).

fill=x Optional. Specifies the amount of transparency for the contour fill color.

```
Oval(x1, y1, x2, y2, <fill>)
Oval({x1, y1}, {x2, y2}, <fill>)
```

Description

Draws an oval inside the rectangle whose diagonal has the coordinates (*x1*, *y1*) and (*x2*, *y2*). *Fill* is Boolean. If *fill* is 0, the oval is empty. If *fill* is nonzero, the oval is filled with the current fill color. The default value for *fill* is 0.

```
Path(pathMatrix|pathText, <fill>)
```

Description

Draws a stroke along the given path. If a fill is specified, the interior of the path is filled with the current fill color.

Argument

pathMatrix An Nx3 matrix.

pathText A string that contains SVG code.

fill An optional, Boolean argument that specifies whether a line is drawn (0) or the path is filled (1). The default value is 0.

Note

A path matrix has three columns, for x and y, and a flag. The flag value for each point can be 0 for control, 1 for move, 2 for line segment, 3 for cubic Bézier segment, and any negative value to close the path.

Path To Char(path)

Description

Converts a path specification from a matrix to a string.

Returns

A string.

Argument

`path` An Nx3 path matrix.

Note

A path matrix has three columns, for x and y, and a flag. The flag value for each point can be 0 for control, 1 for move, 2 for line segment, 3 for cubic Bézier segment, and any negative value to close the path.

Pen Color(n)

Description

Sets the color used for the pen.

Pen Size(n)

Description

Sets the thickness of the pen in pixels.

Pick Color(<"window title">, <name|index|RGBlist>

Description

Creates a color picker, which enables the user to select a color to apply to graphs. The operating system color picker lets users select a predefined color or create their own color. You can also specify a default color in your script. If you omit the default color, Black is selected.

Returns

The color that the user selected in the operating system's color picker.

Optional Arguments

`window title` Specifies the title of the color picker window.

`name` The name of the default JMP color.

`index` The number of the default JMP color.

RGBlist The RGB values of the default color.

Notes

See the Scripting Graphs chapter in the *Scripting Guide* for details.

Pie(x1, y1, x2, y2, startangle, endangle)

Description

Draws a filled pie slice. The two points describe a rectangle, within which is a virtual oval. Only the slice described by the start and end angles is drawn.

Pixel Line To(x, y)

Description

Draws a one-pixel-wide line from the current pixel location to the location given in pixel coordinates. Set the current pixel location using the Pixel Origin and Pixel Move To commands.

Pixel Move To(x, y)

Description

Moves the current pixel location to a new location given in pixel coordinates.

Pixel Origin(x, y)

Description

Sets the origin, in graph coordinates, for subsequent Pixel Line To or Pixel Move To commands.

Polygon({x1, y1}, {x2, y2}, ...)
Polygon(xmatrix, ymatrix)

Description

Draws a filled polygon defined by the listed points.

Polygon Area({x1, y1}, {x2, y2}, ...)
Polygon Area(xmatrix, ymatrix)

Description

Calculates the area of the specified polygon.

Examples

```
area = Polygon Area( {0, 0}, {0, 10}, {10, 10}, {10, 0} );
area = Polygon Area( [10 20 30], [10 30 20] );
```

`Polygon Centroid({x1, y1}, {x2, y2}, ...)`

`Polygon Centroid(xmatrix, ymatrix)`

Description

Calculates the centroid of the specified polygon.

Examples

```
{cx, cy} = Polygon Centroid( {0, 0}, {0, 10}, {10, 10}, {10, 0} );
centroid = Polygon Centroid( [10 20 30], [10 30 20] );
```

`Rect(x1, y1, x2, y2, <fill>)`

`Rect({x1, y1}, {x2, y2}, <fill>)`

Description

Draws a rectangle whose diagonal has the coordinates (*x1*, *y1*) and (*x2*, *y2*). *Fill* is Boolean. If *fill* is 0, the rectangle is empty. If *fill* is nonzero, the rectangle is filled with the current fill color. The default value for *fill* is 0.

`Remove Color Theme("Name"|{"Name", <flags>, {color, ...}, <{position, ...}>}>`

Description

Removes a custom color theme from the global list, either by name or by the full color theme object.

Arguments

`Name` The name of the color theme.

`flags` A number that represents metadata such as whether the theme is continuous or categorical. Run `Get Color Theme Details("name")` on the color theme and use the flag that is returned.

`color` The RGB values for the color.

`position` A number between 0 and 1. There is one number per color that indicates where on the gradient that color is, where 0 is the beginning and 1 is the end. If positions are not supplied, the colors are positioned with equal spacing.

Example

```
Remove Color Theme( {"Yellow Blue", 0, {{255, 255, 0}, {0, 0, 255}}, {0.0,
    1.0}} );
```

`RGB Color(r, g, b)`

`RGB Color({r, g, b})`

Description

Converts red, green, and blue values into a JMP color number.

Returns

An integer that is a JMP color number.

Arguments

Red, green, and blue, or a list containing the three RGB values. All values should be between 0 and 1.

Text(<properties>, ({x, y}|{left, bottom, right, top}), "text")

Description

Draws the quoted string *text* at the given point, either the x and y axes or the left, bottom, right, and top axes.

Properties can be any of several named arguments: Center Justified, Right Justified, Erased, Boxed, Counterclockwise, Position, and named arguments. The position, named arguments, and strings can be added in any order. The position and named arguments apply to all the strings.

Text Color(n)

Description

Sets the color for Text strings.

Text Size(n)

Description

Sets the font size in points for Text strings.

Transparency(alpha)

Description

Sets the transparency of the current drawing, with *alpha* between 0 and 1 where 0 is clear (no drawing) and 1 is completely opaque (the default).

Note

Not all operating systems support transparency.

V Line(x, <y1, y2>)

Description

Draws a vertical line at *x* across the graph. If you specify start and end points on the *y*-axis (*y1* and *y2*), the line is drawn vertically at *x* from *y1* to *y2*. You can also draw multiple lines by using a matrix of values in the *x* argument.

V Size()

Description

Returns the vertical size of the graphics frame in pixels

X Function(expr, symbol, <Min(min), Max(max), Fill(value), Inc(bound), Show Details(n)>)

Description

Draws a plot of the function as the *symbol* is varied over the *y*-axis of the graph.

X Origin()

Description

Returns the *x*-value for the left edge of the graphics frame.

X Range()

Description

Returns the distance from the left to right edge of the display box. For example, X Origin() + X Range() is the right edge.

X Scale(xmin, xmax)

Description

Sets the range for the horizontal scale. The default value for *xmin* is 0, and the default value for *xmax* is 100.

XY Function(x(t), y(t), t, min(min), max(max), inc(bound) | steps(min))

Description

Combines an expression of *x(t)* and *y(t)* to draw an x-y curve for the specified range of parameter *t*.

Note: Either *inc()* or *steps()* is needed if the default granularity misses details.

Y Function(expr, symbol, <Min(min), Max(max), Fill(value), Inc(bound), Show Details(n)>)

Description

Draws a plot of the function as the symbol is varied over the *x*- axis of the graph.

Y Origin()

Description

Returns the *y*-value for the bottom edge of the graphics frame.

Y Range()

Description

Returns the distance from the bottom to top edges of a display box. For example,
Y Origin() + Y Range() is the top edge.

Y Scale(ymin, ymax)

Description

Sets the range for the vertical scale. If you do not specify a scale, it defaults to (0, 100).

List Functions

As List(matrix)

Description

Converts a matrix into a list. Multi-column matrices are converted to a list of row lists.

Returns

A list.

Argument

matrix Any matrix.

Concat Items({string1, string2, ...}, <delimiter>})

Description

Converts a list of string expressions into one string, with each item separated by a delimiter.
The delimiter is a blank, if unspecified.

Returns

The concatenated string.

Arguments

string any string

delimiter an optional string that is placed between each item. The delimiter can be more
than one character long.

Example

```
str1 = "one";
str2 = "two";
str3 = "three";

comb = Concat Items({str1, str2, str3});
    "one two three"
comb = Concat Items({str1, str2, str3}, " : ");
    "one : two : three"
del = ",";
comb = Concat Items({str1, str2, str3}, del);
    "one,two,three"
```

Eval List(list)

Description

Evaluates expressions inside *list*.

Returns

A list of the evaluated expressions.

Arguments

list A list of valid JSL expressions.

Insert(source, item, <position>)

Insert(source, key, value)

Description

Inserts a new *item* into the *source* at the given *position*. If *position* is not given, *item* is added to the end.

For an associative array: Adds the *key* into the *source* associative array and assigns *value* to it. If the *key* exists in *source* already, its value is overwritten with the new *value*.

Arguments

source A string, list, expression, or associative array.

item or key Any value to be placed within *source*. For an associative array, *key* might or might not be present in *source*.

position Optional numeric value that specifies the position in *source* to place the *item* into.

value A value to assign to the *key*.

```
Insert Into(source, item, <position>)
```

```
Insert Into(source, key, value)
```

Description

Inserts a new item into the *source* at the given position in place. The *source* must be an L-value.

Arguments

`source` A variable that contains a string, list, display box, expression, or associative array.

`item` or `key` Any value to be placed within source. For an associative array, *key* might or might not be present in *source*.

`position` Optional numeric value that specifies the position in *source* to place the *item* into.

`value` A value to assign to the *key*.

```
Is List(x)
```

Description

Returns 1 if the evaluated argument is a list, or 0 otherwise.

```
List(a, b, c, ...)
```

```
{a, b, c, ...}
```

Description

Constructs a list from a set of items.

```
N Items(source)
```

Description

Determines the number of elements in the *source* specified.

Returns

For a list or display box, the number of items in the list or display box is returned. For an associative array, the number of keys is returned. For the matrix, the number of elements in the matrix is returned. For the namespace, the number of items in the namespace is returned. For a class, the number of classes is returned.

Arguments

`source` A list, associative array, matrix, display box, or namespace.

```
Remove(source, position, <n>)
```

```
Remove(source, {items})
```

```
Remove(source, key)
```

Description

Deletes the *n* item(s), starting from the indicated *position*. If *n* is omitted, the item at *position* is deleted. If *position* and *n* are omitted, the item at the end is removed. For an associative array: Deletes the *key* and its value.

Returns

A copy of the *source* with the items deleted.

Arguments

source A string, list, expression, or associative array.

position or key An integer (or list of integers) that points to a specific item (or items) in the list or expression.

n Optional. An integer that specifies how many items to remove.

```
Remove From(source, position, <n>)
```

```
Remove From(source, key)
```

Description

Deletes the *n* item(s) in place, starting from the indicated *position*. If *n* is omitted, the item at *position* is deleted. If *position* and *n* are omitted, the item at the end is removed. For an associative array: Deletes the *key* and its value. The *source* must be an L-value.

Returns

The original *source* with the items deleted.

Arguments

source A string, list, expression, display box, or associative array.

position or key An integer (or list of integers) that points to a specific item (or items) in the list or expression.

n Optional. An integer that specifies how many items to remove.

```
Reverse(source)
```

Description

Reverse order of elements or terms in the *source*.

Argument

source A string, list, or expression.

Reverse Into(source)

Description

Reverses the order of elements or terms in *source* in place.

Argument

source A string, list, display box, or expression.

Shift(source, <n>)

Description

Shifts an item or *n* items from the front to the back of the *source*.

Arguments

source A string, list, or expression.

n Optional. An integer that specifies the number of items to shift. Positive values shift items from the beginning of the *source* to the end. Negative values shift items from the end of the *source* to the beginning. The default value is 1.

Shift Into(source, <n>)

Description

Shifts items in place.

Arguments

source A string, list, display box, or expression.

n Optional. An integer that specifies the number of items to shift. Positive values shift items from the beginning of the *source* to the end. Negative values shift items from the end of the *source* to the beginning. The default value is 1.

Sort List(list|expr)

Description

Sort the elements or terms of *list* or *expr*.

Sort List Into(list|expr)

Description

Sort the elements or terms of *list* or *expr* in place.

```
Substitute(string, substring, replacementString, ...)
```

```
Substitute(list, listItem, replacementItem, ...)
```

```
Substitute(Expr(sourceExpr), Expr(findExpr), Expr(replacementExpr), ...)
```

Description

This is a search and replace function. It searches for a specific portion (second argument) of the source (first argument), and replaces it (third argument).

If a string, finds all matches to *substring* in the source *string,* and replaces them with the *replacementString*.

If a list, finds all matches to *listItem* in the source *list,* and replaces them with the *replacementItem*.

If an expression, finds all matches to the *findExpr* in the *sourceExpr,* and replaces them with the *replacementExpr*. Note that all expressions must be enclosed within an Expr() function.

Arguments

`string, list, sourceExpr` A string, list, or expression in which to perform the substitution.

`substring, listItem, findExpr` A string, list item, or expression to be found in the source string, list, or expression.

`replacementString, replacementItem, replacementExpr` A string, list item, or expression to replace the found string, list item, or expression.

```
Substitute Into(string, substring, replacementString, ...)
```

```
Substitute Into(list, listItem, replacementItem, ...)
```

```
Substitute Into(Expr(sourceExpr), Expr(findExpr), Expr(replacementExpr),
...)
```

Description

This is a search and replace function, identical to Substitute() except in place. It searches for a specific portion (second argument) of the source (first argument), and replaces it (third argument). The first argument must be an L-value.

If a string, finds all matches to *substring* in the source *string,* and replaces them with the *replacementString*.

If a list, finds all matches to *listItem* in the source *list,* and replaces them with the *replacementItem*.

If an expression, finds all matches to the *findExpr* in the *sourceExpr,* and replaces them with the *replacementExpr*. Note that all expressions must be enclosed within an Expr() function.

Arguments

> `string, list, sourceExpr` A string, list, or expression in which to perform the substitution.

> `substring, listItem, findExpr` A string, list item, or expression to be found in the source string, list, or expression.

> `replacementString, replacementItem, replacementExpr` A string, list item, or expression to replace the found string, list item, or expression.

Words("text", <"delimiters">)

Description

Extracts the words from *text* according to the delimiters given. The default delimiter is space. If you include a second argument, any and all characters in that argument are taken to be delimiters.

Examples

```
Words( "the quick brown fox" );
   {"the","quick","brown","fox"}
Words( "Doe, Jane P.","", ." );
   {"Doe","Jane","P"}
```

MATLAB Integration Functions

JMP provides the following interfaces to access MATLAB. The basic execution model is to first initialize the MATLAB connection, perform the required MATLAB operations, and then terminate the MATLAB connection. In most cases, these functions return 0 if the MATLAB operation was successful or an error code if it was not. If the MATLAB operation is not successful, a message is written to the Log window. The single exception to this is MATLAB Get( ), which returns a value.

See the Extending JMP chapter in the *Scripting Guide* for details on working with MATLAB.

MATLAB JSL Function Interfaces

MATLAB Connect(<named arguments>)

Description

Initializes the MATLAB integration interfaces and returns an active MATLAB integration interface connection as a scriptable object.

Returns

MATLAB scriptable object.

Named Arguments

> `Echo(Boolean)` Sends the MATLAB source lines to the JMP log. The default value is true.

MATLAB Control(<named arguments>)

Description

> Sends control operations to signal MATLAB with external events such as source line echoing.

Returns

> None.

Arguments

> None.

Named Arguments

> `Echo(Boolean)` Global. Echo MATLAB source lines to the JMP log.

> `Visible(Boolean)` Global. Determine whether to show or hide the active MATLAB workspace.

MATLAB Execute({ list of inputs }, { list of outputs }, mCode, <named arguments>)

Description

> Submits the MATLAB code to the active global MATLAB connection given a list of inputs. Upon completion, retrieves a list of outputs.

Returns

> 0 if successful, otherwise nonzero.

Arguments

> `{ list of inputs }` Positional, name list. List of JMP variable names to send to MATLAB as inputs.

> `{ list of outputs }` Positional, name list. List of JMP variable names to retrieve from MATLAB as outputs.

> `mCode` Positional, string. The MATLAB code to submit.

Named Arguments

> `Expand(Boolean)` Perform an Eval Insert on the MATLAB code prior to submission.

> `Echo(Boolean)` Echo MATLAB source lines to the JMP log. Default is true.

Example

> The following example sends the JMP variables x and y to MATLAB, executes the MATLAB statement $z = x * y$, and then gets the MATLAB variable z and returns it to JMP.

```
MATLAB Init();
x = [1 2 3];
```

```
y = [4 5 6];
MATLAB Execute( {x, y}, {z}, "z = x * y;" );
Show( z );
```

MATLAB Get(name)

Description

Gets named variable from MATLAB to JMP.

Returns

Value of named variable.

Arguments

name Positional. The name of a JMP variable to be sent to MATLAB.

Example

Suppose that a matrix named qbx and a structure named df are present in your MATLAB connection.

```
// Get the MATLAB variable qbx and placed it into a JMP variable qbx.
qbx = MATLAB Get( qbx );

// Get the MATLAB variable df and placed it into a JMP data table referenced
  by df.
df = MATLAB Get( df );
```

Table 2.1 shows what JMP data types can be exchanged with MATLAB using the MATLAB Get( ) function. Getting lists from MATLAB recursively examines each element of the list and sends each base MATLAB data type. Nested lists are supported.

Table 2.1 JMP and MATLAB Equivalent Data Types for MATLAB Get( )

MATLAB Data Type	JMP Data Type
Double	Numeric
Logical	Numeric (0 | 1)
String	String
Integer	Numeric
Date/Time	Numeric
Structure	Data Table
Matrix	Numeric Matrix
Numeric Vector	Numeric Matrix

Table 2.1 JMP and MATLAB Equivalent Data Types for `MATLAB Get( )` *(Continued)*

MATLAB Data Type	JMP Data Type
String Vector	List of Strings
Graph	Picture object

MATLAB Get Graphics(format)

Description

Get the last graphic object written to the MATLAB graph display window in a specific graphic format. The graphic object can be returned in several graphic formats.

Returns

JMP Picture object.

Argument

`format` Positional. The format the MATLAB graph display window contents are to be converted to. Valid formats are `"png"`, `"bmp"`, `"jpeg"`, `"jpg"`, `"tiff"`, and `"tif"`.

MATLAB Init(<named arguments>)

Description

Initializes the MATLAB integration interfaces.

Returns

Return code.

Named Arguments

`Echo(Boolean)` Sends MATLAB source lines to the JMP log. This option is global. The default value is true.

MATLAB Is Connected()

Description

Determines whether a MATLAB connection is active.

Returns

1 if connected, otherwise 0.

MATLAB JMP Name To MATLAB Name(name)

Description

Maps a JMP variable name to its corresponding MATLAB variable name using MATLAB variable name naming rules.

Returns

String, mapped MATLAB variable name.

Argument

name Positional. The name of a JMP variable to be sent to MATLAB.

MATLAB Send(name, <named arguments>)

Description

Sends the named variable from JMP to MATLAB.

Returns

0 if successful, otherwise nonzero.

Arguments

name Positional. The name of a JMP variable to be sent to MATLAB.

Named Arguments

The following optional arguments apply to data tables only:

Selected(Boolean) Send selected rows from the referenced data table to MATLAB.

Excluded(Boolean) Send only excluded rows from the referenced data table to MATLAB.

Labeled(Boolean) Send only labeled rows from the referenced data table to MATLAB.

Hidden(Boolean) Send only hidden rows from the referenced data table to MATLAB.

Colored(Boolean) Send only colored rows from the referenced data table to MATLAB.

Markered(Boolean) Send only markered rows from the referenced data table to MATLAB.

Row States(Boolean, <named arguments>) Send row states from referenced data table to MATLAB by adding an additional data column named "RowState". Create multiple selections by adding together individual settings. The row state consists of individual settings with the following values:

- Selected = 1
- Excluded = 2
- Labeled = 4
- Hidden = 8
- Colored = 16
- Markered = 32

The following optional, named Row States arguments are supported:

Colors(Boolean) Send row colors. Adds additional data column named "RowStateColor".

`Markers(Boolean)` Send row markers. Adds additional data column named
　　"RowStateMarker".

Example
```
// Create a matrix, assign it to X, and send the matrix to MATLAB.
X = [1 2 3];
ml = MATLAB Send( X );

// Open a data table, assign a reference to it to dt, and send the data table
   along with its current row states to MATLAB.
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
ml = MATLAB Send( dt, Row States( 1 ) );
```

Table 2.2 shows what JMP data types can be exchanged with MATLAB using the `MATLAB Send( )` function. Sending lists to MATLAB recursively examines each element of the list and sends each base JMP data type. Nested lists are supported.

Table 2.2 JMP and MATLAB Equivalent Data Types for `MATLAB Send( )`

MATLAB Data Type	JMP Data Type
Double	Numeric
String	String
Double Matrix	Matrix
Structure	Data Table

Example
```
MATLAB Init( );
X = 1;
MATLAB Send( X );
S = "Report Title";
MATLAB Send( S );
M = [1 2 3, 4 5 6, 7 8 9];
MATLAB Send( M );
MATLAB Submit( "
X
S
M
" );
MATLAB Term( );
```

MATLAB Submit File('pathname', <named arguments>)

Description

Submits statements to MATLAB using a file pointed to by pathname.

Returns

0 if successful, otherwise nonzero.

Arguments

Pathname Positional, string. Pathname to file containing MATLAB source lines to be executed.

Named Arguments

Expand(Boolean) Perform an Eval Insert on the MATLAB code prior to submission.

Echo(Boolean) Echo MATLAB source lines to the JMP log. Default is true.

MATLAB Submit(mCode, <named arguments>)

Description

Submits the MATLAB code to the active global MATLAB connection.

Returns

0 if successful, otherwise nonzero.

Arguments

mCode Positional, string. The MATLAB code to submit.

Named Arguments

Expand(Boolean) Perform an Eval Insert on the MATLAB code prior to submission.

Echo(Boolean) Echo MATLAB source lines to the JMP log. Default is true.

Example

The following example creates two vectors of random points and plots them as x and y variables.

```
MATLAB Init();
mc = MATLAB Submit("/[
    x = rand(5);
    fprintf('%f/n', x);
    y = rand(5);
    fprintf('%f/n', x);
    z = plot(x, y);
]/" );
```

MATLAB Term();

Description

Terminates the currently active MATLAB integration interface.

Returns

1 if an active MATLAB connection exists, otherwise returns 0.

Arguments

None.

Matrix Functions

All(A, ...)

Returns

1 if all matrix arguments are nonzero; 0 otherwise.

Any(A, ...)

Returns

1 if one or more elements of one or more matrices are nonzero; 0 otherwise.

B Spline Coef(x, Internal Knot Grid, <degree=3>, <Knot End Points=min(x)||max(x)>)

Description

Finds the matrix of B-spline coefficients for the data in the *x* argument.

Returns

The matrix of B-spline coefficients. This can be used as a design matrix in a linear model.

Arguments

x A matrix that contains the data.

Internal Knot Grid Either a single number that designates the number of desired knot points based on percentiles of *x* or a vector of values that designate the internal knot points.

degree The degree of the B-splines.

Knot End Points A 2x1 matrix that designates the lower and upper knot points. If this argument is not specified, the default lower and upper knot points are the minimum and maximum values of *x*, respectively.

CDF(Y)

Description

Returns values of the empirical cumulative probability distribution function for *Y,* which can be a vector or a list. Cumulative probability is the proportion of data values less than or equal to the value of *QuantVec*.

Syntax

```
{QuantVec, CumProbVec} = CDF(YVec)
```

Chol Update(L, V, C)

Description

If L is the Cholesky root of an *nxn* matrix A, then after calling `cholUpdate` L is replaced with the Cholesky root of A+V*C*V' where C is an *mxm* symmetric matrix and V is an n*m matrix.

Cholesky(A)

Description

Finds the lower Cholesky root (L) of a positive semi-definitive matrix, L*L' = A.

Returns

L (the Cholesky root).

Arguments

A   a symmetric matrix.

Correlation(matrix, < <<"Pairwise">, < <<"Shrink">, < <<Freq(vector)>, < <<Weight(vector)>)

Description

Calculates the correlation matrix of the data in the *matrix* argument.

Returns

The correlation matrix for the specified matrix.

Argument

`matrix` A matrix that contains the data. If the data has *m* rows and *n* columns, the result is an m-by-m matrix.

`"Pairwise"` Uses the pairwise method for missing values rather than the row-wise method.

`"Shrink"` Performs the Schafer-Strimmer shrinkage estimate.

`<<Freq(vector)` A vector that specifies frequencies for the rows of the matrix argument.

`<<Weight(vector)` A vector that specifies weights for the rows of the matrix argument.

Notes

By default, rows are discarded if they contain missing values. If the "Pairwise" option is specified, all pairs of nonmissing values are used in the correlation matrix calculation.

This function uses multithreading if available, so it is recommended for large problems with many rows.

When a column is constant, the correlations for it are 0, and the diagonal element is also 0.

`Covariance(matrix, < <<"Pairwise">, < <<"Shrink">, < <<Freq(vector)>, < <<Weight(vector)>)`

Description

Calculates the covariance matrix of the data in the *matrix* argument.

Returns

The covariance matrix for the specified matrix.

Argument

`matrix` A matrix that contains the data. If the data has *m* rows and *n* columns, the result is an m-by-n matrix.

`"Pairwise"` Uses the pairwise method for missing values rather than the row-wise method.

`"Shrink"` Performs the Schafer-Strimmer shrinkage estimate.

`<<Freq(vector)` A vector that specifies frequencies for the rows of the matrix argument.

`<<Weight(vector)` A vector that specifies weights for the rows of the matrix argument.

Notes

By default, rows are discarded if they contain missing values. If the "Pairwise" option is specified, all pairs of nonmissing values are used in the covariance matrix calculation.

This function uses multithreading if available, so it is recommended for large problems with many rows.

`Design(vector, < levelsList | <<levels, <<ElseMissing >)`

Description

Creates a design matrix that contains a column of 1s and 0s for each unique value of a *vector* of values.

Returns

A design matrix with a column of 1s and 0s for each unique value of the argument or a list that contains the design matrix and a list of levels.

Argument

`vector` A vector.

levelsList An optional list or matrix argument that specifies the levels in the returned matrix.

<<levels An optional argument that changes the return value to a list that contains the design matrix and a list of the levels.

<<ElseMissing An optional argument that changes the handling of values in the *vector* argument that do not appear in the *levelsList* argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

Note

Missing values in the *levelsList* argument are not ignored. For example:

```
Show( Design ( ., [. 0 1] ),
Design( 0, [. 0 1] ),
Design( 1, [. 0 1] ),
Design( [0 0 1 . 1], [. 0 1] ),
Design( {0, 0, 1, ., 1}, [. 0 1] ) );
   Design(., [. 0 1]) = [1 0 0];
   Design(0, [. 0 1]) = [0 1 0];
   Design(1, [. 0 1]) = [0 0 1];
   Design([0 0 1 . 1], [. 0 1]) =
   [ 0 1 0,
     0 1 0,
     0 0 1,
     1 0 0,
     0 0 1];
   Design({0, 0, 1, ., 1}, [. 0 1]) =
   [ 0 1 0,
     0 1 0,
     0 0 1,
     1 0 0,
     0 0 1];
```

Design Last(vector, < levelsList, <<ElseMissing >)

Description

Creates a design matrix that contains a column of 1s and 0s for all but the last of the unique values of the argument. The last level is coded as a row of 0s.

Returns

A full-rank design matrix or a list that contains the design matrix and a list of levels.

Arguments

vector A vector.

levelsList An optional list or matrix argument that specifies the levels in the returned matrix. If this argument is specified, the last level in this list or matrix is treated as the last level in the design matrix. Otherwise, the last level is defined as the largest value in the *vector* argument.

        `<<ElseMissing` An optional argument that changes the handling of values in the *vector*
        argument that do not appear in the *levelsList* argument. If this argument is specified,
        missing values are placed in the design matrix. Otherwise, 0s are placed in the design
        matrix.

`Design Nom(vector, < levelsList | <<levels, <<ElseMissing >)`

`DesignF(vector, < levelsList | <<levels, <<ElseMissing >)`

Description

Creates a design matrix that contains a column of 1s and 0s for all but the last of the unique
values of the argument. The last level is coded as a row of -1s.

Returns

A full-rank design matrix or a list that contains the design matrix and a list of levels.

Argument

`vector` A vector.

`levelsList` An optional list or matrix argument that specifies the levels in the returned
matrix. If this argument is specified, the last level in this list or matrix is treated as the
last level in the design matrix. Otherwise, the last level is defined as the largest value in
the *vector* argument.

`<<levels` An optional argument that changes the return value to a list that contains the
design matrix and a list of levels.

`<<ElseMissing` An optional argument that changes the handling of values in the *vector*
argument that do not appear in the *levelsList* argument. If this argument is specified,
missing values are placed in the design matrix. Otherwise, 0s are placed in the design
matrix.

Note

Missing values in the *levelsList* argument are not ignored. For example:

```
Show( Design Nom( ., [. 0 1] ),
Design Nom( 0, [. 0 1] ),
Design Nom( 1, [. 0 1] ),
Design Nom( [0 0 1 . 1], [. 0 1] ),
Design Nom( {0, 0, 1, ., 1}, [. 0 1] ) );
    Design Nom(., [. 0 1]) = [1 0];
    Design Nom(0, [. 0 1]) = [0 1];
    Design Nom(1, [. 0 1]) = [-1 -1];
    Design Nom([0 0 1 . 1], [. 0 1]) = [0 1, 0 1, -1 -1, 1 0, -1 -1];
    Design Nom({0, 0, 1, ., 1}, [. 0 1]) = [0 1, 0 1, -1 -1, 1 0, -1 -1];
```

```
Design Ord(vector, < levelsList | <<levels, <<ElseMissing >)
```

Description

Creates a design matrix that contains a column for all but the last of the unique values of the argument. The first level is coded as a row of 0s. Each subsequent (nth) level in the *levelsList* argument is coded as a row of (n-1) 1s and the rest 0s.

Returns

A full-rank design matrix or a list that contains the design matrix and a list of levels.

Argument

vector A vector.

levelsList An optional list or matrix argument that specifies the levels in the returned matrix.

<<levels An optional argument that changes the return value to a list that contains the design matrix and a list of levels.

<<ElseMissing An optional argument that changes the handling of values in the *vector* argument that do not appear in the *levelsList* argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

Note

Missing values in the *levelsList* argument are not ignored. For example:

```
Show( Design Ord( ., [. 0 1] ),
Design Ord( 0, [. 0 1] ),
Design Ord( 1, [. 0 1] ),
Design Ord( [0 0 1 . 1], [. 0 1] ),
Design Ord( {0, 0, 1, ., 1}, [. 0 1] ) );
    Design Ord(., [. 0 1]) = [0 0];
    Design Ord(0, [. 0 1]) = [1 0];
    Design Ord(1, [. 0 1]) = [1 1];
    Design Ord([0 0 1 . 1], [. 0 1]) = [1 0, 1 0, 1 1, 0 0, 1 1];
    Design Ord({0, 0, 1, ., 1}, [. 0 1]) = [1 0, 1 0, 1 1, 0 0, 1 1];
```

```
Det(A)
```

Description

Determinant of a square matrix.

Returns

The determinant.

Argument

A A square matrix.

Diag(A, <B>)

Description

Creates a diagonal matrix from a square matrix or a vector. If two matrices are provided, concatenates the matrices diagonally.

Returns

The matrix.

Argument

A a matrix or a vector.

Direct Product(A, B)

Description

Direct (Kronecker) product of square matrices or scalars A[i,j]*B.

Returns

The product.

Arguments

A, B Square matrices or scalars.

Distance(x1, x2, <scales>, <powers>)

Description

Produces a matrix of distances between rows of x1 and rows of x2.

Returns

A matrix.

Arguments

x1, x2 Two matrices.

scales Optional argument to customize the scaling of the matrix.

powers Optional argument to customize the powers of the matrix.

E Div(A, B)

A:/B

Description

Element-by-element division of two matrices.

Returns

The resulting matrix.

Arguments

A, B Two matrices.

E Mult(A, B)

A:*B

Description

Element-by-element multiplication of two matrices.

Returns

The resulting matrix.

Arguments

A, B Two matrices.

Eigen(A)

Description

Eigenvalue decomposition.

Returns

A list {M, E} such that E * Diag(M) * E = A'.

Argument

A A symmetric matrix.

G Inverse(A)

Description

Generalized (Moore-Penrose) matrix inverse.

H Direct Product(A, B)

Description

Horizontal direct product of two square matrices of the same dimension or scalars.

Hough Line Transform(matrix, <NAngle(number)>, <NRadius(number)>)

Description

Takes a matrix of intensities and transforms it in a way that is useful for finding streaks in the matrix. Produces a matrix containing the Hough Line Transform with angles as columns and radiuses as rows.

Argument

matrix A matrix that can be derived from the intensities of an image, but is more likely from a semiconductor wafer that may have defects across in a streak due to planarization machines.

NAngle(number) Enter the number of the angle to obtain a different sized transform. The default is 180 degrees.

NRadius(number) Enter the number of the radius to obtain a different sized transform. The default is sqrt(NRow*nRow+nCol*nCol).

Identity(n)

Description

Creates an *n*-by-*n* identity matrix with ones on the diagonal and zeros elsewhere.

Returns

The matrix.

Argument

n An integer.

Index(i, j, <increment>)

i::j

Description

Creates a column matrix whose values range from *i* to *j*.

Returns

The matrix.

Arguments

i, j Integers that define the range: *i* is the beginning of the range, *j* is the end.

increment Optional argument to change the default increment, which is +1.

Inv()

See "Inverse(A)" on page 178.

Inv Update(A, X, 1|-1)

Description

Efficiently update an **X′X** matrix.

Arguments

A The matrix to be updated.

X One or more rows to be added to or deleted from the matrix *A*.

1|-1 The third argument controls whether the row or rows defined in the second argument, *X*, are added to or deleted from the matrix *A*. 1 means to add the row or rows and -1 means to delete the row or rows.

```
Inverse(A)
```

```
Inv(A)
```

Description

Returns the matrix inverse. The matrix must be square non-singular.

```
Is Matrix(x)
```

Description

Returns 1 if the evaluated argument is a matrix, or 0 otherwise.

```
J(nrows, <ncols>, <value>)
```

Description

Creates a matrix of identical values.

Returns

The matrix.

Arguments

nrows Number of rows in matrix. If ncols is not specified, nrows is also used as ncols.

ncols Number of columns in matrix.

value The value used to populate the matrix. If value is not specified, 1 is used.

```
KDTable(matrix)
```

Description

Returns a table to efficiently look up near neighbors.

Returns

A KDTable object.

Argument

matrix A matrix of k-dimensional points. The number of dimensions or points is not limited. Each column in the matrix represents a dimension to the data, and each row represents a data point.

Messages

<<Distance between rows(row1, row2) Returns the distance between two the two specified rows in the KDTable. The distance applies to removed and inserted rows as well.

<<K nearest rows(stop, <position>) Returns a matrix. Position is a point that is described as a row vector for the coordinate of a row, or as the number of a row. If *position* is not specified, returns the *n* nearest rows and distances to all rows. If *position* is specified, returns the *n* nearest rows and distances to either a point or a row.

Stop is either *n* or {*n*, *limit*}. The limit parameter limits the number of rows that will be found. It can be specified one of two ways: a number, like 5, means return the 5 nearest rows. A list, like {5,10}, means return up to 5 nearest rows, stopping when the distance of 10 is exceeded. In the second case, the last row may have a distance greater than 10. Since the command continues until it finds the closest row beyond the stop radius, this point is also returned. This can be especially useful if there are no rows within the radius.

<<Remove rows(number | vector) Remove either the row specified by *number* or the rows specified by *vector*. Returns the number of rows that were removed. Rows that were already removed are ignored.

<<Insert rows(number | vector) Re-insert either the row specified by *number* or the rows specified by *vector*. Returns the number of rows that were inserted. Rows that were already inserted are ignored.

Note

When rows are removed or inserted, the row indices do not change. You can remove and re-insert only rows that are in the KDTable object. If you need different rows, construct a new KDTable.

Least Squares Solve(y, X, < <<noIntercept, <<weights(OptionalWeightVector), <<method("Sweep"|"GInv")>)

Description

Computes least squares regression estimates for the assumed model y = X * beta + error.

Returns

A list that contains the matrix Beta=Inverse(X'X)X'y and the estimated variance matrix of Beta.

Optional Named Arguments

<<noIntercept Specifies a no-intercept model.

<<weights(optional weight vector) Specifies a vector of weights to perform weighted least squares.

<<method("Sweep" | "GInv") Specifies the method for solving the normal equations. The default Sweep method is more computationally efficient, but you can also specify the generalized inverse ("GInv") method, which is more numerically stable.

Linear Regression(y, X, < <<noIntercept, <<printToLog, <<weight(OptionalWeightVector), <<freq(OptionalFreqVector)>)

Description

Fits a linear regression for the assumed model y = X * beta + error.

Returns

A list that contains a vector of the estimates, a vector of the standard error, and a list of diagnostics. The list of diagnostics contains vectors of the *t* statistics and *p*-values for the estimates, as well as the R-Square and adjusted R-Square values for the regression fit.

Optional Named Arguments

`<<noIntercept` Excludes the intercept.

`<<printToLog` Prints a summary of the fit to the log.

`<<weight(vector)` Specifies a vector of weights to perform weighted least squares.

`<<freq(vector)` Specifies a vector of frequencies for each row of y and X.

Example

```
n = 10;
x = J( n, 1, Random Normal() );
y = 1 + x * 3 + J( n, 1, Random Normal() );
{Estimates, Std_Error, Diagnostics} = Linear Regression( y, x, <<printToLog );
As Table( y || x );
Bivariate( Y( :Col1 ), X( :Col2 ), Fit Line( 1 ) );
```

Loc(A)

Loc(list, item)

Description

Creates a matrix of subscript positions where *A* is nonzero and nonmissing. For the two-argument function, Loc returns a matrix of positions where *item* is found within *list*.

Returns

The new matrix.

Argument

A a matrix

list a list

item the item to be found within the list

Loc Max(A)

Description

Returns the position of the minimum element in a matrix.

Returns

An integer that is the specified position.

Argument

A a matrix

Loc Min(A)

Description

Returns the position of the minimum element in a matrix.

Returns

An integer that is the specified position.

Argument

A a matrix

Loc NonMissing(matrix, ..., {list}, ...)

Description

Returns indices of nonmissing rows in matrices or lists. In lists, the function can also return indices of nonempty characters.

Returns

The new matrix or list.

Loc Sorted(A, B)

Description

Returns a column vector of subscript positions where the values of *A* have values less than or equal to the values in *B* based on a binary search. *A* must be a matrix sorted in ascending order without missing values.

Returns

The new matrix.

Argument

A, B matrices

Matrix({{x11, x12, ..., x1m}, {x21, x22, ..., 2m}, {...}, {xn1, xn2, ..., xnm}})

Description

Constructs an *n*-by-*m* matrix from a list of *n* lists of *m* row values or from the number of rows and columns.

Returns

The matrix.

Arguments

A list of lists in which each list forms a row with the specified values.

Example

```
mymatrix = Matrix({{1, 2, 3}, {4, 5, 6}, {7, 8, 9}, {10, 11, 12}});
```

```
[ 1 2 3,
  4 5 6,
  7 8 9,
  10 11 12]
```

Equivalent Expression

```
[x11 x12 ... x1m,
   ...,
 xn1 xn2 ... xnm ]
```

Matrix Mult(A, B)

C=A*B, ...

Description

Matrix multiplication.

Arguments

Two or more matrices, which must be conformable (all matrices after the first one listed must have the same number of rows as the number of columns in the first matrix).

Note

Matrix Mult() allows only two arguments, while using the * operator enables you to multiply several matrices.

Mode(list or matrix)

Description

Selects the most frequent item from a numeric or character list or a numeric matrix. In the event of a tie, the lower value is selected. If multiple arguments are specified, a combination of numeric values and character strings is acceptable.

Arguments

Specify either a list or a matrix.

Multivariate Normal Impute(yVec, meanYvec, symCovMat, colMin, colMax)

Description

Imputes missing values in yVec based on the mean and covariance.

Arguments

yVec The vector of responses.

meanYvec The vector of response means.

symCovMat A symmetric matrix containing the response covariances. If the covariance matrix is not specified, then JMP imputes with means.

colMin A vector of column minimums. Provides lower bounds for the imputations.

colMax A vector of column maximums. Provides upper bounds for the imputations.

NChooseK Matrix(n, k)

Description

Returns a matrix of *n* things taken *k* at a time (*n* select *k*).

N Col(x)

N Cols(x)

Description

Returns the number of columns in either a data table or a matrix.

Argument

x Can be a data table or a matrix.

Ortho(A, <Centered(0)>, <Scaled(1)>)

Description

Orthonormalizes the columns of matrix *A* using the Gram Schmidt method. `Centered(0)` makes the columns to sum to zero. `Scaled(1)` makes them unit length.

Ortho Poly(vector, order)

Description

Returns orthogonal polynomials for a *vector* of indices representing spacings up to the *order* given.

Print Matrix(M, <named arguments>)

Description

Returns a string that contains a well-formatted matrix. You can use the function, for example, to print the matrix to the log.

Argument

M A matrix.

Named Arguments

Note that the following named arguments are all optional.

`<<ignore locale(Boolean)` Set to false (0) to use the decimal separator for your locale. Set to true (1) to always use a period (.) as a separator. The default value is false (0).

`<<decimal digits(n)` An integer that specifies the number of digits after the decimal separator to print.

`<<style("style name")` Use one of three available styles: Parseable is a reformatted JSL matrix expression. Latex is formatted for LaTex. If you specify Other, you must define the following three arguments.

> <<separate("character") Define the separator for concatenated entries.
>
> <<line begin("character") Define the beginning line character.
>
> <<line end("character") Define the ending line character.

QR(A)

Description

Returns the QR decomposition of *A*. Typical usage is {Q, R} = QR(A).

Rank Index(vector)

Rank(vector)

Description

Returns a vector of indices that, used as a subscript to the original *vector,* sorts the vector by rank. Excludes missing values. Lists of numbers or strings are supported in addition to matrices.

Ranking(vector)

Description

Returns a vector of ranks of the values of *vector,* low to high as 1 to *n,* ties arbitrary. Lists of numbers or strings are supported in addition to matrices.

Ranking Tie(vector)

Description

Returns a vector of ranks of the values of *vector,* but ranks for ties are averaged. Lists of numbers or strings are supported in addition to matrices.

Shape(A, nrow, <ncol>)

Description

Reshapes the matrix *A* across rows to the specified dimensions. Each value from the matrix A is placed row-by-row into the re-shaped matrix.

Returns

The reshaped matrix.

Arguments

A a matrix

nrow the number of rows that the new matrix should have.

ncol optional. The number of columns the new matrix should have.

Notes

If *ncol* is not specified, the number of columns is whatever is necessary to fit all of the original values of the matrix into the reshaped matrix.

If the new matrix is smaller than the original matrix, the extra values are discarded.

If the new matrix is larger than the original matrix, the values are repeated to fill the new matrix.

Examples

```
a = Matrix({ {1, 2, 3}, {4, 5, 6}, {7, 8, 9} });
   [  1 2 3,
      4 5 6,
      7 8 9]

Shape(a, 2);
   [  1 2 3 4 5,
      6 7 8 9 1]

Shape(a, 2, 2);
   [  1 2,
      3 4]

Shape(a, 4, 4);
   [  1 2 3 4,
      5 6 7 8,
      9 1 2 3,
      4 5 6 7]
```

Solve(A, b)

Description

Solves a linear system. In other words, x=inverse(A)*b.

Sort Ascending(source)

Description

Returns a copy of a list or matrix *source* with the items in ascending order.

Sort Descending(source)

Description

Returns a copy of a list or matrix *source* with the items in descending order.

Spline Coef(x, y, lambda)

Description

Returns a five column matrix of the form `knots||a||b||c||d` where `knots` is the unique values in *x*.

`x` is a vector of regressor variables, `y` is the vector of response variables, and `lambda` is the smoothing argument. Larger values for `lambda` result in smoother splines.

Spline Eval(x, coef)

Description

Evaluates the spline predictions using the `coef` matrix in the same form as returned by `SplineCoef()`, in other words, `knots||a||b||c||d`. The `x` argument can be a scalar or a matrix of values to predict. The number of columns of `coef` can be any number greater than 1 and each is used for the next higher power. The powers of `x` are centered at the knot values. For example, the calculation for `coef` of `knots||a||b||c||d` is `j` is such that `knots[j]` is the largest knot smaller than `x`.

`xx = x-knots[j]` is the centered *x* value:

`result = a[j] + xx * (b[j] + xx * (c[j] + xx * d[j]))`

The following line is equivalent:

`result = a[j] + b[j] * xx + c[j] * xx ^ 2 + d[j] * xx ^ 3`

Spline Smooth(x, y, lambda)

Description

Returns the smoothed predicted values from a spline fit.

`x` is a vector of regressor variables, `y` is the vector of response variables, and `lambda` is the smoothing argument. Larger values for `lambda` result in smoother splines.

SVD(A)

Description

Singular value decomposition.

Sweep(A, <indices>)

Description

Sweeps, or inverts a matrix a partition at a time.

Trace(A)

Description

The trace, or the sum of the diagonal elements of a square matrix.

Transpose(A)

Description

Transposes the rows and columns of the matrix *A*.

Returns

The transposed matrix.

Arguments

A   A matrix.

Equivalent Expression

A'

V Concat(A, B, ...)

Description

Vertical concatenation of two or more matrices.

Returns

The new matrix.

Arguments

Two or more matrices.

V Concat To(A, B, ...)

Description

Vertical concatenation in place. This is an assignment operator.

Returns

The new matrix.

Arguments

Two or more matrices.

V Max(matrix)

Description

Returns a row vector containing the maximum of each column of *matrix*.

V Mean(matrix)

Description

Returns a row vector containing the mean of each column of *matrix*.

V Min(matrix)

Description

Returns a row vector containing the minimum of each column of *matrix*.

V Standardize(matrix)

Description

Returns a matrix column-standardized to mean = 0 and standard deviation = 1.

V Std(matrix)

Description

Returns a row vector containing the standard deviations of each column of *matrix*.

V Sum(matrix)

Description

Returns a row vector containing the sum of each column of *matrix*.

Varimax(matrix, <norm=1>)

Description

Performs a varimax rotation.

Returns

A list that contains the rotated matrix and the orthogonal rotation matrix.

Arguments

matrix A matrix to be rotated.

norm Specify 1 to perform a normalized rotation, and specify 0 to perform a non-normalized rotation. The default value is 1.

Vec Diag(A)

Description

Creates a vector from the diagonals of a square matrix *A*.

Returns

The new matrix.

Arguments

A   A square matrix.

Note

Using a matrix that is not square results in an error.

Vec Quadratic(symmetric matrix, rectangular matrix)

Description

Constructs an *n*-by-*m* matrix. Used in calculation of hat values.

Returns

The new matrix.

Arguments

Two matrices. The first must be symmetric.

Equivalent Expression

Vec Diag(X*Sym*X')

Numeric Functions

Abs(n)

Description

Calculates the absolute value of *n*.

Returns

Returns a positive number of the same magnitude as the value of *n*.

Argument

n   Any number.

Ceiling(n)

Description

If *n* is not an integer, rounds *n* to the next highest integer.

Returns

Returns the smallest integer greater than or equal to *n*.

Argument

n   Any number.

Derivative(expr, {name, ...}, ...)

Description

Calculates the derivative of the *expr* expression with respect to *name*.

Returns

Returns the derivative.

Arguments

expr Any expression. Indirect arguments (for example, Name Expr, Expr, Eval) are supported.

name Can be a single variable or a list of variables.

Note

Adding an additional variable (Derivative(expr, name, name2)) takes the second derivative.

Floor(n)

Description

If *n* is not an integer, rounds *n* to the next lowest integer.

Returns

Returns the largest integer less than or equal to *n*.

Argument

n Any number.

Examples

```
Floor( 2.7 );
   2
Floor( -.5 );
   -1
```

Integrate(expr, varname, lowLimit, upLimit, <<Tolerance(1e-10), <<StoreInfo(list), <<StartingValue(val))

Description

Integrates an expression with respect to a scalar value, using the adaptive quadrature method from Gander and Gautschi (2000).

Arguments

expr an expression that defines the integrand.

varname the name of the variable of integration. If this variable contains a value, that value specifies a starting value that is used as a typical value to improve the accuracy of the integral.

lowLimit specifies the lower limit of integration. To specify negative infinity as the lower limit of integration, set this to missing.

upLimit specifies the upper limit of integration. To specify positive infinity as the upper limit of integration, set this to missing.

StoreInfo saves diagnostics of the numerical integration routine to the argument of StoreInfo().

StartingValue specifies a starting value that is used as a typical value to improve the accuracy of the integral.

Invert Expr(expr, name)

Description

Attempts to unfold *expr* around *name*.

Mod()

See "Modulo(number, divisor)" on page 191

Modulo(number, divisor)

Mod(number, divisor)

Description

Returns the remainder when *number* is divided by *divisor*.

Examples

```
Modulo( 6, 5 );
    1
```

Normal Integrate(muVector, sigmaMatrix, expr, x, nStrata, nSim)

Description

Returns the result of radial-spherical integration for smooth functions of multivariate, normally distributed variables.

Arguments

muVector A vector.

sigmaMatrix A matrix.

expr An expression in terms of the variable *x*.

x The variable used in the expression *expr*.

nStrata Number of strata.

nSim Number of simulations.

```
Num Deriv(f(x,...), <parnum=1>)
```

Description

Returns the numerical derivative of the *f(x,...)* function with respect to one of its arguments. You can specify that argument as the second argument in the *Num Deriv* function. If no second argument is specified, the derivative is taken with respect to the function's first argument. The derivative is evaluated using numeric values specified in the *f(x,...)* function expression.

Notes

The `Num Deriv()` function might appear not to produce the correct results as seen here:

```
x = 3;
n = Num Deriv( 3 * x ^ 2 );
    // 9.00000000001455
```

The preceding usage is not correct. The function was designed to be used in the Nonlinear platform to differentiate functions for which it does not know the analytic derivatives. The proper usage takes the following form:

```
x = 3;
f = Function( {x}, 3 * x ^ 2 );
n = Num Deriv( f( x ), 1 );
    // 18.000029999854
```

```
Num Deriv2(f(x,...))
```

Description

Returns the numerical second derivative of the *f(x,...)* function with respect to *x*. The derivative is evaluated using numeric values specified in the *f(x,...)* function expression.

```
Round(n, places)
```

Description

Rounds *n* to number of decimal *places* given.

```
Simplify Expr(expr(expression))
```

```
Simplify Expr(nameExpr(global))
```

Description

Algebraically simplifies an expression

Optimization Functions

Constrained Maximize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description

Finds the values for the *x* arguments, specified as a list, that maximize the *expr* expression with optional linear constraints. You must specify lower and upper bounds in parentheses for each argument.

In the following messages, A is a matrix of coefficients. x = [x1, x2, ...] is the vector of arguments. b is a vector that forms the right side of the expression.

Messages

<<Less than EQ({A, b}) Sets the constraint to less than or equal to the specified values (A*x <= b).

<<Greater Than EQ({A, b}) Sets the constraint to greater than or equal to the specified values (A*x >= b).

<<Equal To({A, b}) Sets the constraint as equal to the specified values (A*x = b).

<<Starting Values([x1Start, x2Start, ...]) Specifies a starting point.

<<Max Iter(int) An integer that specifies the maximum number of iterations to be performed.

<<Tolerance(p) *p* sets the tolerance for the convergence criterion. The default tolerance is 10^5.

<<Show Details("true") Returns a list with the final values for (objective value, number of iterations, gradient, and Hessian). Shows the step-by-step results of the optimizer in the log.

Constrained Minimize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description

Finds the values for the *x* arguments, specified as a list, that minimize the *expr* expression with optional linear constraints. You must specify lower and upper bounds in parentheses for each argument.

In the following messages, A is a matrix of coefficients. x = [x1, x2, ...] is the vector of arguments. b is a vector that forms the right side of the expression.

Messages

<<Less than EQ({A, b}) Sets the constraint to less than or equal to the specified values (A*x <= b).

<<Greater Than EQ({A, b}) Sets the constraint to greater than or equal to the specified values (A*x >= b).

    `<<Equal To({A, b})` Sets the constraint as equal to the specified values (A*x = b).

    `<<Starting Values([x1Start, x2Start, ...])` Specifies a starting point.

    `<<Max Iter(int)` An integer that specifies the maximum number of iterations to be performed.

    `<<Tolerance(p)` *p* sets the tolerance for the convergence criterion. The default tolerance is 10^5.

    `<<Show Details("true")` Returns a list with the final values for (objective value, number of iterations, gradient, and Hessian). Shows the step-by-step results of the optimizer in the log.

Desirability(yVector, desireVector, y)

Description

Fits a function to go through the three points, suitable for defining the desirability of a set of response variables (*y*'s). *yVector* and *desireVector* are matrices with three values, corresponding to the three points defining the desirability function. The actual function depends on whether the desire values are in the shape of a larger-is-better, smaller-is-better, target, or antitarget.

Returns

The desirability function.

Arguments

`yVector` Three input values.

`desireVector` the corresponding three desirability values.

`y` the value of which to calculate the desirability.

LPSolve(A, b, c, L, U, neq, nle, nge, <slackVars(Boolean)>)

Description

Returns a list containing the decision variables (and slack variables if applicable) in the first list item and the optimal objective function value (if one exists) in the second list item.

Arguments

`A` A matrix of constraint coefficients.

`b` A matrix that is a column of right hand side values of the constraints.

`c` A vector of cost coefficients of the objective function.

`L, U` Matrices of lower and upper bounds for the variables.

`neq` The number of equality constraints.

`nle` The number of less than or equal inequalities.

`nge` The number of greater than or equal inequalities.

slackVars(Boolean) Optional. Determines whether the slack variables are returned in
    addition to the decision variables. The default value is 0.

Note

The constraints must be listed as equalities first, less than or equal inequalities next, and
greater than or equal inequalities last.

Maximize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description

Finds the values for the *x* arguments, specified as a list, that maximize the expression *expr*.
You can specify lower and upper bounds in parentheses for each argument. Additional
arguments for the function enable you to set the maximum number of iterations, tolerance
for convergence, and view more details about the optimization. The Newton-Raphson
method is used when an analytical derivative is found for the Hessian. Otherwise, the
Symmetric-Rank One method (SR1), a quasi-Newton method, is used.

Messages

<<Max Iter(int) An integer that specifies the maximum number of iterations to be
    performed.

<<Tolerance(p) *p* sets the tolerance for the convergence criterion. The default tolerance is
    10^{-8}.

<<Show Details("true") Returns a list with the final values for the objective value,
    number of iterations, gradient, and Hessian. Shows the step-by-step results of the
    optimizer in the log.

Minimize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description

Finds the values for the *x* arguments, specified as a list, that minimize the expression *expr*.
You can specify lower and upper bounds in parentheses for each argument. Additional
arguments for the function enable you to set the maximum number of iterations, tolerance
for convergence, and view more details about the optimization. The Newton-Raphson
method is used when an analytical derivative is found for the Hessian. Otherwise, the
Symmetric-Rank One method (SR1), a quasi-Newton method, is used.

Messages

<<Max Iter(int) An integer that specifies the maximum number of iterations to be
    performed.

<<Tolerance(p) *p* sets the tolerance for the convergence criterion. The default tolerance is
    10^{-8}.

<<Show Details("true") Returns a list with the final values for the objective value,
    number of iterations, gradient, and Hessian. Shows the step-by-step results of the
    optimizer in the log.

Probability Functions

`Beta Density(x, alpha, beta, <theta=0>, <sigma=1>)`

Description

Returns the probability density function (pdf) evaluated at *x* of the beta distribution. The pdf is parameterized as follows:

$$f(x) = \frac{1}{B(\alpha, \beta)\sigma^{\alpha + \beta - 1}}(x - \theta)^{\alpha - 1}(\theta + \sigma - x)^{\beta - 1},$$

where $B(\cdot)$ is the Beta function.

Arguments

x A quantile between *theta* and *theta* + *sigma* at which the pdf is evaluated.

alpha, beta Shape parameters α and β that must both be greater than 0.

theta Optional threshold parameter θ. The allowable range is $-\infty < \theta < \infty$. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Notes

The beta distribution is useful for modeling the probabilistic behavior of random variables that are constrained to fall in the interval [0, 1], such as proportions.

`Beta Distribution(x, alpha, beta, <theta=0>, <sigma=1>)`

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the beta distribution. The cdf uses the same parameterization as the `Beta Density()` function.

Arguments

x A quantile between *theta* and *theta* + *sigma* at which the cdf is evaluated.

alpha, beta Shape parameters α and β, which must both be greater than 0.

theta Optional threshold parameter θ. The allowable range is $-\infty < \theta < \infty$. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

`Beta Quantile(p, alpha, beta, <theta=0>, <sigma=1>)`

Description

Returns the pth quantile from a beta distribution with shape arguments *alpha* and *beta*. The quantile function does not have a closed form equation.

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

alpha, beta Shape parameters α and β, which must both be greater than 0.

theta Optional threshold parameter θ. The allowable range is $-\infty < \theta < \infty$. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Cauchy Density(q, <center=0>, <scale=1>)

Description

Returns the probability density function (pdf) evaluated at *q* of a Cauchy distribution. The pdf is parameterized as follows:

$$f(q) = \frac{1}{\pi\sigma}\frac{1}{1 + \left(\frac{q-\mu}{\sigma}\right)^2}$$

Arguments

q A quantile at which the pdf is evaluated.

center Optional location parameter μ. The default is 0.

sigma Optional scale parameter, σ, which must be greater than 0. The default is 1.

Cauchy Distribution(q, <center=0>, <scale=1>)

Description

Returns the cumulative distribution function (cdf) probability that a Cauchy distributed random variable is less than *q*. The cdf is parameterized as follows:

$$F(q) = \frac{1}{2} + \frac{1}{\pi}\arctan\left(\frac{x-\mu}{\sigma}\right)$$

Arguments

q A quantile at which the cdf is evaluated.

center Optional location parameter μ. The default is 0.

sigma Optional scale parameter, σ, which must be greater than 0. The default is 1.

Cauchy Quantile(p, <center=0>, <scale=1>)

Description

Returns the pth quantile from a Cauchy distribution. The pth quantile is the value for which the probability is *p* that a random value would be less than or equal to *p*. The quantile function is parameterized as follows:

$$F^{-1}(p) = \sigma\tan\left[\pi\left(p + \frac{1}{2}\right)\right] + \mu$$

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

center Optional location parameter μ. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

ChiSquare Density(q, df, <nc=0>)

Description

Returns the probability density function (pdf) evaluated at *q* of the chi-square distribution.

Arguments

q A quantile at which the pdf is evaluated.

df The degrees of freedom *n*, which must be greater than 0.

nc Optional non-centrality parameter λ, which must be non-negative. The default is 0.

ChiSquare Distribution(q, df, <nc=0>)

Description

Returns cumulative distribution function at quantile *x* for chi-square with *df* degrees of freedom centered at *center*.

Arguments

q A quantile at which the cdf is evaluated.

df The degrees of freedom, *n*, must be greater than 0.

nc The optional non-centrality parameter, λ, must be non-negative. The default is 0.

ChiSquare Log CDistribution(x, df, <nc=0>)

Description

Returns the log of (1 - value), where value is the cumulative distribution function evaluated at *x* of the chi-square distribution with *df* degrees of freedom and non-centrality parameter *nc*.

ChiSquare Log Density(x, df, <nc=0>)

Description

Returns the log of the value of the probability density function evaluated at *x* of the chi-square distribution with *df* degrees of freedom and non-centrality parameter *nc*.

ChiSquare Log Distribution(x, df, <nc=0>)

Description

Returns the log of the value of the cumulative distribution function evaluated at quantile *x* of the chi-square distribution with *df* degrees of freedom and non-centrality parameter *nc*.

ChiSquare Noncentrality(x, df, prob)

Description

Returns the chi-square distribution non-centrality parameter that satisfies the following:

prob = ChiSquare Distribution(*x, df, nc*)

Arguments

x A quantile at which the cdf is evaluated.

df The degrees of freedom *n,* which must be greater than 0.

prob The probability of the quantile desired; *prob* must be between 0 and 1.

ChiSquare Quantile(p, df, <nc=0>)

Description

Returns the pth quantile from a chi-square distribution with *df* degrees of freedom, centered at *nc*. The quantile function does not have a closed form equation.

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

df The degrees of freedom *n,* which must be greater than 0.

nc Optional non-centrality parameter λ, which must be non-negative. The default is 0.

Dunnett P Value(q, nTrt, dfe, <lambdaVec=.>)

Description

Returns the *p*-value from Dunnett's multiple comparisons test.

Returns

A number that is the *p*-value.

Arguments

q A number that is the test statistic.

nTrt The number of treatments being compared to the control treatment.

dfe The error degrees of freedom.

lambdaVec A vector of parameters. If *lambdaVec* is missing (.), each of the parameters is set to 1/Sqrt(2).

Dunnett Quantile(1-alpha, nTrt, dfe, <lambdaVec=.>)

Description

Returns quantile needed in from Dunnett's multiple comparisons test.

Returns

A number that is the quantile.

Arguments

`1-alpha` A number that is the confidence level.

`nTrt` The number of treatments being compared to the control treatment.

`dfe` The error degrees of freedom.

`lambdaVec` A vector of parameters. If *lambdaVec* is missing (`.`), each of the parameters is set to 1/Sqrt(2).

Exp Density(x, <theta=1>)

Description

Returns the probability density function (pdf) evaluated at *x* of the exponential distribution. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\theta}\exp(-x/\theta)$$

Arguments

`x` A quantile at which the pdf is evaluated. *x* must be greater than or equal to 0.

`theta` Optional scale parameter θ, which must be greater than 0. The default is 1.

Exp Distribution(x, <theta=1>)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the exponential distribution. The cdf is parameterized as follows:

$$F(x) = 1 - \exp(-x/\theta)$$

Arguments

`x` A quantile at which the cdf is evaluated. *x* must be greater than or equal to 0.

`theta` Optional scale parameter θ, which must be greater than 0. The default is 1.

Exp Quantile(p, <theta=1>)

Description

Returns the pth quantile from an exponential distribution with scale parameter *theta*. The quantile function is parameterized as follows:

$$F^{-1}(p) = -\theta\log(1-p)$$

Arguments

p   The probability of the quantile desired; p must be between 0 and 1.

theta   Optional scale parameter θ, which must be greater than 0. The default is 1.

F Density(x, dfnum, dfden, <nc>)

Description

Returns the probability density function (pdf) evaluated at *x* for the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden,* with optional noncentrality parameter *nc.*

F Distribution(x, dfnum, dfden, <nc>)

Description

Returns cumulative distribution function (cdf) evaluated at *x* for the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden* and noncentrality parameter *nc.*

F Log CDistribution(x, dfn, dfd, <nc>)

Description

Returns the log of (1 - value), where value is the cumulative distribution function evaluated at *x* of the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden,* with optional noncentrality parameter *nc.*

F Log Density(x, dfn, dfd, <nc>)

Description

Returns the log of the value of the probability density function (pdf) evaluated at *x* for the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden,* with optional noncentrality parameter *nc.*

F Log Distribution(x, dfn, dfd, <nc>)

Description

Returns the log of the value of the cumulative distribution function (cdf) evaluated at *x* for the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden* and noncentrality parameter *nc.*

F Noncentrality(x, dfn, dfd, prob)

Description

Returns the F distribution non-centrality parameter that satisfies the following:

$prob$ = F Distribution(*x, dfn, dfd, nc*)

F Power(alpha, dfh, dfm, d, n)

Description

Returns the power from a given situation involving an *F* test or a *t* test.

F Quantile(x, dfnum, dfden, <nc>)

Description

Returns the pth quantile from the F distribution with numerator and denominator degrees of freedom *dfnum* and *dfden* and noncentrality parameter *nc*.

F Sample Size(alpha, dfh, dfm, d, power)

Description

Returns the sample size from a given situation involving an *F* test or a *t* test.

Frechet Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of the Fréchet distribution. The pdf is parameterized as follows:

$$f(x) = \exp\left[-\exp\left(-\frac{\log(x) - \mu}{\sigma}\right)\right]\exp\left(-\frac{\log(x) - \mu}{\sigma}\right)\frac{1}{x\sigma}$$

Arguments

x A number at which the pdf is evaluated. *x* must be greater than 0.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

Frechet Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the Fréchet distribution. The cdf is parameterized as follows:

$$F(x) = \exp\left[-\exp\left(-\frac{\log(x) - \mu}{\sigma}\right)\right]$$

Arguments

x A number at which the cdf is evaluated. *x* must be greater than 0.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

Frechet Quantile(p, mu, sigma)

Description

Returns the pth quantile from a Fréchet distribution with location *mu* and scale `sigma`. The quantile function is parameterized as follows:

$$F^{-1}(p) = \exp[-\sigma \log\{\log(p)\} + \mu]$$

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

Gamma Density(x, <alpha=1>, <scale=1>, <threshold=0>)

Description

Returns the probability density function (pdf) evaluated at *x* of the Gamma distribution. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\Gamma(\alpha)\beta^{\alpha}}(x - \theta)^{\alpha - 1}\exp(-(x - \theta)/\beta)$$

Arguments

x A number at which the pdf is evaluated. *x* must be greater than θ.

alpha Optional shape parameter α, which must be greater than 0. The default is 1.

scale Optional scale parameter β, which must be greater than 0. The default is 1.

threshold Optional threshold parameter θ. The allowable range is $-\infty < \theta < \infty$. The default is 0.

`Gamma Distribution(x, <alpha=1>, <scale=1>, <threshold=0>)`

`IGamma(x, <alpha=1, scale=1, threshold=0>)`

Description

Returns the cumulative distribution function (cdf) evaluated at quantile *x* for the gamma distribution with parameters *alpha, scale,* and *threshold*.

`Gamma Log CDistribution(x, <alpha=1>, <scale=1>, <threshold=0>)`

Description

Same as `Log(1 - Gamma Distribution(x, alpha))` except that it has a much greater range.

`Gamma Log Density(x, <alpha=1>, <scale=1>, <threshold=0>)`

Description

Same as `Log(Gamma Density(x, alpha))` except that it has a much greater range.

`Gamma Log Distribution(x, <alpha=1>, <scale=1>, <threshold=0>)`

Description

Same as `Log(Gamma Distribution(x, alpha))` except that it has a much greater range.

`Gamma Quantile(p, <alpha=1>, <scale=1>, threshold>)`

Description

Returns the *p*th quantile from the gamma distribution with the *alpha, scale,* and *threshold* parameters given.

`GenGamma Density(x, mu, sigma, lambda)`

Description

Returns the probability density function (pdf) evaluated at *x* of an extended generalized gamma probability distribution. The pdf is parameterized as follows:

$$
f(x) = \begin{cases} \dfrac{|\lambda|}{x\sigma}\phi_{\lg}[\lambda\omega + \log(\lambda^{-2});\quad \lambda^{-2}] & \text{if } \lambda \neq 0 \\[2ex] \dfrac{1}{x\sigma}\phi_{\text{nor}}(\omega) & \text{if } \lambda = 0 \end{cases}
$$

where $\omega = [\log(x) - \mu]/\sigma$. Note that

$$
\phi_{\lg}(z;\kappa) = \frac{1}{\Gamma(\kappa)}\exp[\kappa z - \exp(z)]
$$

is the pdf for the standardized log-gamma variable and $\kappa > 0$ is a shape parameter.

Arguments

x A number at which the pdf is evaluated. *x* must be greater than 0.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

lambda A shape parameter λ. The allowable range is $-12 < \lambda < 12$.

GenGamma Distribution(x, mu, sigma, lambda)

Description

Returns the cumulative distribution function (cdf) of the extended generalized gamma distribution. The cdf is parameterized as follows:

$$
F(x) = \begin{cases}
\Phi_{lg}[\lambda\omega + \log(\lambda^{-2}); \quad \lambda^{-2}] & \text{if } \lambda > 0 \\
\Phi_{nor}(\omega) & \text{if } \lambda = 0 \\
1 - \Phi_{lg}[\lambda\omega + \log(\lambda^{-2}); \quad \lambda^{-2}] & \text{if } \lambda < 0
\end{cases}
$$

where $\omega = [\log(x) - \mu]/\sigma$. Note that

$$
\Phi_{lg}(z;\kappa) = \Gamma_I[\exp(z);\kappa]
$$

is the cdf for the standardized log-gamma variable and $\kappa > 0$ is a shape parameter.

Arguments

x A number at which the cdf is evaluated. *x* must be greater than 0.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

lambda A shape parameter λ. The allowable range is $-12 < \lambda < 12$.

GenGamma Quantile(p, mu, sigma, lambda)

Description

Returns the pth quantile from an extended generalized gamma distribution with parameters *mu, sigma,* and *lambda*. The quantile function does not have a closed form equation.

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

lambda A shape parameter λ. The allowable range is $-12 < \lambda < 12$.

GLog Density(x, mu, sigma, lambda)

Description

Returns the probability density function (pdf) evaluated at *x* of a generalized logarithmic distribution. The pdf is parameterized as follows:

$$f(x) = \phi\left\{\frac{1}{\sigma}\left[\log\left(\frac{x + \sqrt{x^2 + \lambda^2}}{2}\right) - \mu\right]\right\}\frac{x + \sqrt{x^2 + \lambda^2}}{\sigma(x^2 + \lambda^2 + x\sqrt{x^2 + \lambda^2})}$$

where $\phi(\cdot)$ is the standard normal pdf.

Arguments

x A number at which the pdf is evaluated.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

lambda A shape parameter λ, which must be greater than 0.

GLog Distribution(x, mu, sigma, lambda)

Description

Returns the probability that a generalized logarithmically distribution random variable is less than *x*.

GLog Quantile(p, mu, sigma, lambda)

Description

Returns the pth quantile from a generalized logarithmic distribution.

IGamma()

See "Gamma Distribution(x, <alpha=1>, <scale=1>, <threshold=0>)" on page 204.

Johnson Sb Density(q, gamma, delta, theta, sigma)

Description

Returns the probability density function (pdf) evaluated at *q* of a Johnson Sb distribution. The pdf is parameterized as follows:

$$f(q) = \phi\left[\gamma + \delta\ln\left(\frac{q - \theta}{\sigma - (q - \theta)}\right)\right]\left(\frac{\delta\sigma}{(q - \theta)(\sigma - (q - \theta))}\right)$$

where $\phi(\cdot)$ is the standard normal pdf.

Arguments

q A value that is in the interval *theta* to *theta* + *sigma*.

gamma Shape parameter γ that can be any value.

delta Shape parameter δ that must be greater than 0.

theta Location parameter θ that can be any value.

sigma Scale parameter σ that must be greater than 0.

Johnson Sb Distribution(q, gamma, delta, theta, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *q* of a Johnson Sb distribution. The pdf is parameterized as follows:

$$f(q) = \Phi\left[\gamma + \delta \ln\left(\frac{q - \theta}{\sigma - (q - \theta)}\right)\right]$$

where $\Phi(\cdot)$ is the standard normal cdf.

Arguments

q A value that is in the interval *theta* to *theta* + *sigma*.

gamma Shape parameter γ that can be any value.

delta Shape parameter δ that must be greater than 0.

theta Location parameter θ that can be any value.

sigma Scale parameter σ that must be greater than 0.

Johnson Sb Quantile(p, gamma, delta, theta, sigma)

Description

Returns the pth quantile whose value for which the probability is *p* that a random value would be lower.

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

gamma Shape parameter that can be any value.

delta Shape parameter that must be greater than 0.

theta Location parameter that can be any value.

sigma Scale parameter that must be greater than 0.

Johnson Sl Density(x, gamma, delta, theta, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of a Johnson Sl distribution. The pdf is parameterized as follows:

$$f(q) = \frac{\delta}{|x - \theta|} \phi \left[\gamma + \delta \ln \left(\frac{x - \theta}{\sigma} \right) \right]$$

where $\phi(\cdot)$ is the standard normal pdf.

Arguments

x   A value that is greater than *theta* if *sigma* is 1 and less than *theta* if *sigma* is -1.

gamma   Shape parameter γ that can be any value.

delta   Shape parameter δ that must be greater than 0.

theta   Location parameter θ that can be any value.

sigma   Parameter σ that defines if the distribution is skewed positively or negatively. Sigma must be equal to either +1 (skewed positively) or -1 (skewed negatively).

Johnson Sl Distribution(q, gamma, delta, theta, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *q* of a Johnson Sl distribution.

Arguments

q   A value that is in the interval *theta* to +infinity.

gamma   Shape parameter that can be any value.

delta   Shape parameter that must be greater than 0.

theta   Location parameter that can be any value.

sigma   Parameter that defines if the distribution is skewed positively or negatively. Sigma must be equal to either +1 (skewed positively) or -1 (skewed negatively).

Johnson Sl Quantile(p, gamma, delta, theta, sigma)

Description

Returns the pth quantile from a Johnson Sl distribution.

Arguments

p   The probability of the quantile desired; *p* must be between 0 and 1.

gamma   Shape parameter that can be any value.

delta   Shape parameter that must be greater than 0.

theta Location parameter that can be any value.

sigma Parameter that defines if the distribution is skewed positively or negatively. `Sigma` must be equal to either +1 (skewed positively) or -1 (skewed negatively).

Johnson Su Density(x, gamma, delta, theta, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of a Johnson Su distribution. The pdf is parameterized as follows:

$$\frac{\delta}{\sigma}\left[1+\left(\frac{x-\theta}{\sigma}\right)^2\right]^{-1/2}\phi\left[\gamma+\delta\sinh^{-1}\left(\frac{x-\theta}{\sigma}\right)\right]$$

where $\phi(\cdot)$ is the standard normal pdf.

Arguments

x A value that is between -infinity and +infinity.

gamma Shape parameter γ that can be any value.

delta Shape parameter δ that must be greater than 0.

theta Location parameter θ that can be any value.

sigma Scale parameter σ that must be greater than 0.

Johnson Su Distribution(q, gamma, delta, theta, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *q* of a Johnson Su distribution. The cdf is parameterized as follows:

$$\Phi\left[\gamma+\delta\sinh^{-1}\left(\frac{x-\theta}{\sigma}\right)\right]$$

where $\Phi(\cdot)$ is the standard normal cdf.

Arguments

q A value that is between -infinity and +infinity.

gamma Shape parameter γ that can be any value.

delta Shape parameter δ that must be greater than 0.

theta Location parameter θ that can be any value.

sigma Scale parameter σ that must be greater than 0.

Johnson Su Quantile(p, gamma, delta, theta, sigma)

Description

Returns the pth quantile whose value for which the probability is *p* that a random value would be lower.

Arguments

p The probability of the quantile desired; *p* must be between 0 and 1.

gamma Shape parameter that can be any value.

delta Shape parameter that must be greater than 0.

theta Location parameter that can be any value.

sigma Scale parameter that must be greater than 0.

LEV Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of the largest extreme value distribution with location *mu* and scale *sigma*. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\sigma}\exp\left[-\frac{x-\mu}{\sigma} - \exp\left(-\frac{x-\mu}{\sigma}\right)\right]$$

Arguments

x A number at which the pdf is evaluated.

mu The location parameter, μ.

sigma The scale parameter σ, must be greater than 0.

LEV Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the largest extreme value distribution with location *mu* and scale *sigma*. The cdf is parameterized as follows:

$$F(x) = \exp\left[-\exp\left(-\frac{x-\mu}{\sigma}\right)\right]$$

Arguments

x A number at which the cdf is evaluated. *x* must be greater than *sigma*.

mu The location parameter μ.

sigma The scale parameter σ, which must be greater than 0.

LEV Quantile(p, mu, sigma)

Description

Returns the pth quantile from a largest extreme value distribution with location *mu* and scale *sigma*. The quantile function is parameterized as follows:

$$F^{-1}(p) = -\sigma\log(-\log(p)) + \mu$$

Arguments

p   The probability of the quantile desired; p must be between 0 and 1.

mu   The location parameter, μ.

sigma   The scale parameter σ, must be greater than 0.

LogGenGamma Density(x, mu, sigma, lambda)

Description

Returns the probability density function (pdf) evaluated at *x* of a log generalized gamma probability distribution with parameters *mu*, *sigma*, and *lambda*. The pdf is parameterized as follows:

$$f(x) = \begin{cases} \dfrac{|\lambda|}{\sigma}\phi_{\text{lg}}[\lambda\omega + \log(\lambda^{-2});\lambda^{-2}] & \text{if } \lambda \neq 0 \\[2ex] \dfrac{1}{\sigma}\phi_{\text{nor}}(\omega) & \text{if } \lambda = 0 \end{cases}$$

where $\omega = [\log(x) - \mu]/\sigma$. Note that

$$\phi_{\text{lg}}(z;\kappa) = \frac{1}{\Gamma(\kappa)}\exp[\kappa z - \exp(z)]$$

is the pdf for the log-gamma variable and $\kappa > 0$ is a shape parameter.

Arguments

x   A number at which the pdf is evaluated.

mu   The location parameter, μ.

sigma   The scale parameter σ, which must be greater than 0.

lambda   A shape parameter λ. The allowable range is $-12 < \lambda < 12$.

LogGenGamma Distribution(x, mu, sigma, lambda)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the log generalized gamma distributed random variable (with parameters *mu*, *sigma*, and *lambda*) The cdf is parameterized as follows:

$$F(x) = \begin{cases} \Phi_{lg}[\lambda\omega + \log(\lambda^{-2});\lambda^{-2}] & \text{if } \lambda > 0 \\ \Phi_{nor}(\omega) & \text{if } \lambda = 0 \\ 1 - \Phi_{lg}[\lambda\omega + \log(\lambda^{-2}); \quad \lambda^{-2}] & \text{if } \lambda < 0 \end{cases}$$

where $\omega = [\log(x) - \mu]/\sigma$. Note that

$$\Phi_{lg}(z;\kappa) = \Gamma_I[\exp(z);\kappa]$$

is the cdf for the log-gamma variable and $\kappa > 0$ is a shape parameter.

Arguments

x   A number at which the cdf is evaluated.

mu   The location parameter, μ.

sigma   The scale parameter σ, which must be greater than 0.

lambda   A shape parameter λ. The allowable range is $-12 < \lambda < 12$.

LogGenGamma Quantile(p, mu, sigma, lambda)

Description

Returns the pth quantile from a log generalized gamma distribution (with parameters *mu*, *sigma*, and *lambda*), the value for which the probability is *p* that a random variable would be lower.

Logistic Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of a logistic distribution with location *mu* and scale *sigma*. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\sigma}\frac{\exp\left(-\frac{x-\mu}{\sigma}\right)}{\left[1 + \exp\left(-\frac{x-\mu}{\sigma}\right)\right]^2}$$

Arguments

x　A number at which the pdf is evaluated.

mu　The location parameter μ.

sigma　The scale parameter σ, which must be greater than 0.

Logistic Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the logistic distribution with location *mu* and scale *sigma*. The cdf is parameterized as follows:

$$F(x) = \frac{1}{\left[1 + \exp\left(-\frac{x-\mu}{\sigma}\right)\right]}$$

Arguments

x　A number at which the cdf is evaluated. *x* must be greater than σ.

mu　The location parameter μ.

sigma　The scale parameter σ, which must be greater than 0.

Logistic Quantile(p, mu, sigma)

Description

Returns the pth quantile from a logistic distribution with location *mu* and scale *sigma*. The quantile function is parameterized as follows:

$$F^{-1}(p) = -\sigma\log\left(\frac{1}{p} - 1\right) + \mu$$

Arguments

p　The probability of the quantile desired; *p* must be between 0 and 1.

mu　The location parameter μ.

sigma　The scale parameter σ, which must be greater than 0.

Loglogistic Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of a loglogistic distribution with location *mu* and scale *sigma*. The pdf is parameterized as follows:

$$f(x) = \frac{1}{x\sigma} \frac{\exp\left(\frac{\log(x) - \mu}{\sigma}\right)}{\left[1 + \exp\left(\frac{\log(x) - \mu}{\sigma}\right)\right]^2}$$

Arguments

x   A number at which the pdf is evaluated.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

Loglogistic Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the loglogistic distribution with location *mu* and scale *sigma*. The cdf is parameterized as follows:

$$F(x) = \frac{1}{1 + \exp\left(-\frac{\log(x) - \mu}{\sigma}\right)}$$

Arguments

x   A number at which the cdf is evaluated.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

Loglogistic Quantile(p, mu, sigma)

Description

Returns the pth quantile from a loglogistic distribution with location *mu* and scale *sigma*. The quantile function is parameterized as follows:

$$F^{-1}(p) = \exp\left[-\sigma\log\left(\frac{1}{p} - 1\right) + \mu\right]$$

Arguments

p   The probability of the quantile desired; p must be between 0 and 1.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

Lognormal Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of a lognormal distribution with location *mu* and scale *sigma*. The pdf is parameterized as follows:

$$f(x) = \phi\left[\frac{\log(x) - \mu}{\sigma}\right]$$

where $\phi(\cdot)$ is the standard normal pdf.

Arguments

x   A number at which the pdf is evaluated. *x* must be greater than or equal to 0.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

Lognormal Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of a lognormal distribution with location *mu* and scale *sigma*. The cdf is parameterized as follows:

$$F(x) = \Phi\left[\frac{\log(x) - \mu}{\sigma}\right]$$

where $\Phi(\cdot)$ is the standard normal cdf.

Arguments

x   A number at which the pdf is evaluated. *x* must be greater than or equal to 0.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

Lognormal Quantile(x, mu, sigma)

Description

Returns the pth quantile of a lognormal distribution with location *mu* and scale *sigma*.

Normal Biv Distribution(x, y, r, <mu1>, <s1>, <mu2>, <s2>)

Description

Computes the probability that an observation (X, Y) is less than or equal to (*x*, *y*) with correlation coefficient *r* where X is individually normally distributed with mean *mu1* and standard deviation *s1* and Y is individually normally distributed with mean *mu2* and

standard deviation *s2*. If *mu1*, *s1*, *mu2*, and *s2* are not given, the function assumes the standard normal bivariate distribution with *mu1*=0, *s1*=1, *mu2*=0, and *s2*=1.

Normal Density(x, <mean=0>, <stddev=1>)

Description

Returns the probability density function (pdf) evaluated at *x* for the normal distribution with *mean* and *stddev*. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}}\exp\left[-\frac{(x-\mu)^2}{2\sigma^2}\right]$$

Arguments

x A number at which the pdf is evaluated.

mu Optional location parameter μ. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Normal Distribution(x, <mean=0>, <stddev=1>)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* for the normal distribution with *mean* and *stddev*. The cdf is parameterized as follows:

$$F(x) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

Note that $\Phi(\cdot)$ is the standard normal cdf, defined as follows:

$$\Phi(x) = \frac{1}{\sqrt{2\pi}}\int_0^x \exp\left(-\frac{t^2}{2}\right)dt$$

Arguments

x A number at which the pdf is evaluated.

mu Optional location parameter μ. The default is 0.

sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Normal Log CDistribution(x, <mean=0>, <std dev=1>)

Description

Returns 1 - log (value) of the distribution function at quantile *x* for the normal distribution.

`Normal Log Density(x, <mean=0>, <stddev=1>)`

Description

Returns the log of the value of the density function at quantile *x* for the normal distribution with *mean* and *stddev*. The default *mean* is 0. The default *stddev* is 1.

`Normal Log Distribution(x, <mean=0>, <std dev=1>)`

Description

Returns the log of the value of the distribution function at quantile *x* for the normal distribution.

`Normal Mixture Density(q, mean, stdev, probability)`

Description

Returns the density at *q* of a normal mixture distribution with group means *mean,* group standard deviations *stdev,* and group probabilities *probability*. The *mean, stdev,* and *probability* arguments are all vectors of the same size.

`Normal Mixture Distribution(q, mean, stdev, probability)`

Description

Returns the probability that a normal mixture distributed variable with group means *mean,* group standard deviations *stdev,* and group probabilities *probability* is less than *q*. The *mean, stdev,* and *probability* arguments are all vectors of the same size.

`Normal Mixture Quantile(p, mean, stdev, probability)`

Description

Returns the pth quantile, the values for which the probability is *p* that a random value would be lower. The *mean, stdev,* and *probability* arguments are all vectors of the same size.

`Normal Quantile(p, <mean=0>, <stddev=1>)`

`Probit(p, <mean=0>, <stddev=1>)`

Description

Returns the pth quantile from the normal distribution with *mean* and *stddev*. The default *mean* is 0. the default *stddev* is 1.

`Probit()`

See "Normal Quantile(p, <mean=0>, <stddev=1>)" on page 217.

SEV Density(x, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at *x* of the smallest extreme distribution with location *mu* and scale *sigma*. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\sigma}\exp\left[\frac{x-\mu}{\sigma} - \exp\left(\frac{x-\mu}{\sigma}\right)\right]$$

Arguments

x   A number at which the pdf is evaluated.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

SEV Distribution(x, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at *x* of the smallest extreme distribution with location *mu* and scale *sigma*. The cdf is parameterized as follows:

$$F(x) = 1 - \exp\left[-\exp\left(\frac{x-\mu}{\sigma}\right)\right]$$

Arguments

x   A number at which the cdf is evaluated. *x* must be greater than σ.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

SEV Quantile(p, mu, sigma)

Description

Returns the pth quantile of the smallest extreme distribution with location *mu* and scale *sigma*. The quantile function is parameterized as follows:

$$F^{-1}(p) = \sigma\log[-\log(1-p)] + \mu$$

Arguments

p   The probability of the quantile desired; p must be between 0 and 1.

mu   The location parameter μ.

sigma   The scale parameter σ, which must be greater than 0.

SHASH Density(x, gamma, delta, theta, sigma)

Description

Returns the density at *x* of a sinh-arcsinh (SHASH) distribution.

SHASH Distribution(x, gamma, delta, theta, sigma)

Description

Returns the probability that the sinh-arcsinh (SHASH) distribution is less than *x*.

SHASH Quantile(p, gamma, delta, theta, sigma)

Description

Returns the pth quantile at *p* of the sinh-arcsinh (SHASH) distribution.

Students t Density()

Students t Distribution()

Students t Quantile()

t Density(q, df)

Students t Density(q, df)

Description

Returns the value of the density function at quantile *x* for the Student's t distribution with degrees of freedom *df*.

t Distribution(q, df, <nonCentrality>)

Students t Distribution(q, df, <nonCentrality>)

Description

Returns the probability that a Student's *t* distributed random variable is less than *q*. *nonCentrality* defaults to 0.

t Log CDistribution(x, df, <nc>)

Description

Returns 1 - log (value) of the normal distribution function at quantile *x* for the *t* distribution.

t Log Density(x, df, <nc>)

Description

Returns the log of the value of the density function at quantile *x* for the *t* distribution.

t Log Distribution(x, df, <nc>)

Description

Returns the log of the value of the distribution function at quantile *x* for the *t* distribution.

t Noncentrality(x, df, prob)

Description

Solves the noncentrality such that

prob=T Distribution (*x*, *df*, *nc*)

t Quantile(p, df, <nonCentrality=0>)
Students t Quantile(p, df, <nonCentrality=0>)

Description

Returns the pth quantile from the Student's *t* distribution with degrees of freedom *df*. *nonCentrality* defaults to 0.

Tukey HSD P Value(q, n, dfe)

Description

Returns the *p*-value from Tukey's HSD multiple comparisons test.

Arguments

q The test statistic.

n The number of groups in the study.

dfe The error degrees of freedom, based on the total study sample.

Tukey HSD Quantile(1-alpha, n, dfe)

Description

Returns the quantile needed in Tukey's HSD multiple comparisons test.

Arguments

`1-alpha` The confidence level.

`n` The number of groups in the study.

`dfe` The error degrees of freedom, based on the total study sample.

Weibull Density(x, shape, <scale=1>, <threshold=0>)

Description

Returns the probability density function (pdf) evaluated at *x* of the Weibull distribution. The pdf is parameterized as follows:

$$f(x) = \frac{\beta}{\alpha}\left(\frac{x-\theta}{\alpha}\right)^{\beta-1} \exp\left[-\left(\frac{x-\theta}{\alpha}\right)^{\beta}\right]$$

Arguments

`x` A number the pdf is evaluated at. Must be greater than *threshold*.

`shape` Shape parameter β, which must be greater than 0.

`scale` Optional scale parameter α, which must be greater than 0. The default is 1.

`threshold` Optional threshold parameter θ. The default is 0.

Weibull Distribution(x, shape, <scale=1>, <threshold=0>)

Description

Returns the cumulative distribution function (cdf) at *x* of the Weibull distribution. The cdf is parameterized as follows:

$$F(x) = 1 - \exp\left[-\left(\frac{x-\theta}{\alpha}\right)^{\beta}\right]$$

Arguments

`x` A number at which the pdf is evaluated. Must be greater than *threshold*.

`shape` Shape parameter β, which must be greater than 0.

`scale` Optional scale parameter α, which must be greater than 0. The default is 1.

`threshold` Optional threshold parameter θ. The default is 0.

Weibull Quantile(p, shape, <scale=1>, <threshold=0>)

Description

Returns the pth quantile from the Weibull distribution with the parameters given. The quantile function is calculated as follows:

$$F^{-1}(p) = \alpha[\ln(1-p)]^{\frac{1}{\beta}} + \theta$$

Arguments

p The probability of the quantile desired; p must be between 0 and 1.

shape Shape parameter β, which must be greater than 0.

scale Optional scale parameter α, which must be greater than 0. The default is 1.

threshold Optional threshold parameter θ. The default is 0.

Programming Functions

As Boolean(x)

Description

Evaluates a JSL expression and returns a JSL Boolean value for use with JSON data.

Example

```
x = 45;
b = As Boolean( x > 2 );
Show( b );
    b = 1;
```

As Column(name)

As Column(dt, name)

:name

dt:name

Description

This scoping operator forces *name* to be evaluated as a data table column in the current data table (or the table given by the optional data table reference argument, *dt*) rather than as a global variable.

Arguments

name Variable name.

dt The data table reference

Note

:name refers to a column name in the current data table. You can also specify which data table to refer to by use dt:name.

As Constant(expr)

Description

Evaluates an expression once to create a value that does not change after it is computed.

Returns

The result of the evaluation.

Argument

`expr` Any JSL expression.

Notes

A few platforms that can save prediction columns to a data table use `As Constant()`. The function is wrapped around the part of the formula that is constant across all rows. The argument is evaluated for the first row and then the result is used without re-evaluation for subsequent rows.

As Global(name)

::name

Description

This scoping operator forces *name* to be evaluated as a global variable rather than as a data table column.

Arguments

`name` Variable name.

As List(matrix)

See "As List(matrix)" on page 156.

As Name(string)

Description

Evaluates argument as a string and changes it into a name.

Returns

A name.

As Namespace(name)

Description

Accesses the specified namespace. An error is thrown if no such namespace exists.

Returns

The namespace.

Arguments

`name` Unquoted name of a defined namespace.

As Scoped(namespace, variable)

namespace:variable

Description

Accesses the specified *variable* within the specified *namespace*.

Returns

The value of the variable, or an error the scoped variable is not found.

Arguments

`namespace` The name of a defined namespace.

`variable` A variable defined within *namespace*.

Associative Array({key, value}, ...)

Associative Array(keys, values)

Description

Creates an associative array (also known as a dictionary or hash map).

Returns

An associative array object.

Arguments

Either list of key-value pairs; or a list, matrix, or data table column that contains keys followed by a list, matrix, or data table column, respectively, that contains the corresponding values.

Class Exists(class reference)

Description

Returns a value indicating whether a class definition represented by the class reference is a defined class.

Returns

0 or 1.

Argument

`class reference` Class reference to an instantiated object.

Clear Globals(<name>, <name>, ...)

Description

Clears the values for all global symbols. Symbols in any scope other than global are not affected. If one or more names are specified, only those global symbols are cleared.

Returns

Null.

Arguments

name Optional: any global variable name(s).

See

"Clear Symbols(<name>, <name>, ...)" on page 225

Clear Log()

Description

Empties the log.

Clear Symbols(<name>, <name>, ...)

Description

Clear the values for all symbols in any and all scopes. If one or more names are specified, only those symbols are cleared.

Returns

Null.

Arguments

name Optional: any global variable name(s).

See

"Clear Globals(<name>, <name>, ...)" on page 225.

Close Log()

Description

Closes the log.

Define Class("class name" <, Base Class{"base class name"<, "base class name"><, Using Namespace(namespace)><, Show(All(Boolean expression)|(Members(Boolean expression)|Methods(Boolean expression)|Functions(Boolean expression))

Description

Defines a new class.

Example

```
Define Class(
    "aa",
    {_init_ = Method( {} ), x = 1, m1 = Method( {a, b}, a * b )}
);
```

Delete Classes(<Force(Boolean expression)>, < <class reference>, ...>)

Description

Deletes all currently defined classes.

Optional Arguments

`Force(Boolean expression)` Deletes the class even if it's in use.

`class reference` Specifies the classes to delete. You can specify more than one class reference.

Delete Globals(<name>, <name>, ...)

Description

Deletes all global symbols, except global symbols that are locked. Symbols in any scope other than global are not affected. If one or more names are specified, only those global symbols are cleared.

Arguments

`name` Optional: any global variable name(s).

See

See "Delete Symbols(<name>, <name>, ...)" on page 227.

Delete Namespaces(<Force(Boolean expression)>, < <namespace reference>, ...>)

Delete(<Force(Boolean expression)>, < <namespace reference>, ...>)

Description

Deletes all currently defined namespaces.

Optional Arguments

`Force(Boolean expression)` Deletes the namespace even if it's in use.

`namespace reference` Specifies the namespaces to delete. You can specify more than one namespace reference.

Notes

• When you delete a namespace that contains locked namespaces, an error appears in the log. Use the `Force()` argument to delete the locked namespaces.

• With no arguments, `Delete Namespaces()` ignores locked namespaces.

Delete Symbols(<name>, <name>, ...)

Description

Deletes all symbols in any and all scopes. If one or more names are specified, only those symbols are deleted.

Arguments

name Optional: any global variable name(s).

See

Eval(expr)

Description

Evaluates expr, and then evaluates the result of expr (unquoting).

Returns

The result of the evaluation.

Argument

expr Any JSL expression.

Eval Insert(string, <startDel>, <endDel>, < <<Use Locale(1) >)

Description

Allows for multiple substitutions.

Returns

The result.

Arguments

string A quoted string with embedded expressions.

startDel Optional starting delimiter. The default value is ^.

endDel optional ending delimited. The default value is the starting delimiter.

Use Locale(1) Optional argument that preserves locale-specific numeric formatting.

Eval Insert Into(string, <startDel>, <endDel>)

Description

Allows for multiple substitutions in place. The same operation as in Eval Insert is performed, and the result is placed into *string*.

Returns

The result.

Arguments

`string` A string variable that contains a string with embedded expressions.

`startDel` Optional starting delimiter. The default value is ^.

`endDel` optional ending delimited. The default value is the starting delimiter.

Eval List

See "Eval List(list)" on page 157.

Exit(<NoSave>)

Quit(<NoSave>)

Description

Exits JMP.

Returns

Void.

Arguments

`NoSave` Optional, named command; exits JMP without prompting to save any open files. This command is *not* case-sensitive, and spaces are optional.

First(expr, <expr>, ...)

Description

Evaluates all expressions provided as arguments.

Returns

Only the result of the first evaluated expression.

Arguments

`expr` Any valid JSL expression.

Function({arguments}, <{local variables}>, <Return(<expr>)>, script)

Description

Stores the body *script* with *arguments* as local variables.

Returns

The function as defined. If the Return() argument is specified, the expression is returned.

When called later, it returns the result of the *script* given the specified *arguments*.

Arguments

`{arguments}` A list of arguments to pass into the function. You can specify some arguments as optional or required.

{local variables} A list of variables that are local to the function. You can declare local variables in three ways:

```
{var1, var2}
{var1=0, var1="a string"}
{Default Local}
```

The last option declares that all unscoped variables used in the function are local to the function.

Return(expr) This optional argument returns an expression from an user defined function. If a null expression is used, a period, ".", is returned.

script Any valid JSL script.

Get Class Names(< <class reference>, ...>)

Description

Gets a set of names to all classes or the set of specific class references.

Arguments

A set of class references to instantiated objects.

Returns

A list of class names as determined by the arguments to the function.

Get Classes(< <class reference>, ...>)

Description

Gets a set of references to all classes or the set of specific class references.

Arguments

A set of class references to an instantiated objects.

Returns

A list of class references as determined by the arguments to the function.

Get Environment Variable("variable")

Description

Retrieves the value of an operating system environment variable.

Returns

A string that contains the value of the specified environment variable. If the specified variable is not found, an empty string is returned.

Arguments

"variable" A string that contains the name of an environment variable.

Notes

On Macintosh, environment variable names are case-sensitive. On Windows, the names are case-insensitive.

Get Class Names(< <class reference>, ...>)

Description

Gets a list or a specific set of class references. You can specify more than one class reference.

Get Classes(< <class reference>, ...>

Description

Gets a list of all or a specific set of class references. You can specify more than one class reference.

Get Log(<n>)

Description

Returns a list of lines from the log.

Returns

A list of strings. Each string contains one line from the log.

Argument

n Optional, integer. If no argument is specified, all the lines are returned. If a positive number is specified, the first *n* lines are returned. If a negative number is specified, the last *n* lines are returned. If *n*=0, no lines are returned (an empty list). If the log is empty, an empty list is returned.

Get Namespace Names(< <namespace reference>,...>)

Description

Returns a list of the names of all currently defined namespaces.

Example

```
nsaa = New Namespace(
    "aa",
    {
        x = 1
    }
);
nsbb = New Namespace(
    "bb",
    {
        y = 1
    }
```

```
      );
      lns = Get Namespace Names();
      Show( lns );
      nsaa << Delete;
      nsbb << Delete;
```

Get Namespaces(< <namespace reference>,...>)

Description

Returns a list of currently defined namespaces.

Example

```
      nsaa = New Namespace(
         "aa",
         {
            x = 1
         }
      );
      nsbb = New Namespace(
         "bb",
         {
            y = 1
         }
      );
      lns = Get Namespaces();
```

Include("pathname", <named arguments>)

Description

Opens the script file identified by the quoted string *pathname*, parses the script in it, and executes it.

Returns

Whatever the included script returns. If you use the <<Parse Only option, Include returns the contents of the script.

Named Arguments

<<Parse Only Parses the script but does not execute the script.

<<New Context Causes the included script to be run its own unique namespace. When the parent and included scripts use the global namespace, include <<Names Default to Here along with <<New Context.

<<Allow Include File Recursion Lets the included script include itself.

Notes

If a trailing space is included in the path name, the space is ignored on Windows. On Macintosh, the script fails.

See the Programming Methods chapter in the *Scripting Guide* for details about the function.

Include File List()

Description

Returns a list of files that are included at the point of execution.

Is Class

Description

Returns a value that indicates whether the class reference is a class based object.

Argument

A class reference to an instantiated object.

Returns

Returns a zero or a 1.

Is Log Open()

Description

Returns result if log window is open.

List

See

Local({name=value, ...}, script)

Description

Resolves *names* to local expressions.

Local Here(expression)

Description

Creates a local Here namespace block. Use this function to prevent name collisions when multiple scripts are executed from the same root namespace (for example, when a script executes two button scripts that have the same variables). The argument can be any valid JSL expression.

Lock Namespaces(<string>,|< {string}, ...>)

Lock(<string>,|< {string}, ...>)

Description

Locks all variables or specified named variables in this namespace and prevents variables from being added, changed, or removed.

Example

```
ns = New Namespace(
  "aaa"
);
ns << Lock Namespaces;
Try( ns << Delete Namespaces, Show( exception_msg ) );
Delete Namespaces();
Try( Delete Namespaces( "aaa" ), Show( exception_msg ) );
```

Lock Globals(name1, name2, ...)

Description

Locks one or more global variables to prevent it or them from being changed.

Lock Symbols(<name>, <name>, ...)

Description

Locks the specified symbols, which prevents them from being modified or cleared. If no symbols are provided, all global symbols are locked. If no symbols are provided and the script has the *Names Default To Here* mode turned on, then all local symbols are locked.

LogCapture(expr)

Description

Evaluates the expr, captures the output that would normally be sent to the log, and instead returns it.

Returns

A string that contains the log output.

Argument

Any valid JSL expression.

Note

No output appears in the log.

N Items

See "N Items(source)" on page 158.

Names Default To Here(Boolean)

Description

Determines where unresolved names are stored, either as a global or local (if *Boolean* is 0) or in the Here scope (if *Boolean* is 1).

Namespace(name)

Description

Returns a reference to the named namespace (*name*).

Argument

Name A namespace name string or a reference to a namespace.

Namespace Exists(name)

Description

Returns 1 if a namespace with the specified *name* exists; otherwise, returns 0.

New Namespace(<"name">, <{expr, ...}>)

Description

Creates a new namespace with the specified name. If a name is not provided, an anonymous name is provided.

Returns

A reference to the namespace.

Arguments

name An optional, quoted string that contains the name of the new namespace.

{list of expressions} An optional list of expressions within the namespace.

Open Log()

Description

Opens the log. Include the Boolean argument (1) to make the window active, even if it is already open.

New Object("class name|class name|class reference(constructor arguments)

Description

Creates an instance object of a class.

Arguments

"class name" Name of the class to be instantiated.

class name Unquoted name of the class to be instantiated.

class reference Reference to an existing class object that will be used to instantiate a
new object of the same class.

constructor arguments Set of arguments to be passed to the _init_ constructor.

Example

```
Define Class(
    "complex",
    {real = 0, imag = 0, _init_ = Method( {a, b},
        real = a;
        imag = b;
    ), Add = Method( {y},
        complex( real + y:real, imag + y:imag )
    ), Sub = Method( {y},
        complex( real - y:real, imag - y:imag )
    ), Mul = Method( {y},
        complex( real * y:real - imag * y:imag, imag * y:real + real * y:imag )
    ), Div = Method( {y},
        t = complex( 0, 0 );
        mag2 = y:Magsq();
        t:real = real * y:real + imag * y:imag;
        t:imag = imag * y:real + real * y:imag;
        t:real = t:real / mag2;
        t:imag = t:imag / mag2;
        t;
    ), Magsq = Method( {},
        real * real + imag * imag
    ), Mag = Method( {},
        Sqrt( real * real + imag * imag )
    ), To String = Method( {},
        Char( real ) || " + " || Char( imag ) || "i"
    )}
);
cl = New Object( complex( 1, 2 ) );
cl << Delete;
Delete Classes( "complex" );
```

Parameter({name=value, ...}, model expression)

Description

Defines formula parameters for models for the Nonlinear platform.

Parse(string)

Description

Converts a character string into a JSL expression.

Print(expr, expr, ...)

Description

Prints the values of the specified *expressions* to the log.

Quit()

See "Exit(<NoSave>)" on page 228.

Recurse(function)

Description

Makes a recursive call of the defining *function*.

Save Log(pathname)

Description

Writes the contents of the log to the specified file location.

Send(obj, message)

obj << message

Description

Sends a *message* to a platform *object*.

Set Environment Variable("variable", <"value">)

Description

Sets the environment variable to the value specified. If the "value" argument is missing or is an empty string, then the environment variable is deleted from the JMP process environment variable table.

Show(expr, expr, ...)

Description

Prints the name and value of each *expression* to the log.

Show Classes(< <class reference>,...>)

Description

Shows the contents of all user-defined classes, both named and anonymous. You can specify more than one class.

Example

```
Define Class(
```

```
"aa",
{_init_ = Method( {} ), x = 1, m1 = Method( {a, b}, a * b )}
);
Define Class(
"bb",
{_init_ = Method( {} ), y = 1, m2 = Method( {a, b}, a / b )}
);
Show Classes();
  lcl = {Define Class("aa", {
  _init_ = Method( {} ),
  m1 = Method( {a, b}, a * b ),
  x = 1
  }), Define Class("bb", {
  _init_ = Method( {} ),
  m2 = Method( {a, b}, a / b ),
  y = 1
  })};
```

Show Globals()

Description

Shows the values for all global symbols. Symbols in any scope other than global are not shown.

See

"Show Symbols()" on page 237.

Show Namespaces(< <namespace reference>,...>)

Description

Shows the contents of all user-defined namespaces, both named and anonymous. You can specify zero or more namespaces.

Show Symbols()

Description

Shows the values for all symbols in any and all scopes.

See

"Show Globals()" on page 237.

Sort List

See "Sort List(list|expr)" on page 160.

Sort List Into

See "Sort List Into(list|expr)" on page 160.

Throw("text")

Description

Returns a Throw. If you include *text,* throwing stores *text* in a global *exception_msg.* If *text* begins with "!" and is inside a Try() expression, throwing creates an error message about where the exception was caught. "!" stops the script even if the Throw() is caught by the second argument of Try().

See Also

For more information, see Throw and Catch Exceptions in the *Scripting Guide*.

Try(expr1, expr2)

Description

Evaluates *expr1.* If the evaluation returns a Throw, execution stops, and nothing is returned. *expr2* is evaluated next to return the result.

Examples

```
Try( Sqrt( "s" ), "invalid" );
    "invalid"

Try( Sqrt( "s" ), exception_msg );
    {"Cannot convert argument to a number [or matrix]"(1, 2, "Sqrt",
       Sqrt/*###*/("s"))}
```

Note

Expr2 can be a character string or the global exception message (exception_msg) that contains more information about the error returned.

Type(x)

Description

Returns a string that names the type of object *x* is. The list of possible types is: Unknown, List, DisplayBox, Picture, Column, TableVar, Table, Empty, Pattern, Date, Integer, Number, String, Name, Matrix, RowState, Expression, Associative Array, Blob.

Unlock Symbols(name1, name2, ...)

Unlock Globals(name1, name2, ...)

Description

Unlocks the specified symbols that were locked with a Lock Symbols() or Lock Globals() command.

Wait(n)

Description

Pauses *n* seconds before continuing the script.

Watch(all | name1, ...)

Description

Shows variables (global, local, and variables within namespaces) and their values in a window. If "all" is provided as the argument, all globals are placed into the window.

Note

New globals are not added to the window list.

Watching associative arrays that have been modified using messages is not supported.

Wild()

Description

Only used with `Extract Expr()` for expression matching to denote a wildcard position that matches any expression.

Wild List()

Description

Only used with `Extract Expr()` for expression matching to denote a series of wildcard arguments that match any expression.

Write("text")

Description

Prints *text* to the log without surrounding quotation marks.

Python Integration Functions

Python Connect(<named_arguments>)

Description

Initializes the Python integration interfaces and returns an active Python integration interface connection as a scriptable object.

Returns

A Python scriptable object.

Optional Named Arguments

`Echo(Boolean)` Global argument. Prints the Python source lines to the JMP log. The default value is true.

`Use Python Version(string)` Specifies which version of Python should be used for JMP-to-Python processing.

Python Control(<named arguments>)

Description

Sends control operations to signal Python with external events, such as source line echoing.

Returns

Returns 0 if the call succeeded and 1 if an error occurred.

Optional Named Arguments

`Interactive(Boolean)` Enables interactive mode in the Python matplotlib package. Determines whether the graphics window is released or closed when graphics rendering is complete.

`Echo(Boolean)` Global argument. Prints the Python source lines to the JMP log. The default value is true.

Python Disconnect

Description

Terminates the Python interfaces.

Python Execute({list of inputs}, {list of outputs}, Python_Code, named_arguments)

Description

Submits Python code to the active global Python integration interface connection given a list of inputs. On completion, returns a list of outputs.

Returns

Returns 0 if successful and 1otherwise.

Positional Arguments

`{list of inputs}` A list of JMP variable names to be sent to Python as inputs.

`{list of outputs}` A list of JMP variable names to be retrieved from Python as outputs.

`Python_Code` The Python code to submit.

Named Arguments

See "Python Submit(Python_Code, <named_arguments>)" on page 243.

Example

The following example sends the JMP x and y variables to Python, executes the Python
statement z <- x * y, and then gets the Python z variable and returns it to JMP.

```
Python Init();
x = [1 2 3];
Python Send( x );
y = [4 5 6];
Python Send( y );
Python Submit( "\[
import numpy as np
p = np.multiply(x, y) # matrix product
]\" );
p = Python Get( p );
Show( p );
Python Term();
  p = [4 10 18];
  0
```

Python Get(name)

Description

Gets a named variable from Python to JMP.

Returns

Returns the value of the named variable.

Argument

name The name of the JMP variable to be sent to Python. The argument can represent any
    of the following Python data types: numeric, string, matrix, list, or data frame.

Example

```
Python Init(); // initiate the Python connection

qbx = "The right stuff";
Python Send( qbx );
// send the qbx variable and sample data table "Animals.jmp" to Python

dt = Open( "$SAMPLE_DATA/Animals.jmp" );
Python Send( dt );
Close( dt, nosave );

qbx = Python Get( qbx );
// get the Python variable qbx and place it into a JMP variable qbx

df = Python Get( dt );
/* get the Python variable dt and place it into a JMP data table
   referenced by df */
```

```
Python Term();

Show( qbx );
df << New Data View;
Wait( 10 );
Close( df, nosave );
Python Term();
    qbx = "The right stuff";
    0
```

Python Get Graphics(format)

Description

Gets the last graphics object written to the Python graph display window in the specified graphics format. The graphics object can be returned in several different graphic formats.

Returns

Returns a JMP picture object.

Argument

format The format that the Python graph display window contents are to be converted to. Valid formats are PNG, BMP, JPEG, JPG, TIFF, and TIF.

Python Get Submit Status

Description

Gets the status of the last submit for the current server.

Python Get Version

Description

Returns the version number of Python being used with the JMP Python interfaces.

Python Init(<named_arguments>)

Description

Initializes the Python integration interfaces.

Returns

Returns 0 if operation is successful and 1 if not successful.

Optional Named Arguments

Echo(Boolean) Global argument. Prints the Python source lines to the JMP log. The default value is true.

Use Python Version(string) Specifies which version of Python should be used for JMP-to-Python processing.

Python Is Connected

Description

Determines whether a Python integration interface connection is currently connected to Python.

Returns

Returns 1 if connected and 0 otherwise.

Python JMP Name to Python Name(name)

Description

Maps a JMP variable name to its corresponding Python variable name using Python variable name naming rules.

Returns

Returns a string, the mapped Python name.

Argument

name The name of the JMP variable to be sent to Python.

Python Send(name)

Description

Sends a named variable from JMP to Python.

Returns

Returns a string, the mapped Python name.

Argument

name The name of the JMP variable to be sent to Python

Python Send File(filename, <, Python Name(name)>)

Description

Sends a data file to Python. The filename argument is a string that specifies a pathname to the file to be sent to Python.

Python Submit(Python_Code, <named_arguments>)

Description

Submits Python code to the active global Python integration interface connection.

Returns

Returns 0 if successful and 0 otherwise.

Named Arguments

    `Python_Code` The Python code to submit. Statements can be a string value or a list of string values.

    `Expand(Boolean)` Optional. Performs an `Eval Insert()` on the Python code before submission.

    `Echo(Boolean)` Optional. Prints the Python source lines to the JMP log.

Example

```
Python Init(); // initiate the Python connection
commands =
"
friends = ['john', 'pat', 'gary', 'michael']
print(friends)
for i, name in enumerate(friends):
    print( \!"iteration {iteration} is {name}\!".format(iteration=i,
  name=name))
";
Python Submit( commands );
Python Term();
  ['john', 'pat', 'gary', 'michael']
  iteration 0 is john
  iteration 1 is pat
  iteration 2 is gary
  iteration 3 is michael

  0
```

Python Submit File(path)

Description

Submits statements to Python using the file specified in the path name.

Argument

path The path to the file that contains the Python source lines to be executed.

Python Term

Description

Terminates the currently active Python integration interface.

Returns

Returns 1 if an active SAS connection exists and 0 otherwise.

R Integration Functions

R Connect(<named_arguments>)

Description

Returns the current R connection object. If there is no connection to R, it intializes the R integration interfaces and returns an active R integration interface connection as a scriptable object.

Returns

R scriptable object.

Arguments

Echo(Boolean) Optional. Sends all source lines to the JMP log. This option is global. The default value is true.

R Execute({ list of inputs }, { list of outputs }, "rCode", <named_arguments>)

Description

Submit the specified R code to the active global R connection given a list of inputs. On completion, the outputs are returned into the specified list.

Returns

0 if successful; nonzero otherwise.

Arguments

{ list of inputs } A list of JMP variable names to be sent to R as inputs.

{ list of outputs } A list of JMP variable names to contain the outputs returned from R.

rCode A quoted string that contains the R code to submit.

Expand(Boolean) An optional, Boolean, named argument. Performs an Eval Insert() on the R code before submitting to R.

Echo(Boolean) An optional, Boolean, named argument. Sends all source lines to the JMP log. This option is global. The default value is true.

Example

Send the JMP variables x and y to R, execute the R statement z <- x * y, and then get the R variable z and return it to JMP.

```
x = [1 2 3];
y = [4 5 6];
rc = R Execute( {x, y}, {z}, "z <- x * y" );
```

R Get(variable_name)

Description

Gets the named variable from R to JMP.

Returns

The value of the named variable.

Argument

name Required. The name of an R variable whose value to return to JMP.

Example

Assume that a matrix named qbx and a data frame named df are present in your R connection.

```
// Get the R variable qbx and placed it into a JMP variable qbx
qbx = R Get( qbx );

// Get the R variable df and placed it into a JMP data table referenced by df
df = R Get( df );
```

R Get Graphics("format")

Description

Gets the last graphics object written to the R graph display window in the specified format.

Returns

A JMP picture object.

Argument

format Required. Specifies the graphics format to be used. The valid formats are `"png"`, `"bmp"`, `"jpeg"`, `"jpg"`, `"tiff"`, and `"tif"`.

R Init(named_arguments)

Description

Initializes the R session.

Returns

0 if the initialization is successful; any nonzero value otherwise.

Argument

Echo(Boolean) Optional. Sends all source lines to the JMP log. This option is global. The default value is `true`.

R Is Connected()

Description

Determines whether a connection to R exists.

Returns

1 if connected; 0 otherwise.

Arguments

None.

R JMP Name to R Name(name)

Description

Maps the specified JMP variable name to the corresponding R variable name using R naming rules.

Argument

name The name of a JMP variable to be sent to R.

Returns

A string that contains the R name.

R Send(name, <R Name(name)>)

Description

Sends named variables from JMP to R.

Returns

0 if the send is successful; any nonzero value otherwise.

Arguments

name required. The name of a JMP variable to be sent to R.

R Name(name) Optional. You can give the variable that you send to R a different name. For example

```
R Send(Here:x, R Name("localx"))
```

For data tables only:

Selected(Boolean) optional, named, Boolean. Send only selected rows from the referenced data table to R.

Excluded(Boolean) optional, named, Boolean. Send only excluded rows from the referenced data table to R.

Labeled(Boolean) optional, named, Boolean. Send only labeled rows from the referenced data table to R.

Hidden(Boolean) optional, named, Boolean. Send only hidden rows from the referenced data table to R.

Colored(Boolean) optional, named, Boolean. Send only colored rows from the referenced data table to R.

Markered(Boolean) optional, named, Boolean. Send only markered rows from the referenced data table to R.

`Row States(Boolean, <named arguments>)` optional, named. Includes a Boolean argument and optional named arguments. Send row state information from the referenced data table to R by adding an additional data column named "RowState". Multiple row states are created by adding together individual settings. The individual values are as follows:

– Selected = 1

– Excluded = 2

– Hidden = 4

– Labeled = 8

– Colored = 16

– Markered = 32

The named arguments for the `Row States()` argument are as follows:

`Colors(Boolean)` optional, named, Boolean. Sends row colors. Adds additional data column named "RowStateColor".

`Markers(Boolean)` optional, named, Boolean. Sends row markers. Adds additional data column named "RowStateMarker".

Examples

Create a matrix, assign it to X, and send the matrix to R:

```
X = [1 2 3];
rc = R Send( X );
```

Open a data table, assign a reference to it (*dt*), and send the data table, along with its current row states, to R:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
rc = R Send( dt, Row States(1) );
```

R Send File("pathname", <R Name("name")>)

Description

Sends the specified data file from JMP to R.

Returns

0 if the send is successful; any nonzero value otherwise.

Arguments

`pathname` required. A quoted string that contains a pathname for a file.

`R Name(name)` Optional. You can give the data file that you send to R a different name.

R Submit("rCode", <named_arguments>)

Description

Submits the specified R code to the active global R connection.

Returns

0 if successful; nonzero otherwise.

Arguments

rCode A required, quoted string that contains the R code to submit.

Expand(Boolean) An optional, Boolean, named argument. Performs an Eval Insert() on the R code before submitting to R.

Echo(Boolean) An optional, Boolean, named argument. Sends all source lines to the JMP log. This option is global. The default value is true.

Async(Boolean) An optional, Boolean, named argument. If set to true (1), the submit can be canceled either by pressing the ESCAPE key, or by using this message to an R connection: rconn<<Control(Interrupt(1)). False (0) is the default value.

Example

```
rc = R Submit("\[
  x <- rnorm(5)
  print(x)
  y <- rnorm(5)
  print(y)
  z = plot(x, y)
]\" );
```

R Submit File("pathname")

Description

Submits statements to R using a file pointed in the specified *pathname*.

Returns

0 if successful; nonzero otherwise.

Argument

Pathname A quoted string that contains the pathname to the file that contains the R code to be executed.

R Term()

Description

Terminates the currently active R integration interface

Returns

1 if an active R connection exists; otherwise 0.

Arguments

None

Random Functions

Col Shuffle()

Description

Shuffles the values randomly each time it's evaluated.

Returns

The last value placed into the last row.

Argument

Example

```
 For Each Row(x=:shuffle = colshuffle());
 show(x)
   x = 6
```

In a table with 40 rows, the above script places the values 1-40 randomly into each row of the column named shuffle. All numbers appear only once. Each time the script is run, the numbers are placed in a different random order. If the value placed into the row 40 of column shuffle is 6, that number is assigned to x, as in the above example.

Random Beta(alpha, beta, <theta>, <sigma>)

Description

Generates a pseudo-random number from a beta distribution using two shape parameters, *alpha* and *beta*. Optionally generates the lower threshold parameter, *theta,* and the scale parameter, *sigma*. The default values are *theta* = 0 and *sigma* = 1.

Random Beta Binomial(n, p, <delta>)

Description

Returns a random number from a beta binomial distribution for *n* trials with probability *p* and correlation *delta*. The default value for *delta* is 0.

Random Binomial(n, p)

Description

Returns random numbers from a binomial distribution with *n* trials and probability *p* of the event of interest occurring.

Random Category(probA, resultA, ProbB, resultB, resultElse)

Description

Returns a random category given pairs of probability and result expressions. A random uniform number is generated and compared to the *prob* arguments to determine which *result* argument is returned.

Random Cauchy(<alpha>, <beta>)

Description

Returns a Cauchy distribution with given *alpha* (location) and *beta* (scale).

Random ChiSquare(df, <noncentral>)

Description

Returns a Chi-Square distribution with given *df* (degrees of freedom). The noncentrality parameter must be greater than or equal to zero, which is the default value.

Random Exp()

Description

Returns a random number distributed exponentially from 0 to infinity. Equivalent to the negative log of Random Uniform.

Random F(dfn, dfd, <noncentral>)

Description

Returns a random number from an F distribution with a given *dfn* (degrees of freedom numerator) and *dfd* (degrees of freedom denominator). The noncentrality parameter must be greater than or equal to zero, which is the default value.

Random Frechet(<mu>, <sigma>)

Description

Returns a random number from a Fréchet distribution with the location *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

Random Gamma(lambda, <scale>)

Description

Gives a gamma distribution for given *lambda* and optional *scale*. The default value for *scale* is 1.

```
Random Gamma Poisson(lambda, <sigma>)
```

Description

Returns a random number from a gamma Poisson distribution with parameters *lambda* and *sigma*. The default value for *sigma* is 1.

```
Random GenGamma(<mu=0>, <sigma=1>, <lambda=0>)
```

Description

Returns a random number from an extended generalized gamma distribution with parameters *mu, sigma,* and *lambda*.

```
Random Geometric(p)
```

Description

Returns random numbers from the geometric distribution with probability *p* that a specific event occurs at any one trial.

```
Random GLog(mu, sigma, lambda)
```

Description

Returns a random number from a generalized logarithmic distribution.

```
Random Index(n, k)
```

Description

Returns a *k* by 1 matrix of random integers between 1 and *n* with no duplicates.

```
Random Integer(k, n)
```

Description

Returns a random integer from 1 to *n* or from *k* to *n*.

```
Random Johnson Sb(gamma, delta, theta, sigma)
```

Description

Returns a random number from the Johnson Sb distribution.

```
Random Johnson Sl(gamma, delta, theta, <sigma>)
```

Description

Returns a random number from the Johnson Sl distribution. The default value for sigma is 1.

`Random Johnson Su(gamma, delta, theta, sigma)`

Description

Returns a random number from the Johnson Su distribution.

`Random LEV(<mu>, <sigma>)`

Description

Returns a random number from an LEV distribution with the location *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

`Random LogGenGamma(<mu=0>, <sigma=1>, <lambda=0>)`

Description

Returns a random number from a log generalized gamma distribution with parameters *mu, sigma,* and *lambda*.

`Random Logistic(<mu>, <sigma>)`

Description

Returns a random number from a logistic distribution with the location *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

`Random Loglogistic(<mu>, <sigma>)`

Description

Returns a random number from a loglogistic distribution with the location *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

`Random Lognormal(<mu>, <sigma>)`

Description

Returns a Lognormal-distributed random number with location parameter *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

`Random Negative Binomial(r, p)`

Description

Generates a negative binomial distribution for *r* successes with probability of success *p*.

Random Normal(<mu>, <sigma>)

Description

Generates random numbers that approximate a normal distribution with mean *mu* and standard deviation *sigma*. The default values are *mu* = 0 and *sigma* = 1.

The normal distribution is bell shaped and symmetrical.

Random Normal Mixture(mean, std_dev, probabilities)

Description

Returns a random number from a normal mixture distribution with the specified arguments.

Arguments

mean A vector that contains group means.

std_dev A vector that contains the group standard deviations.

probabilities A vector that contains the group probabilities.

Random Poisson(lambda)

Description

Generates a Poisson variate for given *lambda*.

Random Reset(seed)

Description

Restarts the random number sequences with *seed*.

Random SEV(<mu>, <sigma>)

Description

Returns a random number from an SEV distribution with the specified location *mu* and scale *sigma*. The default values are *mu* = 0 and *sigma* = 1.

Random SHASH(gamma, delta, theta, sigma)

Description

Returns a random number from a sinh-arcsinh (SHASH) distribution.

Random Seed State(<seed state)

Description

Retrieves or restores the random seed state to or from a blob object.

```
Random Shuffle(matrix)
```

Description

Returns the matrix with the elements shuffled into a random order.

```
Random t(df, <noncentral>)
```

Description

Returns a random number from a t distribution with the specified *df* (degrees of freedom). The noncentrality argument may be negative or positive. The default value of *noncentral* is 0.

```
Random Triangular(min, mode, max)
```

```
Random Triangular(mode, max)
```

```
Random Triangular(mode)
```

Description

Generates a random number from a triangular distribution between 0 and 1 with the *mode* that you specify. The triangular distribution is typically used for populations that have a small number of data.

Arguments

min Specifies the lower limit of the triangular distribution. The default value is 0.

mode Specifies the mode of the triangular distribution.

max Species the upper limit of the triangular distribution. The default value is 1.

Notes

If you specify only the mode, the minimum value is 0, and the maximum value is 1. If you specify the mode and maximum value, the minimum value is 0 by default.

```
Random Uniform(<x>)
```

```
Random Uniform(<min>, <max>)
```

Description

Generates a random number from a uniform distribution between 0 and 1. Random Uniform(x) generates a number between 0 and x. Random Uniform (min, max) generates a number between *min* and *max*. The result is an approximately even distribution.

```
Random Weibull(beta, <alpha>)
```

Description

Returns a random number from a Weibull distribution. The default value for *alpha* is 1.

Resample Freq(<rate, <column>>)

Description

Generates a frequency count for sampling with replacement. If no arguments are specified, the function generates a 100% resample.

Arguments

rate Optional. Specifies the rate of resampling. The default value is 1. A negative value specifies that fractional frequencies are allowed.

column Optional. If you specify column, you must also specify rate. The sample size is calculated by the rate multiplied by the sum of the specified column. If rate is negative, then the sample size is the negative of the rate multiplied by the sum of the specified column.

Note

A typical use of this function generates a column with many 1s, some 0s, some 2s, and so forth, corresponding to which rows were randomly assigned any of *n* randomly selected rows.

A typical use of this with an *existing* frequency column produces a new frequency column whose values are similar to the old frequency column (have that expected value); however, the values vary somewhat due to random selection at the rates corresponding to the old frequency column.

Example

To ensure that the numbers in the frequency column match each time you run the script, use As Constant(). As Constant() evaluates an expression to create a constant value that does not change after it has been computed.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dc = dt << New Column( "column",
   Formula(
      As Constant(
         Random Reset( 123 );
         0;
      ) + Resample Freq()
   )
);
dc << Eval Formula;
```

Row Functions

As Table(matrix, <matrix 2, ...>, < <<invisible >, < <<private >, <
<<Column Names(list) >)

Description

Creates a new data tables from the *matrix*.

Returns

The new data table.

Argument

matrix Any matrix.

<<invisible Creates an invisible data table that hides the table from view but lists it in
the JMP Home Window and Window menu.

<<private Hides the table completely. Creating a private data table speeds the process of
getting to the data; it does not save the computer from allocating the memory necessary
to hold the data table data.

<<Column Names(list) The list specified column names for the data. The argument is a
list of quoted column names.

Col Stored Value(<dt>, col, <row>)

Description

Returns the data values stored in the column and disregards values assigned through
column properties (such as Missing Value Codes).

Arguments

dt Optional reference to a data table. If this value is not supplied, the current data table is
used.

col Name of the column.

row Optional. Row name or number. If this value is not specified, the current row is used.

Example

Suppose that the Missing Value Codes column property is assigned to the x1 column to
treat "999" as a missing value. Another column includes a formula that calculates the mean.
To use the value "999" instead of a missing value to calculate the mean, use Col Stored
Value() in the formula:

 Mean(Col Stored Value(:x1), :x2, :x3)

```
Column(<dt>, "name", "formatted")
```

```
Column(<dt>, n)
```

Description

Gets a reference to the data table column.

Arguments

dt Optional reference to a data table. If this is not supplied, the current data table is used.

name Quoted string that is the name of the column.

formatted Quoted string that returns the formatted string of the cell value.

n Column number.

```
Column Name(n)
```

Description

Determines the name of the column specified by number.

Returns

The name of the nth column as an expression (not a string).

Argument

n The number of a column.

```
Count(from, to, step, times)
```

Description

Used for column formulas. Creates row by row the values beginning with the *from* value and ending with the *to* value. The number of *steps* specifies the number of values in the list between and including the *from* and *to* values. Each value determined by the first three arguments of the count function occurs consecutively the number of *times* that you specify. When the *to* value is reached, count starts over at the *from* value. If the *from* and *to* arguments are data table column names, count takes the values from the first row only. Values in subsequent rows are ignored.

Returns

The last value.

Arguments

from Number, column reference, or expression. Count starts counting with this value.

to Number, column reference, or expression. Count stops counting with this value.

step Number or expression. Specifies the number of steps to use to count between *from* and *to,* inclusive.

times Number or expression. Specifies the number of times each value is repeated before the next step.

Examples

```
For Each Row(:colname[row()]=count(0, 6, 3, 1))
//The rows in the column named colname are filled with the series 0, 3, 6, 0,
    ... until all rows are filled.

For Each Row(:colname[row()]=count(0, 6, 3, 2))
//The rows in the column named colname are filled with the series 0, 0, 3, 3,
    6, 6, 0, ... until all rows are filled.
```

Note

Count() is dependent on Row(), and is therefore mainly useful in column formulas.

Current Data Table(<dt>)

Description

Without an argument, gets the current (topmost) data table. With an argument, sets the current data table.

Returns

Reference to the current data table.

Argument

dt   Optional name of or reference to a data table.

Notes

Private tables cannot be made current with Current Data Table().

Data Table(n)

Data Table("name")

Description

Gets reference to the *n*th open data table or the table with the given *name* in a global variable.

Returns

Reference to the specified data table.

Argument

n   Number of a data table.

name   Quoted string, name of a data table.

Dif(col, n)

Description

Calculates the difference of the value of the column *col* in the current row and the value *n* rows previous to the current row.

Returns

The difference.

Arguments

`col` A column name (for example, `:age`).

`n` A number.

Dim(<dt|matrix>)

Description

Returns a row vector with the dimensions of the current data table, a specified data table, or a matrix. The dimensions are the number of rows and the number of columns and are listed in that order.

Arguments

`dt` A data table.

`matrix` A matrix.

Notes

If no argument is specified, the dimensions of the current data table are returned.

Get Data Table List(<Project(title|index|box|window>)

Description

Returns a list of all open data tables.

Notes

Use `Project(0)` to specify no project when running the expression in a project.

Lag(col, n)

Description

Returns for each row the value of the column *n* rows previous.

N Row(dt); NRow(matrix)

N Rows(dt); NRows(matrix)

Description

Returns the number of rows in the data table given by *dt* or in the *matrix.*

N Table()

Description

Returns the number of open data tables. Private tables are not included.

```
New Column("name", <"data type">, <"modeling type">, Format("format",
width), <Formula()>, <Set Values>, <properties>)
```

Description

Adds a new column named "*name*" after the last column in *dt*. Unless otherwise specified, columns are numeric, continuous, and 12 characters wide.

Returns

A column reference.

Note

Can also be used as a message: `dt<<New Column`.

See Also

See "dt<<New Column("name", <"data type">, <"modeling type">, Format("format", width), <Formula()>, <Set Values>, <properties>)" on page 357 in the "JSL Messages" chapter for details about the `New Column` function and message arguments.

```
New Table("name", <visibility("invisible" | "private" | "visible")>,
<actions>)
```

Description

Creates a new data table with the specified *name*.

Arguments

`name` A quoted string that contains the name of the new table.

`visibility` Optional quoted keyword. `invisible` hides the data table from view but lists it in the JMP Home Window and Window menu. `private` hides the table completely. `visible` shows the data table. `"visible"` is the default value.

Note: Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

`actions` Optional argument that can define the new table.

```
Row()
```

```
Row() = y
```

Description

Returns or sets the current row number. No argument is expected.

```
Sequence(from, to, <stepSize>, <repeatTimes>)
```

Description

Produces an arithmetic sequence of numbers across the rows in a data table. The *stepSize* and *repeatTimes* arguments are optional, and the default value for both is 1.

```
Subscript(a, b, c)
```

```
list[i]
```

```
matrix[b, c]
```

Description

Subscripts for lists extract the *i*th item from the *list,* or the *b*th row and the *c*th column from a *matrix*.

```
Suppress Formula Eval(Boolean)
```

Description

Turns off automatic calculation of formulas for all data tables.

Row State Functions

```
As Row State(i)
```

Description

Converts *i* into a row state value.

Returns

A row state from the *i* given.

Argument

i   an integer

```
Color Of(rowstate)
```

Description

Returns or sets the color index.

Returns

The color index of *rowstate*.

Argument

rowstate   a row state argument

Example

Set the color of the fifth row to red.

```
colorof(rowstate(5))=3
```

Color State(i)

Description

Returns a row state with the color index of *i*.

Returns

A row state.

Argument

i　index for a JMP color

Combine States(rowstate, rowstate, ...)

Description

Generates a row state combination from two or more row state arguments.

Returns

A single numeric representation of the combined row states.

Arguments

rowstate　Two or more row states.

Excluded(rowstate)

Description

Returns or sets an excluded index.

Returns

The excluded attribute, 0 or 1.

Argument

rowstate　One or more row states.

Excluded State(num)

Description

Returns a row state for exclusion from the *num* given.

Hidden(rowstate)

Description

Returns or sets the hidden index.

Hidden State(num)

Description

Returns a row state for hiding from the *num* given.

Hue State(num)

Description

Returns a hue state from the *num* given.

Labeled(rowstate)

Description

Returns or sets the labeled index.

Labeled State(num)

Description

Returns a labeled state from the *num* given.

Marker Of(rowstate)

Description

Returns or sets the marker index of a row state.

Marker State(num)

Description

Returns a marker state from the *num* given.

Row State(<dt,> <n>)

Description

Returns the row state changed from the initial condition of the active row or the *n*th row.

Arguments

dt Optional positional argument: a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.

n The row number.

Example

The following example creates the data table references and then returns the row state of row 1 in Big Class.jmp:

```
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
Row State( dt1, 1 );
```

Selected(rowstate)

Description

Returns or sets the selected index.

Selected State(num)

Description

Returns a selected state from the *num* given.

Shade State(num)

Description

The Shade State function assigns 5 shade levels to a color or hue.

SAS Integration Functions

As SAS Expr(x)

Description

Converts an expression to a version that is more suitable for SAS DATA step. The code must be wrapped in a PROC DS2 call. Use `Expr(...)` for literal expressions. Use `NameExpr(name)` for expressions stored in a variable. Otherwise, the expression returns the expression to convert.

Returns

A string.

Current Metadata Connection()

Description

Returns the active SAS metadata server connection, if any, as a scriptable object.

Current SAS Connection()

Description

Gets the active global SAS server connection, if any, as a scriptable object.

Get SAS Version Preference()

Description

Returns the SAS version selected in the SAS Integration page of the Preferences as a string.

```
JMP6 SAS Compatibility Mode(Boolean)
```

Description

Setting this to 1 (true) causes SAS operators to operate in a mode compatible with JMP 6 capabilities.

```
Meta Connect(<"machine", port>, <"authDomain">, <"username">, <"password">,
<named arguments>)
```

```
Meta Connect(<Profile("profile name")>, <Password("password")>, <named
arguments>)
```

```
Meta Connect(<Environment("environment name")>, <named arguments>)
```

Description

Connects to a SAS Metadata Server. If no arguments are specified, an empty connection window appears. If some arguments are specified, a window partially filled in with the argument values appears. If all arguments are specified, the connection is made and no window appears.

Returns

1 if connection is successful, 0 if not.

Arguments

machine Optional: quoted string that contains the DNS name of the machine.

port Required if machine is specified. Quoted string or integer that contains the port on which the metadata server listens.

authDomain Optional: quoted string that contains the authentication domain for the credentials supplied. Not necessary unless *username* and *password* are included.

username Optional: quoted string that contains the user name for the connection.

password Optional: quoted string that contains the password for the connection.

Named Arguments

All named arguments are optional.

Profile("profile_name") A quoted string that contains the name of the metadata server connection profile from which connection information should be retrieved.

Environment("environment_name") A quoted string that contains the name of the WIP environment from which connection information should be retrieved.

Password("password") A quoted string that contains the password for the specified profile name.

CheckPreferenceOnly(0|1) If specified, Meta Connect returns the status of the **I want to connect to a SAS Metadata Server** option in the SAS Integration page of JMP Preferences. If that box is checked, **Meta Connect** returns 1; if not, 0.

Repository("string") Takes a quoted string that contains the name of the repository to which to connect.

ProfileLookup(0|1) If *machine* and *port* are specified rather than a profile name, and ProfileLookup is specified, an attempt is made to find a metadata server connection profile with a machine name and port matching those provided. If one is found, other connection information (such as authentication domain, user name, and password) is obtained from that profile.

Prompt(Always|Never|IfNeeded) Takes one of the keywords Always (always prompt before attempting to connect), Never (never prompt, just fail), or IfNeeded (the default; prompt if connection with the given arguments fails).

SASVersion("<version number>" <,Strict>) Attempts to change the SAS version preference to the specified value before making the metadata server connection. If the SAS version is already locked to a different version than the one specified, the SASVersion argument will fail. By default, if the SAS version cannot be set, JMP will try the metadata server connection. However, if you include Strict as the second argument, the inability to change the SAS version will be treated as an error, and JSL processing will stop. If you do not include Strict, the SAS version argument is treated as a hint and will set the version preference if it can. JMP will still try to connect if the version cannot be set. The order you put these arguments in can make a difference. The attempt to change the SAS Version is made immediately when that argument is encountered. That can affect the validity of other arguments, particularly for MetaConnect. Valid values for SASVersion are "9.1.3", "9.2", "9.3", and "9.4". Note: Using the SASVersion argument has the same effect as changing the SAS Server Version on the SAS Integration Preferences page.

Notes

If no arguments are included and if no profile is saved, the Connect to SAS Metadata Server window appears.

Meta Create Profile("profile", <named arguments>)

Description

Creates a metadata server connection profile and adds it to the current user's set of saved metadata server connection profiles.

Returns

1 if *profile* was successfully created, otherwise 0.

Arguments

profile A quoted string that contains the name of the created profile. If a profile by the given name already exists, MetaCreateProfile fails unless *Replace* is specified.

Named Arguments

The following named arguments are all optional.

`HostName("name")` A quoted string that contains the name of the host computer running the SAS Metadata Server that this profile will connect to.

`Port(n)` The port number (*n*) that the SAS Metadata Server is listening for connections on.

`AuthenticationDomain("domain")` | `AuthDomain("domain")` A quoted string that sets the authentication domain to use for the connection.

`Description("desc")` | `Desc("desc")` A quoted string that sets a description for this profile.

`Password("password")` A quoted string that contains the password to store in this profile.

`Replace(0|1)` If *name* matches a profile that already exists, `Replace` must be specified for the existing profile to be replaced by the one provided. The default value is False (0).

`Repository("repository")` A quoted string that contains the name of the repository in the SAS Metadata Server that this profile will connect to. This option is valid only for connections to SAS 9.1.3 Metadata Servers.

`UserName("username")` A quoted string that contains the user name that this profile uses to connect to the SAS Metadata Server.

`UseSingleSignOn(0|1)` If specified, this profile attempts to use Single Sign-On (currently also known as Integrated Windows Authentication) to connect to the SAS Metadata Server. This option is valid only for connecting to SAS 9.2 or higher Metadata Servers. If `UseSingleSignOn` is True(1), *UserName* and *Password* cannot be specified. The default value is False (0).

Meta Delete Profile("name")

Description

Deletes the named metadata server connection profile from the current user's set of saved metadata server connection profiles

Returns

1 if profile was successfully deleted, otherwise 0.

Argument

`name` A quoted string that contains the name of the profile to delete.

Meta Disconnect()

Description

Disconnect the current SAS Metadata Server connection, if any.

Returns

Void.

Meta Get Repositories()

Description

Gets a list of the repositories available on the current SAS Metadata Server connection.

Returns

A list of repository names as strings.

Meta Get Servers()

Description

Get a list of the SAS Servers that are registered in the SAS Metadata Repository to which the session is currently connected.

Returns

A list of server names as strings.

Meta Get Stored Process("path")

Description

Get a stored process object from the currently connected SAS Metadata Repository.

Returns

Stored Process scriptable object.

Arguments

path Quoted string that is the path to the stored process in metadata, starting at the BIP Tree.

Meta Is Connected()

Description

Determines whether a current connection to a SAS Metadata Server exists.

Returns

1 if a connection exists; 0 otherwise.

Arguments

None.

Meta Set Repository("repositoryName")

Description

Set the SAS Metadata Repository to use for metadata searches.

Returns

1 if setting the repository was successful, 0 otherwise.

Arguments

repositoryName Quoted string that contains the name of the repository to make current.

SAS Assign Lib Refs("libref", "path", <"engine">, <"engine options">)

Description

Assign a SAS libref on the active global SAS server connection.

Returns

1 if successful, 0 otherwise.

Arguments

libref Quoted string that contains a library reference (8-character maximum) to assign.

path Quoted string that contains the full path on the SAS server to the library being assigned.

engine Optional, quoted string that contains the engine for the SAS server to use when accessing members of this library.

engine options Optional, quoted string that contains the options needed for the engine being used.

SAS Connect(<"machine_name">, <"port">, <named_arguments>)

Description

Connect to a local, remote, or logical SAS server.

Returns

SAS Server scriptable object.

Arguments

machine_name Optional: quoted string that can contain a physical machine name or the name of a metadata-defined (logical) server. In the first case, the port must be provided. In the second case, a port must *not* be provided. If neither *name* nor *port* are included, and JMP is running on Windows, a connection to SAS on the local machine (via COM) is attempted, and all named arguments are ignored.

port Optional: quoted string or integer. If *name* is a physical machine name, this is the port on that machine to connect to. If *name* is a metadata-defined (logical) server, *port* must *not* be included.

Named Arguments

All the named arguments are optional.

UserName("name") A quoted string that contains the user name for the connection.

Password("password") A quoted string that contains the password for the connection.

ReplaceGlobalConnection(0|1) A Boolean. The default value is True. If True, and a successful SAS server connection is made, this connection replaces the active SAS

connection that becomes the target of other global SAS JSL function calls. If `False`, the global SAS connection is not changed, and the returned SASServer scriptable object should be used to send messages to this server connection.

`ShowDialog(0|1)` A Boolean. The default value is `False`. If `True`, other arguments (except `ReplaceGlobalConnection`) are ignored and the SAS Server Connection window appears. This provides the JSL programmer a way to open the SAS Connect window.

`Prompt(Always|Never|IfNeeded)` A keyword. `Always` means always prompt before attempting to connect. `Never` means never prompt even if the connection attempt fails (just fail and send an error message to the log), and `IfNeeded` (the default value) means prompt if the attempt to connect with the given arguments fails (or is not possible with the information given).

`ConnectLibraries(0|1)` A Boolean. Defaults to the SAS Integration Preference setting governing whether to automatically connect metadata-defined libraries when connecting to a SAS server. If true, all metadata-defined libraries are connected at SAS server connection time, which can be time-consuming. If false, metadata-defined libraries are not connected. To connect specific libraries later, use the `SAS Connect Libref` global function or `Connect Libref` message to a SAS server object.

`SASVersion("<version number>" <,Strict>)` Attempts to change the SAS version preference to the specified value before making the metadata server connection. If the SAS version is already locked to a different version than the one specified, the SASVersion argument will fail. By default, if the SAS version cannot be set, the metadata server connection will still be tried. However, if you include `Strict` as the second argument, the inability to change the SAS version will be treated as an error and JSL processing will stop. If you do not include `Strict`, the SAS version argument is treated as a hint and will set the version preference if it can, but if it cannot it will still try to connect. The order you put these arguments in can make a difference. The attempt to change the SAS Version is made immediately when that argument is encountered. That can affect the validity of other arguments, particularly for MetaConnect. Valid values for `SASVersion` are "9.1.3", "9.2", "9.3", and "9.4". Note: Using the `SASVersion` argument has the same effect as changing the SAS Server Version on the SAS Integration Preferences page.

SAS Deassign Lib Refs("libref")

Description

De-assign a SAS libref on the active global SAS server connection.

Returns

1 if successful; 0 otherwise.

Arguments

`libref` Quoted string that contains the library reference to de-assign.

SAS Disconnect()

Description

Disconnect the active global SAS connection, if any.

Returns

1 if a SAS connection exists and was successfully disconnected, 0 otherwise.

Arguments

None.

SAS Export Data(dt, "library", "dataset", <named_arguments>)

Description

Exports a JMP data table to a SAS data set in a library on the active global SAS server connection.

Returns

1 if the data table was exported successfully; 0 otherwise.

Arguments

dt data table or a reference to a data table.

"library" the library to which to export the data table.

"dataset" the name of the new SAS data set.

Named Arguments

All the named arguments are optional.

Columns(list)|Columns(col1, col2, ...) A list of columns or a comma-separated list of columns.

Password("password") A string that contains the password to serve as the READ, WRITE, and ALTER password for the exported SAS data set. If the exported data set is replacing an existing data set with an ALTER password, this password is used as the ALTER password for overwriting the data set. If *Password* is specified, values for *ReadPassword, WritePassword,* and *AlterPassword* are ignored.

ReadPassword("password") A string that contains the password to serve as the READ password for the exported SAS data set.

WritePassword("password") A string that contains the password to serve as the WRITE password for the exported SAS data set.

AlterPassword("password") A string that contains the password to serve as the ALTER password for the exported SAS data set. If the exported data set is replacing an existing data set with an ALTER password, this password is used as the ALTER password for overwriting the data set.

PreserveSASColumnNames(0|1) A Boolean. If true *and* the JMP data table originally came from SAS, the original SAS column names are used in the exported SAS data set. The default value is False.

PreserveSASFormats(0|1) A Boolean. If true *and* the JMP data table originally came from SAS, the original SAS formats and informats are applied to the columns in the exported SAS data set. The default value is True.

ReplaceExisting(0|1) A Boolean. If true, an existing SAS data set with the specified name in the specified library is replaced by the exported SAS data set. If false, a data set with the specified name already exists in the specified library; the export is stopped. The default value is false.

SaveJMPMetadata(0|1) Includes SAS 9.4 Extended Attributed to store JMP metadata (such as table script and column properties). Default is 0 (disabled).

HonorExcludedRows(0|1) A Boolean. If true, any rows in the JMP data table that are marked as excluded are not exported. The default value is false.

Note

Information about the export is sent to the log.

SAS Get Data Sets("libref")

Description

Returns a list of the data sets defined in a SAS library.

Returns

List of strings.

Arguments

libref Quoted string that contains the SAS libref or friendly library name associated with the library for which the list of defined SAS data sets is returned.

SAS Get File("source", "dest", "encoding")

Description

Get a file from the active global SAS server connection. JMP creates a FILENAME statement (with an encoding, if specified) and uses it to read the file on the SAS server.

Returns

1 if successful, 0 otherwise.

Arguments

source Quoted string that contains the full path of file on the server to be downloaded to the client machine.

dest Quoted string that contains the full path on the client machine for where to put the copy of the file downloaded from the server.

encoding Quoted string that contains the encoding used in the file (for example, `"utf-8"`). The server must support the specified encoding.

SAS Get File Names("fileref")

Description

Get a list of filenames found in the given fileref on the active global SAS server connection.

Returns

List of strings.

Arguments

fileref Quoted string that contains the name of the fileref from which to retrieve filenames.

SAS Get File Names In Path("path")

Description

Get a list of filenames found in the given path on the active global SAS server connection.

Returns

List of strings.

Arguments

path Quoted string that contains the directory path on the server from which to retrieve filenames.

SAS Get File Refs()

Description

Get a list of the currently defined SAS filerefs on the active global SAS server connection.

Returns

List of two lists. The first list is a list of quoted strings of fileref names. The second is a corresponding list of quoted strings of physical names.

SAS Get Lib Refs(<named arguments>)

Description

Get a list of the currently defined SAS librefs on the current global SAS server connection.

Returns

List of strings.

Named Arguments

`Friendly Names(0|1)` Optional, Boolean. If `True`, then for any libraries that have friendly names (metadata-defined libraries), the friendly name is returned rather than the 8-character libref.

SAS Get Log()

Description

Retrieve the SAS Log from the active global SAS server connection.

Returns

A string.

SAS Get Output()

Description

Retrieve the listing output from the last submission of SAS code to the current global SAS server connection.

Returns

A string.

SAS Get Results()

Description

Retrieve the results of the previous SAS Submit as a scriptable object, which allows significant flexibility in what to do with the results.

Returns

A SAS Results Scriptable object.

SAS Get Var Names(string, <"dataset">, <password("password")>)

Description

Retrieves the variable names contained in the specified data set on the current global SAS server connection.

Returns

List of strings.

Arguments

`string` A quoted string that contains one of the following:

– The name of the SAS Library containing the SAS data set to be imported. In that case, the *dataset* name argument is required.

– The full member name of the SAS data set to be imported, in the form
  "libname.membername".

– The SAS Folders tree path to a logical SAS data table to be imported. This option
  requires a connection to a SAS 9.2 or higher Metadata Server.

`dataset` Optional: quoted string that contains the name of the data set from which to
retrieve variable names.

`password("password")` Optional, quoted string that contains the read password for the
data set. If this is not provided and the data set has a read password, the user is
prompted to enter it.

SAS Import Data(string, <"dataset">, <named arguments>)

Description

Import a SAS data set from the active global SAS server connection into a JMP table.

Returns

JMP Data Table object.

Arguments

`string` A quoted string that contains one of the following:

– The name of the SAS Library containing the SAS data set to be imported. In that case,
  the *"dataset"* name argument is required.

– The full member name of the SAS data set to be imported, in the form
  "libname.membername".

– The SAS Folders tree path to a logical SAS data table to be imported. This option
  requires a connection to a SAS 9.2 or higher Metadata Server.

`dataset` Optional: quoted string that contains the name of the data set.

Named Arguments

All named arguments are optional.

`Columns("list")|Columns(col1, col2, ...)` A quoted string list or multiple strings
that contain the names of columns to include in the import.

`ConvertCustomFormats(0|1)` The default value is True (1). If True and custom formats
are found in the SAS data set being imported, an attempt is made to convert the SAS
custom formats to JMP value labels for those columns.

`Invisible(0|1)` The default value is False (0). If true, the JMP data table is hidden from
view. The data table appears only in the JMP Home Window and the Window menu.
Hidden data tables remain in memory until they are explicitly closed, reducing the
amount of memory that is available to JMP. To explicitly close the hidden data table, call
`Close(dt)`, where *dt* is the data table reference returned by SASImportData.

Where("filter") A quoted string that contains the filter to use when importing data, as in Where("salary<50000").

Password("password") A quoted string that contains the read password for the data set. If this is not provided and the data set has a read password, the user is prompted to enter it.

UseLabelsForVarNames(0|1) If True, the labels from the SAS data set become the column names in the resulting JMP table. If False, the variable names from the SAS data set become the column names in the JMP table. The default value is False.

RestoreJMPMetadata(0|1) Includes SAS 9.4 Extended Attributed to store JMP metadata. Default is 0 (disabled).

Sample(named arguments) optional, named. Allows a random sample of the SAS data set to be imported into JMP. If both Where and Sample are specified, the WHERE clause is used to filter the SAS data set first, and then a random sample of the resulting rows is taken based on the arguments supplied to Sample. Note that Sample uses PROC SURVEYSELECT on the SAS server, which is available only if the SAS/STAT package is licensed and installed on that server. The documentation for PROC SURVEYSELECT might be helpful in understanding how sampling is performed. By default (if no arguments are supplied), a 5% simple random sample is taken. Available arguments (all optional) to Sample are as follows:

– Simple | Unrestricted: If Simple is specified, sampling is performed without replacement. If Unrestricted is specified, sampling is performed with replacement. These two options are mutually exclusive and only one can be specified.

– SampleSize(int) | N(int): Total number of rows for the sample, or number of rows per strata level for stratified sampling

– SampleRate(number) | Rate(number) | Percent(number): Specifies the sampling rate. For stratified sampling, the rate is applied to each strata level. Note that the supplied value is assumed to be a percentage, so SampleRate(3.5) means a 3.5% sampling rate.

– Strata({col1, col2, ...}) | Strata(col1, col2, ...): Perform stratified random sampling using the column names supplied as Strata variables.

– NMin(int): Minimum number of rows (either overall or per strata level for stratified sampling) to return. Only applies to rate-based sampling.

– NMax(int): Maximum number of rows (either overall or per strata level for stratified sampling) to return. Only applies to rate-based sampling.

– Seed(int): Number to use as the seed for sampling. Useful for replicating the same sample. By default, the seed is a random number based on time of day. See PROC SURVEYSELECT documentation for more information.

– OutputHits(0|1): Boolean; the default value is false. When doing Unrestricted sampling, if the same row of the input data set is selected more than once, by default that row still appears only once in the resulting JMP data table, with the NumberHits

column indicating the number of times that the row was selected. Setting OutputHits to true causes an input row that is selected multiple times to appear multiple times in the resulting JMP data table.

– `SelectAll(0|1)`: Boolean, the default value is true. If `SelectAll` is true, PROC SURVEYSELECT selects all stratum rows whenever the stratum sample size exceeds the total number of rows in the stratum. If `SelectAll` is false and PROC SURVEYSELECT finds a case where the stratum sample size exceeds the total number of rows in a given stratum, an error results and sampling fails. `SelectAll` only applies to Simple random sampling.

`SQLTableVariable(0|1)` If `True`, an SQL table variable is created in the resulting JMP table that shows the SQL that was submitted to SAS to obtain the data. If `False`, the SQL table variable is not created. The default value is `True`. If an SQL table variable is created and the data set required a read password, the password is masked.

SAS Import Query("sqlquery", <named arguments>)

Description

Execute the requested SQL query on the current global SAS server connection, importing the results into a JMP data table.

Returns

JMP Data Table object.

Arguments

`sqlquery` Quoted string that contains the SQL query to perform and from which to import the result.

Named Arguments

All named arguments are optional.

`ConvertCustomFormats(0|1)` The default value is true. If true and custom formats are found in the SAS data set being imported, an attempt is made to convert the SAS custom formats to JMP value labels for those columns.

`Invisible(0|1)` The default value is false. If true, the JMP data table is hidden from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call `Close(dt)`, where *dt* is the data table reference returned by `SAS Import Query`.

`UseLabelsForVarNames(0|1)` The default value is true. If `True`, the labels from the SAS data set become the column names in the resulting JMP table. If `False`, the variable names from the SAS data set become the column names in the JMP table.

`RestoreJMPMetadata(0|1)` Includes SAS 9.4 Extended Attributes to store JMP metadata. Default is 0 (disabled).

SQLTableVariable(0|1) The default value is true. If `True`, an SQL table variable is created in the resulting JMP table that shows the SQL that was submitted to SAS to obtain the data. If `False`, the SQL table variable is not created. If an SQL table variable is created and the data set required a read password, the password is masked.

SAS Is Connected()

Description

Discovers whether there is an active global SAS server connection.

Returns

1 if an active global SAS connection exists, 0 otherwise.

SAS Is Local Server Available()

Description

Returns True if a local SAS Server is available; otherwise, returns False.

SAS Load Text File("path")

Description

Download the file specified in path from the active global SAS server connection and retrieve its contents as a string.

Returns

String.

Arguments

"path" Quoted string that contains the full path on the server of the file to download and retrieve the contents as a string.

SAS Name("name")

SAS Name({list of names})

Description

Converts JMP variable names to SAS variable names by changing special characters and blanks to underscores and various other transformations to produce a valid SAS name.

Returns

A string that contains one or more valid SAS names, separated by spaces.

Argument

"name" A quoted string that represents a JMP variable name; or a list of quoted JMP variable names.

SAS Open For Var Names("path")

Description

Opens a SAS data set only to obtain the names of its variables, returning those names as a list of strings.

Returns

A list of variable names in the file.

Argument

`path` A quoted string that is a pathname of a SAS data set.

SAS Send File("source", "dest", "encoding")

Description

Send a file from the client machine to the active global SAS server connection. JMP creates a FILENAME statement (with an encoding, if specified) and uses it to save the file on the SAS server.

Returns

1 if successful, 0 otherwise.

Arguments

`source` Quoted string that contains the full path of the file on the client machine to be uploaded to the server.

`dest` Quoted string that contains the full path on the server that receives the file uploaded from the client machine.

`encoding` Quoted string that contains the encoding used in the file (for example, "utf-8"). The server must support the specified encoding.

SAS Submit("sasCode", <named arguments>)

Description

Submit some SAS code to the active global SAS server connection.

Returns

1 if successful, 0 otherwise.

Arguments

`sasCode` Quoted string that contains the SAS code to submit.

Named Arguments

All named arguments are optional.

`Async(0|1)` A Boolean. If True (1), the submit occurs asynchronously (in the background). Use the `Get Submit Status()` message on the SAS Server Scriptable Object to determine the status of the submit. The default value is False (0).

ConvertCustomFormats(0|1) A Boolean. When SAS data sets generated by submitted
 SAS code are imported into JMP after the submit completes (see Open Output Datasets),
 the value of ConvertCustomFormats determines whether an attempt is made to convert
 any custom formats found on columns in the SAS data to JMP value labels. The default
 value is True (1).

DeclareMacros(var1, var2, ...) JSL variable names. Provides a simple way to pass
 the values of JSL variables to SAS as macro variables. Each JSL variable specified should
 evaluate to a string or numeric value. Fully qualified JSL variables names, only the
 variable name is sent to SAS. For example, namespace:variable_name becomes
 variable_name in SAS.

GetSASLog(<Boolean|OnError>, <JMPLog|Window>) A Boolean. If no arguments are
 supplied, the SAS Log is retrieved and displayed in the location indicated in SAS
 Integration Preferences. The first argument to GetSASLog can be either a Boolean value or
 the keyword OnError. If a Boolean value is supplied, true means display the SAS Log,
 and false means not to display it. OnError instructs JMP to only show the SAS Log if an
 error occurred in the submit. The second argument to GetSASLog tells JMP where to
 display the SAS Log. If JMPLog is specified, the SAS Log is appended to the JMP Log. If
 Window is specified, the SAS Log is opened in a separate window.

GraphicsDevice(string) or GDevice(string) A string that specifies a value for the
 GDEVICE SAS option to be used for graphics generated by the submitted SAS code. The
 value must be a valid SAS graphics device. The default value is determined in
 Preferences.

Interactive(0|1) JMP includes the QUIT statement in the generated wrapper code.
 Interactive PROCs work even if JMP is generating the ODS wrapper. On every SUBMIT,
 specify the argument that is part of an interactive sequence. Otherwise, QUIT will be
 generated in both the prologue-generated and epilogue-generated code.

NoOutputWindow A Boolean. If True, the SAS Output window containing the listing output
 from the submission does not appear. The default value is False.

ODS(0|1) If true, additional SAS code is submitted causing ODS results to be generated for
 the submitted SAS code. The default value is determined in Preferences.

ODSFormat(string) A quoted string that determines the format of generated ODS results.
 Valid values are "HTML", "RTF", and "PDF". The default value is determined in
 Preferences.

ODSGraphics(0|1) If true, ODS statistical graphics are generated for the submitted SAS
 code. Setting ODSGraphics to true causes ODS to also be set to true. The default value is
 determined in Preferences.

ODSStyle(string) A quoted string that specifies the ODS Style to use when generating
 ODS results. *String* must be a valid SAS Style. The default value is determined in
 Preferences.

> ODSStyleSheet(path) A quoted string that specifies a local CSS style sheet to use when formatting generated ODS results. *Path* must be a path to a CSS file valid for the client machine (the machine running JMP). The default value is determined in Preferences.

> OnSubmitComplete(script) A quoted string that specifies a JSL script that should be run when the submit completes. This is especially useful for asynchronous submits. If script is the name of a defined JSL function, that function is executed, with the SAS Server scriptable object passed as the first argument.

> OpenODSResults(0|1) If true, ODS results that are generated by the submitted SAS code (due to ODS being true) are automatically opened after the submit completes. The default value is True (1).

> OpenOutputDatasets(<All|None|dataset1, dataset2, ...>) JMP detects when submitted SAS code creates new SAS data sets. OpenOutputDatasets (which can be abbreviated OutData) determines what, if anything, is done with those data sets with the SAS Submit completes. If All is specified, all data sets generated by the SAS code are imported into JMP when the SAS Submit completes. If None is specified, none of the generated data sets are imported. If there are specific data sets known to be generated by the submitted SAS code that you want to be imported into JMP when the SAS submit completes, you can alternative provide their names, and only the requested data sets are imported. The default value is determined in Preferences.

> Title(string) A quoted string that specifies the window title to use for the window that displays ODS output from the submit.

SAS Submit File("filename", <named arguments>)

Description

Submit a SAS code file to the active global SAS server connection.

Returns

1 if successful; 0 otherwise.

Arguments

filename Quoted string that contains the name of file containing SAS code to submit.

Named Arguments

Same as for SAS Submit.

SQL Functions

Note: Database table names that contain the characters $# -+/%()&|;? are not supported.

```
As SQL Expr(x, <style>)
```

Description

Converts an expression to code that you can use in an SQL Select statement. Use `Expr(...)` for literal expressions. Use `NameExpr(name)` for expressions stored in a variable. Otherwise, the expression returns the expression to convert.

Returns

A string that contains the expression converted to valid SQL syntax for use in an SQL Select statement.

```
New SQL Query(Connection
("ODBC:connection_string")|("SAS:connection_string"),
Select(Column("column", "t1")), From(Table("table", <Schema("schema")>,
<Alias("t1")>)), <Options(JMP 12 Compatible(1)|JMP 13 Compatible(1)|Run on
Open(1)))>
```

```
New SQL
Query(Connection("ODBC:connection_string;")|("SAS:connection_string;"),
Custom("SELECT col1, col2, col3 FROM table;")), <Options(JMP 12
Compatible(1)|JMP 13 Compatible(1)|Run on Open(1))>
```

Creates an SQL Query object for the specified connection, columns, data table, or for the custom SQL query.

Returns

A data table that contains the queried data. The data table includes the SQL query string and table scripts for modifying and updating the query.

Arguments

`Connection` The string for an ODBC or SAS connection.

`Select` The column that you want to select and its alias.

`From` The table that is queried and the optional schema and column alias.

`Custom` An SQL statement that selects columns from the specified table.

`Version` The minimum JMP version required to open the query. If this condition is not met, a message regarding compatibility is written to the log, and the query does not open.

`Options` Boolean. `JMP 12 Compatible` is included in generated scripts when you select the Query Builder preference to create a JMP 12 compatible option or select the corresponding Query Builder red triangle menu option. The option enables JMP 12 users to run a JMP 13 query that might contain compatibility issues. Include `Run on Open(1)` to run the query when opened rather than opening the query in edit mode.

Example

```
New SQL Query(
    Connection(
```

```
        "ODBC Connection String..."
    ),
    QueryName( "g6_Movies" ),
    Select( Column( "ItemNo", "t1" ), Column( "LengthMins", "t1" ), Column(
    "Genre", "t1" ) ),
    From( Table( "g6_Movies", Schema( "SQBTest" ), Alias( "t1" ) ) )
) << Run Background( On Run Complete( dt = queryResult ) );
```

```
Show( dt );
```

Note that Query Builder creates a symbol called queryResult in the context of an On Run
Complete() script. This is a reference to the data table imported by the query. queryResult
enables you to assign a global variable to the table for later use.

Query(<<dt1|Table(dt1, alias1)>, ..., <dtN, aliasN)>>, <private |
invisible>, <scalar>, sqlStatement)

Description

Performs a SQL query on selected data tables.

Returns

The result of the query, either a data table or a single value.

Arguments

dt1, dtN Optional. A variable that has been assigned to the data table.

Table Optional. Passes a reference to the data table.

alias1, aliasN Specifies the alias of the database table.

private Optional. Avoids showing the resulting data table. Using a private data table
   speeds the process of getting to the data; it does not save the computer from allocating
   the memory necessary to hold the data table data.

invisible Optional. Hides the resulting data table from view. The data table appears only
   in the JMP Home Window and the Window menu. Hidden data tables remain in
   memory until they are explicitly closed, reducing the amount of memory that is available
   to JMP. To explicitly close the hidden data table, call Close(dt), where *dt* is the data
   table reference.

scalar Optional. Indicates that the query returns a single value.

sqlStatement Required. The SQL statement, most likely a SELECT statement. The
   statement must be the last argument.

Example

The following example selects all data for students who are older than 14 years of age.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query( Table( dt, "t1" ), "SELECT * FROM t1 WHERE age > 14;" );
```

Notes

See Appendix A, "SQL Functions Available for JMP Queries" for details about SQLite commands that Query() supports. See the Extending JMP chapter in the *Scripting Guide* for more examples.

Statistical Functions

```
Arc Finder(X(col), Y(col), Group(lot, wafer))
```

Description

Finds arcs in the point data and creates a new column that identifies the arcs.

Example

```
dt = Open( "$SAMPLE_DATA/Wafer Stacked.jmp" );
Arc Finder(
    Group( :Lot, :Wafer ),
    X( :X_Die ),
    Y( :Y_Die ),
    Min Distance( 12 ), // minimum distance among 3 points to seed an arc
    Min Radius( 15 ), // minimum radius of the acceptable arc
    Max Radius( 2000 ), // maximum radius of acceptable arc
    Max Radius Error( 2 ), // how close a point needs to be added
    Min Arc Points( 5 ), // how many points to define an arc
    Number of Searches( 500 ), // how many random probes of data
    Max Number Arcs( 3 ) // number of arcs searched for
);
dt << Color or Mark by Column( :Arc Number );
dt << Graph Builder(
    Size( 1539, 921 ),
    Variables( X( :X_Die ), Y( :Y_Die ), Wrap( :Lot_Wafer Label ), Color( :Arc
    Number ) ),
    Elements( Points( X, Y, Legend( 6 ) ) )
);
```

Notes

- The function is scaled for data that have a range of 30 to 50 units.

- The function is suitable only for data that are subset to the interesting defect points.

- It is not suitable when the density of points is high.

ARIMA Forecast(column, length, model, estimates, from, to)

Description

Determines the forecasted values for the specified rows of the specified column using the specified model and estimates.

Returns

A vector of forecasted values for *column* within the range defined by *from* and *to*.

Arguments

column A data table column.

length Number of rows within the column to use.

model Messages for Time Series model options.

estimates A list of named values that matches the messages sent to ARIMA Forecast(). If you perform an ARIMA Forecast and save the script, the estimates are part of the script.

from, to Define the range of values. Typically, *from* is between 1 and *to,* inclusive. If *from* is less than or equal to 0, and if *from* is less than or equal to *to,* the results include filtered predictions.

Best Partition(xindices, yindices, <<Ordered, <<Continuous Y, <<Continuous X)

Description

Experimental function to determine the optimal grouping.

Returns

A list.

Arguments

xindices, yindices Same-dimension matrices.

Col Cumulative Sum(name, <By var, ...>)
Cumulative Sum(name)

Description

Returns the cumulative sum for the current row. Col Cumulative Sum supports By columns, which do not need to be sorted.

Arguments

name A column name.

By var Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Col Maximum(name, <By var, ...>)

Col Max(name)

Description

Calculates the maximum value across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The maximum value that appears in the column.

Arguments

name a column name.

By var Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Mean(name, <By var, ...>)

Description

Calculates the mean across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The mean of the column.

Argument

name a column name.

By var Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Minimum(name, <By var, ...>)

Col Min(name)

Description

Calculates the minimum value across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The minimum value that appears in the column.

Argument

`name` a column name.

`By var` Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a `For Each Row()` function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

`Col Moving Average(name, options, <By var, ...>)`

`Moving Average(name, options)`

Description

Returns the moving average over a given interval based at the current row. `Col Moving Average` supports By columns.

Arguments

`name` A column name.

`Weighting(1|0|n)` Required positional argument. Determines how the values are weighted. 1 indicates uniform weighting. 0 indicates incremental weighting (a ramp or triangle). Any other number is the parameter for an exponential moving average (EWMA or EMA).

`Before(1|0|n)` Positional argument. Controls the size of the range (or window) by including the specified number of items before the current item in the average (in addition to the current item). The default value, -1, means all of the preceding items.

`After(1|0|n)` Positional argument. Controls the size of the range (or window) by including the specified number of items after the current item in the average (in addition to the current item). The default value, 0, means no following items.

`Partial Window is Missing` Boolean positional argument. Controls how missing values are treated. By default, missing values are ignored. 0 computes the average of partial windows.

`By var` Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a `For Each Row()` function.

Examples

```
Col Moving Average( x, 1, 4 );
// equal weighting of a five-item lagging range
Col Moving Average( x, 0 );
// ramp weighting of all preceding items
Col Moving Average( x, 0, 2, 2 );
```

```
// triangle weighting of a five-item centered range
Col Moving Average( x, 0.25 );
// exponential weighting of all preceding items
```

Col N Missing(name, <By var, ...>)

Description

Calculates the number of missing values across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The number of missing values in the column.

Argument

name a column name.

By var Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a `For Each Row()` function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Number(name, <By var, ...>)

Description

Calculates the number of nonmissing values across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The number of nonmissing values in the column.

Argument

name a column name.

By var Optional: A By variable to compute statistics across groups of rows.Use the By variable in a column formula or in a `For Each Row()` function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Quantile(name, p, <ByVar>)

Description

Calculates the specified quantile *p* across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns

The value of the quantile.

Argument

name a column name.

p a specified quantile *p* between 0 and 1.

ByVar the By group.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Col Quantile( :height, .5 );
    63
```

63 is the 50th percentile, or the median, of all rows in the height column.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Rank(column, <ByVar, ...>, <<tie("average"|"arbitrary"|"row"|"minimum")

Description

Ranks each row's value, from 1 for the lowest value to the number of columns for the highest value. Ties are broken arbitrarily.

Argument

ByVar (Optional) A By variable to compute statistics across groups of rows.

column The column to be ranked.

<<tie Determines how the tie is broken. A tie occurs when the values being ranked are the same. For the data [33 55 77 55], 33 has rank 1 and 77 has rank 4, and the question is how to assign ranking for the 55s. average reports the average of the possible rankings, 2.5, for both 55s. arbitrary matches JMP 12 behavior by assigning the possible rankings in an unspecified order, which could be 2 and 3 or 3 and 2. row assigns the ranks in the order that they originally appear. (The first 55 would be 2 and the second 55 would be 3.) minimum gives both values the lowest possible rank, 2.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Standardize(name)

Description

Calculates the column mean divided by the standard deviation across all rows of the specified column.

Returns

The standardized mean.

Argument

`name` a column name.

Notes

Standardizing centers the variable by its sample standard deviation. Thus, the following commands are equivalent:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "stdht", Formula( Col Standardize( height ) ) );
dt << New Column( "stdht2",
    Formula( (height – Col Mean( height )) / Col Std Dev( height ) )
);
```

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

Col Std Dev(name,<By var, ...>)

Description

Calculates the standard deviation across rows in a column. The result is internally cached to speed up multiple evaluations.

Returns

The standard deviation.

Argument

`name` a column name.

`By var` Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a `For Each Row()` function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

`Col Sum(name,<By var, ...>)`

Description

Calculates the sum across rows in a column. Calculating all missing values (`Col Sum(.,.)`) returns missing. The result is internally cached to speed up multiple evaluations.

Returns

The sum.

Argument

`name` a column name.

`By var` Optional: A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a `For Each Row()` function.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use `Col Stored Value()` to base the calculation on the value stored in the column instead. See "Col Stored Value(<dt>, col, <row>)" on page 257.

`Fit Censored(Distribution("name"), YLow(vector) | Y(Vector), <YHigh(vector)>, <Weight(vector)>, <X(matrix)>, <Z(matrix)>, <HoldParm(vector)>, <Use random sample to compute initial values(percent)>, <Use first N observations to compute initial values(nobs)>)`

Description

Fits a distribution using censored data.

Returns

A list that contains parameter estimates, the covariance matrix, the log-likelihood, the AICc, the BIC, and a convergence message.

Arguments

`Distribution("name")` The quoted name of the distribution to fit.

`YLow(vector) | Y(Vector)` If you do not have censoring, then use Y and an array of your data, and do not specify YHigh. If you do have censoring, then specify YLow and YHigh as the lower and upper censoring values, respectively.

Optional Arguments

`YHigh(vector)` A vector that contains the upper censoring values. Specify this only if you have censoring and also specify YLow.

`Weight(vector)` A vector that contains the weight values.

`X(matrix)` The regression design matrix for location.

`Z(matrix)` The regression design matrix for scale.

`HoldParm(vector)` An array of specified parameters. The parameters should be nonmissing where they are to be held fixed, and missing where the are to be estimated. This is primarily used to test hypotheses that certain parameters are zero or some other specific value.

`Use random sample to compute initial values(percent)` A percent of the observations to be used in the computation of the initial values. Specify this if the data vector is large.

`Use first N observations to compute initial values(nobs)` A number of observations at the start of the data vector to be used in the computation of the initial values. Specify this if the data vector is large.

Fit Circle(Xvec, Yvec)

Description

Fits a circle that best goes through three or more points using a least squares approach. If only three points are specified, a direct solution can be found, and the sum of squared errors is zero.

Returns

A list that contains the X and Y coordinates of the center point of the circle, the length of the radius, and the sum of squared errors.

Arguments

`Xvec` Vector of X coordinates of three or more points.

`Yvec` Vector of Y coordinates of three or more points.

Syntax

```
{Xcenter, yCenter, radius, SSE} = Fit Circle(Xvec, Yvec)
```

Hier Clust(x)

Description

Returns the clustering history for a hierarchical clustering using Ward's method (without standardizing data).

Argument

`x` A data matrix.

IRT Ability(Q1, <Q2, Q3, ... Qn,> parmMatrix)

Description

Returns scores for the latent variable in an item response theory model with n binary items and a matrix of known parameters. The parameter matrix should contain as many rows as there are parameters in the model and as many columns as there are items in the analysis.

Arguments

Q1, Q2, ..., Qn A set of n binary items.

parmMatrix A matrix of parameters from an item response theory model.

KDE(vector, <named arguments>)

Description

Returns a kernel density estimator with automatic bandwidth selection.

Argument

vector A vector.

Named Arguments

All the named arguments are optional.

<<weights Must be a vector of the same length as vector, and can contain any nonnegative real numbers. Weights represents frequencies, counts, or similar concepts.

<<bandwidth(n) A nonnegative real number. Enter a value of 0 to use the bandwidth selection argument.

<<bandwidth scale(n) A positive real number.

<<bandwidth selection(n) *n* must be 0, 1, 2, or 3, corresponding to Sheather and Jones, Normal Reference, Silverman rule of thumb, or Oversmoother, respectively.

<<kernel(n) *n* must be 0, 1, 2, 3, or 4, corresponding to Gaussian, Epanechnikov, Biweight, Triangular, or Rectangular, respectively.

LenthPSE(x)

Description

Returns Lenth's pseudo-standard error of the values within a vector.

Argument

x A vector.

Max()

See "Maximum(var1, var2, ...)" on page 295.

```
Maximum(var1, var2, ...)
```

```
Max(var1, var2, ...)
```

Description

Returns the maximum value of the arguments or of the values within a single matrix argument. If multiple arguments are specified, they must be either all numeric values or all strings.

```
Mean(var1, var2, ...)
```

Description

Rowwise mean of the variables specified.

```
Min
```

See "Minimum(var1, var2, ...)" on page 295.

```
Minimum(var1, var2, ...)
```

```
Min(var1, var2, ...)
```

Description

Returns the minimum value of the arguments or of the values within a single matrix argument. If multiple arguments are specified, they must be either all numeric values or all strings.

```
N Missing(expression)
```

Description

Rowwise number of missing values in variables specified.

```
Number(var1, var2, ...)
```

Description

Rowwise number of nonmissing values in variables specified.

```
Product(i=initialValue, limitValue, bodyExpr)
```

Description

Multiplies the results of *bodyExpr* over all *i* until the *limitValue* and returns a single product.

Quantile(p, arguments)

Description

Returns the pth quantile of the arguments. The first argument can be a scalar or a matrix of values between 0 and 1. The remaining arguments can also be specified as values within a single matrix or list argument.

Std Dev(var1, var2, ...)

Description

Rowwise standard deviation of the variables specified.

Sum(var1, var2, ...)

Description

Rowwise sum of the variables specified. Calculating all missing values (Sum(.,.))returns missing.

SSQ(x1, ...)

Description

Returns the sum of squares of all elements. Takes numbers, matrices, or lists as arguments and returns a scalar number. Skips missing values.

Summarize(<dt>, <by>, <count>, <sum>, <mean>, <min>, <max>, <stddev>, <corr>, <quantile>, <first>)

Description

Gathers summary statistics for a data table and stores them in global variables.

Returns

None.

Arguments

dt Optional positional argument: a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.

All other arguments are optional and can be included in any order. Typically, each argument is assigned to a variable so you can display or manipulate the values further.

name=By(col | list | Eval) Using a BY variable changes the output from single values for each statistic to a list of values for each group in the BY variable.

```
Summarize YByX(X(<x columns>), Y (<y columns>), Group(<grouping columns>),
Freq(<freq column>), Weight(<weight column>))
```

Description

Calculates all Fit Y by X combinations on large-scale data sets.

Returns

A data table of *p*-values and LogWorth values for each Y and X combination. See the Response Screening chapter in *Predictive and Specialized Modeling*.

Arguments

`X(col)` The factor columns used in the fit model.

`Y(col)` The response columns used in the fit model.

`Group(gcol)` The group of columns used in the fit model.

`Freq(col)` The frequency (for each row) column used in the fit model.

`Weight(col)` The importance (or influence) column used in the fit model.

Note

Performs the same function as the Response Screening platform. See the Response Screening chapter in the *Predictive and Specialized Modeling* book for details.

```
Summation(init, limitvalue, body)
```

Description

Summation sums the results of the *body* statement(s) over all *i* to return a single value.

```
Tolerance Limit(1-alpha, p, n)
```

Description

Constructs a *1-alpha* confidence interval to contain proportion *p* of the means with sample size *n*.

Transcendental Functions

```
Arrhenius(n)
```

Description

Converts the temperature *n* to the value of explanatory variable in Arrhenius model.

Returns

11605/(n+273.15)

Argument

n Temperature in Celsius.

Notes

This is frequently used as a transformation.

Arrhenius Inv(n)

Description

The inverse of the Arrhenius function. Converts the value *n* to the temperature in Celsius.

Returns

11605/(n-273.15)

Argument

n The value of the converted explanatory variable in Arrhenius model.

Notes

This is frequently used as a transformation.

Beta(a, b)

Description

$$\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$$

Returns

Returns the beta function.

Arguments

a, b numbers

Digamma(n)

Description

The derivative of the log of the gamma function (LGamma).

Returns

The digamma function evaluated at *n*.

Argument

n A number

Exp(a)

Description

Raises e to the power *a*.

Returns

e^a.

Argument

a A number

Equivalent Expression

e()^a

ExpM1(x)

Description

Returns a more accurate calculation of *Exp(x)-1* when *x* is very small.

Factorial(n)

Description

Multiplies all numbers 1 through *n*, inclusive

Returns

The product.

Arguments

n Any integer

Notes

One and only one argument must be specified.

FFT(list, <named arguments>)

Description

Conducts a Fast Fourier Transformation (FFT) on a list of matrices.

Returns

The function takes one matrix, or a list of matrices for complex numbers. The returned value is a list of two matrices with the same dimensions as the first argument.

Argument

List A list of one or two matrices. If one is provided, it is considered to be the real part. If two are provided, the first is the real part and the second is the imaginary part. Both matrices must have the same dimensions, and both must have more than one row.

Named Arguments

All named arguments are optional.

<<inverse(Boolean) If true (1), an inverse FFT is conducted.

<<multivariate(Boolean) If true (1), a multivariate FFT is conducted. If false(0), a spatial FFT is conducted.

<<scale(number) Multiplies the return values by the specified *number*.

Fit Transform To Normal(Distribution("name"), Y(vector), <Freq(vector))

Description

Fits a transformation to normality for a vector of data. This includes the Johnson Sl, Johnson Sb, Johnson Su, and GLog distributions.

Returns

A list that contains parameter estimates, the covariance matrix, the log-likelihood, AICc, a convergence message, and the transformed values.

Gamma(t, <limit>)

Description

The gamma function of *x*, or for each row if *x* is a column:

$$\Gamma(t) = \int_0^\infty x^{t-1} e^{-x} dx$$

Returns

The gamma.

Note

Gamma(t, limit) is the same integral as Gamma(t) but with the limit of integration that is defined instead of infinity.

Arguments

t a number or a column

limit optional limit. The default is infinity.

LGamma(t)

Description

Returns the log gamma function for *t*, which is the natural log of gamma.

Ln(n)

LnZ(n)

Description

Returns the natural logarithm (base *e* logarithm) of *n*.

Note

LnZ() is intended for internal use by derivatives. The Ln(n) function is recommended instead.

Log(n, <base>)

Description

Returns the natural logarithm (base e logarithm) of n. An optional second argument lets you specify a different base. For example, `Log(n,3)` for the base 3 logarithm of n. The Log argument can be any numeric expression. The expression `Log(e())` evaluates as 1, and `Log(32,2)` is 5.

Log10(n)

Description

Returns the common (base 10) logarithm of *n*.

Log1P(n)

Description

Same as Log(1 + *x*), except that it is more accurate when *x* is very small.

Logit(p)

Description

Returns `log(p/(1-p))`.

N Choose K(n, k)

Description

This function returns the number of n things taken k at a time ("n choose k") and is computed in the standard way using factorials, as $n!/(k!(n-k)!)$. For example, `NChooseK(5,2)` evaluates as 10.

Note

This is implemented internally in JMP using lGamma functions. The result is not always an integer.

Power(a, <b>)

a^b

Description

Raises *a* to the power of *b*.

Returns

The product of *a* multiplied by itself *b* times.

Arguments

a　Can be a variable, number, or matrix.

b Optional. Can be a variable or a number.

Notes

For Power(), the second argument (*b*) is optional, and the default value is 2. Power(a) returns a^2.

Root(n, <r>)

Description

Returns the *r*th root of *n,* where *r* defaults to 2 for square root.

SbInv(z, gamma, delta, theta, sigma)

Description

Johnson Sb inverse transformation. If argument is normal, the result is Johnson Sb.

SbTrans(x, gamma, delta, theta, sigma)

Description

Johnson Sb transformation from a doubly bound variable to a standard normal (0, 1) distribution.

Scheffe Cubic(x1, x2)

Description

Returns x1*x2*(x1-x2). This function supports notation for cubic mixture models.

SHASHInv(z, gamma, delta, theta, sigma)

Description

Returns a transformation of a standard normal variable into a sinh-arcsinh (SHASH) distributed variable.

SHASHTrans(x, gamma, delta, theta, sigma)

Description

Returns a transformation of a sinh-arcsinh (SHASH) distributed variable into a standard normal distributed variable.

SlInv(z, gamma, delta, theta, sigma)

Description

Johnson Sl inverse transformation. If argument is normal, the result is Johnson Sl.

SlTrans(x, gamma, delta, theta, sigma)

Description

Johnson Sl transformation from a doubly bound variable to a standard normal (0, 1) distribution.

Sqrt(n)

Description

Returns the square root of *n*.

Squash(expr)

Description

An efficient computation of the function 1/ [1 + exp(*expr*)].

Squish(expr)

Description

Equivalent to Squash(-expr), or $1/(1 + e^{-\mathrm{expr}})$.

SuInv(z, gamma, delta, theta, sigma)

Description

Johnson Su inverse transformation. If argument is normal, the result is Johnson Su.

SuTrans(x, gamma, delta, theta, sigma)

Description

Johnson Su transformation from a doubly bound variable to a standard normal (0, 1) distribution.

Trigamma()

Description

Returns the trigamma function evaluated at *n*. The trigamma function is the derivative of the digamma function.

Trigonometric Functions

JMP's trigonometric functions expect all angle arguments in radians.

ArcCosH(x)

Description

Inverse hyperbolic cosine.

Returns

The inverse hyperbolic cosine of *x*.

Argument

x Any number, numeric variable, or numeric expression.

ArcCosine(x)

ArcCos(x)

Description

Inverse cosine.

Returns

The inverse cosine of *x*, an angle in radians.

Argument

x Any number, numeric variable, or numeric expression.

ArcSine(x)

ArSin(x)

Description

Inverse sine.

Returns

The inverse sine of *x*, an angle in radians.

Argument

x Any number, numeric variable, or numeric expression.

ArcSinH(x)

Description

Inverse hyperbolic sine.

Returns

The inverse hyperbolic sine of *x*.

Argument

x Any number, numeric variable, or numeric expression.

ArcTangent(x1, <x2=1>)

ArcTan(x1 <x2=1>)

ATan(x1 <x2=1>)

Description

Inverse tangent.

Returns

The inverse trigonometric tangent of *x1/x2*, where the result is in the range -Pi()/2, Pi()/2.

Argument

x1 Any number, numeric variable, or numeric expression.

x2=1 Specifies *atan2*.

ArcTanH(x)

Description

Inverse hyperbolic tangent.

Returns

The inverse hyperbolic tangent of *x*.

Argument

x Any number, numeric variable, or numeric expression.

CosH(x)

Description

Hyperbolic cosine.

Returns

The hyperbolic cosine of *x*.

Argument

x Any number, numeric variable, or numeric expression.

Cosine(x)

Cos(x)

Description

Cosine.

Returns

The cosine of *x*.

Argument

x Any number, numeric variable, or numeric expression. The angle in radians.

`Sine(expr)`

`Sin(expr)`

Description

Returns the sine.

`SinH(expr)`

Description

Returns the hyperbolic sine.

`Tangent(expr)`

`Tan(expr)`

Description

Returns the tangent of an argument given in radians.

`TanH(expr)`

Description

Returns the hyperbolic tangent of its argument.

Utility Functions

`Add(a, b, ...)`

`a+b+...`

Description

Adds the values of the listed arguments. No arguments are changed.

Returns

The sum.

Arguments

For `Add()`, a comma-separated list of variables, numbers, or matrices.

For `a+b`, any number of variables, numbers, or matrices.

Notes

Any number of arguments is permitted. If no argument is specified, `Add()` returns 0.

Add() returns missing if any arguments are missing. To ignore missing values, use Sum().
See "Sum(var1, var2, ...)" on page 296 for details.

See Also

The Data Structures chapter in the *Scripting Guide*.

Beep()

Description

Produces an alert sound.

Returns

Null.

Blob MD5(blob)

Description

Converts the *blob* argument into a 16-byte blob.

Note

The 16-byte blob is the MD5 checksum, or the hash, of the source blob.

Blob Peek(blob, offset, length)

Description

Creates a new blob from a subrange of bytes of the *blob* argument.

Returns

A blob object.

Arguments

blob a binary large object.

offset An integer that specifies how many bytes into the blob to begin construction. The
first byte is at offset 0, the second byte at offset 1.

length An integer that specifies how many bytes to copy into the new blob, starting at the
offset.

Build Information()

Description

Returns the build date and time, whether it's a release or debug build, and the product
name in a comma-delimited string.

```
Caption({h, v}, "text", <Delayed(seconds)>, <Font(font)>, <Font
Size(size)>, <Text Color("color")>, <Back Color("color")>, <Spoken(Boolean)
```

Description

Displays a caption window at the location described by *{h, v}* that displays *text*. The caption can be delayed before being displayed by *seconds,* or can be spoken. You can also specify the font type, size, and color and background color.

Returns

Null.

Arguments

{h, v} a list with two values. *h* is the horizontal displacement from the top left corner of the monitor in pixels. *v* is the vertical displacement from the top left corner in pixels.

text A quoted string or a reference to a string that is to be displayed in the caption.

Delayed(seconds) *seconds* is optional delay before displaying the caption. Setting this option causes this caption and all subsequent captions to be delayed by the specified number of seconds.

Font(font) Specify the font type.

Font Size(size) Specify the font size.

Text Color("color") Specify the color of text.

Back Color("color") Specify the background color.

Spoken(Boolean) Causes *text* to be spoken as well as displayed. The current setting (on or off) remains in effect until switched by another Caption statement that includes a Spoken setting.

```
Datafeed()
```

See "Open Datafeed()" on page 321.

```
Debug Break()
```

When the JSL Debugger is open, this function stops a JSL script from executing at that point in the script. This function is useful for tracking in the debugger under user-specified conditions. If the JSL Debugger is not running, this function does not execute.

```
Decode64 Blob("string")
```

Description

Decodes a printable string of base 64 text into a blob.

Returns

A blob.

Arguments

`string` a base 64 encoded string.

Example

```
 Decode64 Blob( "dGhlIHF1aWNrIGJyb3duIGZveA==" );
   Char To Blob( "the quick brown fox", "ascii~hex" )
```

Decode64 Double("string")

Description

Creates a floating point number from a base 64 encoded string.

Returns

A floating point number.

Arguments

`string` a base 64 encoded string.

Divide(a, b)

Divide(x)

a/b

Description

Divides *a* by *b*. If only one argument is given (`divide(x)`), divides 1 by *x*.

Returns

The quotient of *a/b*; or the reciprocal of *x* (1/*x*) if only one argument is provided.

Arguments

`a, b, x` Can be a variable, number, or matrix.

Notes

If both arguments are matrices, it does matrix division.

See Also

The Data Structures chapter in the *Scripting Guide*.

Empty()

Description

Does nothing. Used in the formula editor for making empty boxes.

Returns

Missing.

Arguments

None.

Encode64 Blob(x)

Description

Encodes a blob into a printable string of base 64 text.

Returns

A base 64 encoded string.

Example

```
Encode64 Blob( Char To Blob( "the quick brown fox" ) );
    "dGhlIHF1aWNrIGJyb3duIGZveA=="
```

Encode64 Double(n)

Description

Creates a base 64 encoded string from a floating point number.

Returns

A base 64 encoded string.

Arguments

n   A floating point number.

Faure Quasi Random Sequence(nDim, nRow)

Description

Generates a sequence of spacefilling quasi random numbers using the Faure sequence.

Get Addin("id")

Description

Retrieves a registered add-in by *id*.

Returns

A scriptable object for the add-in. Returns empty if no add-in with the specified ID was found.

Argument

"id"   The ID of an installed add-in.

Get Addins()

Returns

A list of all registered add-ins.

Get Addr Info("address", <port>)

Description

Converts a name to its numeric address.

Returns

A list of strings. The first element is the command (Get Addr Info). The second is the results (for example, "ok" if the command was successful). The third is a list of strings of information. Included in that information is the address that corresponds to the name that was supplied.

Arguments

address A quoted string that specifies the name (for example, "www.sas.com").

port The port of the address.

Get Clipboard()

Description

Returns text from the computer's clipboard. If the content is not text, the result is null.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Copy Table Script( "Distribution" );
s = Get Clipboard();
nw = New Window( "Script", Script Box( s ) );
```

Get Name Info("address", <port>)

Description

Converts a numeric address to its name.

Returns

A list of strings. The first element is the command (GetNameInfo). The second is the results (for example, "ok" if the command was successful). The third is a list of strings of information. Included in that information is the port name that corresponds to the address that was supplied.

Arguments

address A quoted string that specifies the numeric address (for example, "149.173.5.120").

port The port of the address.

```
Get Platform Preferences(<platform <(option, ...)> ... >)
Get Platform Preference(<platform <(option, ...)> ... >)
```

Description

Returns the preferences for the specified platforms.

Returns

A list of platform preferences.

Argument

platform Optional. Specifies the platform name. If not specified, all platform preferences are returned. You can specify one or more preferences for a platform.

option Optional. Specifies the preference value. If not specified, all platform preference values are returned.

Notes

Table 2.3 describes the syntax for getting platform preferences.

Table 2.3 Get Platform Preferences() Syntax

Syntax	Description
`Get Platform Preferences( )`	Returns the current option values for all platform preferences.
`Get Platform Preferences( Platform )`	Returns the current option values for the specified platform preferences.
`Get Platform Preferences( Platform( Option ) )`	Returns the current option values for the specified platform.
`Get Platform Preferences( <<Changed )`	Returns the current option values that have changed for all platforms.
`Get Platform Preferences( Platform( <<Changed ) )`	Returns the current option values that have changed for all platform preferences.
`Get Platform Preferences( Platform( Option ( <<Changed ) ) )`	Returns the current option values that have changed for the specified platform.

Examples

Suppose that the user modified several platform preferences through the JMP Platforms window or a script.

```
Platform Preferences(
    Distribution( Set Bin Width( 2 ), Horizontal Layout( 1 ) ),
    Model Dialog( Keep Dialog Open( 1 ) ),
    Graph Builder( Legend Position( "Bottom" ) )
);
```

To return all of the modified platform preferences, use Get Platform Preferences(<<Changed):

```
Get Platform Preferences( <<Changed );
    Platform Preferences(
        Distribution( Horizontal Layout( 1 ), Set Bin Width( 2, <<On ) ),
        Graph Builder( Legend Position( "Bottom", <<On ) ),
        Model Dialog( Keep dialog open( 1 ) )
    );
```

Get Preferences(<preference_name>)

Get Preference(<preference_name>)

Description

Returns the settings for the specified preferences.

Returns

A list of preference settings.

Argument

preference_name Optional. If no preference is specified, all preferences are returned. Otherwise, the settings for the specified preference are returned.

Notes

The preferences for the following areas are not accessible in JSL: Text Data Files, Windows Specific, Macintosh OS Settings, Fonts, Communications, Script Editor, and JMP Updates. For details about getting platform preferences, see "Get Platform Preferences(<platform <(option, ...)> ... >)" on page 312.

Glue(expr1, expr2, ...)

expr1; expr2

Description

Evaluates each argument in turn.

Returns

The result of the last argument evaluated.

Arguments

One or more valid JSL expressions.

Note

A semicolon placed between expressions is the more commonly used form for `Glue()`.

Gzip Compress(blob)

Description

Compresses a blog of data into a gzip blob.

Example

```
Gzip Compress(
  Char To Blob(
    "random data does not usually compress well and may get larger"
  )
);
```

Char To Blob(

*"~1F~8B~08~00~00~00~00~00~00~0A~0D~CA~C1~0D~00~21~08~04~C0V~B6~B5~CDA~FC
~80~5C~00c~EC^~E7=~C9)~E1~106~21~A1~85~19~8DU~8Bf~07_~F8~9FZ~85~ADfx~13~
CE~83~A1~0Dc~0E~CD~0B~94*~16~1E=~00~00~00",*
"ascii~hex"

Gzip Uncompress(blob)

Description

Uncompresses a blob of gzip data into a blob.

Example

```
Gzip Uncompress( /*typically this data might come from Gzip Compress() but
  might also come from a .gz file using Load Text File() with the blob
  option*/
  Char To Blob(

    "~1F~8B~08~00~00~00~00~00~00~0A~0D~CA~C1~0D~00~21~08~04~C0V~B6~B5~CDA~FC~8
0~5C~00c~EC^~E7=~C9)~E1~106~21~A1~85~19~8DU~8Bf~07_~F8~9FZ~85~ADfx~13~CE~8
3~A1~0Dc~0E~CD~0B~94*~16~1E=~00~00~00",
    "ascii~hex"
  )
);
```

Char To Blob(
"random data does not usually compress well and may get larger",
"ascii~hex"
)

Host Is("argument")

Description

Determines whether the host environment is the specified OS.

Returns

True (1) if the current host environment matches the argument, false (0) otherwise.

Argument

Argument `"Windows"` or `"Mac"` tests for the specified operating system. `"Bits32"` or `"Bits64"` tests for the specified 32-bit or 64-bit JMP application.

Note

Only one argument can be tested at a time. Invalid arguments return false (0).

Is Alt Key()

Description

Returns 1 if the Alt key is being pressed, or 0 otherwise.

Note

On a Macintosh, `Is Alt Key()` tests for the Option key.

Is Command Key()

Description

Returns 1 if the Command key is being pressed, or 0 otherwise.

Is Context Key()

Description

Returns 1 if the Context key is being pressed, or 0 otherwise.

Is Control Key()

Description

Returns 1 if the Control key is being pressed, or 0 otherwise.

Note

On a Macintosh, `Is Control Key()` tests for the Command key.

Is Option Key()

Description

Returns 1 if the Option key is being pressed, or 0 otherwise.

Is Shift Key()

Description

Returns 1 if the Shift key is being pressed, or 0 otherwise.

JMP Product Name()

Description

Returns either `"Standard"`, `"Pro"`, or `"Student"`, depending on which version of JMP is licensed.

JMP Version()

Description

Returns the version number of JMP that you are running.

Returns

release.revision<.fix>

Arguments

Load DLL("path" <,AutoDeclare(Boolean | Quiet | Verbose)>)

Load DLL("path" <, Quiet | Verbose>)

Description

Loads the DLL in the specified *path*.

Arguments

`path` A pathname that specifies where to load the DLL.

`AutoDeclare(Boolean | Quiet | Verbose)` Optional argument. `AutoDeclare(1)` and `AutoDeclare(Verbose)` write verbose messages to the log. `AutoDeclare(Quiet)` turns off log window messages. If you omit this option, verbose messages are written to the log.

`Quiet | Verbose` Optional argument. When you use `Declare Function()`, this option turns off log window messaging (`Quiet`) or turns on log window messaging (`Verbose`).

See Also

Once a DLL is loaded, you send the DLL object messages to interact with it. See "Dynamic Link Libraries (DLLs)" on page 415 in the "JSL Messages" chapter for details about these messages. The Extending JMP chapter in the *Scripting Guide* also includes examples.

```
Mail("address"|"addresses", "subject", "message", <"attachment filepath" |
{"attachment 1 filepath", "attachment 2 filepath", ...}>)
```

Description

(Windows) Sends e-mail (using MAPI) to the *address* with the specified *subject* and *message* texts. Sends one or more attachments specified by the optional *attachment* argument. The attachment argument can evaluate to a string or list of strings.

(Macintosh) Creates an e-mail in the user's Mail application. The user must click **Send** in the e-mail. In Microsoft Outlook, you must manually add attachments to the e-mail.

Examples

To send an email with multiple attachments on Windows:

```
Mail(
    "yourname@company.com",
    "New data and script",
    "Today's updated data table and script are attached.",
    {"$DOCUMENTS/wd.jsl", "$DOCUMENTS/survey.jmp"}
);
```

or:

```
list = {"$DOCUMENTS/wd.jsl", "$DOCUMENTS/survey.jmp"};
Mail(
    "yourname@company.com",
    "New data and script",
    "Today's updated data table and script are attached.",
    list
);
To send an email to multiple recipients:
Mail(
    {"hername@company.com", "hisname@company.com"},
    "Database updates",
    "Today's sales database contains the numbers from last month."
);
```

Notes

On Macintosh, Mail() works on Yosemite and later operating systems.

```
Main Menu(string, <string>)
```

Description

Execute the command found on JMP's menu named by the quoted *string*.

Arguments

string The internal path name as shown in the menu editor for items. For example, "NEW" is the internal name for the New subcommand in the File menu.

string Optional. The name of the window to send the command to.

Examples

`Main Menu()` accepts either a full path or a partial path. If a partial name is used, and there are other menu items with the same name, the first menu item found is executed. JMP searches the top-level menu (File, Tables, DOE, and so on) first for the partial name and then searches inside each of those menus in order.

```
 Main Menu( "File:New:Data Table" ); // full path
 Main Menu( "Data Table" ); // partial path
```

Minus(a)

-a

Description

Reverses the sign of *a*.

Returns

-*a* if *a* is positive (a=3; -a=-3; Minus(a)=-3).

a if *a* is negative (a=-3; -a=3; Minus(a)=3).

0 if *a* is 0 (a=0; -a=0; Minus(a)=0).

Missing if *a* is missing.

Argument

a   Can be variable or a number. A variable must contain a number or a matrix.

Multiple File Import(arguments)

Description

Imports one or more files into a data table. You can create this JSL by selecting Save Script to Script Window from the Multiple File Import window.

Returns

Creates a Multiple File Import Object. The object accepts messages to set a folder, filter files, and specify import options.

Arguments

<<Set Folder   Specifies the folder that contains the files you want to import.

<<Set Name Filter   (Optional) Specifies the file name or extension of the files. The name filter uses * to represent zero-or-more characters ? to represent exactly one character. * and ? also match a period. The default setting is *.*, or all files.

<<Set Name Enable(Boolean)   Enables the name filter. The setting is off by default.

<<Set Size Filter   (Optional) Filters the file list by file size. Specify the sizes by kB (kilobytes, or 1000 bytes) in a list. The default values are based on the size range of the files in the file list.

<<Set Size Enable(Boolean)   (Optional) Enables the size filter. The default setting is off.

<<Set Date Filter (Optional) Filters the file list by date and time. Specify the date and time in a list in seconds. The default values are based on the date and time range of the files in the file list.

<<Set Date Enable(Boolean) (Optional) Enables the date filter. The default setting is off.

<<Set Add File Name Column(Boolean) (Optional) Includes a column that contains the imported file name. The default setting is off.

<<Set Add File Size Column(Boolean) (Optional) Includes a column that contains the size of the imported file. The default setting is off.

<<Set Add File Date(Boolean) (Optional) Includes a column that contains the time and date stamp of the imported file. The default setting is off.

<<Set Import Mode(Row Per File|Row Per Line|CSV Data) (Optional) Specifies the format of the file that is imported: whole file on one row, one line on one row, and CSV. CSV Data is the default setting.

<<Set Charset(Best Guess|utf-8|utf-16|us-ascii|windows-1252|x-mac-roman|x-mac-japanese|shift-jis|euc-jp|utf-16be|gb2312) (Optional) The character set in the imported file. The character set specified in the General preferences (Open Text File Charset) is set by default.

<<Set Stack Mode(Stack Similar|TablePerFile) (Optional) Specifies how the files are combined. Stack Similar is the default setting. (When JMP detects that the files have the same columns, the files are concatenated into a single data table.)

<<Set CSV Has Headers(Boolean) (Optional) Specifies whether the CSV file contains a header row. The setting is on by default.

<<Set CSV Allow Numeric(Boolean) (Optional) Sets the data type to numeric. The setting is on by default.

<<Set CSV First Header Line(*n*) (Optional) Specifies the header row number. 1 is the default setting.

<<Set CSV Number of Header Lines(*n*) (Optional) Specifies the number of header rows. 1 is the default setting.

<<Set CSV First Data Line(n) (Optional) Specifies the first line that contains data. 2 is the default setting.

<<Set CSV EOF Comma(Boolean) (Optional) Specifies a comma delimiter. The setting is on by default.

<<Set CSV EOF Tab(Boolean) (Optional) Specifies a tab delimiter.

<<Set CSV EOF Space(Boolean) (Optional) Specifies a space delimiter.

<<Set CSV EOF Spaces(Boolean) (Optional) Specifies spaces as the delimiter.

<<Set CSV EOF Other("") (Optional) Specifies a custom delimiter.

    `<<Set CSV EOF CRLF(Boolean)` (Optional) Specifies carriage return and line feed end-of-line characters. The setting is on by default.

    `<<Set CSV EOF CR(Boolean)` (Optional) Specifies a carriage return end-of-line character. The setting is on by default.

    `<<Set CSV EOF LF(Boolean)` (Optional) Specifies a line feed end-of-line character.

    `<<Set CSV Semicolon(Boolean)` (Optional) Specifies a semicolon end-of-line character. The setting is off by default.

    `<<Set CSV EOL Other("")` (Optional) Specifies a custom end-of-line character.

    `<<Set CSV Quote("")` (Optional) Specifies the character used as a quote. The default setting is \!", a double quotation mark.

    `<<Set CSV Escape("")` (Optional) Specifies the escape sequence such as a backlash instead of doubling the quotation mark.

`<<Import Data` Imports the data.

Example

```
mfi = Multiple File Import(
    <<Set Folder( "$SAMPLE_IMPORT_DATA" ),
    <<Set Name Filter( "UN*.csv" ), // import files with this name
    <<Set Name Enable( 1 ) // display the file name in a column
)
 <<Import Data();
```

Multiply(a, b, ...)

a*b*...

Description

Multiplies all values. No arguments are changed.

Returns

The product.

Arguments

Any number of variables, numbers, or matrices.

Notes

Any number of arguments is permitted. If no argument is specified, `Multiply()` returns 1.

See Also

The Data Structures chapter in the *Scripting Guide*.

```
Open Datafeed()
```

```
Datafeed()
```

Description

Creates a Datafeed object and window.

Returns

A reference to the Datafeed object.

Arguments

No arguments are required. You usually set up the basic operation of the data feed within the `Open Datafeed()` command, however.

```
Parse XML(string, On Element("tagname", Start Tag(expr), End Tag(expr)))
```

Description

Parses an XML expression using the `On Element` expressions for specified XML tags.

```
Platform Preferences(platform(option(value)), ...)
```

```
Platform Preference(platform(option(value)), ...)
```

```
Set Platform Preferences(platform(option(value)), ...)
```

```
Set Platform Preference(platform(option(value)), ...)
```

Description

Sets and resets values for platform options and turns the options on and off.

Arguments

`platform` Specifies the platform of the preference.

`option` Specifies the preference name.

`value` Specifies the preference value.

Notes

Table 2.4 describes the syntax for setting platform preferences.

Table 2.4 Platform Preferences() Syntax

Syntax	Description

`Platform Preferences( <<Default )`
`Platform Preferences( <<Factory Default )`
`Platform Preferences( Default )`
	Resets all platform preferences to their default values.

Table 2.4 Platform Preferences() Syntax *(Continued)*

Syntax	Description
Platform Preferences(Platform(<<Default)) Platform Preferences(Platform(<<Factory Default)) Platform Preferences(Platform(Default))	Resets the specified platform preferences to their default values.
Platform Preferences(Platform(option (<<Default))) Platform Preferences(Platform(option (<<Factory Default)))	Resets the specified platform option to its default value.
Platform Preferences(Platform(option(value)))	Sets the value of the specified platform option. Turned on by default.
Platform Preferences(Platform(option))	Resets the specified platform option back to its default value.
Platform Preferences(Platform(option(<<On)))	Turns on the specified platform option.
Platform Preferences(Platform(option(<<Off)))	Turns off the specified platform option.
Platform Preferences(Platform(option(value, <<On)))	Sets the value of the specified platform option and turns it on.
Platform Preferences(Platform(option(value, <<Off)))	Sets the value of the specified platform option and turns it off.

Example

The following expression selects (or turns on) Set Bin Width in the Distribution platform preferences and sets the value to 2:

```
Platform Preferences( Distribution( Set Bin Width( 2 ) ) );
```

The following expression changes the Set Bin Width value and turns the option off:

```
Platform Preferences( Distribution( Set Bin Width( 2, <<Off ) ) );
```

The following expression resets the default Set Bin Width value and deselects the preference:

```
Platform Preferences( Distribution( Set Bin Width( <<Default ) ) );
```

`Polytope Uniform Random(samples, A, b, L, U, neq, nle, nge, <nwarm=200>, <nstride=25>)`

Description

Generates random uniform points over a convex polytope.

Arguments

`Samples` The number of random points to be generated.

`A` The constraint coefficient matrix.

`B` The right hand side values of constraints.

`L, U` The lower and upper bounds for the variables.

`neq` The number of equality constraints.

`nle` The number of less than or equal inequalities.

`nge` The number of greater than or equal inequalities.

`nwarm` Optional: The number of warm-up repetitions before points are written to the output matrix.

`nstride` Optional: The number of repetitions between each point that is written to the output matrix.

Note

The constraints must be listed as equalities first, less than or equal inequalities next, and greater than or equal inequalities last.

`Preferences(pref1(value1), ...)`

`Preference(pref1(value1), ...)`

`Pref(pref1(value1), ...)`

`Prefs(pref1(value1), ...)`

`Set Preferences(pref1(value1), ...)`

`Set Preference(pref1(value1), ...)`

Description

Sets preferences for JMP.

Arguments

`Add Files Opened by Scripts to the Recent Files List(Boolean)` Determines whether a file that is opened by a script is added to the Home Window's Recent Files list.

`Analysis Destination(window)` Specifies where to route new analyses.

`Annotation Font("font", size, "style")` Font choice for annotations in reports.

`Axis Font("font", size, "style")` Font choice for axis labels.

`Axis Title Font("font", size, "style")` Font choice for axis titles.

`Background Color( {R, G, B} | <color> )` Sets the background color for windows.

`Calculator Boxing(Boolean)` Turns on boxing to show hierarchy of expressions.

`Conditional Formatting Rules` Creates rules for conditionally formatting text in reports. See for an example.

`Data Table Font("font", size, "style")` Font choice for data tables.

`Data Table Title on Output(Boolean)` Titles reports with name of data table.

`Date Title on Output(Boolean)` Titles reports with current date.

`Evaluate OnOpen Scripts("always"|"never"|"prompt")` Determines whether an `On Open` table script is run after the user opens the data table. By default, the user is prompted. Their choice is remembered each time they open the data table in the current JMP session. Scripts that execute other programs are never run.

`Excel Has Labels(Boolean)` When on, forces JMP to interpret the first row of data as column headings.

`Excel Selection(Boolean)` When on, the user is prompted for which non-blank Excel worksheets should be imported from an Excel workbook.

`File Location Settings(<Directory Type>("<path>"<,"initial directory">))` Valid directory types are:

   `Data Files Directory` Sets the default location for data files.

   `Help Files Directory` Sets the default location for help files.

   `Installation Directory` By default, this location is set to the JMP installation folder on Windows:

   "C:/Program Files/SAS/JMP/14", "C:/Program Files/SAS/JMPPro/14", or "C:/Program Files/SAS/JMPSW/14"

   `License File Path` Sets the default location for JMP license file.

   `Preferences File Directory` Sets the default location for the preferences settings file.

   `Save As Directory` Sets the default location for Save As file operations.

`Foreground Color(color)` Sets the foreground color for windows.

`Formula Font("font", size, "style")` Font choice for the formula editor.

`Graph Background Color(color)` Sets the color for the background area inside the graph frame.

`Graph Marker Size(size)` Default size for drawing markers.

`Heading Font("font", size, "style")` Font choice for table column headings in reports.

`Initial JMP Starter Window(Boolean)` Specifies whether the JMP Starter window is shown at launch.

`Initial Splash Window(Boolean)` Enables you to show or suppress the initial splash screen.

`Maximum JMP Call Depth(size)` Sets the default for the maximum call depth (or stack size) for JMP in which JSL built-in functions, user-defined functions, or `Recurse()` function calls can be made. By default, the maximum call depth is set to 256KB.

Each thread that JMP creates has a 2MB stack by default. Increasing the maximum call depth can cause a physical runtime stack overflow, so incrementally increase this preference in small amounts until you find the best value that works for your JSL script.

`Marker Font("font", size, "style")` Font choice for markers used in plots.

`Monospaced Font("font", size, "style")` Font choice for monospaced text.

`ODBC Suppress Internal Quoting(Boolean)` Prevents internal quoting in SQL statements that contain table and variable names with mixed case and spaces.

`Outline Connecting Lines(Boolean)` Draws lines between titles for same-level outline nodes.

`Print Settings(option(value), ... )` Changes print options on the Page Setup window:

  `Margins( <n>, <n>, <n>, <n>)` sets the left, top, right, and bottom margins. Margins are in inches.

  `Margins(<n>)` sets all margins to the same value in inches.

  `Orientation("portrait" | "landscape")` changes the page's print orientation.

  `Headers(<"char">, <"char">, <"char">)` specifies text that appears in the left, middle, and right header.

  `Headers(<"char">)` specifies the only text in the header.

  `Footers(<"char">, <"char">, <"char">)` specifies text that appears in the left, middle, and right footer.

  `Footers(<"char">)` specifies the only text in the footer.

  `Scale(<n>)` decreases or increases the percentage at which the content prints.

`Show Explanations(Boolean)` Some analyses have optional text that explains the output.

`Show Menu Tips(Boolean)` Turns menu tips on or off. (Windows only)

`Show Status Bar(Boolean)` Turns display of the status bar on or off.

`Small Font("font", size, "style")` Font choice for small text.

`Text Font("font", size, "style")` Font choice for general text in reports.

`Thin Postscript Lines(Boolean)` Macintosh only. Specifies that line widths drawn to a Postscript printer be narrower than otherwise.

`Title Font("font", size, "style")` Font choice for titles. Arguments are name of font (for example, `"Times"`), size in points, and style (`"bold"`, `"plain"`, `"underline"`, `"italic"`).

Use Triple-S Labels as Headings(Boolean) When on, this argument forces JMP to interpret label names as column headings. Example: Pref(Name("Use Triple-S Labels as Headings")(0)); turns off the preference.

Examples

The following expressions reset all preferences to their default values.

```
Preferences( "Default" );
Preferences( "Factory Default" );
```

The following script creates conditions for formatting text in reports.

```
Preferences(
    Conditional Formatting Rules(
        RuleSet(
            RuleName( "Warning" ),
            NotEqualTo( Value( 0 ), Format( TextAlpha( 0.8 ) ) )
            // If the value is not equal to 0, format the text as 80% gray.
        )
    )
);
```

Notes

The preferences for the following areas are not accessible in JSL: Text Data Files, Windows Specific, Macintosh OS Settings, Fonts, Communications, Script Editor, and JMP Updates. See "Platform Preferences(platform(option(value)), ...)" on page 321 for information about setting platform preferences.

Register Addin("unique_id", "home_folder", <named_arguments>)

Description

Register a JMP Add-In and load the add-in if it registers successfully.

Returns

If successful, returns a scriptable object representing the registered add-in. If unsuccessful, returns Empty.

Arguments

unique_id A quoted string that contains the unique identifier for the add-in. The string can contain up to 64 characters. The string must begin with a letter and contain only letters, numbers, periods, and underscores. Reverse-DNS names are recommended to increase the likelihood of uniqueness.

home_folder A quoted string that contains the filepath for the folder containing the add-in files. The filepath must conform to the valid pathname requirement for the host operating system.

DisplayName("name") An optional, quoted string that contains a name that can be displayed in the JMP user interface wherever add-in names are displayed, instead of the unique ID.

JMPVersion("version") An optional string that contains a specific version of JMP. The default value is "All", which enables the add-in to be loaded and run in any version of JMP that supports add-ins. "Current" restricts the use of the add-in to only the current version. Any quoted version number (for example, "7" or "9") restricts the add-in to a single specific version of JMP.

LoadsAtStartup(Boolean) An optional Boolean. The default value is True (1), which causes the add-in to be loaded when JMP is started. If the value is False (0), the add-in is not loaded automatically.

LoadNow(Boolean) Loads the add-in immediately.

Note

If a file named addin.def is found in the specified home folder, values from that file are used for any optional arguments that are not included in the Register Addin() function.

Example

In the following example, the first argument is the unique identifier. The second argument identifies where the add-in is installed. The third argument is the name that appears where add-in names are displayed (for example, the **View > Add-Ins** menu on Windows).

```
Register Addin("com.company.lee.dan.MyAddIn","$DOCUMENTS/myaddin",
    displayname( "Calculator Addin" ));
```

The second argument becomes the $ADDIN_HOME path variable definition. When you refer to the add-in scripts, be sure to include a trailing slash after the path variable.

```
Include("$ADDIN_HOME(com.jmp.jperk.texttocols)/texttocols.jsl");
```

Revert Menu()

Description

Resets your JMP menus to factory defaults.

Run Program(Executable("path/filename.exe"), Options({"/a", "/b", "..."}), Read Function(expression), Write Function(expression), Parameter(expression))

Description

Runs the external program specified by the Executable argument, with the command line arguments specified by the Options argument.

Results

Returns either a string, a blob, or a Run Program object as controlled by the Read Function argument.

Arguments

Executable The path to the executable. On Macintosh, type the full path to the executable.

Options Command line arguments for the executable.

Read Function If Read Function("text") is specified, a text string is returned. If Read Function("blob") is specified, a blob is returned. The script waits until the external program closes its stdout. Run Program then returns all data that the external program has written to its stdout as a string or a blob.

If Read Function is not specified, a Run Program object is returned.

Write Function Optional argument that accepts a function as its value; it does not accept "text" or "blob".

Parameter Optional argument to read and write the expression in Read Function.

Notes:

- Use global variables when Run Program() is inside a function.

- The Run Program object, which is returned if Read Function is not specified, accepts the following messages to read data from the external program's stdout:

  – <<Read: reads any available data as a string. If no data is available, an empty string is returned.

  – <<Can Read: returns true if there is data available to be read.

  – <<Is ReadEOF: returns true when the external program has completed and all its data has been read.

  You can use these messages to poll for data and process the data as it is produced by the external program.

- A Run Program object accepts the following messages to write data to the external program's stdin:

  – <<Write("text"): sends data to the external program's stdin.

  – <<Can Write: returns true if the external program will accept data immediately; otherwise, calling <<Write causes your script to block.

  – <<WriteEOF: signals to the external program that you are done sending data to it.

- Instead of sending messages to the returned Run Program object, you can specify the Read Function argument as an inline function. RP is the Run Program object.

```
RP = Run Program(
  Executable( ... ),
  Read Function(
    Function( {RP},
        <your code here>
      RP << Read
  )
 )
);
```

The `Parameter(optParm)` argument is optional in `Read Function`. If specified, the functions defined for `Read Function` and `Write Function` can receive a second argument, which is the value of `optParm`.

Examples

The following script is an example of the `Write Function` argument. `RP` is the `Run Program` object. In this context, it accepts the `<<Write` and `<<WriteEOF` messages.

```
RP = Run Program(
   Executable( ... ),
   Write Function(
      Function( {RP},
         <your code here>
         RP << Write( "Program finished." )
      )
   )
);
```

The following script shows an example of `Parameter(optParm)` argument:

```
RP = Run Program(
   Executable( ... ),
   Parameter( x ),
   Read Function( Function( {RP, optParm},... ) )
);
```

Within the `Read Function`, `optParm` contains the value of *x*. Do not attempt to access the `optParm` argument in your function if you have not specified a `Parameter` argument.

Schedule(n, script)

Description

Queues an event to run the *script* after *n* seconds.

Set Clipboard(string)

Description

Evaluates the "*string*" argument looking for a character result, and then places the string on the clipboard.

Example

Set Clipboard("copy me");

SetJVMOption(Version("<version number>"))

Description

Sets the Java Runtime Environment (JRE) version that you want JMP to use (rather than the version installed with JMP). This script must be run before JMP connects to the JRE.

Argument

version (Windows only) In the Windows registry, there are two requirements for the
JavaSoft/Java Runtime Environment key: the key must include a string called
"RuntimeLib" that points to a valid jvm.dll. And the Java Runtime Environment key must
include a key named after the quoted JVM version number.

Set Platform Preference()

Set Platform Preferences()

See "Platform Preferences(platform(option(value)), ...)" on page 321.

Set Preference()

Set Preferences()

See "Preferences(pref1(value1), ...)" on page 323.

Set Toolbar Visibility("toolbar name" | default | all, window type | all, "true" | "false")

Description

On Windows, shows or hides a toolbar based on the window type or for all windows.

Arguments

toolbar name | default | all The internal name of the toolbar (see the **View >
Toolbars** list in JMP), the default toolbar for the specified window type, or all toolbars.
Include quotes around "toolbar name".

window type | all Data table, script, report, journal, or all windows.

true | false Quoted string that shows or hides the toolbar.

Shortest Edit Script(A, B)

Shortest Edit Script(strings(A, B, <matrix(0|1)>, <limit(*number*)>))

Shortest Edit Script(lines(A, B, <matrix(0|1)>, <limit(*number*)>, <separators(*characters*)>, <ignore(*characters*)|ignore white space( )>))

Shortest Edit Script(sequences(nA, nB, Function({iA, iB}, adata[iA] == bdata[ib])))

Description

Compares two strings, lines, or sequences.

Returns

Returns a list or a matrix of edit commands. The simplest form returns a list. strings and
lines return a matrix (if set to 1) or a list. sequences returns a matrix.

There are three possible commands: common data in both strings, delete data from the first string, and keep data from the second string.

Optional Strings Arguments

`matrix` Indicates whether the returned value is a matrix.

`limit` Stops the evaluation when the edit list exceeds the specified number of inserted or deleted items. Two random strings have a lot of common characters in a lot of distinct sections. The function runs for a long time trying to find a best match. `limit` stops the function sooner.

Optional Lines Arguments

`matrix` Indicates whether the returned value is a matrix.

`limit` Stops the evaluation when the edit list exceeds the specified number of inserted or deleted items. Two random strings have a lot of common characters in a lot of distinct sections. The function runs for a long time trying to find a best match. `limit` stops the function sooner.

`separators` A character that separates words.

`ignore` Ignores the specified spaces or characters in a line.

`ignore white space` Ignores white space in a line.

Optional Sequences Argument

`Function` A user-defined function.

Examples

The following example compares two strings with three common sequences of characters between them.

```
Shortest Edit Script( "abcdef", "abdezgh" );
    {{"Common", "ab"}, {"Remove", "c"}, {"Common", "de"}, {"Insert", "zgh"},
        {"Remove", "f"}}
```

The following example examines each line in string aa and bb:

```
aa = "this is
a test of
shortest
edit script
lines with several words";

bb = "this is
a test 2 of
shortest
edit ?., script
lineswithseveral words";

Shortest Edit Script( lines( aa, bb, separators( "\!n" ),
    // quote and newline separators
    ignore( "?., " ) ) ); // ignore these characters and spaces
```

```
{{"Common", "this is // lines in aa and bb contain "this is"
"}, {"Remove", "a test of // only on line 2 of aa
"}, {"Insert", "a test 2 of // only on line 2 of bb
"},
{"Common", "shortest
edit script
lines with several words"}}
// lines in aa and bb contain "shortest", "edit script", and "lines with
    several words"
```

For more information, see the Programming Methods chapter in the *Scripting Guide*.

Show Addins Dialog()

Description

Opens the Add-In Status window (**View > Add-Ins**).

Arguments

None.

Show Commands()

Description

Lists scriptable objects and operators. Arguments are All, DisplayBoxes, Scriptables, Scriptable Objects, StatTerms, Translations.

Show Preferences(<"all">)

Description

Shows current preferences. If no argument is specified, preferences that have been changed are shown. If "all" is given as the argument, all preferences are shown.

Show Properties(object)

Description

Shows the messages that the given *object* can interpret, along with some basic syntax information.

Sobol Quasi Random Sequence(nDim, nRow)

Description

Generates a sequence of space-filling quasi random numbers using the Sobol sequence in up to 4000 dimensions.

Socket(<STREAM | DGRAM>)

Description

Creates a socket.

Returns

The socket that was created.

Arguments

STREAM | DGRAM Optional argument to specify whether the socket is a stream or datagram socket. If no argument is supplied, a stream socket is created.

Speak(text, <wait(Boolean)>)

Description

Calls system's speech facilities to read aloud the text. If Wait is turned on, script execution pauses until speaking is done.

Status Msg("message")

Description

Writes the message string to the status bar.

Subtract(a, b)

a-b-...

Description

Subtracts the values of the listed arguments, left to right. No arguments are changed.

Returns

The difference.

Arguments

Two or more variables, numbers, or matrices.

Notes

Two or more arguments are permitted. Specifying fewer than two arguments produces an error.

See Also

The Data Structures chapter in the *Scripting Guide*.

Unregister Addin("unique_id")

Description

Unregisters (removes) a previously registered add-in.

Argument

unique_id A quoted string that contains the unique identifier for the add-in to unregister.

Web(string, <JMP Window>)

Description

Opens the URL stored in *string* in the default system web browser. Under Microsoft Windows, you can add JMP Window as the second argument to have the HTML open in a JMP browser.

The http:// prefix in the URL is optional.

Examples

```
url = "www.jmp.com";
Web( url );

Web( "www.jmp.com" );
Web( "www.jmp.com", JMP Window );
```

XML Attr("attr name")

Description

Extracts the string value of an xml argument in the context of evaluating a Parse XML command

XML Decode("xml")

Description

Decodes symbols in XML to ordinary text. For example, & becomes &, and < becomes <.

Argument

xml A quoted string containing XML.

XML Encode("text")

Description

Prepares text for embedding in XML. For example, & becomes &, and < becomes <.

Argument

xml A quoted string containing plain text.

XML Text()

Description

Extracts the string text of the body of an XML tag in the context of evaluating a `Parse XML` command.

JSL Messages

Summary of Messages for Objects and Display Boxes

This topic provides abbreviated descriptions for many of JMP's general object messages. For complete information about object messages, see the JMP Scripting Index. In JMP, select **Help > Scripting Index**.

For information about platform messages, see the Scripting Platforms chapter in the *Scripting Guide*.

Contents

Alpha Shape

For the following messages, ashape stands for an alpha shape or a reference to one.

ashape <<Get Alpha

Returns the current alpha value.

ashape <<Set Alpha(alpha)

Sets the current alpha value and recomputes the triangulation.

ashape <<Get Tri Alpha

Returns the alpha values for each triangle.

Associative Arrays

For the following messages, map stands for an associative array or a reference to one.

map<<First

Returns the first key within *map,* or Empty() if *map* has no keys. Note that keys are returned in lexicographical order.

map<<Get Contents

Returns a list of all key-value pairs within *map.*

map<<Get Keys

Returns a list of all the keys within *map.*

map<<Get Default Value()

Returns the implicit value of all absent keys, or Empty() if none has been set.

map<<Get Value(key)

Returns the value for the *key* within *map.*

```
map<<Get Values(<keylist>)
```

If no argument is provided, a list of all values within *map* is returned.

If a list of keys is provided, a list of the values corresponding to only those keys is returned.

```
map<<Insert(key, value)
```

Inserts the *key* into *map* and assigns *value* to it. If *key* already exists in *map*, its value is replaced by the new *value* given. This message is equivalent to the function Insert Into.

```
map<<Next(key)
```

Returns the key following the given *key* within the *map*, or Empty() if *map* has no keys. Note that keys are returned in lexicographical order.

```
map<<Remove(key)
```

Removes the *key* and *value* from *map*. This message is equivalent to the function Remove From.

```
map<<Set Default Value(v)
```

Sets the implicit value of all absent keys. Any key added without a value is assigned this value by default.

Data Tables

```
dt<<Add Column Properties(property argument, ...)
```

Adds the specified properties to the selected column.

```
dt<<Add Multiple Columns("column prefix", n, <before first|after
last|after(column)>, Character|Numeric|Row State, <field width(n)>)
```

Adds *n* columns to *dt* at the position indicated.

```
dt<<Add Rows(<n>, <at start|at end|after(m)>|{list of (column
name=value) pairs})
```

Description

Adds rows at the start, at the end, or after a specified row in the data table. The message can also add rows based on the specified column name and value pairs. Those rows are added to the end of the data table.

Examples

The following example specifies the start and end of the new rows:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Rows( 3, after( 5 ) );
```

The following example specifies the column name and value pairs. The new row is added to the end of the data table.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Rows( {name = "David", age = 15} );
```

`dt<<Add Scripts to Table(script, ...)`

`dt<<Add Properties to Table(script, ...)`

Adds the specified scripts to the data table.

`dt<<Anonymize(<columns(name(s))>, <Output Table Name(string)>);`

Removes unique identifiers from data, some column properties, and table scripts. Applies to a data table or selected columns.

`dt<<Begin Data Update`

Holds off display updating to allow for quick updating of data table cells. Use End Data Update in conjunction with this command to turn display updating back on.

Notes

Begin Data Update does not affect the data refresh due to some other table manipulations. For example, when you delete or add columns, the data table is updated and then the data update begins.

`dt<<Clear Column Selection`

Deselects all selected columns.

`dt<<Clear Edit Lock(<"modify cells">, <"add rows">, <"add columns">, <"delete rows">, <"delete columns">)`

Allows the specified data table operation again.

`dt<<Clear Row States`

Cancels any row states in effect.

`dt<<Clear Select`

Turns off the current selection.

```
dt<<Clone Formula Column(column, n, Substitute Column
Reference(column1, {list}))
```

Creates *n* new formula columns, substituting references to *column1* with columns from the *list* into the formula from the original *column*.

```
dt<<Close Data Grid(Boolean)
```

Closes the data table grid.

```
dt<<Close Side Panels(Boolean)
```

Closes the side panel in a data table.

```
dt<<Color or Mark by Column(col, <optional arguments>)
```

```
dt<<Color by Column(col, <optional arguments>)
```

Function

Assigns colors or markers according to the values of a data table column. If no optional arguments are provided, row states are used.

Arguments

`Color Number(n)` Uses the specified quoted JMP color.

`Color Theme("theme")` Uses the specified quoted color theme.

`Marker Theme("named argument")` Uses the specified quoted marker theme: "standard", "hollow", "paired", "classic", or "alphanumeric".

`Continuous Scale` For `Color by Column`, assigns colors in a chromatic sequential fashion based on the values in the highlighted column.

`Reverse Scale` Reverses the color scheme in use.

`Excluded Rows` Applies the row states to excluded columns.

`Make Window with Legend` Creates a separate window with a legend.

```
dt<<Color Rows by Row State
```

Colors the rows in the data table grid using the color assignments by row states. Send the message again to turn off the row colors.

```
dt<<Combine Columns
```

Combines several columns into a single column. Each source columns' values are separated by the specified delimiter.

Examples

```
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
```

```
dt << Combine Columns(
  Delimiter( "," ),
  Columns(
    :Brush After Waking Up,
    :Brush After Meal,
    :Brush Before Sleep,
    :Brush Another Time
  ),
  Column Name( "When to Brush" )
);
```

dt<<Compress File When Saved(Boolean)

Compresses the file when the data table is saved.

dt<<Compress Selected Columns({column1, ...})

Compresses the listed columns into the most compact form that is possible. Columns with character data are compressed to 1 byte if there are fewer than 255 levels. Columns with numeric data are compressed to 1 byte if the numeric values are between -127 and 127.

dt<<Concatenate(dt2, ..., Keep Formulas, Output Table Name("name"))

Description

Creates a new table (*"name"*) from the rows of *dt* and *dt2*.

Returns

A reference to the concatenated data table.

dt<<Copy Multi Columns Properties

Copies all of the column properties for the selected columns into a list of separate lists of properties. Optionally, you can specify a list of source columns instead of preselecting them in the data table.

Example

```
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Select Columns( :MODULUS, :ELONG );
dt << Copy Multi Columns Properties;
New Window( "Script", Script Box( "//Try paste here" ) );
```

or

```
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Copy Multi Columns Properties( {:MODULUS, :ELONG} );
New Window( "Script", Script Box( "//Try paste here" ) );
```

dt<<Copy Selected Properties

Copies the selected table properties to the clipboard.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Properties( {"Distribution", "Oneway"} );
proplist = dt << Copy Selected Properties();
New Window( "Script", Script Box( "//Try pasting here" ) );
```

dt<<Copy Table Script("No data")

Copies the script to recreate the data table onto the clipboard so that it can be pasted somewhere else. Includes the table scripts. Add the "no data" keyword to omit the data.

dt<<Copy Table Scripts

dt<<Copy Selected Properties

Description

Copies the selected scripts to the clipboard.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Properties( {"Distribution", "Oneway"} );
proplist = dt << Copy Table Scripts();
New Window( "Script", Script Box( "//Try pasting here" ) );
```

dt<<Data Filter(<Mode(...)>, <Add Filter (...)>)

Constructs a data filter. If no arguments are specified, the Add Filter Columns window appears.

Arguments for Mode() include Select(), Show(), and Include(). They are all Boolean. Select defaults to true(1), and Show and Include default to false (0).

Arguments for Add Filter() include Columns(), and Where(). Columns() takes one or more column names separated by commas. You can add one or more WHERE clauses to define the filter.

No Outline Box(Boolean) omits or adds an outline and red triangle menu at the top of the filter window.

or more information, see the Data Tables chapter in the *Scripting Guide* and the JMP Reports chapter in the *Using JMP* book

dt<<Get Header Height

Returns the column header's display height (in pixels).

`dt<<Data View(<"options">)`

Description

Duplicates the data table in a new window. If you specify one of the following quoted arguments, the new data table includes only the corresponding rows.

Returns

A reference to the data view.

Optional Arguments

`excluded` Quoted. The new data table includes only the rows that are marked as excluded in the original data table.

`labeled | labelled` Quoted. The new data table includes only the rows that are marked as labeled in the original data table.

`hidden` Quoted. The new data table includes only the rows that are marked as hidden in the original data table.

`selected` Quoted. The new data table includes only the rows that are selected in the original data table.

`dt<<Delete Columns(col, col2, ...)`

`dt<<Delete Column`

Deletes column(s) from the data table *dt*. Specify which column or columns to delete. Without an argument, deletes the selected columns, if any. `Delete Column` is a synonym.

`dt<<Delete Rows(<n>)`

`dt<<Delete Rows({n, o, p, ...})`

`dt<<Delete Rows({n::q})`

Deletes the currently selected rows or rows specified. Returns the number of rows that were deleted.

`dt<<Delete Scripts("name"|{script1, script2, ...})`

Deletes the specified script or scripts.

Note

In JMP versions prior to 14, use `Delete Property` to delete a script.

`dt<<Delete Table Property("name"|{property1, property2, ...})`

Deletes a table property (for example, a script or variable).

```
dt<<Delete Table Variable("name")
```

Deletes a table variable.

```
dt<<Disable Undo(Boolean)
```

Disables undo operations in the data table.

```
dt<<End Data Update
```

Resumes display updating after a `Begin Data Update` message. These commands are used for quick updates of the data table when many changes have to be made. Speed is gained by turning off display updating.

```
dt<<Exclude
```

```
dt<<Unexclude
```

Toggles selected rows in *dt* from excluded to unexcluded or *vice versa*.

```
dt<<Get All Columns As Matrix
```

Returns the values from all columns of *dt* in a matrix. Character columns are numbered according to the levels, starting at 1.

```
dt<<Get As Matrix(<list of columns by name>, <list of columns by
number>, <column range>)
```

Returns values from the numeric columns of *dt* in a matrix. The default output is all numeric columns.

Examples

```
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
colnames = dt1 << Get As Matrix(); // returns all numeric columns
Show( colnames );
    colnames =
    [ 12 59 95,
      12 61 123,
      12 55 74,...]
colnums = dt1 << Get As Matrix( {4, 5} ); // returns columns four and five
Show( colnums );
    colnums = [ 59 95, 61 123, 55 74, 66 145, 52 64, 60 84, 61 128, ...]

dt2 = Open( "$SAMPLE_DATA/Probe.jmp" );
colrange = dt2 << Get As Matrix( 10::22); // returns columns 10 through 22
Show( colrange );
    colrange =
    [ -0.08818069845438 0.711340010166168 1.85904002189636 0.396923005580902
```

```
4.50656986236572 7.86504983901978 1.53891003131866 -2.76178002357483
0.0711032971739769 5.75577020645142 -3.62023997306824 -0.971698999404907
-0.0525696985423565, ...]
```

dt<<Get As Report

Returns the data table as a report. If rows and columns are selected in the data table, only those rows and columns are in the report.

Example

The following script returns Big Class.jmp as a report and displays it and a distribution in one window.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dtRpt = dt << Get As Report;
distRpt = V List Box(
    dt << Distribution(
        Continuous Distribution( Column( :weight ) ),
        Nominal Distribution( Column( :age ) )
    )
);
New Window( "Example", H List Box( dtRpt, distRpt ) );
```

dt<<Get Cell Height

Returns the column header's cell height.

dt<<Get Column Names("arguments")

Returns a list of column names in a data table. The *"arguments"* restrict the names retrieved as follows:

"Numeric", "Ordinal", "Rowstate", "Continuous", "Ordinal", and "Nominal" get only the specified types of columns. More than one can be specified. "String" returns a list of strings rather than a list of column references.

dt<<Get Column Reference(list or matrix of col names)

Returns the column reference of the strings in the list or matrix. If no list or matrix is used, JMP returns all column names.

dt<<Get Display Width

Returns the column display width in pixels.

dt<<Get Edit Lock

Returns the disallowed operations on the data table (if cells cannot be edited; rows cannot be added or deleted; and columns cannot be added or deleted).

dt<<Get Excluded Columns

Returns the currently excluded columns in the data table.

dt<<Get Excluded Rows

Returns the rows that are excluded in the data table.

dt<<Get Hidden Columns

Returns the columns that are hidden in the data table.

dt<<Get Hidden Rows

Returns the currently hidden rows in the data table.

dt<<Get Journal

Returns a string that contains journal source for the display box.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( :weight ), X( :height ) );
rbiv = biv << Report;
Print( rbiv << Get Journal );
```

dt<<Get Label Columns

dt<<Get Labeled Columns

dt<<Get Labelled Columns

Returns the currently labeled columns in the data table.

Example

In PopAgeGroup.jmp, the Country and Year columns are labeled. The following script returns a list of the labeled column names.

```
dt = Open( "$SAMPLE_DATA/PopAgeGroup.jmp" );
dt << Get Labeled Columns;
    {:Country, :Year}
```

dt<<Get Labeled Rows

dt<<Get Labelled Rows

Returns the currently labeled rows in the data table.

dt<<Get Name

Returns the *name* of the table.

dt<<Get Path

Returns the absolute path for the JMP data table. Note that this function is not for imported data that is not saved yet.

dt<<Get Property("name")

Returns the *script* in the property *name*.

dt<<Get Row Change Function

Returns the expression that is evaluated when a row is selected.

dt<<Get Row ID Width

Returns the row ID display width in pixels.

dt<<Get Row States

Returns a vector containing the row state for every row in the data table or data filter.

dt<<Get Rows Where(WHERE clause)

Returns the rows in the data table that match the specified where criteria. Some examples are as follows:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Get Rows Where( :sex == "M" );
dt << Get Rows Where( :sex == "M" & :age < 15 );
```

dt<<Get Script(<"script name">)

Returns the specified script. If the script name is omitted, Get Script returns a text representation of the data table and all scripts in the table.

```
dt<<Get Script Group("name")
```

Returns the list of table scripts in the group. See the Data Tables chapter in the *Scripting Guide* for examples.

```
dt<<Get Script Group Names
```

Returns the list of names of table script groups. See the Data Tables chapter in the *Scripting Guide* for examples.

```
dt<<Get Scroll Locked Columns
```

Returns a list of columns that are locked from scrolling.

```
dt<<Get Selected(<"column reference">)
```

Returns a list of selected items. Include the optional `"column reference"` to return column references instead, such as when you are adding a column to a col list box.

```
dt<<Get Selected Columns(<"string">)
```

Returns a list of selected columns as column references. Include the *"string"* argument to return the selected columns in a string.

Examples

```
 dt << Get Selected Columns();
   {:age, :sex, :height}
 dt << Get Selected Columns( "string" );
   {"age", "sex", "height"}
```

```
dt<<Get Selected Properties(<{list of properties}>)
```

Description

Returns the selected table properties in a list.

Optional Argument

`list of properties` specifies the properties to get.

Example

```
 dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
 dt << Select Properties( {2, 4} );
 proplist = dt << Get Selected Properties();
 // returns the second and fourth table scripts and highlights them
 // in the data table
```

```
dt<<Get Selected Rows()
```

Returns the selected rows.

`dt<<Get Table Script Names()`

Returns a list of the names of all the scripts and properties in the data table.

`dt<<Get Table Variable("name")`

Returns the value from the variable or script *name*.

`dt<<Get Table Variable Names()`

Returns a list of the names of all the variables in the data table.

`dt<<Go To Row(n)`

Locates and selects row number *n* in *dt*.

`dt<<Group Columns({col1, col1, ...})`

`dt<<Group Columns("group name", col, n)`

Groups the columns under the specified group name. You can provide either a list of columns to group, or a column name and the number of columns to group. In the latter case, the number *n* specifies to group the column given with the *n*-1 columns that follow.

`dt<<Group Scripts({script1, script2, ...})`

Groups a list of tables scripts in the data table. See the Data Tables chapter in the *Scripting Guide* for examples.

`dt<<Hide`

`dt<<Unhide`

Toggles selected rows in *dt* from hidden to unhidden or *vice versa*.

`dt<<Hide and Exclude`

Hides the selected rows from graphs and excludes them from contributing to calculations.

`dt<<Invert Column Selection( <list of columns> )`

Selects any column that is currently deselected and deselects any column that is currently selected. If the list of columns is specified, the columns that are not in the list are selected. See the Data Tables chapter in the *Scripting Guide* for examples.

`dt<<Invert Row Selection`

Selects any row that is currently deselected and deselects any row currently selected.

`dt<<Is Dirty`

Returns 1 if the table has been modified from its saved state. Otherwise, returns 0.

`dt<<JMP Query Builder`

Enables you to build a query that contains one or more data tables.

```
dt<<Join(With(dataTable), <Private>, <Invisible>, Select(columns),
Select With(columns), (By Matching Columns(col1=col2,
...)|Cartesian|By Row Number), <Merge Same Name Columns>, <Match
Flag>, <Copy Formula(Boolean)>, <Suppress Formula
Evaluation(Boolean)>, Update, <Drop Multiples(Boolean, Boolean)>,
<Include Non Matches(Boolean, Boolean)>, <Preserve Main Table Order>,
<Output Table Name("name"))>
```

Description

Combines data tables *dt* and *table* side to side. For details about joining tables, see the Reshape Data chapter in the *Using JMP* book.

Returns

A data table.

Arguments

`Private` Optional. Does not open the resulting data table.

`Invisible` Optional. Opens the data table but hides it. The table is displayed in the JMP Home Window's Window List or the Window > Unhide list.

`With(dataTable)` The secondary data table.

`Select(columns)` Selects the columns from the main table to be added to the output table. Optional.

`Select With(columns)` Selects the columns from the secondary table to be added to the output table.

`By Matching Columns(col1=col2, ...)|Cartesian|By Row Number` Determines the method for joining the tables. `By Matching Columns(col1=col2, ...)` matches values in `col1` with `col2`. If they match, those values will be joined. `Cartesian` joins two tables using a Cartesian method, where it forms a new table consisting of all possible combinations of the rows from two original tables. JMP crosses the data in the first table with the data in the second to display all combinations of the values in each set. `By Row Number` joins the two tables side by side. `By Matching Columns` is the default value.

    `Merge Same Name Columns` Optional. Merges columns with the same name. Off by default.

    `Match Flag` Optional. Off by default. Omits the Match Flag column from the joined data table when you are matching by column.

    `Copy Formula(Boolean for main table, Boolean for secondary table)` Optional. Copies the formulas from the table that you are joining. On by default.

    `Suppress Formula Evaluation()` Optional. Prevents JMP from evaluating columns' formulas during the creation of the new table. On by default. Use `Suppress Main Table Formula Evaluation` to suppress evaluation only in the main table. Use `Suppress Second Table Formula Evaluation` to suppress evaluation only in the secondary table.

    `Update` Optional. Replace the data in the main table with the corresponding data from the secondary table. `Update` is an alias for `Update First Table with Data from Second Table`.

    `Drop Multiples(Boolean for main table, Boolean for secondary table)` Optional. Only the first match found is written to the new data table. If you do not enable Drop Multiples in either table, a Cartesian join is performed within each group of matching column values. Off by default.

    `Include Non Matches(Boolean for main table, Boolean for secondary table)` Optional. Includes non-matching columns. Off by default.

    `Preserve Main Table Order` Optional. Maintains the order of the original data table in the joined table, instead of sorting by the matching columns. On by default.

    `Output Table Name("name"))` Optional. The name of the resulting table.

---

dt<<Journal

Makes a journal from the data table. Only the data grid is included, not notes, variables, or scripts.

Notes

Journals that are created in JMP 14 or later might contain compressed matrix data for large matrices. If you have JSL scripts that open journals and extract data from them, you might need to use the `Get Journal` message (which does not compress the matrices) rather than saving the journal to disk with the `Journal` message. See for an example.

---

dt<<Journal Link(Save(<*filepath*>)|Embed(), <Button Name(*string*)>))

Adds a link to the data table in the current journal. If a journal does not exist, a new one is created.

Arguments

filepath Optional argument. The complete path and filename where the table should be saved. If omitted, the data table should already have a disk location (previously saved or loaded), otherwise the journal link is incomplete and will not reload the table.

Embed Optional argument. Embeds a JSL script to recreate the data table.

Button Name Optional argument. The name that is displayed on the button. If the button name is not specified, the button is named after the data table.

dt<<Label

dt<<Unlabel

Toggles selected rows in *dt* from labeled to unlabeled or *vice versa*.

dt<<Last Modified

Returns the date on which the data table was last saved.

dt<<Layout

Layout is deprecated and will be removed in a future release. Use Journal instead.

dt<<Lock Data Table

Locks the data table so that data and column properties cannot be added or changed. See "dt <<Set Edit Lock(<"modify cells">, <"add rows">, <"add columns">, <"delete rows">, <"delete columns">)" on page 362 for details about locking specific components of a data table.

dt<<Make Indicator Columns(<Append Column Name(*Boolean*)>, <Include Missing(*Boolean*)>);

Creates indicator columns of 0 and 1 values for the specified categorical column.

Example

The following example creates indicator columns for the sex column. Append Column Name creates columns named sex_F and sex_M. Otherwise, the columns are named after each level (F and M). Include Missing includes missing values.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Make Indicator Columns(
    Columns( :sex ),
    Append Column Name( 1 ),
    Include Missing( 1 )
);
```

dt<<Make RowState Handler

Creates a row state handler function. The argument of the function holds the rows whose row states get changed.

dt<<Make SAS Data Step

Returns the data table as a SAS Data Step.

dt<<Make SAS Data Step Window

Returns the data table as a SAS Data Step and places it in a SAS script window.

dt<<Marker by Column(col)

Assigns markers according to the values of a data table column.

dt<<Markers(n)

Assigns marker *n* to the selected rows.

dt<<Maximize Display

Deprecated. Use `Optimize Display` instead.

Forces the data table to remeasure all of its columns and zoom to the best-sized window.

dt<<Move Script Group(group name, to first|to last|after(script)|after(group))

Rearranges the table script groups. See the Data Tables chapter in the *Scripting Guide* for examples.

dt<<Move Selected Column("name(s)", to first|to last|after("name"))
dt<<Move Selected Columns("name(s)", to first|to last|after("name"))

Moves the selected column or columns in the data table to the specified position. See the Data Tables chapter in the *Scripting Guide* for examples.

dt<<Move Rows(At Start|At End|After(n))

Moves the selected rows in the data table to the specified position.

```
dt<<New Column("name", <"data type">, <"modeling type">,
Format("format", width), <Formula()>, <Set Values>, <properties>)
```

Description

Adds a new column named "*name*" after the last column in *dt*. Unless otherwise specified, columns are numeric, continuous, and 12 characters wide.

Returns

A column reference.

Arguments

name A quoted string that contains the name of the new column.

data type An optional argument that defines the data type (Numeric, Character, Row State, or Expression).

modeling type A quoted string describing the modeling type ("Continuous", "Nominal", "Ordinal", "Multiple Response", "Unstructured Text", "None", or "Vector").

Format An optional argument that sets the format type and column width. See "col<<Format(<width>, <decimal places>, <"Use thousands separator">)" on page 367 for examples of setting other numeric format properties.

Set Values Specifies the data in the column.

properties The optional actions arguments are any messages that data table columns support. Action arguments are found in the Column Properties menu in the New Column dialog. Two common action arguments are Formula and Set Values.

Note

The message can also be used as the function New Column().

See Also

The Data Tables chapter in the *Scripting Guide*

The Column Info Window chapter in the *Using JMP* book

```
dt<<New Data Box()
```

Makes a data table view in a display box tree. Useful for displaying the data table and report in one window. A data browser box is created when you send the New Data Box message to the data table object.

Example

The following script creates a data table view and report in one window. The data table is placed in a data browser box. The width of that box is set to 800 pixels. Because auto stretch is turned off, the data table view remains 800 pixels wide even if you stretch the right border of the window.

```
dtA = Open( "$SAMPLE_DATA/Semiconductor Capability.jmp", invisible );
nw = New Window( "Example",
```

```
     H List Box(
        V List Box( dtbox = dtA << New Data Box() ),
        dtA << Distribution(
           Continuous Distribution( Column( :NPN1 ) ),
           Continuous Distribution( Column( :PNP1 ) )
        )
     )
  );
  dtbox << Set Auto Stretching( 0, 0 ) << Set Width( 800 );
```

---

dt<<New Data View

Opens a duplicate of the data table. The second data table is identical to and linked to the original data table, so that any changes made in one are reflected in the other. Closing either data table also closes the other and all references to the data tables are deleted.

This can be useful to show an invisible data table.

---

dt<<New Script("name", script)

dt<<Set Property("name", script

Creates a new table property using the specified *name* that stores the specified *script*.

Use New Script() or Set Property() rather than the deprecated New Property() and New Table Property().

Example

```
 dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
 dt << Set Property( "Bivariate Example", Bivariate( Y( :weight ), X( :height
    ), Fit Line ) );
```

---

dt<<New Table Variable("name", value)

dt<<Set Table Variable("name", value)

Creates a new table variable with the specified *name* and *value*.

---

dt<<Next Selected

Scrolls data table down to show the next selected row that is not already in view.

---

dt<<Optimize Display

Forces the data table to remeasure all of its columns and zoom to the best-sized window.

---

dt<<Original Order

Restores saved order of columns in *dt*.

dt<<Paste Multi Columns Properties

Pastes multiple lists of column properties to multiple columns. Optionally, you can specify a list of target columns instead of selecting them in the data table.

Example

```
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Copy Multi Columns Properties( {:MODULUS, :ELONG} );
dt2 = New Table( "test it",
   New Column( "T1", numeric, continuous ),
   New Column( "T2", numeric, continuous ),
   New Column( "T3", numeric, continuous ),
   Add Rows( 10 )
);
dt2 << Paste Multi Columns Properties( {:T1, :T3} );
// pastes the column properties from MODULUS and ELONG to T1 and T3
```

dt<<Previous Selected

Scrolls data table up to show the previous selected row that is not already in view.

dt<<Print Window(<"Show Dialog">)

Prints the window. If the optional argument "Show Dialog" is specified, the print window is displayed. Otherwise, the window is printed to the default printer using the current settings, and no print window is displayed.

dt<<Rename Script Group("oldname", "newname")

Renames the table script group. See the Data Tables chapter in the *Scripting Guide* for an example.

dt<<Reorder By Data Type

Reorders columns in *dt*, row state first, then character, then numeric.

dt<<Reorder By Modeling Type

Reorders columns in *dt* to continuous, then ordinal, then nominal.

dt<<Reorder By Name

Reorders columns in *dt* to alphanumeric order by name.

```
dt<<Rerun Formulas
```

Recalculates all formula-based data table variables. Recalculations are performed in the proper dependency order.

```
dt<<Reverse Order
```

Reverses columns in *dt* from current order.

```
dt<<Revert
```

Reverts to the most recently saved version of *dt*.

```
dt<<Run Formulas
```

Performs all pending formula evaluations, including evaluations that are pending as a result of evaluating other formulas.

```
dt<<Run Script("name")
```

Finds the table property *name* and runs it as a JSL script.

```
dt<<Save("path")
```

```
dt<<Save As("path")
```

Saves the table under the "*path*" given.

For information about supported formats, see the Save and Share Data chapter in the *Using JMP* book.

```
dt<<Save Database("connection_information", "table_name", <Replace>)
```

Saves the data table to the database named using the connection and table name specified. The Replace option replaces the existing database with the current database.

```
dt<<Save Script to Script Window
```

Saves a script to reproduce the data table in a script editor window. Appends the script to any script that currently appears in the script editor.

```
dt<<Select All Rows
```

Selects all rows in the data table.

```
dt<<Select Columns(<column1>, <column2>, | all, ...)
```

Selects the specified columns (or all columns) in the data table.

```
dt<<Select Duplicate Rows
```

Selects the second and subsequent duplicate rows. If columns are selected, duplicate values are found in the rows of those columns. The duplicate values are case sensitive.

See the Data Tables chapter in the *Scripting Guide* for examples.

```
dt<<Select Excluded
```

Selects only those rows in the data table that are currently excluded.

```
dt<<Select Hidden
```

Selects only those rows in the data table that are currently hidden.

```
dt<<Select Labeled
```

Selects only those rows in the data table that are currently labeled.

```
dt<<Select Randomly(p|n)
```

Randomly selects the given percentage *p* of the rows in the data table, or the number of rows *n*.

```
dt<<Select Rows({list})
```

Selects the rows given in the list of row numbers.

```
dt<<Select Script Group(<name|{group1, group2, ...}>)
```

Selects a table script group. If no argument is provided, all groups are selected.

```
dt<<Select Where(condition)
```

Selects the rows in *dt* where the condition evaluates as true.

```
dt<<Set Dirty(Boolean)
```

Marks the data table as changed, even if no changes have been made.

```
dt <<Set Edit Lock(<"modify cells">, <"add rows">, <"add columns">,
<"delete rows">, <"delete columns">)
```

Prevents cells from being modified; rows from being added or deleted; and columns from being added or deleted. See the Data Tables chapter in the *Scripting Guide* for examples.

```
dt <<Set Cell Height(num)
```

Sets the cell height to the specified number of pixels.

```
dt<<Set Header Height(num)
```

Sets the column header's height to the specified number of pixels.

```
dt<<Set Label Columns(column_1, ...)
```

Assigns the specified columns as label columns.

```
dt<<Set Matrix(matrix)
```

Inserts matrix into a data table, adding new columns and rows as necessary.

```
dt<<Set Name("name")
```

Description

Gives a *"name"* to the table.

Returns

The data table name as a string.

Notes

A change was made to the Set Name message so that now the new table name is returned as a string. In previous releases, Set Name returned a scriptable data table object. As a result of this change, JMP scripts might need to be updated for the desired result to be returned. For example, rewrite the following script:

```
dt = Open( "$SAMPLE_DATA\Big Class.jmp" ) << Set Name( "Test" );
```

Separate the messages so that *dt* represents the data table instead of "Test":

```
dt = Open( "$SAMPLE_DATA\Big Class.jmp" );
dt << Set Name( "Test" );
```

The result is the same as in previous releases but will run successfully in both earlier and newer versions of JMP.

```
dt<<Set Property("name", script)
```

See "dt<<New Script("name", script)" on page 358.

```
dt<<Set Label Columns("name", ...)
```

```
dt<<Set Label Columns
```

Turns on the Label attribute for the specified columns. If no columns are listed, turns Label attribute off.

```
dt<<Set Row ID Width(expr)
```

Sets the row ID display width to the expr in pixels.

```
dt<<Set Row States(matrix)
```

Sets the row states for all rows in the data table.

```
dt<<Set Scroll Lock Columns("name", ...)
```

Locks scrolling for the specified columns. If no columns are listed, unlocks scrolling.

```
dt<<Set Table Variable("name", value)
```

See "dt<<New Table Variable("name", value)" on page 358.

```
dt<<Sort(By(columns), order("Descending" or "Ascending"), Output
Table Name("name"))
```

Description

Creates a new table (*"name"*) by rearranging the rows of *dt* according to the values of one or more *columns*.

Returns

A reference to the sorted table.

```
dt<<Split (Split(column), Split by(column), Group(column), <Private>
| <Invisible>, <Remaining Columns(Keep All | Drop All |
Select(columns))>, <Copy formula(0|1)>, <Suppress formula
evaluation(0|1)>, <Sort by Column Property("Value Ordering" {"string",
"string"} | "Row Order Levels")>, <Output Table ("name")>)
```

Description

Un-stacks multiple rows for each Split column into multiple columns as identified by the Split by column. The Split and Split by arguments are required.

Returns

A reference to the split data table.

```
dt<<Stack(Stack(columns), ID(columns), Stacked(newcol), Output Table
Name("name"))
```

Description

Creates a new table (*"name"*) by combining the values from several columns in *dt* into one column *newcol*.

Returns

A reference to the stacked data table.

```
dt<<Subscribe( "keyname"(<"client">), On Delete Columns | On Add
Columns | On Add Rows | On Delete Rows | On Rename Column | On Close
| On Save | On Rename ( function ) )
```

Description

Subscribes to a data table to get messages regarding changes in the data table.

Returns

The name of the data table as a string.

```
dt<<Subset(Columns(columns), Rows(matrix), Linked, Table
Name("name"), Copy Formula(1|0), Suppress Formula Evaluation(1|0),
Sampling Rate(rate))
```

Description

Creates a new table (*"name"*) from the rows that you specify in *dt*.

Returns

A reference to the subset data table.

```
dt<<Summary(<Private>, <Invisible>, Group(column), Subgroup(column),
<N>, <Mean(column)>, <Std Dev(column>, <Min(column)>, <Max(column)>,
<Range(column)>, <Sum(column)>, <CV(column)>, Freq(<freq column>),
Weight(<weight column>), Include marginal statistics, Link to
original data table(0), statistics column name format("stat(column)"
| "column" | "stat of column" | "column stat")
```

Description

Creates a new table of summary statistics for the *col* that you specify, according to groups and subgroups.

Returns

A reference to the summary data table.

```
dt<<Suppress Formula Eval(Boolean)
```

Turns off automatic calculation of formulas for data table *dt*.

```
dt<<Text to Columns(Delimiters( <"separator">, <TAB>, <NEWLINE>),
Columns(column 1, column 2...))
```

Makes a set of text columns or indicator columns from a delimited text column. NEWLINE includes the three forms \r, \n, and \r\n.

Example

```
 dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
 dt << Text To Columns(
   delimiter( "," ),
   columns( :Brush Delimited )
 );
```

```
dt<<Transpose(Columns(columns), Rows(matrix), Output Table
Name("name"))
```

Description

Creates a new table (*"name"*) from the rows and columns that you specify.

Returns

A reference to the transposed data table.

```
dt<<Ungroup Columns({col1, col1, ...})
```

Ungroups the columns defined in the list argument.

```
dt<<Ungroup Scripts("name of script group"|{script1, script2,...})
```

Removes the specified table scripts or group from the group. See the Data Tables chapter in the *Scripting Guide* for examples.

```
dt<<Unsubscribe("keyname", On Delete Columns | On Add Columns | On
Add Rows | On Delete Rows | On Close | On Col Rename | All)
```

Releases any previous subscriptions to the data table.

```
dt<<Update from Database
```

Updates the data in the table with data reimported from the database.

Columns

```
col<<Add Column Properties ("name", expression)
```

Adds the property *"name"* with the *expression* given. You can add any standard column property by name or a user-specified property.

`col<<Add From Row States`

Updates a row state column with any currently used row state changes that are not the default state.

`col<<Add To Row States`

Copies all row state values in a column that are not the default state to the currently used row state in the data table.

`col<<Color Cells("color")`

Colors the cells of the column within the data table grid. Use any quoted named color or 0 to clear the color.

`col<<Color Cell by Value(Boolean)`

Colors the cells of the column in the data table grid using the value color property.

`col<<Copy Column Properties`

Copies the column properties into the buffer.

`col<<Copy From Row States`

Copies all row state values currently used in the data table to a column.

`col<<Copy to Row States`

Copies all row state values in the column to the currently used row state in the data table.

`col<<Data Type("type", <Format("format string")>, <Input Format("format string")>, <width>)`

`col<<Set Data Type("type", <Format("format string")>, <Input Format("format string")>, <width>)`

Description

Sets the *"type"* for *col*; choices are "Numeric", "Character", "Rowstate", or "Expression".

Arguments

type Specifies the "Numeric", "Character", "Row State", or "Expression" data type.

Format (Optional) Specifies the way the data are formatted, such as h:m for hours and minutes.

Input Format (Optional) Specifies the way the data are displayed, such as h:m.

width (Optional for numeric data) Specifies 1, 2, or 4 (the number of bytes in the column).

col<<Delete Formula

Deletes the formula from a column.

col<<Delete Property(name)

col<<Delete Column Property(name)

Deletes the property name from a column.

col<<Eval Formula

Forces the formula to evaluate (perhaps again). If formula suppression is enabled, the evaluation is not performed.

col<<Exclude(0|1)

Turns the excluded or unexcluded state on, depending on the Boolean argument.

```
col<<Format(<width>, <decimal places>, <"Use thousands separator">)
```

```
col<<Format("Best", <width>, <"Use thousands separator">)
```

```
col<<Format(("Fixed Dec"|"Percent"), <width>, <decimal places>, <"Use
thousands separator">)
```

```
col<<Format("Pvalue", <width>)
```

```
col<<Format(("Scientific"|"Engineering"|"Engineering SI"), <width>,
<decimal places>)
```

```
col<<Format("Precision", <width>, <decimal places>, <"Use thousands
separator">, <"Keep trailing zeroes">, <"Keep all whole digits">)
```

```
col<<Format("Currency", <"currency code">, <width>, <decimal places>,
<"Use thousands separator">);
```

```
col<<Format("Datetime", <width>, <input format>)
```

```
col<<Format(("Latitude DDD"|"Latitude DDM"|"Latitude DMS"|"Longitude
DDD"|"Longitude DDM"|"Longitude DDM"), <width>, <decimal places>,
("PUN"|"DIR"|"PUNDIR"))
```

```
col<<Format("Custom", Formula(...), <width>, <input format>)
```

Description

Sets the numeric display specified format.

Arguments

See The Column Info Window chapter in the *Using JMP* book for details about the
arguments.

Examples

```
<<Format( 10, 2, "Use thousands separator");
<<Format( "Currency", "EUR", 20 );
<<Format( "m/d/y", 10 );
<<Format( "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole digits"
    );
<<Format( "Latitude DDD", "PUNDIR"); // "PUN" for punctuation, "DIR" for
    direction, PUNDIR for both
<<Format( "Custom", Formula( Abs( value ) ), 15 );
```

Notes

For a list of currency codes, see the Types of Data chapter in the *Scripting Guide*. The
currency code is based on the locale if the code is omitted.

`col<<Formula(expression)`

`col<<Set Formula(expression)`

Sets the formula for the variable and evaluates it.

`col<<Get Column Field Width`

Returns the field width used for displaying data in the column.

`col<<Get Data Type`

Returns the data type of *col*.

`col<<Get Data Type Length`

Returns the data type and length of the data column. Only the data type is returned if the
data length is not fixed, as with character columns.

`col<<Get Format`

Returns the format of the column.

`col<<Get Formula`

Returns the formula.

col<<Get Hidden

Returns 1 if the column is hidden.

col<<Get Input Format

Returns the format used for input and storing of data for the column.

col<<Get Labeled

Returns 1 if the column is labeled.

col<<Get List Check

Returns the list check definition. If list check is not defined for the column, a message is sent to the log stating so.

col<<Get Lock

Returns the current Lock setting.

col<<Get Modeling Type

Returns the modeling type of the column.

col<<Get Name

Returns the name of the column.

col<<Get Property

Returns the specified property definition. If the specified property is not defined for the column, a message is sent to the log stating so.

col<<Get Range Check

Returns the range check definition. If range check is not defined for the column, a message is sent to the log stating so.

col<<Get Role

Returns the preselected role of *col*.

col<<Get Script

Returns the script to reproduce the column.

col<<Get Scroll Locked

Returns 1 if the column is scroll locked.

col<<Get Selected

Returns 1 if the column is selected, or 0 otherwise.

col<<Get Stored Values

Returns the values in the columns without considering the Missing Value Codes column property.

col<<Get Value Labels

Returns the value labels definition. If value labels is not defined for the column, a message is sent to the log stating so.

col<<Get Use Value Labels

Returns 1 if the value labels are set to be used for the column, or 0 otherwise.

col<<Get Values

Returns the values in the column.

col<<Hide(Boolean)

Turns the Hide attribute on or off according to the Boolean argument given.

col<<Ignore Errors

Ignores formula evaluation errors in a column, and sets the cell value to missing when a formula error occurs.

col<<Input Format("format")

Sets the format used for input and storage for the column. The argument is the name of any JMP format (for example, "ddmmyyyy" for a date column).

date_col<<Is Transformed On SAS Export

Returns true if the data in the resulting SAS data set for the date column will be changed when it is exported to SAS.

```
col<<Label(Boolean)
```

Turns the Label attribute on or off according to the Boolean argument given.

```
col<<Lock(Boolean)
```

```
col<<Set Lock(Boolean)
```

Turns the Lock attribute on or off according to the Boolean argument given.

```
col<<Preselect Role("role")
```

Preselects the role for the column. Choices are "Y", "X", "Weight", "Freq", and "None", or "No Role".

```
col<<Set Display Width(n)
```

Sets the column display width to the n in pixels.

```
col<<Set Each Value(n)
```

Sets all the values in the column to *n*.

```
col<<Set Excluded
```

Excludes the column.

```
col<<Set Field Width(n)
```

Sets the field width for the column to *n*.

```
col<<Set Hidden
```

Hides the column.

```
col<<Set Labelled
```

Uses the column's data values for labels.

```
col<<Set Modeling Type("type")
```

Sets the modeling type for the variable. Choices are "Continuous", "Ordinal", "Nominal", "None", "Row State", "Unstructured", "Multiple Response", or "Vector".

```
col<<Set Name("name")
```

Sets the name for the column.

col<<Set Property ("name", {argument list})

Sets the property *"name"* to the *expression* given. You can set any standard column property by name or a user-specified property.

Examples

The following example adds the Value Colors column property to the sex column, with pink for females and blue for males.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "sex" ) << Set Property( "Value Colors", {"F" = 78, "M" = 69} );
```

The following example adds a custom column property named *Date recorded* to the height column.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "height" ) << Set Property( "Date recorded", 05Jan1990 );
```

Notes

The Data Tables chapter in the *Scripting Guide* provides more examples. See The Column Info Window chapter in the *Using JMP* book for details about each property.

col<<Set Scroll Locked(Boolean)

Turns the Scroll Lock attribute on or off according to the Boolean argument given.

col<<Set Selected(Boolean)

Sets the column to be selected (true or 1) or not selected (false or 0).

col<<Set Use for Marker

col<<Use for Marker

Uses the values in the column as markers in graphs. Designed to use with expression columns and character columns that have IDs. In the Big Class Families.jmp sample data table, the picture column is specified to use as markers in graphs. Not supported in Bubble Plot.

col<<Set Values([matrix] or {list})

col<<Values([matrix] or {list})

Sets values for the matrix (for numeric variables) or list (for character variables).

col<<Suppress Eval(Boolean)

Turns off automatic calculation of formulas for the column.

```
col<<UseForMarker(Boolean)
```

Uses the values in the column as markers in graphs or turns off the option. Designed to use with expression columns and character columns that have IDs. In the Big Class Families.jmp sample data table, the picture column is specified to use as markers in graphs.

Rows

```
row<<Colors(n)
```

Assigns the color *n* to the selected rows.

```
row<<Exclude(0|1)
```

```
row<<Unexclude(0|1)
```

Turns the excluded or unexcluded state on for the selected rows according to the Boolean argument given. Omit the argument to toggle the row state.

```
row<<Hide(0|1)
```

```
row<<Unhide(0|1)
```

Turns the Hide attribute on or off according to the Boolean argument given. Omit the argument to toggle the row state.

```
row<<Hide and Exclude
```

Hides the selected rows from appearing on graphs and excludes them from contributing to calculations.

```
row<<Label(0|1)
```

```
row<<Unlabel(0|1)
```

Turns the Label attribute on or off according to the Boolean argument given. Omit the argument to toggle the row state.

```
row<<Markers("marker")
```

Assigns the "*marker*" to the selected rows.

```
row<<Next Selected
```

Causes the next selected row in the data table to blink.

---
row<<Previous Selected

Causes the previous selected row in the data table to blink.

---
row<<Row Editor

Opens the Row Editor window for the selected rows.

Data Filter

---
dtf<<Add Favorites(name|string)

Description

Associates the current filter selection with the specified name and saves it in the Favorites list.

Returns

The favorite as a string.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Add Filter(
        Columns( :age, :sex, :height, :weight ),
        Where( :sex == "F" ),
        Where( :height >= 55 & :height <= 65 )
    ),
    Mode( Select )
);
Wait( 1 ); // for demonstration purposes
fav1 = df << Add Favorites( "Female Average Ht" );
```

---
dtf<<Add Filter(columns(column <,col>), <Where(clause)>)

Add one or more filter columns in a new OR group.

---
dtf<<Auto Clear(0|1)

Clears all currently selected rows before setting a new selection.

---
dtf<<Clear

Clears the currently selected rows.

```
dtf<<Close
```

Closes the data filter window.

```
dtf<<Columns(col1, col2, ...)
```

Sets the columns to use in the data filter.

```
dtf<<Data Table Window
```

Shows the data table that the data filter window is using.

```
dtf<<Delete All
```

Removes all filters that are set.

```
dtf<<Delete(col1, col2, ...
```

Removes the specified columns from the data filter.

```
dtf<<Display(col, <Size(x, y)>, "Blocks Display"|"List
Display"|"Single Category Display"|"Checkbox Display")
```

Sets how the specified categorical column levels are displayed in the filter. The specified column must be categorical.

```
dtf<<Get Script
```

Returns the data filter script as text in the log.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Add Filter( Columns( :age, :sex ), Where( :age == 12 ) )
);

txt = df << Get Script;
Show( txt );
```

```
dtf<<Local Data Filter
```

Embeds the data filter in the specified window.

```
dtf<<Location(x, y)
```

Moves the data filter window to the specified location. X and y are measured in pixels. 0,0 is the top left of the monitor.

dtf<<Make Filter Change Handler(Function(a))

Returns the number of rows that are filtered in the data filter. The number of filtered rows is returned in the argument to Function().

Example

```
dist = Distribution( Automatic Recalc( 1 ), Continuous Distribution( Column(
    :POP ) ) );
filter = dist << Local Data Filter( Add Filter( Columns( :Region ) ) );
f = Function( {a}, Print( a ) );
rs = filter << Make Filter Change Handler( f );
```

dtf<<Make Subset

Creates a new subset data table that contains the rows that are selected in the data filter.

dtf<<Match(Filter Columns(:col1, :col2, ...), Where(WHERE clause)

Sets the filter conditions for each column. The WHERE clause is used for all the columns listed. To use different WHERE clauses for different columns, send the Match message separately for each column.

dtf<<Mode(Select(0|1)|Show(0|1)|Include(0|1))

Sets the action, or mode, that is used when rows are selected using the data filter.

dtf<<Save and restore current row states

Saves the current row states for the data table, and then restores those states when the data filter is closed.

dtf<<Show Columns Selector(0|1)

Displays or hides the column selector after completing a filter.

dtf<<to Clipboard

Creates a WHERE clause from the current state of the data filter and places it on the clipboard, where it can be pasted elsewhere.

dtf<<to Data Table

Creates a WHERE clause from the current state of the data filter and saves it as a property to the data table.

dtf<<to Journal

Creates a WHERE clause from the current state of the data filter and appends it to the current journal. If there is no current journal, a new journal is opened and the WHERE clause is added to it.

dtf<<to Row State Column

Creates a row state column whose formula is the WHERE clause.

dtf<<to Script Window

Creates a WHERE clause from the current state of the data filter and appends it to the current script window. If there is no current script window, a new script window is opened and the WHERE clause is added to it.

dtf<<Use Floating Window(0|1)

Sets whether the data filter window floats on top of its associated data table or behaves as a normal window.

dtf<<Where(WHERE clause)

Sets a condition for selecting rows.

Databases

dt<<Save Database("connectInfo", "TableName")

Saves a data table to a database.

Data Feed (Windows Only)

feed<<Close

(Windows only) Closes the data feed object and its window.

feed<<Connect(portSettings)

(Windows only) Sets up port settings for the connection to the device.

feed<<Disconnect

(Windows only) Disconnects the device from the data feed queue but leaves the data feed object active.

feed<<EOL("CR", "LF", "CRLF")

(Windows only) Sets the line ending value used as a separator when parsing incoming lines of data. The value is also used as the terminator in outgoing lines of data.

- – CR: ASCII character 13 (carriage return)
- – LF: ASCII character 10 (line feed)
- – CRLF: Uses both CR and LF in sequence.

feed<<Get Line

(Windows only) Returns and removes one line from the data feed queue.

feed<<Get Lines

(Windows only) Returns as a list and removes all lines from the data feed queue.

feed<<Print Queue

(Windows only) Prints the internal queue of messages to the log window.

feed<<Queue Line(string)

(Windows only) Sends one line to the end of the data feed queue. Queue Line is primarily useful for testing your script without requiring it to be attached to a device. You can essentially simulate the data coming from the device to make sure the rest of your code handles the values properly when it's really attached to a working device.

feed<<Restart

(Windows only) Restarts processing queued lines.

feed<<Set Script(script)

(Windows only) Assigns the *script* that is run each time a line of data is received.

feed<<Stop

(Windows only) Stops processing queued lines.

```
feed<<Write("string")
```

Description

(Windows only) Sends a string to the data feed device.

Example

```
exfeed = Open Datafeed(
   Connect( Port( "com1" ), Baud rate( 4800 ), Parity( even ), DataBits( 8 ) ),
   Set Script(
      ex = exfeed << Get Line;
      Show( ex );
   )
);
exfeed << Write( "Ready" );
/* Example - send a message to external device over the serial port to trigger
   data messages. This can be used to send control messages to a sensor or
   other attached device.*/
```

```
feed<<Write Line("string")
```

Description

(Windows only) Sends a string to the data feed device. If EOL has been set for the data feed, the strings are terminated by the specified EOL value. If EOL has not been set, the line is terminated with CRLF.

Example

```
exfeed = Open Datafeed(
   Connect( Port( "com1" ), Baud rate( 4800 ), Parity( even ), DataBits( 8 ) ),
   Set Script(
      ex = exfeed << Get Line;
      Show( ex );
   )
);
exfeed << Write Lines( "Ready" );
/* Example - send a message to external device over the serial port to trigger
   data messages. This can be used to send control messages to a sensor or
   other attached device.*/
```

```
feed<<Write Lines({"string1", "string2", "string3"})
```

Description

(Windows only) Sends a list of strings to the data feed device. If EOL has been set for the data feed, the strings are terminated by the specified EOL value. If EOL has not been set, the line is terminated with CRLF.

Example

```
exfeed = Open Datafeed(
```

```
      Connect( Port( "com1" ), Baud rate( 4800 ), Parity( even ), DataBits( 8 ) ),
      Set Script(
         ex = exfeed << Get Line;
         Show( ex );
      )
);
exfeed << Write Lines( {"Ready", "Set", "Go"} );
/* Example – send a message to external device over the serial port to trigger
   data messages. This can be used to send control messages to a sensor or
   other attached device.*/
```

Display Boxes

For additional examples, see the Display Trees chapter in the *Scripting Guide* and the JMP Scripting Index.

All Display Boxes

`db<<Add Text Annotation(Text("string"), Text Box(<x1, y1, x2, y2>))`

Draws a text annotation box at the specified pixel location that contains the string. The Text Box argument controls where the text annotation box is drawn in the window, from the upper left corner to the lower right corner.

Note that x1, y1, x2, and y2 are not graph axis values but the specific pixel locations in the window. Exactly where the text box appears depends on the user's window size, display resolution, and so on.

`db<<Append(db2)`

Adds *db2* as the last child of the *db*.

`db<<Child`

Returns the child of the box.

`db<<Class Name`

Returns the name of the display class for the box.

`db<<Clone Box`

Makes a new copy of the display box.

db<<Close Window

Closes the containing window.

db<<Copy Picture

Puts a picture of the box on the clipboard.

db<<Delete

Deletes the display box.

db<<Enable(Boolean)

Controls the ability to interact with the display box. 0 disables the display box. 1 enables the display box.

db<<Get HTML

Returns a string containing HTML source for the box.

db<<Get Journal

Returns a string containing journal source for the box.

db<<Get Menu Item State(index)

Returns the popup menu item state of the index menu item. The state can be normal (0), checked (1), or disabled (-1).

db<<Get Menu Items

Returns the menu items used for popup menu when the button is clicked. For submenus see <<Get Submenu(index). Menu items are returned in a list.

db<<Get Menu Script

Returns the menu script attached to the calling object.

db<<Get Page Setup()

Returns the page setup settings.

Example

The example below creates a new window and returns the page setup configuration.

```
w = New Window( "Window",
    Text Box( "Page Setup Test" )
```

```
  );
 w << Get Page Setup();
```

The results of the message:

```
    {Margins( {0.75, 0.75, 0.75, 0.75} ), Scale( 1 ), Portrait( 1 ),
    Paper Size( "Letter" )}
```

---

db<<Get Picture(<Scale(*n*)>)

Captures *db* as a picture object. The scale is a factor of the original picture size. For example, Scale(2) makes the picture object twice as large.

---

db<<Get RTF

Returns a string containing RTF source for the box.

---

db<<Get Script

Returns the script for recreating the display box.

---

db<<Get Size

Returns either { x, y } or { h, v } in pixels:

```
 xy = DisplayBox << Get Size;
```

Returns x and y in pixels:

```
 { x, y } = DisplayBox << Get Size;
```

---

db<<Get Submenu (index)

Returns the number of submenu items under the given menu item.

Example

The example below creates a menu containing "A", "B", and "C" with "A" having a submenu "A1" and "A2" and "B" having a submenu "B1", "B2", and "B3". <<Get Submenu(inc) returns the number of submenu items under each indexed menu item.

```
 New Window( "Title",
 obj = Outline Box( "title" ) );
 submenus = { };
 obj << Set Menu Script(
    {"A", "", "A1", Print( "A1" ), "A2", Print( "A2" ),
    "B", "", "B1", Print( "B1" ), "B2", Print( "B2" ), "B3", Print( "B3" ),
    "C", Print( "C" )}
 );
 obj << Set Submenu( 1, 2 ); // menu A with 2 items in submenu A1 and A2
 obj << Set Submenu( 4, 3 ); // menu B with 3 items in submenu B1, B2, and B3
 For( inc = 1, inc <= N Items( Words( obj << Get Menu Script, "," ) ), inc++,
```

```
    Insert Into( submenus, obj << Get Submenu( inc ) );
  );
  submenus;
    {2, 0, 0, 3, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0}
```

The log output indicates that index(1) contains two submenu items and index(3) contains three submenu items.

db<<Get Text

Returns a string containing the text of the box.

db<<Horizontal Alignment("position")

Aligns a child display box inside the display parent box according to the specified *position*. The default value is left, or you can specify center or right.

Example

```
New Window( "Example",
  Outline Box( "Parent display box",
    Button Box( "OK", <<Horizontal Alignment( "Center" ) )
  )
);
```

db<<Inval

Invalidates the display box area in the window. The window is updated the next time the operating system has an opportunity to update windows (for example, when the user resizes the display box).

Notes

Consider including the message <<Update Window rather than including Wait(0). The problem with using Wait(*n*) is knowing how large *n* should be.

Many display box messages, such as <<Set Text, automatically mark the box as invalid, so the <<Inval message is usually unnecessary. Some interactive scripts that use sliders with JSL callbacks may need <<Update Window to keep various parts of the display synchronized with the slider.

db<<Is Enabled

Returns the enabled state of the control. The message is supported in Busy Light Box(), Button Box(), Calendar Box(), Check Box(), Col List Box(), Combo Box(), Completion Box(), Filter Col Selector(), gtext(), List Box(), Number Edit Box(), Popup Box(), Radio Box(), Range Slider Box(), Slider Box(), Spin Box(), Text Edit Box(), Tree Box(), Tree Map Box(), and Tree Map Seg().

```
db<<Journal
```

Appends the box to the journal.

```
db<<Journal Window
```

Appends the containing window of the display box to the journal; compare with Journal.

```
db<<Move Window(x, y)
```

Moves the window to the (x,y) location on your screen.

```
db<<Page Break
```

Inserts a page break before the box.

```
db<<Parent
```

Returns the parent of this display box.

```
db<<Prepend(db2)
```

Add *db2* to the display tree before *db*.

```
db<<Reshow
```

Invalidates the display box's area in the window and immediate removes invalid areas from the window.

```
db<<Save Capture("path", <"format">, <Add Sibling(n)>)
```

Saves the display box as a graphic to the specified "*path*" in the specified "*format*". The optional Add Sibling argument adds the number of sibling display boxes to include in the capture. The default value is 1, which captures only the specified display box. Note that the specified portion of the report is not guaranteed to be scrolled into view or unobstructed by other windows. If the display box is not visible, the saved graphic will not contain the contents that you expect.

```
db<<Save HTML("" | "path", "format")
```

Saves HTML source and folder of graphics in "*format*" specified.

```
db<<Save Interactive HTML( "path" )
```

Saves the display box as a web page that includes interactive HTML features. Non-JMP users can then explore the data.

Examples

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( weight ), x( height ) );
rbiv = (biv << Report);
rbiv << Save Interactive HTML( "$DOCUMENTS/MyInteractiveHTML.htm" );
```

db<<Save Journal("" | "path")

Saves journal source for the box.

db<<Save MSWord("pathname", Native)

Saves the display box as a Microsoft Word document. (Windows Only)

db<<Save PDF(<"pathname">, <Show Page Setup(Boolean)>, <Portrait(Boolean)>)

Description

Saves a PDF of the display box.

Optional Arguments

pathname   The path and file name. If the argument is omitted, you are prompted for a file name.

Show Page Setup(Boolean)   Windows only) Displays the Page Setup window, where you can specify page orientation, headers and footers, margins, page scale, and paper size.

Portrait(Boolean)   Displays the content in portrait or landscape orientation.

Note

The PDF file contains headers and footers. Use Save Picture to omit these components.

db<<Save Picture("" | "pathname", "format")

Description

Saves a picture of the display box.

Notes

- If no argument is provided, the user is prompted to save the file.
- Valid file formats include PDF, PNG, GIF, JPG or JPEG, and EMF.
- On Windows, the Windows Specific preferences determine the resolution (or DPI), or you can run the following script:

  `Pref( Save Image DPI( <number> ) );`

- On Macintosh, the operating system determines the DPI.

- Use `Save Picture` to export a report as a PDF file with no headers or footers. Use `Save PDF` to include these components.

```
db<<Save Presentation("path", <template("path")>,
<(Insert("Begin"|"End"|N) | Replace("Begin"|"End"|N) | "Append")>,
<Outline
Titles("None"|"Hide"|"TopLeft"|"TopRight"|"BottomLeft"|"BottomRight"
)>, <format>)
```

Saves display boxes in a Microsoft PowerPoint presentation. You can open the file in any presentation software program.

Arguments

path The quoted location of the saved file. You must include the .pptx extension in the filename. An existing file with the same name is overwritten.

template Optional. The quoted path name and file name of a custom PowerPoint template. Without this argument, JMP uses the default template located in the pptx folder of the installation directory.

Include a simple table in your template, or a default table format is applied to report tables. For an example on Windows, see /**pptx/JMPExportTemplate.pptx** in the JMP installation folder.

Insert Optional. Determines where the slides are inserted in an existing presentation.

- *n* inserts the slides as the *n*th slide number.
- "Begin" inserts the slides at the beginning of the presentation.
- "End" inserts the slides at the end of the presentation.

Replace Optional. Determines which slides are replaced in an existing presentation. The arguments are *n*, "Begin", and "End" as described for `Insert`.

Append Optional. The slides are inserted at the end of an existing presentation.

Outline Titles Optional. The location of the outline titles on the slide. By default, outline titles appear in the bottom left corner of the slide.

- "None" omits the slide title above the graphic and the outline titles.
- "Hide" omits the outline titles.
- "TopLeft", "TopRight", "BottomLeft", "BottomRight" determine the position of the outline titles on the slide. The outline title and its parent titles are included.

format Optional. The quoted format of the embedded graphics. Options are "Native", "EMF", "PNG", "JPG", "BMP", "GIF", "TIF". On Windows, the native format is EMF. On Macintosh, the native format is PDF. See "Notes" for compatibility issues. Without this argument, JMP applies the "Image Format for PowerPoint" General preference.

Notes

Windows does not support the native PDF graphics produced on Macintosh. Macintosh does not support the native EMF graphics produced on Windows. For cross-platform compatibility, specify `"PNG"`, `"JPG"`, `"GIF"`, or `"TIF"`.

```
db<<Save RTF("" | "pathname", "format")
```

Saves RTF source with graphics in "*format*" specified.

```
db<<Save Text("" | "pathname", "format")
```

Saves a file containing the text of the box.

```
db<<Scroll Window(Display
Box|relative-vertical-pixels|relative-horizontal-pixels,
relative-vertical-pixels|{absolute-vertical-pixels,
absolute-horizontal-pizels})
```

Scrolls the containing window.

```
db<<Select
```

```
db<<Deselect
```

Selects (highlights) or deselects the box.

```
db<<Set Menu Item State(index, 0 | 1 | -1)
```

Sets the popup menu item at index to be normal (0), selected (1), or disabled (-1).

```
db<<Set Page Setup<margins(left, right, top, bottom)>,
<scale(s)>,<portrait(Boolean)>, <paper size("paper"))
```

```
db<<Set Page Setup<margins({left, right, top, bottom})>,
<scale(s)>,<portrait(Boolean)>, <paper size("paper"))
```

Sets the page settings. Margins are set in inches. Scale variable *s* is a number in the range of 10 (for 1000%) to 0.2 (for 20%) with the default as 1 (for 100%). If portrait is True the page is oriented for portrait, otherwise the page is landscape. Paper size is a string specifying the paper size, for example, "Letter" or "Legal".

Example

The example below creates a new window and configures the page setup.

```
w = New Window( "Window",
  Text Box( "Page Setup Test" )
);
w << Set page setup(
```

```
    margins( 1, 1, 1, 1 ),
    scale( 1 ),
    portrait( 1 ),
    paper size( "Letter" )
);
```

---

db<<Set Print Headers(left header, center header, right header)

Description

Sets the left, center, and right header for PDF output.

Example

```
w = New Window( "Window", Text Box( "Header Example" ) );
w << Set Print Headers(
    "Today is: &d;" // left,
    "&wt;" // center,
    "Page &pn; of &pc;" // right
);
w << Print Window;
```

---

db<<Set Print Footers(left footer, center footer, right footer)

Description

Sets the left, center, and right footer for PDF output.

Example

```
w = New Window( "Window", Text Box( "Footer Example" ) );
w << Set Print Footers(
    "Today is: &d;" // left,
    "&wt;" // center,
    "Page &pn; of &pc;" // right
);
w << Print Window;
```

---

db<<Set Submenu (index, submenu count)

Description

Sets the submenu items for the item (specified by index number) by specifying the number
of items in the submenu.

Example

The example below creates a menu containing "A", "B", and "C" with "A" having a
submenu "A1" and "A2" and "B" having a submenu "B1", "B2", and "B3".

```
New Window( "title", ob = Outline Box( "title" ) );
ob << Set Menu Script(
    {"A", "", "A1", Print( "A1" ), "A2", Print( "A2" ),
    "B", "", "B1", Print( "B1" ), "B2", Print( "B2" ), "B3", Print( "B3" ),
```

```
      "C", Print( "C" )}
);
ob << Set Submenu(1, 2); // menu A with 2 items in submenu A1 and A2
ob << Set Submenu(4, 3); // menu B with 3 items in submenu B1, B2, and B3
```

db<<Set Report Title("title")

Sets a new title.

Show Properties(db)

Shows the messages a given display box can interpret.

db<<Sib

Returns the sibling of the box.

db<<Sib Append(db2)

Appends a display as a sibling to this one. The argument must evaluate to a display box owner or reference.

db<<Size Window(x, y)

Resizes the containing window.

db<<Update Window

Updates the window that holds the display box (and possibly other windows as well, depending on the operating system) if there are invalidated regions. Previously invalidated box areas are redrawn with their new content.

Notes

In some interactive JSL scripts that combine sliders with JSL callbacks, you might need to use <<Update Window to keep parts of the display synchronized with the slider.

db<<Zoom Window

Resizes the window to be large enough to show all of its contents.

Axis Boxes

`axis box<<Axis Settings(<named_arguments>)`

Opens the axis specification window or specifies axis settings such as tick marks and axis labels.

If no arguments are included, the axis specification window appears.

Otherwise, specify named arguments for each axis.

– Specify the Y axis as `axis box(1)`.

– Specify the X axis as `axis box(2)`.

The following example creates a bivariate plot and defines settings for the X and Y axes.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( X( :height ), Y( :weight ), FitLine );
rbiv = biv << Report;
xaxis = rbiv[axis box( 2 )];
yaxis = rbiv[axis box( 1 )];
xaxis << Axis Settings( Show Major Grid( 1 ) );
yaxis << Axis Settings( Decimal( 10, 3 ) );
```

`axis box<<Add Axis Label("string")`

Adds an axis label with the specified string.

`axis box<<Add Ref Line(number, "linestyle", <"color">, <"label">, <width>)`

Adds a reference line at *number* in the *linestyle* ("Solid" | "Dashed" | "Double"), "*color*" (using "*color name*" or *index number*), "*label*", and *width* (in pixels) specified. **Note:** When a reference line is added that uses the same "*label*" as an existing reference line, the existing reference line is removed and the new line added.

`axis box<<Decimal(width, decimal places)`

Changes the numeric format for axis values.

`axis box<<Format("name")`

Changes to the numeric format given by *"name"*.

`axis box<<Get Inc(n)`

Gets the increment value of the axis.

```
axis box<<Inc(n)
```

Sets the increment between ticks.

```
axis box<<Interval("format")
```

Specifies the units used for Inc() with date/time formats: "Numeric", "Year", "Quarter", "Month", "Week", "Day", "Hour", "Minute", or "Second".

```
axis box<<Label Orientation("format")
```

Description

Rotates the axis label to one of the following quoted formats: "Automatic" (based on the width of the label), "Horizonal", "Vertical", "Perpendicular", "Parallel", and "Angled".

```
axis box<<Major Grid Line Color("color")
```

Sets the color for the major grid (if enabled) using either the "*color name*" or index number.

```
axis box<<Max(max)
```

Changes the maximum value on the axis.

```
axis box<<Minor Grid Line Color("color")
```

Sets the color for the minor grid (if enabled) using either the "*color name*" or index number.

```
axis box<<Min(min)
```

Changes the minimum value on the axis.

```
axis box<<Minor Ticks(number)
```

Specifies the *number* of minor tick marks between major tick marks.

```
axis box<<Remove Axis Label
```

Removes any label added with Add Axis Label.

```
axis box<<Reverse Scale(Boolean)
```

Reverses the normal scale direction so that the highest value is on the left or bottom (that is, closest to the origin).

`axis box<<Revert Axis`

Restores the axis' original settings (from time of creation).

`axis box<<Scale("type")`

Changes the scale of the axis to *type* (`"Linear"` | `"Log"` | `"Exp Prob"`| `"Weibull Prob"` | `"Logistic Prob"` | `"Frechet Prob"` | `"Normal"` | `"Cube Root"` | `"Johnson Su Scale"` | `"Geodesic"` | `"Geodesic US"` | `"Custom Scale"` | `"Power"`).

If the type is `Custom Scale`, this message expects two additional clauses: `Scale to Internal(expr)` and `Scale to External(expr)`.

`axis box<<Tick Font("name", <size>, <"style" | "style style...">, "<angle>")`

Sets the font name and properties for tick marks. To specify more than one style, include a space between each style and place them in quotes.

`axis box<<Show Labels(Boolean)`

Shows or hides labels for the axis values.

`axis box<<Show Major Grid(Boolean)`

Adds or removes grid lines at the major tick values.

`axis box<<Show Major Ticks(Boolean)`

Shows or hides major tick marks.

`axis box<<Show Minor Grid(Boolean)`

Adds or removes grid lines at the minor tick values.

`axis box<<Show Minor Ticks(Boolean)`

Shows or hides minor tick marks.

`axis box<<Tick Label List(<i>, {"text1","text2", ...},{n1, n2, ...})`

Sets the values and positions of the axis tick labels.

Note: Major tick increments are automatically set to 1.0 if the tick labels are not specified.

The first (optional) integer, `i`, is the label row index. Leaving it out clears any existing label rows and creates one new one as specified. Including it allows you to override any

particular label row; using an index higher than the current number of label rows adds a new label row on to the end.

The second list argument is the string titles for your labels.

The third list argument is optional and specifies the values corresponding to each label; if the value list is omitted, the labels will be on integer increments starting with 1.

Border Boxes

Note: Border boxes support only one display box argument.

`border box<<Set Background Color( {R, G, B} | <"color">)`

Sets the background color for a border box. Specify a "*color name*" or a list of RGB values. For example:

```
border box<<Set Background Color("red");
```

or

```
border box<<Set Background Color( {255, 192, 3} );
```

`border box<<Set Color( {R, G, B} | <"color">)`

Sets the border color for a border box. Specify a "*color name*" or a list of RGB values. For example:

```
border box<<Set Color("red");
```

`border box<<Get Color`

Gets the border color for a border box.

`border box<<Set Style ("style")`

Sets the border style for a border box. Specify the style as one of the following numbers or keywords: 0 ("Solid"), 1 ("Dotted"), 2 ("Dashed"), 3 ("DashDot"), or 4 ("DashDotDot"). For example:

```
border box<<Set Style("dotted");
```

`border box<<Get Style`

Gets the border style for a border box.

Button Boxes

button box<<Style(Normal|Underline|Toggle)

Sets the style of the button.

Data Browser Boxes

dbb<<Set Data Table(<data_table>)

Sets the data table for the data browser box.

Data Filter Source Box

dfsb<<Set Row States(dt, rs)

Sets the row states for the given data table within the filter. Selections made in this row state will not be linked with the data table, but will be included in the reports linked to the selection filter.

Frame Boxes

frame box<<Add Graphics Script(<order>,<"description">, <script>)

Description

Adds a script to draw graphics in the frame box.

Arguments

order An optional argument that specifies the order in which the graphics elements are drawn. The value can be the keyword Back or Forward or an integer that specifies the drawing order for a number of graphics elements. 1 means the object is drawn first.

description An optional string that appears in the Customize Graph window next to the graphics script.

script An optional JSL script.

Example

In the following example, the graphics script draws the line first and then draws the other graphics elements: the grid lines, references lines, and markers that create the bivariate plot. Without the 1 order argument, the line is drawn last and covers up the markers.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
obj = dt << Bivariate( Y( :weight ), X( :height ) );
Report( obj )[FrameBox( 1 )] <<
```

```
Add Graphics Script(
   1, // draws the line first
   Description( "Pen Script" ),
   Pen Color( "red" );
   Pen Size( 5 );
   Y Function( 60 + 120 / 2 * (1 + Sine( (2 * Pi() * (x - 50)) / 22.5 )), x );
);
```

frame box<<Append Seg

Adds a display seg to the specified Frame Box.

frame box<<Background Color({R, G, B} | <"color">)

Changes the background color. Specify a "*color name*" or a list of RGB values.

frame box<<Child Seg

Returns the display seg child of the Frame Box.

frame box<<Edit Graphics Script

Brings up a dialog box to view, edit, or delete the current graphics scripts.

frame box<<Find Seg

Returns a display seg with the specified argument (for example, the name of a seg).

frame box<<Frame Size(x, y)

Resets the size of the frame, in pixel units.

frame box<<Make table of graphs like this

Creates a data table of graphs.

frame box<<Marker Size(size)

Changes the marker size.

```
frame box<<Row Colors(color)
```

```
frame box<<Row Markers(marker)
```

```
frame box<<Row Exclude
```

```
frame box<<Row Hide
```

```
frame box<<Row Label
```

Forwards commands to the data table associated with the report, so that the row states of selected rows can be manipulated. For <<Row Exclude, <<Row Hide, and <<Row Label, omitting the argument toggles the option. If the option is off, the message turns it on. If the option is on, the message turns it off.

```
frame box<<Set Background Fill(Boolean)
```

Enables or disables filling the background with the background color. Use this option when you want to paste a graph and make the background transparent.

Example

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = Bivariate( y( weight ), x( height ) );
rbiv = biv << Report;
framebox = rbiv[Frame Box( 1 )];
// set background color
framebox << Background Color( "red" );
// for demonstration purposes: wait to see the color change
Wait( 1 );
// turn off background fill color
framebox << Set Background Fill( 0 );
```

```
frame box<<X Axis(min, max, inc, named arguments)
```

Scales the X coordinate system.

```
frame box<<Y Axis(min, max, inc, named arguments)
```

Scales the Y coordinate system.

Matrix Boxes

```
matrix box<<Get
```

Returns the matrix contents.

```
matrix box<<Make Into Data
Table(<Invisible(Boolean)|Private(Boolean)>)
```

Description

Turns the matrix into a new data table. `Invisible(1)` hides the data table from view. An invisible data table can be open from the JMP Home Window or the Window menu. `Private(1)` avoids opening the data table. A private data table is generally for scripts that want better control of the data table by not exposing it to general use.

Returns

A reference to the new data table.

```
matrix box<<Set Format(<width>, <decimal places>, <"Use thousands
separator">)
```

Description

Sets the numeric format for matrix elements.

Arguments

A number of other formats can be set on matrix boxes. See "number col box<<Set Format(<width>|<width, decimal places>, <"Use thousands separator">)" on page 399 for details about the syntax.

```
matrix box<<Sort(column_num, ascending_bool)
```

Sorts the rows of the matrix based on the column number specified by `column_num`. The default sort order is ascending.

If `column_num` is 0, the sort is removed.

If `ascending_bool` is "`True`", the sort is performed in ascending order. If `ascending_bool` is "`False`", the sort is in descending order.

Nom Axis Boxes

```
nom axis box<<Divider Lines(Boolean)
```

Adds or removes divider lines between labels in the axis box.

```
nom axis box<<Lower Frame(Boolean)
```

Adds or removes a lower frame around the axis.

```
nom axis box<<Rotated Tick Labels(Boolean)
```

Rotates or unrotates the labels at each tick value.

Number Col Boxes

number col box<<Add Element(item)

Adds the item to the Number Col Box. Item can be a single number, a list of numbers, or a matrix of numbers.

number col box<<Get

number col box<<Get(i)

Gets the values in a list, or the *i*th value.

number col box<<Get As Matrix

Gets the values in a matrix, specifically a column vector.

number col box<<Get Format

Returns the current format.

number col box<<Get Heading

Returns the column heading text.

number col box<<Remove Element(row number)

Removes an element from the column at the specified position.

```
number col box<<Set Format(<width>|<width, decimal places>, <"Use
thousands separator">)
```

```
number col box<<Set Format("Best", <width>, <"Use thousands
separator">)
```

```
number col box<<Set Format(("Fixed Dec"|"Percent"), <width>|<width,
decimal places>, <"Use thousands separator">)
```

```
number col box<<Set Format("Pvalue", <width>)
```

```
number col box<<Set Format(("Scientific"|"Engineering"|"Engineering
SI"), <width>|<width, decimal places>)
```

```
number col box<<Set Format("Precision", <width>|<width, decimal
places>, <"Use thousands separator">, <"Keep trailing zeroes">,
<"Keep all whole digits">)
```

```
number col box<<Set Format("Currency", <"currency code">,
<width>|<width, decimal places>, <"Use thousands separator">)
```

```
number col box<<Set Format("datetime", <width>, <input format>)
```

```
number col box<<Set Format(("Latitude DDD"|"Latitude DDM"|"Latitude
DMS"|"Longitude DDD"|"Longitude DDM"|"Longitude DDM"),
<width>|<width, decimal places>, ("PUN"|"DIR"|"PUNDIR"))
```

```
number col box<<Set Format("Custom", Formula(...), <width>, <input
format>)
```

Description

Sets the column format.

Arguments

The Column Info Window chapter in the *Using JMP* book describes the arguments. Note
that Matrix Box(), Number Col Box(), Number Col Edit Box(), Number Edit Box() have
the same Set Format syntax.

Examples

```
<<Set Format( 10, 2, "Use thousands separator");
<<Set Format( "Currency", "EUR", 20, );
<<Set Format( "m/d/y", 10 );
<<Set Format( "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole
  digits" );
<<Set Format( "Latitude DDD", "PUNDIR"); // "PUN" for punctuation, "DIR" for
  direction, PUNDIR for both
<<Set Format( "Custom", Formula( Abs( value ) ), 15 );
```

Notes

- For a list of currency codes, see the Types of Data chapter in the *Scripting Guide*. The
  currency code is based on the locale if the code is omitted.

- If you don't specify the format, set the decimal places to greater than 100 for datetime values and to 97 for *p*-values.

- You must always precede the number of decimal places with the width.

- Options can be defined in a list or a variable, or they can be in a Function() that is evaluated.

  ```
  ncbFunc = Function({}, {"Fixed", 12, 5});
  ```

---

number col box<<Set Heading("string")

Changes the column heading text.

Number Col Edit Boxes

---

number col edit box<<Set Format(<width>, <decimal places>, <"Use thousands separator">)

Description

Sets the column format.

Arguments

A number of other formats can be set on number col edit boxes. See "number col box<<Set Format(<width>|<width, decimal places>, <"Use thousands separator">)" on page 399 for details about the syntax. The Column Info Window chapter in the *Using JMP* book also describes the arguments.

---

number col edit box<<Remove Element(x position, y position, i)

Removes an element from the column at the specified position.

Number Edit Box

---

number edit box<<Set Format(<width>, <decimal places>, <"Use thousands separator">)

Description

Sets the column format.

Arguments

A number of other formats can be set on number edit boxes. See "number col box<<Set Format(<width>|<width, decimal places>, <"Use thousands separator">)" on page 399 for details about the syntax. The Column Info Window chapter in the *Using JMP* book also describes the arguments.

Outline Boxes

```
outline box<<Close(Boolean)
```

Closes the outline box.

```
outline box<<Close All Below
```

Closes all the node's child nodes.

```
outline box<<Close All Like This
```

Closes all nodes similar to this outline box.

```
outline box<<Close Where No Outlines
```

Closes all nodes that do not have children.

```
outline box<<Get Title
```

Gets the title of the outline box.

```
outline box<<Horizontal(Boolean)
```

Horizontally aligns the node's children.

```
outline box<<Open All Below
```

Opens all the node's child nodes.

```
outline box<<Open All Like This
```

Opens all nodes similar to this outline box.

```
outline box<<Set Menu Script({"string1", script1,"string2", script2,
...})
```

Adds an entry to the menu when the red triangle on an outline box is selected.

```
outline box<<Set Title("text")
```

Changes the title of the outline box.

Panel Boxes

`panel box<<Get Title`

Gets the title of the panel box.

`panel box<<Set Title("text")`

Changes the title of the panel box.

Plot Col Boxes

`plot col box<<Get As Matrix`

Gets the values in a matrix, specifically a column vector.

`plot col box<<Remove Element(row number)`

Removes an element from the column at the specified position.

`plot col box<<Set Values([matrix] or {list})`

Sets values for the matrix (for numeric variables) or list (for character variables).

Slider Boxes and Range Slider Boxes

`slider box<<Get(<index>)`

`range slider box<<Get Lower(<index>)`

`range slider box<<Get Upper(<index>)`

Returns the current value of the slider.

`slider box<<Set(n, <index>, <run script(0|1)>)`

`range slider box<<Set Lower(n, <index>, <run script(0|1)>)`

`range slider box<<Set Upper(n, <index>, <run script(0|1)>)`

Sets the value of the slider. run script(0|1) controls whether an on-change script runs after the <<Set, <<Set Lower, or <<Set Upper message.

`slider box<<Get Min()`

Returns the minimum value possible for the range slider and slider.

```
slider box<<Set Min(float, <index>)
```

Sets the minimum value possible for the range slider and slider.

```
slider box<<Get Max()
```

Returns the maximum value possible for the range slider and slider.

```
slider box<<Get Var
```

```
range slider box<<Get Lower Var
```

```
range slider box<<Get Upper Var
```

Returns the variable name associated with the slider.

```
slider box<<Set Max(float, <index>)
```

Sets the maximum value possible for the range slider and slider.

```
slider box<<Set Script(<script>)
```

Sets a script to be run when the range sliders and slider is updated.

```
slider box<<Set Var(slider_var)
```

```
range slider box<<Set Lower Var(slider_var)
```

```
range slider box<<Set Upper Var(slider_var)
```

Sets the variable name associated with the slider.

String Col Boxes

```
string col box<<Add Element(item)
```

Adds the item to the String Col Box. Item can be a single quoted string, a list of quoted strings, or a matrix of quoted strings.

```
string col box<<Get
```

```
string col box<<Get(i)
```

Gets the values in a list, or the ith value.

```
string col box<<Get Heading
```

Returns the column heading text.

```
string col box<<Remove Element(row number)
```

Removes an element from the column at the specified position.

```
string col box<<Set Allow Text Search
```

Description

In table boxes with selectable rows, allows a string column that has focus to respond to keyboard input to change the selected row.

Example

```
// Run the example.
// Select K2.
// Type the letter g. Notice the last row is selected.
// Type the letters ki. Notice the third row is selected.
New Window( "Mountains",
    tb = Table Box(
        sb =
        String Col Box( "Mountain",
            {"K2", "Delphi", "Kilimanjaro",
            "Grand Teton"}
        ),
        Number Col Box( "Elevation (meters)",
            {8611, 681, 5895, 4199}
        ),
        Plot Col Box( "", {8611, 681, 5895, 4199} )
    )
);
tb << Set Selectable Rows( 1 );
sb << Set Allow Text Search( 1 );
```

```
string col box<<Set Heading("text")
```

Changes the column heading *text*.

```
string col box<<Set Justify("right"|"left" |"center")
```

Specifies the alignment of the contents in the string col box to right, left, or center.

Tab Boxes

```
tab box<<Get Tab Margin()
```

Returns a list of the current margins in pixels for the tab box in this order: {left, top, right, bottom}.

```
tab box<<Set Style("tab" | "combo" | "outline" | "vertical spread" |
"horizontal spread" | "minimize size")
```

Changes the appearance of the tab box from a tab to a combo box or outline node.

"vertical spread" and "horizontal spread" change the orientation of the tab title.

"minimize size" bases the tab style on the width of the tab title. See the Display Trees chapter in the *Scripting Guide* for an example.

```
tab box<<Set Tab Margin(n|{...})
```

Sets the tab margin for the tab box. If a single number is specified, all four margins are set to that number of pixels. If a list of two numbers is specified, the left and right margins are set to the first number, and the top and bottom margins are set to the second number. If a list of four numbers is specified, the margins are set in this order: {left, top, right, bottom}.

```
tab box<<Show Tabs(0|1)
```

Shows or hides the tabs for tab boxes. If you hide the tabs, you need to provide another way to select and show tabs. For example, a list box that contains a list of references to the tabs. The default value is 1.

Table Boxes

```
table box<<Get
```

Gets the entries of the table in list form.

```
table box<<Get As Matrix
```

Gets the numeric entries of the table in matrix form.

```
table box<<Get Locked Columns
```

Returns the number of columns that cannot be dragged with the cursor or have any columns dropped before them.

```
table box<<Get Row Change Function
```

Returns the expression that is evaluated when a row is selected.

```
table box<<Get Selectable Rows
```

Returns True if the table box currently allows row selection.

`table box<<Get Selected Row Color`

Returns the index number of the background color of the selected rows in the table box.

`table box<<Make Combined Data Table`

Description

Same as `Make Data Table`, but also searches the report for report tables with the same columns and combine all of these into the new data table.

Returns

A reference to the data table.

`table box<<Make Data Table(name)`

Description

Turns the table entries into a new data table.

Returns

A reference to the data table.

`table box<<Reorder Columns( from column index, to column index)`

Puts the column specified with *from column index* in the place of the column specified with *to column index*. The indexes are 0-based. For example, indicate the first column with "0", and indicate the second column with "1".

`table box<<Set Row Change Function`

Sets the expression that is evaluated when a row is selected.

`table box<<Set Cell Changed Function(Function({this, col box, row},<script>;))`

Sets a function that is called whenever the user edits a cell in a column in a table.

Example

This example prints the new values for the changed cell to the log.

```
 New Window( "Mountains",
    tb = Table Box(
       String Col Edit Box(
          "Mountain",
          {"K2", "Delphi", "Kilimanjaro",
          "Grand Teton"}
       ),
       Number Col Edit Box(
          "Elevation (meters)",
```

```
            {8611, 681, 5895, 4199}
        ),
        Plot Col Box( "", {8611, 681, 5895, 4199} )
    )
);
tb <<
Set Cell Changed Function(
    Function( {this, col, row},
        Print(
            (col << Get Heading) || ": row:" ||
            Char( 3 ) || " is now " ||
            Char( col << Get( row ) )
        )
    )
);
```

table box<<Set Column Borders(Boolean)

Draws a line on each side of the column.

table box<<Set Heading Column Borders(Boolean)

Draws a line on each side of the column headings.

table box<<Set Locked Columns(n)

Locks the first *n* columns. You cannot drag the locked columns or drag columns before them.

table box<<Set Row Borders(Boolean)

Draws a line above and below each row.

table box<<Set Selectable Rows(Boolean)

Makes the rows of the table box selectable or not.

table box<<Set Selected Row Color("color")

If the rows of the table box are selectable (Set Selectable Rows(True)), sets the background color for the selected rows.

table box<<Set Shade Cells(Boolean)

Shades the background of every cell in the table.

`table box<<Set Shade Alternate Rows(Boolean)`

Shades the background of every other row in the table.

`table box<<Set Shade Heading(Boolean)`

Shades the background in column headings.

`table box<<Set Underline Headings(Boolean)`

Draws a line underneath the column headings.

`table box<<Sort By Column(<colnum|coltitle>, <ascending(Boolean)>`

Sorts all rows based on the values in the specific column. The default order sorting is descending. You can sort by multiple columns by sorting the first column and then sorting the second column.

Text Boxes

`text box<<Font Color(n)`

Sets the color for Text strings.

`text box<<Get Hidden State`

Returns the current state of a text box.

`text box<<Get Text`

Returns the string content of the box.

`text box<<Get Tip`

Returns the tooltip for the text box (or a text edit box).

`text box<<Markup`

Returns text formatted with the specified HTML tags. The HTML must be well-formed; make sure you close nested tags correctly.

The following example returns text formatted in bold, italic, and underlined.

```
w = New Window( "Formatted Text",
  Text Box( "This is <b>bold</b> text. This is <b><i>bold italic</i></b>
  text. This is <u>underlined</u> text.",
  <<Markup) );
```

```
text box<<Rotate Text("direction")
```

Rotates the text 90 degrees `"left"` or `"right"`, or returns it to the horizontal.

```
text box<<Set Font("name", <size>, <style | "style style...">,
<angle>)
```

Sets the font name and properties for text strings. To specify more than one style, include a space between each style and place them in quotes.

```
text box<<Set Font Size(n)
```

Sets the font size in points for text strings.

```
text box<<Set Font Style("style" | "style style...")
```

Sets the font style for text strings. To specify more than one style, include a space between each style and place them in quotes. Integers are backwards compatible but not recommended for new scripts.

```
text box<<Set Script(script)
```

Associate a script with a text box. The script executes when the user presses Enter (or the text edit box otherwise loses focus).

```
text box<<Set Text("string")
```

Changes the string content of the box.

```
text box<<Set Tip("string")
```

Sets the tooltip for the text box (or a text edit box).

```
text box<<Set Wrap(n)
```

Set the wrap point, in pixels, in pixels (*n*).

Tree Node and Tree Box

For the following messages, node stands for a tree node or a reference to one and root stands for a tree box or a reference to one.

Caution: If you send a root node that contains one or more nodes with the `Set Node Select Script` defining a collapse message, then Mac runs the script twice. Windows doesn't run the script. This behavior on Macintosh doesn't just affect increments. Any script runs twice. It will print to the log twice, create a column twice, try to delete something twice, and so on.

`node<<Append(<node_ref>)`

Inserts a referenced tree node after this node's children.

`node<<Collapse`

Closes the node. The behavior is not guaranteed if the node has a collapsed parent.

`node<<Expand`

Opens the node. The behavior is not guaranteed if the node has a collapsed parent.

`node<<Get Tip`

Returns the tooltip for the node.

`node<<Prepend(<node_ref>)`

Inserts a tree node before this node's children.

`node<<Remove(<node>)`

Removes the given tree node and all its children from the tree display box.

`node<<Set Selected( <node> )`

Selects the node. The behavior is not guaranteed if the node has a collapsed parent.

`node<<Set Tip("text")`

Specifies a tooltip for the node.

`root<<Collapse(<node>)`

Collapses the given tree node.

`root<<Expand(<node>)`

Expands the given tree node.

```
root<<Get Selected(<node>)
```

Gets the currently selected tree node.

- – In a single-item tree, the currently selected tree node or Empty is returned.
- – Table 3.1 shows the results for a Tree Box() that contains the MultiSelect argument.

Table 3.1 Multi-Select Tree Results

Items Selected in Tree	Result
no items selected	empty
single item selected	list of one tree node
multiple items selected	list of selected tree nodes

```
root<<Is Multiselect
```

Returns 1 for a MultiSelect tree and 0 for a single-select tree.

```
root<<Set Selected(node|{nodes}, <0|1>)
```

Selects the given tree node in the tree display box. In list of tree nodes, all nodes in the list are selected for MultiSelect trees. Otherwise, the first node in the list is selected. Specify the Boolean argument to indicate whether the node or nodes should be selected or unselected. The default value is 1, which selects the nodes.

Notes:

- • On Windows, the <<Set Selected() message expands all nodes between the selected node or nodes and the root of the tree; items that are selected deep within the tree are shown. The expansion state does not change for nodes that were previously selected.

- • On Macintosh, <<Set Selected() does not change the tree expansion state.

Triangulation

For the following messages, tri stands for a triangulation or a reference to one.

```
tri<<Get N Points
```

Returns the number of unique points in the triangulation.

```
tri<<Get Points
```

Returns the coordinates of the unique points in the triangulation.

`tri<<Get Y`

Returns the Y values of the unique points in the triangulation.

`tri<<Get N Hull Points`

Returns the number of points on the boundary of the triangulation.

`tri<<Get Hull Points`

Returns the indices of the points on the boundary of the triangulation.

`tri<<Get N Hull Edges`

Returns the number of edges on the boundary of the triangulation.

`tri<<Get Hull Edges`

Returns the indices of the edges on the boundary of the triangulation.

`tri<<Get Hull Path`

Returns the boundary of the triangulation as a path.

`tri<<Get N Triangles`

Returns the number of triangles.

`tri<<Get Triangles`

Returns the indices of the triangles in the form of an Nx3 matrix.

`tri<<Get N Edges`

Returns the number of edges in the triangulation.

`tri<<Get Edges`

Returns the indices of the edges in the form of an Nx2 matrix.

`tri<<Subset({indices})`

Returns a triangulation resulting from the given subset of points.

`tri<<Peel`

Peel the boundary layer of a triangulation, returning a new triangulation.

Windows

window<<Bring Window to Front

Brings the window to the front.

window<<Close Window(<nosave>)

Closes the window. If the optional argument nosave is specified, the window (journal, report, and so forth) is closed without saving or prompting.

window<<Get Content Size

Returns the size of the window's contents.

window<<Get Window Icon

Returns the name of the window's icon.

window<<Get Window Position

Returns the position of the window.

window<<Get Window Size

Returns the size of the window.

window<<Get Window Title

Returns the title of the window.

window<<Inval

Invalidate the display box. The window updates either when the <<Update Window message is sent or when the operating system has time for the update. See <<Reshow for another method.

window<<Maximize Display

Maximizes the window. Deprecated.

window<<Maximize Window(Boolean)

Maximizes the window. Deprecated.

```
window<<Minimize Window(Boolean)
```

Minimizes the window.

```
window<<Move Window(x, y)
```

Moves the window to the specified position.

```
window<<On Close(script)
```

Runs the script when the window is closed.

```
window<<Pad Window(Boolean)
```

Turns padding around a window's contents on (1) or off (0). The default value is off.

```
window<<Print Window
```

Prints the window to the default printer. Note that the Print window is not opened and user input is not required.

```
window<<Reshow
```

Invalidates the display box and updates the window with the new content. See `<<Inval` and `<<Update Window` messages if more control over timing of the update is required.

```
window<<Set Main Window
```

Sets the specified window as the default window that appears when JMP is run.

```
window<<Set Window Icon("icon name")
```

Sets the window's icon as specified.

```
window<<Set Window Size(x, y)
```

Resizes the window.

```
window<<Show Window(0|1)
```

1 shows the window (only if the window is not currently open). 0 hides the window. If the window is also minimized (on Windows) or docked (on Macintosh), showing the window restores it to the normal state and brings it to the front.

window<<Size Window(x, y)

Resizes the window.

window<<Update Window

Updates or refreshes the window holding the display box if there are invalidated regions.
See also <<Inval and <<Reshow messages for additional methods.

window<<Window Class Name

Returns the name of the window class for the display box. Valid responses include:
DataTable, FormulaEditor, Starter, Journal, Launcher, Report, Dialog, DialogWithMenu,
ModalDialog, FindReplace, User, Generic, ToolWindow, FindReplace, AppBuilder, and
Debugger.

window<<Zoom Window

Resizes the window to be large enough to show all of its contents.

Dynamic Link Libraries (DLLs)

dll object<<Call DLL(function_name, signature, arguments)

Calls the specified function in the DLL with the specified signature and arguments.

dll object<<Declare Function("name", <named_arguments>)

Declares the return type and argument types for the specified function so that it can be
successfully invoked. You can use one of the named arguments for Convention: STDCALL or
PASCAL, or CDECL. The *type* argument for Returns takes the same named arguments as Arg.

Named Arguments

Alias("name") A name you can include if you don't like the name encoded in the DLL.

Arg(type, <"description">, <access_mode>, <array>) Arg is optional and can
appear multiple times, once for each argument to be sent to the function.

Type is one of these keywords that specifies the argument type: Int8, UInt8, Int16,
UInt16, Int32, UInt32, Int64, UInt64, Float, Double, AnsiString, UnicodeString,
Struct, IntPtr, UIntPtr, or ObjPtr.

"description" is an optional string that describes the argument for reference.

access_mode is an optional keyword that specifies how the argument is passed. input
specifies that the argument is passed by value. output specifies that the argument is
passed by address with the initial value undefined. update specifies that the argument is

passed by reference and the value of the JSL variable is set as the initial value. The default value is input.

array is an optional keyword. It is valid only if the Type is specified as Double and the access_mode is specified as either input or update. Specifies that the exported function expects an array of doubles.

Convention(calling_convention) An optional keyword that specifies the calling convention: STDCALL or PASCAL, or CDECL. The default value is STDCALL. STDCALL and PASCAL are equivalent.

MaxArgs(n) An optional integer that specifies the maximum number of arguments that can be supplied.

MinArgs(n) An optional integer that specifies the minimum number of arguments that can be supplied.

Returns(type) Optional. Specifies the data type that the function returns: Int8, UInt8, Int16, UInt16, Int32, UInt32, Int64, UInt64, Float, Double, AnsiString, UnicodeString, Struct, IntPtr, UIntPtr, or ObjPtr.

StackOrder(order) Optional keyword that specifies the order in which arguments are to be placed on the stack when calling the function. Valid values are L2R (left-to-right) and R2L (right-to-left). The default value is R2L.

StackPop(pop) Optional keyword that specifies how the exported function expects the stack to be cleared after the function returns. Valid values are CALLER and CALLEE. The default value is CALLEE.

StructArg(Arg(...), <Arg(...)>, ..., <access_mode>, <pack_mode>, <"description">) Optional and can appear multiple times. If an exported DLL function requires that a structure argument be passed in as an argument, use StructArg to declare the structure members. The Arg arguments use the same syntax as for Arg arguments to DeclareFunction (one for each structure member), an access_mode indicator and a pack_mode indicator.

access_mode is an optional keyword that indicates whether the struct argument should be passed by value (input) or by reference (update).

pack_mode is an optional integer that determines how the structure is packed. Valid values are 1, 2, 4, 8, and 16. The default value is 8.

description is an optional, quoted string that contains a description of the structure for reference.

---

dll object<<Get Declaration JSL

Sends the declaration JSL from the DLL object to log.

`dll object<<Load DLL("path" <,AutoDeclare(Boolean | Quiet | Verbose)>)`

`dll object<<Load DLL("path" <, Quiet | Verbose>)`

Loads the DLL from the specified path.

`path` A quoted pathname that specifies where to load the DLL.

`AutoDeclare(Boolean | Quiet | Verbose)` Optional argument. `AutoDeclare(1)` and `AutoDeclare(Verbose)` write verbose messages to the log. `AutoDeclare(Quiet)` turns off log window messages. If you omit this option, verbose messages are written to the log.

`Quiet | Verbose` Optional argument. When you use `Declare Function()`, this option turns off log window messaging (`Quiet`) or turns on log window messaging (`Verbose`).

`dll object<<Show Functions`

Sends the declared functions for the DLL object to the log.

`dll object<<Unload DLL`

Unloads the DLL.

Images

The Scripting Index provides examples for processing images. In JMP, select **Help > Scripting Index** to view this interactive resource.

Additional resources are available from the JMP File Exchange at
https://community.jmp.com/community/file-exchange.

`img<<Crop(Left(pix), Right(pix), Top(pix), Bottom(pix))`

Creates a new image from an existing image to the specified dimensions (in pixels).

`img<<Filter("name", <n>)`

Filters the image based on the specified algorithm. Filtering is useful for cleaning up noise in the image.

Note: All of the JMP image filters are supported at the operating system level. Images that are processed on Windows might differ from images processed on Macintosh.

Argument

name A quoted string contains the name of a JMP image filter. The following filters are available:

– "despeckle" removes defects (that is, speckles) from a scanned or captured image (for example, scratches, dust, etc.).

– "edge" identifies pixels in an image where the brightness changes sharply and darkens pixels with no sharp change. Edge detection is used to detect changes in surface, depth, material, and lighting.

– "enhance" reduces the contrast between pixels in a noisy image.

– "median" reduces noise (that is, the random variation) and smooths an image by comparing each pixel's brightness with its neighbors' and, if the value is very different, replaces it with the average of the neighbors' values.

– "negate" creates the negative of the color or gray-scale image by changing each pixel color to its complementary color.

– "normalize" changes a color image's pixels to use the full range of the file format's number system. Normalization will make the image's colors more intense.

– "sharpen" reduces blur by sharpening edges of an image.

– "contrast", n brightens or darkens an image. A higher number (>0.0) brightens an image; a lower number (<0.0) darkens an image.

– "gamma", n corrects the image visual display (brightness and intensity) to account for differences in monitor hardware. A higher number (> 1.0) lightens the image; a lower number (< 1.0) darkens the image.

– "reduce noise", n reduces the random variation (or noise) that occurs with higher ISO sensitivity or longer exposure times.

– "gaussian blur", radius, sigma reduces image noise and detail creating a smoother image. Radius is equal to the blur radius around each pixel and sigma is the standard deviation of the Gaussian distribution. Gaussian blur is commonly used when resizing or performing edge detection.

---

img<<Flip Both

Flips the image from left to right and top to bottom.

---

img<<Flip Horizontal

Flips the image from left to right.

---

img<<Flip Vertical

Flips the image from top to bottom.

```
img<<Get EXIF Data
```

Returns EXIF data from the image (such as the shutter speed and aperture value) in an associative array.

```
img<<Get N Frames
```

Description

Returns the number of frames in a multi-frame TIFF or animated GIF file, where the number of frames begins with frame 0.

Example

The following example places a four-frame TIFF file in a new window and shows the image that is in the first frame.

```
img = New Image( "$DOWNLOADS/Multiframe.tif" );
nframes = img << Get N Frames(); // return 4
img << Set Current Frame( 1 ); // show image 1
win = New Window( "Multi-Frame TIFF", img );
```

```
img<<Get Size
```

```
img<<Size
```

Returns a list containing the width and height (in pixels) of the image.

```
img<<Rotate(degrees)
```

Rotates the image by the specified number of degrees.

```
img<<Save Image("filepath")
```

Saves the image to the specified path and filename (`filepath`).

```
img<<Scale(n, <n>)
```

Resizes the image by the specified dimensions. Provide one argument to resize both the width and height. Provide two arguments to resize the width and height separately.

Examples

```
img = New Image( "$SAMPLE_IMAGES/tile.jpg" );
xs = 2;
img << Scale( xs );
New Window( "Tilex 2", img );

img = New Image( "$SAMPLE_IMAGES/tile.jpg" );
img << Scale( 2, 0.5 ); // scale image width by 2 and height by 1/2
New Window( "Tile squished", img );
```

Notes

Using Scale is an alternative to getting the size of the image, multiplying by the scale factor, and then setting the size.

img<<Set Current Frame

Sets the frame that shows in a multi-frame TIFF or animated GIF file. Specify 0 through the number of frames minus 1. For example, with four frames, you can specify frame 0 through frame 3. See "img<<Get N Frames" on page 419 for an example.

img<<Set Size(width, height)

Resizes the image to the specified dimensions (in pixels). To scale the image proportionally, specify a width and height that correspond to the aspect ratio in the original image.

img<<Transparency(fraction)

Sets the transparency for the image where the fraction is between 0.0 (full transparency) to 1.0 (no transparency).

MATLAB

The MATLAB interfaces are scriptable using a MATLAB connection object. Use the MATLAB Connect() JSL function to obtain a scriptable MATLAB connection object. See the Extending JMP chapter in the *Scripting Guide* for details.

mlconn << Control(<named arguments>)

Controls the execution of MATLAB.

Returns

None.

Named Arguments

Echo(Boolean) Global. Echo MATLAB source lines to the JMP Log window.

Visible(Boolean) Global. Determine whether to show or hide the active MATLAB workspace.

mlconn << Disconnect()

Description

Disconnects this MATLAB integration interface connection.

```
mlconn << Execute( { list of inputs }, { list of outputs }, mCode,
<named arguments> )
```

Submits MATLAB code to the active global MATLAB integration interface connection given a list of inputs and upon completion a list of outputs are retrieved.

Returns

0 if successful, otherwise nonzero.

Arguments

`{ list of inputs }` Positional, name list. List of JMP variable names to be sent to MATLAB as inputs.

`{ list of outputs }` Positional, name list. List of JMP variable names to be retrieved from MATLAB as outputs.

`mCode` Positional, string. The MATLAB code to submit.

Named Arguments

`Expand(Boolean)` Perform an Eval Insert on the MATLAB code prior to submission.

`Echo(Boolean)` Echo MATLAB source lines to the JMP Log window. Default is true.

```
mlconn << Get Graphics( format )
```

Gets the last graphic object written to the MATLAB graph display window. The graphic object can be returned in several graphic formats.

Returns

JMP Picture object.

Arguments

`format` Positional. The format the MATLAB graph display window contents are to be converted to. Valid formats are `"png"`, `"bmp"`, `"jpeg"`, `"jpg"`, `"tiff"`, and `"tif"`.

```
mlconn << Get Version()
```

Gets the current version of the installed MATLAB.

Returns

Matrix, returns a vector of length 3 containing the MATLAB version number.

Arguments

None.

```
mlconn << Get( name )
```

Description

Gets a named variable from MATLAB to JMP.

Returns

Value of named variable.

Arguments

name Positional. The name of a JMP variable to be retrieved from MATLAB.

`mlconn << Is Connected()`

Description

Determines whether connection is active.

Returns

1 if connected, otherwise 0.

Arguments

None.

`mlconn << JMP Name To MATLAB Name( JMP name)`

Description

Maps a JMP variable name to its corresponding MATLAB variable name using MATLAB variable name naming rules.

Returns

String, a mapped MATLAB name.

Arguments

names Positional. The name of a JMP variable to be sent to MATLAB.

`mlconn << Send( name, <named arguments> )`

Description

Sends the named variable from JMP to MATLAB.

Returns

0 if successful, otherwise nonzero.

Arguments

name Positional. The name of a JMP variable to be sent to MATLAB.

Named Arguments

The following arguments are for data tables only:

Selected(Boolean) Send selected rows from the referenced data table to MATLAB.

Excluded(Boolean) Send only excluded rows from the referenced data table to MATLAB.

Labeled(Boolean) Send only labeled rows from the referenced data table to MATLAB.

Hidden(Boolean) Send only hidden rows from the referenced data table to MATLAB.

`Colored(Boolean)` Send only colored rows from the referenced data table to MATLAB.

`Markered(Boolean)` Send only markered rows from the referenced data table to MATLAB.

`Row States (Boolean, <named arguments>)` Send row states from referenced data table to MATLAB by adding an additional data column named "RowState". Create multiple selections by adding together individual settings. The row state consists of individual settings with the following values:

– Selected = 1

– Excluded = 2

– Labeled = 4

– Hidden = 8

– Colored = 16

– Markered = 32

The following optional, named Row States arguments are supported:

`Colors(Boolean)` Send row colors. Adds additional data column named "RowStateColor".

`Markers(Boolean)` Send row markers. Adds additional data column named "RowStateMarker".

`mlconn << Submit( mCode, <named arguments> )`

Description

Submits MATLAB code to the active global MATLAB integration interface connection.

Returns

0 if successful, otherwise nonzero.

Arguments

`mCode` Positional, string. The MATLAB code to submit.

Named Arguments

`Expand(Boolean)` Perform an Eval Insert on the MATLAB code prior to submission.

`Echo(Boolean)` Echo MATLAB source lines to the JMP log. Default is true.

`mlconn << Submit File( pathname )`

Description

Submits statements to MATLAB using a file pointed to by pathname.

Returns

0 if successful, otherwise nonzero.

Arguments

> `Pathname` Positional, string. Pathname to file containing MATLAB source lines to be
> executed.

Platforms

obj<<Action

Evaluates expressions. Useful for stringing together multiple platforms interrupted by user
input.

obj<<Automatic Recalc

Redoes the analysis automatically for exclude and data changes. If automatic recalc is on,
you should use `Wait(0)` commands to let the triggers take effect and do the recalculation.

> **Note:** Not supported on all platforms.

obj<<Bring Window To Front

Brings the current window to the front.

obj<<Close Window

Closes window identified by *obj*, typically a platform surface.

obj<<Column Switcher (default column, {col 1, col 2, ...})

Adds a control panel to a platform for switching variables.

obj<<Copy ByGroup Script

Creates a script to produce this analysis containing By variables and place it on the
clipboard.

obj<<Copy Script

Creates a script to produce this analysis and place it on the clipboard.

obj<<Data Table Window

Makes the associated data table window active (front-most).

obj<<Get Data Table

Returns a reference to the data table.

obj<<Get Script

Returns script to reproduce the analysis as an expression in the log.

obj<<Get Script With Data Table

Creates a script to reproduce the analysis, specifically referencing the source data table, and returns it as an expression in the log.

obj<<Get Timing

Times the launch of the platform and returns it in the log.

obj<<Get Web Support

Returns the score for the display tree that is about to be saved as interactive HTML. Possible values are -1 (unsupported), 0 (supported), and 1 (supported). If the score does not equal -1, interactive HTML is supported and <<Save Interactive HTML() can be used.

obj<<Get Window Position

Gets the position of the window. Returns an ordered pair.

obj<<Get Window Size

Gets the window size, in pixels. Returns an ordered pair.

obj<<Ignore Platform Preferences

Ignores the current settings of the platform's preferences.

obj<<Journal Window

Appends the contents of the window to the journal.

obj<<Local Data Filter

Filters data to specific groups or ranges, but stays local to the platform.

`obj<<Maximize Window`

Maximizes the window. Equivalent to pushing the maximize button in the corner of the window. This message takes an optional Boolean argument:

```
// maximize the window:
obj<<Maximize Window(1)
// restore the window:
obj<<Maximize Window(0)
```

`obj<<Minimize Window`

Minimizes the window. Equivalent to pushing the minimize button in the corner of the window. This message takes an optional Boolean argument:

```
// minimize the window:
obj<<Minimize Window(1)
// restore the window:
obj<<Minimize Window(0)
```

`obj<<Move Window(x, y)`

Moves the window to the (x,y) location on your screen.

`obj<<Print Window`

Sends the selected window to the printer.

`obj<<Redo Analysis`

Reruns the analysis with the same options.

`obj<<Redo ByGroup Analysis`

Reruns the same analysis involving By groups.

`obj<<Relaunch Analysis`

Returns to the launch window for this analysis.

`obj<<Relaunch ByGroup`

Returns to the launch window for this analysis involving By groups.

`obj<<Remove Column Switcher`

Removes all Column Switchers that were added to the platform.

`obj<<Remove Local Data Filter`

Removes all Local Data Filters that were added to the platform.

`obj<<Report`

`Report(obj)`

Returns a display box reference for the report in the platform window. For details, see the Display Trees chapter in the *Scripting Guide*.

`obj<<Report View`

Determines the level of detail visible in a platform report. Full shows all detail and Summary shows only select content, dependent upon the specific platform. For customized behavior, use the `Set Summary Behavior` message with display boxes.

`obj<<Save ByGroup Script to Data Table`

Creates a script to produce the analysis involving By variables and saves it as a table property in the data table.

`obj<<Save ByGroup Script to Journal`

Creates a script to produce the analysis involving By variables and adds a button to the journal containing this script.

`obj<<Save ByGroup Script to Script Window`

Creates a script to produce the analysis involving By variables and appends it to the current Script window.

`obj<<Save Script for All Objects`

Saves script to reproduce all analyses found within the object's window in the Script Journal window.

`obj<<Save Script for All Objects to Data Table`

Saves a script for all report objects to the current data table. The script is named after the platform unless you specify the script name in quotes.

```
obj << Save Script for All Objects To Data Table("My Script")
```

`obj<<Save Script to Data Table`

Saves script to reproduce analysis as a property in the associated data table.

`obj<<Save Script to Journal`

Creates a script to produce the analysis and adds a button to the journal containing this script.

`obj<<Save Script to Report`

Saves script to reproduce analysis as a text box at the top of the report.

`obj<<Save Script to Script Window`

Saves a script to reproduce analysis in the Script Journal.

`obj<<Scroll Window(x, y)`

`obj<<Scroll Window({x, y})`

Scrolls the window x pixels to the right and y pixels down from the current position. Negative coordinates go left and up. If the coordinates are a list in braces { }, they are absolute coordinates. The window scrolls to the point x pixels from the left and y pixels from the top.

`obj<<SendToReport`

Used with the Dispatch function to customize the appearance of a report.

`obj<<SendToByGroup`

Sends messages to open platforms or turn on platform features to each level of a by-group.

`obj<<Show Window(0|1)`

1 shows the window (brings it to the front). 0 hides the window. If the window is also minimized (on Windows) or docked (on Macintosh), showing the window restores it to the normal state and brings it to the front.

`obj<<Size Window(x, y)`

Resizes the window to x pixels wide by y pixels high.

`obj<<Title`

Returns the title of the platform.

---

obj<<Top Report

Returns a reference to the top display box in the report. Useful for BY groups or other cases when several platform reports are in one window.

---

obj<<View Web XML

Returns the XML used to create the interactive HTML report. The XML code appears in the log.

---

obj<<Zoom Window

Resizes the window to be large enough to show all of its contents.

Bubble Plot

---

bp<<Set Shape("Circle"|"Triangle"|"Square"|"Diamond"|"Arrow"|"Custom")

Description

Sets the shape for the bubble. When specifying a custom shape, use the Set Custom Path message to specify the path for the bubbles.

See Also

"bp<<Set Custom Path(pathMatrix | pathText)" on page 429.

the Graphics chapter in the *Scripting Guide* for an example.

---

bp<<Set Custom Path(pathMatrix | pathText)

Sets a path for custom bubbles.

Arguments

pathMatrix An *N*x3 matrix.

pathText A string that contains SVG code.

See Also

"bp<<Set Shape("Circle"|"Triangle"|"Square"|"Diamond"|"Arrow"|"Custom")" on page 429.

the Graphics chapter in the *Scripting Guide* for an example.

DOE

```
obj<<Get Prediction Variances
```

Description

Returns a vector of the MC variances used for the FDS plot.

Example

```
dt = Open( "$SAMPLE_DATA/Design Experiment/Bounce Data.jmp" );
d = DOE( Evaluate Design, X( :Silica, :Sulfur, :Silane ), Y( :Stretch ) );
d << Get Prediction Variances;
```

```
obj<<Set Number of FDS Points()
```

Description

Enables you to specify the number of runs used to generate an FDS plot.

Example

```
dt = Open( "$SAMPLE_DATA/Design Experiment/Bounce Data.jmp" );
d = DOE( Evaluate Design, X( :Silica, :Sulfur, :Silane ), Y( :Stretch ) );
d << Set Number of FDS Points( 20000 );
```

Partition

```
obj<<Initial Splits(condition, {left}, {right})
```

Description

Describes the splits that are performed.

Example

```
dt = Open( "$SAMPLE_DATA/Car Poll.jmp" );
obj = Partition(
    Y( :country ),
    X( :sex, :marital status, :age, :type, :size ),
    Method( "Decision Tree" ),
    Initial Splits( :size == {"Large"}, {}, {:size == {"Medium"}} )
);
```

Notes

• The condition is for the left side and is either [name compareoperator value] or [name ==
  list of values]. The left is an empty list if the right has splits. Omit the right side if there
  are no splits. The left and right continue recursively in this format.

Response Screening

```
obj<<Get PValues
```

Returns a reference to a PValues table.

```
obj<<Save PValues
```

Stores the *p*-values in an output data table.

```
obj<<Save Compare Means
```

Stores the means comparisons in an output data table.

```
obj<<Save Mean
```

Stores the means in an output data table.

```
obj<<Save Outlier Indicator
```

Saves Outlier Indicator for each fit.

```
obj<<Save Std Residuals
```

Saves the residual formula for each fit.

```
obj<<Select Columns
```

Select columns in the original table corresponding to selected rows in this table.

Tabulate

```
obj<<Display Column Width(<Data Column(Column
Table(n),"colname_path"), Row Label(Row Table(n), "colname_path")>,
<width>)
```

Returns or sets the display pixel width of a column in a Tabulate table.

Argument

data column Use Column Table and column references to define columns in the main
  body of the table.

row label Use Row Table and heading for columns in the row labels area.

colname_path An optional Column Table or Row Table, and the series of column headings
  that traces the path of the column. **Note:** Column table or row table can be omitted if the
  table referenced is the first table.

width The pixel width of the column.

Examples

```
dt = Open( "$SAMPLE_DATA/Car Poll.jmp" );
obj = dt << Tabulate(
   Add Table(
      Column Table(
         Grouping Columns( :sex, :marital status ),
         Analysis Columns( :age ),
         Statistics( Sum, "% of Total" )
      ),
      Row Table( Grouping Columns( :type ) ),
      Row Table( Grouping Columns( :country, :size ) )
   )
);
Wait( 3 ); // for demonstration purposes
obj << Display Column Width( Row Label( Row Table( 2 ), "country" ), 150 );
Wait( 3 ); // for demonstration purposes
obj << Display Column Width(
   Data Column(
      Column Table( 1 ),
      "sex",
      "Female",
      "marital status",
      "Married",
      "age",
      "Sum"
   ),
   150
);
```

Python Integration Messages

The Python interfaces are also scriptable using a Python connection object. A scriptable
Python connection object can be obtained using the Python Connect() function. See the JSL
Functions chapter in the *JSL Syntax Reference*.

```
pythconn<<Control(<named_argument>)
```

Description

Controls the execution of Python.

Optional Named Arguments

`Interactive(Boolean)` Enables interactive mode in the Python matplotlib package. Determines whether the graphics window is released or closed when graphics rendering is complete.

`Echo(Boolean)` Global argument. Prints the Python source lines to the JMP log. The default value is true.

pythconn<<Disconnect

Disconnects the Python integration interface connection.

pythconn<<Execute({list of inputs}, {list of outputs}, Python_Code, <named_arguments>)

Description

Submits Python code to the active global Python integration interface connection given a list of inputs. On completion, returns a list of outputs.

Returns

Returns 0 if successful and 1 otherwise. The results are returned using the list of outputs. Given each element of the JMP output list, the corresponding Python variable value is returned.

Positional Arguments

`{list of inputs}` A list of JMP variable names to be sent to Python as inputs.

`{list of outputs}` A list of JMP variable names to be retrieved from Python as outputs.

`Python Code` The Python code to submit.

Optional Named Arguments

See

pythconn<<Get(name)

Description

Gets a named variable from Python.

Returns

Returns the value of the named variable.

Argument

`name` The name of the JMP variable to be received from Python. The argument can represent any of the following Python data types: numeric, string, matrix, list, or data frame.

pythconn<<Get Graphics(format)

Description

Gets the last graphics object written to the Python graph display window in the specified graphics format. The graphics object can be returned in several different graphic formats.

Returns

Returns a JMP picture object.

Argument

format   The format that the Python graph display window contents are to be converted to. Valid formats are PNG, BMP, JPEG, JPG, TIFF, and TIF.

pythconn<<Get Version

Description

Gets the current version of the Python installation.

Returns

Returns a list of length 5 that contains the five components of the version number: major, minor, micro, releaselevel, and serial. The releaselevel value is a string.

pythconn<<Is Connected

Description

Determines if the connection is active.

Returns

Returns 1 if connected and 0 otherwise.

pythconn<<JMP Name to Python Name(name)

Description

Maps a JMP variable name to its corresponding Python variable name using Python variable name naming rules.

Argument

name   The name of the JMP variable to be sent to Python.

pythconn<<Send(name)

Description

Sends a named variable from JMP to Python.

Returns

Returns 0 if successful and non-zero otherwise.

Argument

name The name of the JMP variable to be sent to Python.

---

pythconn<<Submit(Python_Code, <named_arguments>)

Description

Submits Python code to the active global Python integration interface connection.

Returns

Returns 0 if successful and 0 otherwise.

Named Arguments

Python_Code The Python code to submit.

Expand(Boolean) Optional. Performs an Eval Insert() on the Python code before submission.

Echo(Boolean) Optional. Prints the Python source lines to the JMP log. The default value is true.

---

pythconn<<Submit File(path_name)

Description

Submits statements to Python using the file specified in the path name.

Argument

path_name The path to the file that contains the Python source lines to be executed.

R Integration Messages

The R interfaces are also scriptable using an R connection object. A scriptable R connection object can be obtained using the R Connect() function.

---

rconn<<Control(Interrupt (1))

If Async is set to true (1) for R Submit(), this message immediately stops the execution of the R code that was submitted.

---

rconn<<Disconnect()

Disconnects this R connection.

---

rconn<<Is Connected()

Returns 1if the R connection is active, 0 otherwise.

```
rconn<<Send("name", named_arguments)
```

Send the specified JMP variable to R.

Returns

0 if successful, nonzero otherwise.

Argument

name A quoted string contains the name of a JMP variable to send to R.

Arguments for Data Tables

Selected(0|1) Optional, Boolean. If true, sends only the selected rows from the
referenced data table to R.

Excluded(0|1) Optional, Boolean. If true, sends only the excluded rows from the
referenced data table to R.

Labeled(0|1) Optional, Boolean. If true, sends only labeled rows from the referenced
data table to R.

Hidden(0|1) Optional, Boolean. If true, sends only hidden rows from the referenced data
table to R.

Colored(0|1) Optional, Boolean. If true, sends only colored rows from the referenced
data table to R.

Markered(0|1) Optional, Boolean. If true, sends only markered rows from the referenced
data table to R.

Row States(0|1, <named arguments>) Optional. Includes a Boolean argument and
optional named arguments. Sends row state information from the referenced data table
to R by adding an additional data column named "RowState". The row state value
consists of individual settings with the values shown in Table 3.2.

Table 3.2 Row States

Multiple row states are created by adding together individual settings.	Selected = 1
	Excluded = 2
	Labeled = 4
	Hidden = 8
	Colored = 16
	Markered = 32

Table 3.2 Row States *(Continued)*

Arguments	Colors(Boolean) Optional, Boolean. If true, sends row colors and adds an additional data column named "RowStateColor".
	Markers(Boolean) Optional, Boolean. If true, sends row markers and adds an additional data column named "RowStateMarker".

rconn<<Send("name")

Send the specified JMP data file to R.

rconn<<Get("name")

Gets the specified variable from R.

Returns

The value of the specified variable.

Arguments

name A quoted string that contains the name of a JMP variable to be retrieved from R.

rconn<<Get Graphics("type")

Gets the last graphics object written to the R graph display window. The graphics object can be returned in different graphic formats.

Returns

A JMP picture object.

Arguments

type The format the R graph display window contents are to be converted to. Valid formats are "png", "bmp", "jpeg", "jpg", "tiff", and "tif".

rconn<<Submit("code", named_arguments)

Submits the R code.

Returns

0 if successful, nonzero otherwise.

Arguments

code A quoted string that contains the R code to submit.

Expand(0|1) Optional, Boolean. Performs an Eval Insert() on the R code before submitting the code.

Echo(0|1) Optional, Boolean. Echoes the R source lines to the JMP log. The default value is true.

Rconn<<Submit File("filepath")

Submits statements to R using the file in the "*filepath*".

Arguments

filepath A quoted string that contains the pathname to the file that contains R code to be executed.

rconn<<Execute({ list of inputs }, { list of outputs }, "code", named_arguments)

Submits the R code to the R connection using the list of inputs. Upon completion, a list of outputs is returned.

Returns

0 if successful, nonzero otherwise.

Arguments

{ list of inputs } List of JMP variable names to be sent to R as inputs.

{ list of outputs } List of JMP variable names to be retrieved from R as outputs.

code A quoted string that contains the R code to submit.

named_arguments See rconn<<Submit("code", named_arguments) on page 437.

rconn<<Control(named_arguments)

Controls the execution of R.

Returns

Void.

Argument

Echo(Boolean) Optional, Boolean. Echoes the R source lines to the JMP log.

rconn<<Get Version()

Gets the current version of R that is installed.

Returns

A vector of length 3 containing the R version number.

rconn<<JMP Name To R Name("name")

Maps a JMP Name to its corresponding R Name using R variable name naming rules.

Returns

A string that contains the R name.

Arguments

name A quoted string that contains the name of a JMP variable to be sent to R.

SAS Integration Messages

Metadata Server Objects

metaserver<<Disconnect()

Function

Disconnects the metadata server.

Returns

Void.

metaserver<<Get Display Name()

Function

Gets the display name of the metadata server.

Returns

A string.

metaserver<<Get Host Name()

Function

Gets the host (machine) name of the metadata server.

Returns

A string.

metaserver<<Get Port()

Function

Gets the port used for the metadata server connection.

Returns

An integer.

`metaserver<<Get User Identity()`

Function

Gets the identify of the connected user as defined in metadata.

Returns

A string.

`metaserver<<Get User Name()`

Function

Gets the user name (login ID) that was used for the metadata server connection.

Returns

A string.

SAS Server Objects

`sasconn<<Assign Libref("libref", "path", engine, engine options)`

Function

Assign a SAS libref on this SAS server connection.

Returns

Void.

Arguments

See "SAS Assign Lib Refs("libref", "path", <"engine">, <"engine options">)" on page 270 in the "JSL Functions" chapter.

`sasconn<<Cancel Submit()`

Function

Cancels the currently running SAS Submit for this server that is presumably running asynchronously.

Returns

1 if a running submit was found and canceled; 0 otherwise.

`sasconn<<Clear Log History()`

Function

Clears the SAS Log history for this server.

Returns

Void.

sasconn<<Clear Output History()

Function

Clears the SAS Output history for this server.

sasconn<<Connect(<named arguments>)

Function

Attempt to reconnect a SAS server connection object that has become disconnected.

Returns

1 if the connection was successful, 0 otherwise.

Named Arguments

All named arguments are optional.

UserName("name") A quoted string that contains the user name for the connection.

Password("password") A quoted string that contains the password for the connection.

Prompt(Always|Never|IfNeeded) A keyword. Always means always prompt before attempt to connect. Never means never prompt even if the connection attempt fails (just fail with an error message going to the log), and IfNeeded (the default) means prompt if the attempt to connect with the given arguments fails (or is not possible with the information given).

sasconn<<Deassign Libref("libref")

Function

De-assign a SAS libref on this SAS server connection.

Returns

Void.

Arguments

libref Quoted string that contains the library reference.

sasconn<<Disconnect()

Function

Disconnect this SAS server connection.

Returns

Void.

`sasconn<Does Module Exist("moduleName")`

Function

Determines whether the specified SAS module exists in the SAS installation represented by the SAS connection. This can be helpful in determining whether certain SAS products are installed. The SAS DATA Step function MODEXIST is used to determine module existence. Because MODEXIST is new for SAS 9.2, this function throws an exception if it is called for a SAS connection that is not version SAS 9.2 or later.

Returns

1 if the specified module is found to exist, 0 if it does not exist.

Argument

moduleName The quoted SAS module, the existence of which should be checked. Do not include any extension.

`sasconn<<Export Data(dt, "library", "dataset", <named arguments>)`

Function

Exports a JMP data table to the specified SAS data set in the specified library on the active SAS server connection.

Returns

1 if the data table was exported successfully; 0 otherwise.

Arguments

See "SAS Export Data(dt, "library", "dataset", <named_arguments>)" on page 272 in the "JSL Functions" chapter.

`sasconn<<Get Data Sets("libref")`

Function

Returns a list of the data sets defined in a SAS library on this SAS server connection.

Returns

List of strings.

Arguments

libref Quoted string that contains the SAS libref or friendly library name associated with the library for which the list of defined SAS data sets will be returned.

`sasconn<<Get Error Count()`

Function

Gets the count of the number of errors encountered in the previous SAS Submit.

Returns

An integer.

sasconn<<Get File("source", "dest")

Function

Download a file from this SAS server connection.

Returns

Void.

Arguments

See "SAS Get File("source", "dest", "encoding")" on page 273 in the "JSL Functions" chapter.

sasconn<<Get File Names("fileref")

Function

Get a list of filenames found in the given "*fileref*" on this SAS server connection.

Returns

List of strings.

Arguments

fileref Quoted string that contains the name of fileref from which to retrieve filenames.

sasconn<<Get File Names In Path("path")

Function

Get a list of filenames found in the given *"path"* on this SAS server connection.

Returns

List of strings.

Arguments

path Quoted string that contains the directory path on the server from which to retrieve filenames.

sasconn<<Get File Refs()

Function

Get a list of the currently defined SAS filerefs on this SAS server connection.

Returns

List of strings.

---

sasconn<<Get Librefs(<named arguments>)

Function

Get a list of the currently defined SAS librefs on this SAS server connection.

Returns

List of strings.

Arguments

See "SAS Get Lib Refs(<named arguments>)" on page 274 in the "JSL Functions" chapter.

---

sasconn<<Get Log()

Function

Retrieve the SAS Log from the last SAS Submit from this SAS server connection.

Returns

String.

---

sasconn<<Get Option Name()

Function

Query SAS for the value of a SAS option variable.

Returns

String.

Example

The following script iterates through the define variables and prints out the values:

```
option_names = sasconn << Get Option Names();
For(i=1, i <= N Items(option_names), i++,
   option_value = sasconn << Get Option Value (option_names[i]);
   output = option_names[i] || "=" || char(option_value) || "/!n";
   Write(output);
);
```

---

sasconn<<Get Output()

Function

Retrieve the listing output from the last submission of SAS code to this SASServer object.

Returns

String.

```
sasconn<<Get Results()
```

Function

Retrieve the results of the previous SAS Submit as a scriptable object, which allows significant flexibility in what to do with the results.

Returns

A SAS Results Scriptable Object.

```
sasconn<<Get Submit Status()
```

Function

Gets the current status of a SAS Submit for this server that is presumably running asynchronously.

Returns

1 if the submit has not started; 2 if the submit is running; 3 if the submit has been canceled; 10 if the submit has completed successfully; 11 if the submit has completed with errors.

```
sasconn<<Get Var Info("libref", "dataset", <"password">)
```

Function

Returns information about the variables the specified SAS data set.

Arguments

libref Quoted string that contains the library reference to de-assign.

dataset Quoted string that contains the name of the data set from which to retrieve variable names.

Password("password") A quoted string that contains the password for the connection.

```
sasconn<<Get Var Names("libref", "dataset", <named arguments>)
```

Function

Retrieves the variable names contained in the specified data set on this SAS server connection.

Returns

List of strings.

Arguments

See "SAS Get Var Names(string, <"dataset">, <password("password")>)" on page 275 in the "JSL Functions" chapter.

sasconn<<Get Version(<"long">)

Function

Returns the SAS version as a string such as "9.1" or "9.2".

Returns

A string that contains the SAS version.

Argument

long An optional quoted keyword that specifies to return the long SAS version, which corresponds to the SYSVLONG SAS macro. For example, "9.02.02M0P01152009".

sasconn<<Get Work Folder()

Function

Returns the full path of the folder corresponding to the WORK library for this server.

Returns

A string that contains the work folder path.

sasconn<<Import Data("library", "dataset", <named arguments>)

Function

Import a SAS data set from this SAS server connection into a JMP table.

Returns

JMP Data Table object.

Arguments

See "SAS Import Data(string, <"dataset">, <named arguments>)" on page 276 in the "JSL Functions" chapter.

sasconn<<Import Query("sqlquery", <named arguments>)

Function

Execute the requested SQL query on this SAS server connection, importing the results into a JMP data table.

Returns

JMP data table object.

Arguments

See "SAS Import Query("sqlquery", <named arguments>)" on page 278 in the "JSL Functions" chapter.

sasconn<<Is Connected()

Function

Determine whether this SAS Server object is currently connected to SAS.

Returns

1 if *sasconn* is connect, 0 otherwise.

sasconn<<Is Product Available("productName")

Function

Determine whether the quoted SAS product is both licensed and installed in the session represented by the SAS connection. The SAS DATA Step functions SYSPROD and MODEXIST are used to determine the licensed and installed status of the product.

Returns

1 if the specified product is licensed, 0 if the product is not licensed, or -1 if the specified product is not recognized by SAS. This function throws an exception if the requested product is not one for which JMP knows how to check the installed status.

Argument

productName The quoted SAS product for which licensing should be checked. The product name can be specified with or without the "SAS/" prefix.

Note

The MODEXIST function is new in SAS 9.2. For SAS 9.1.3, this function only checks the license, not the installed status. In other words, for SAS 9.1.3, this function operates the same way as Is Product Licensed().

sasconn<<Is Product Licensed("productName")

Function

Determines whether the quoted SAS product is licensed in the session represented by the SAS connection. The SAS DATA Step function SYSPROD is used to determine the licensing status of the product.

Returns

1 if the specified product is licensed, 0 if the product is not licensed, or -1 if the specified product is not recognized by SAS.

Argument

productName The quoted SAS product for which licensing should be checked. The product name can be specified with or without the "SAS/" prefix.

`sasconn<<Kill Session(<n>)`

Function

Immediately terminates the SAS connection.

Returns

Void.

Arguments

n An optional number. The system waits n seconds for a normal shut-down before immediately terminating the SAS connection.

`sasconn<<Load Text File("path", <named arguments>)`

Function

Download the file specified in "*path*" from the active SAS server connection and retrieve its contents as a string.

Returns

String.

Arguments

See "SAS Load Text File("path")" on page 279 in the "JSL Functions" chapter.

`sasconn<<Open Log Window()`

Function

Opens (or brings to the front) the SAS Log window for this server.

Returns

Void.

`sasconn<<Open Output Window()`

Function

Opens (or brings to the front) the SAS Output window for this server.

Returns

Void.

`sasconn<<Open SAS Results()`

Function

Open the results from the previous SAS Submit. Intended to be used with asynchronous SAS submits or the use of the OnSubmitComplete option to SAS Submit to give the JSL author a way to conditionally open the results of a submit.

Returns

Void.

---

sasconn<<Open Submit Results()

Function

Opens all the results from the last SAS Submit command.

Returns

Void.

---

sasconn<<Send File("source", "dest")

Function

Upload a file to this SAS server connection.

Returns

Void.

Arguments

See "SAS Send File("source", "dest", "encoding")" on page 280 in the "JSL Functions" chapter.

---

sasconn<<Submit(sasCode, <named arguments>)

Function

Submit some SAS code to this SAS server connection.

Returns

Void.

Arguments

See "SAS Submit("sasCode", <named arguments>)" on page 280 in the "JSL Functions" chapter.

---

sasconn<<Submit File("filename", <named arguments>)

Function

Submit a SAS code file to this SAS server connection.

Returns

Void.

Arguments

See "SAS Submit File("filename", <named arguments>)" on page 282 in the "JSL Functions" chapter.

Stored Processes

`stp<<Begin Run(<named arguments>)`

Function

Start this stored process executing in the background. This message is paired with `End Run`, which should also be called at some point after `Begin Run` to wait for the stored process to complete.

Returns

`-1` = execution failed.

`1` = not started.

`2` = running.

`3` = canceled.

`10` = completed successfully.

`11` = completed with errors.

Arguments

Same as `Run`, except `AutoOpenResults` and `NoAlerts` are not supported. They are available on `EndRun`.

`AutoResume(<"filename">)` Optional, quoted string. If specified with no argument, it specifies that the stored process results should be auto-opened when the stored process completes. If filename is specified, filename is opened rather than all results of the stored process being auto-opened.

`AutoResumeScript("script")` Optional, quoted string that specifies that after stored process execution completes, script should be evaluated. If the script is a function taking at least one argument, the function is evaluated with the scriptable stored process object passed as the first (and only) argument. `AutoResume` and `AutoResumeScript` are mutually exclusive.

`stp<<Delete Results(<named arguments>)`

Function

Delete all results from the execution of this stored process.

Returns

`1` if deletion is successful, `0` otherwise (error message to JMP log).

Arguments

`NoAlerts(0|1)` Optional, Boolean. If `True`, the user is not prompted for confirmation before the attempt is made to delete results.

`DeleteDirectory(0|1)` Optional, Boolean. If true, deletes the directory containing the stored process results along with the result files themselves. The default value is true.

`stp<<Edit Param Values()`

Function

Opens the stored process window for interactively setting parameter values.

Returns

1 if the user clicks **OK** to dismiss the window, 0 if the user clicks **Cancel**.

`stp<<End Run(<named arguments>)`

Function

Waits a specified amount of time (or forever) for a stored process started with `Begin Run` to complete. If the stored process is complete, retrieves the results, and opens them.

Returns

-1 = execution failed.

1 = not started.

2 = running.

3 = canceled.

10 = completed successfully.

11 = completed with errors.

Arguments

`AutoOpenResults(0|1)` Optional, Boolean. If `True`, results are automatically opened if the stored process completes in the time specified by *MaxWait*. If `False`, results are not automatically opened, and can be manually opened via the object returned by the `Get Results` message. Default is `True`.

`MaxWait(milliseconds)` Optional, an integer. Specifies the maximum amount of time in milliseconds to wait for the stored process to complete. If `MaxWait` is not specified, `End Run` waits forever for the stored process to complete.

`NoAlerts(0|1)` Optional, Boolean. If `True`, error messages are sent to the JMP log rather than message boxes. The default value is `False`.

`stp<<Get Metadata Id()`

Function

Returns the metadata ID of the stored process.

Returns

String.

stp<<Get Metadata Path()

Function

Returns the full metadata path of the stored process.

Returns

String.

Stp<<Get Name()

Function

Returns the name of the stored process.

Returns

String.

stp<<Get Param Enum Labels("name")

Function

Get the enumeration labels for a parameter.

Returns

List of strings.

Arguments

name Quoted string that contains the name of the parameter whose enumeration labels to retrieve.

stp<<Get Param Enum Values("name")

Function

Get the possible enumerated values for a parameter.

Returns

List of strings.

Arguments

name Quoted string that contains the name of the parameter whose possible enumerated values to retrieve.

stp<<Get Param Names(<named arguments>)

Function

Get a list of parameter names for this stored process of specific types.

Returns

List of strings.

Arguments

Visible(0|1) Optional, Boolean. If True, get only visible parameters. If False, get only non-visible parameters. If not specified, get both visible and non-visible parameters.

Modifiable(0|1) Optional, Boolean. If True, get only modifiable parameters. If False, get only non-modifiable parameters. If not specified, get both modifiable and non-modifiable parameters.

Required(0|1) Optional, Boolean. If True, get only required parameters. If False, get only non-required parameters. If not specified, get both required and non-required parameters.

Expert(0|1) Optional, Boolean. If True, get only expert parameters. If False, get only non-expert parameters. If not specified, get both expert and non-expert parameters.

---

stp<<Get Param Value("name")

Function

Get the current value of the specified parameter.

Returns

String.

Arguments

name Quoted string that contains the name of the parameter whose value to retrieve.

---

stp<<Get Results()

Function

Get the results generated by the execution of this stored process as a scriptable object.

Returns

SAS Results scriptable object.

---

stp<<Get Status()

Function

Get the execution status of the stored process.

Returns

-1 = execution failed.

1 = not started.

2 = running.

3 = canceled.

10 = completed successfully.

11 = completed with errors.

stp<<Get Status Message()

Function

Get the message associated with the failure of the stored process, if any.

Returns

String.

stp<<Reset Param Values()

Function

Reset all parameter values to their metadata-defined default values.

Returns

Void.

stp<<Run(<named arguments>)

Function

Execute this stored process object in the foreground.

Returns

-1 = execution failed.

1 = not started.

2 = running.

3 = canceled.

10 = completed successfully.

11 = completed with errors.

Arguments

AutoOpenResults(0|1) Optional, Boolean. If True, results are automatically opened
when the stored process completes. If False, results are not auto-opened, and can be
manually opened via the object returned by the GetResults message. The default value
is True.

UserName("username") Optional, quoted string that contains the user name under which
to run the stored process.

Password("password") Optional, quoted string that contains the password for *Username*.

AuthDomain("authDomain") Optional, quoted string that contains the authentication
domain of the credentials (*username, password*) given.

ODSDest("dest") Optional, quoted string that contains an ODS destination (HTML, PDF,
tagsets.SASReport12) for any ODS-generated results from the stored process. This
requires the stored process SAS code to call %STPBEGIN. The default value is HTML.

GraphicsDevice("device") Optional, quoted string that contains the SAS graphics device to use when generating graphics in ODS results. This requires the stored process SAS code to call %STPBEGIN. The default value is GIF.

ODSStyle("styleName") Optional, quoted string that contains an ODS style to apply to the results. This requires the stored process SAS code to call %STPBEGIN. There is no default value.

ODSStyleSheet("cssFile") Optional, quoted string that contains the full path to a CSS file on the client machine that is to be applied to generated ODS results. This requires the stored process SAS code to call %STPBEGIN. There is no default value.

NoAlerts(0|1) Optional, Boolean. If True, error messages are sent to the JMP log rather than message boxes. The default value is False.

---

stp<<Set Param Value("name", "value")

Function

Sets the value of the specified stored process parameter to the specified value.

Returns

1 if successful, 0 otherwise (value can violate the parameter's constraints).

Arguments

name Quoted string that contains the name of the parameter whose value to set.

value Quoted string that contains the value to which to set the parameter.

---

stp<<Set Results Directory("directory")

Function

Sets the directory on the client machine where stored process results are placed.

Returns

String.

Arguments

directory Quoted string that contains the full path of the directory where results of the stored process execution should be placed. The directory must exist or be creatable. If the results directory is not set, a temporary location appropriate for the operating system will be used, and that directory can be retrieved from the stored process Results scriptable object after the stored process executes.

SAS Results

results<<Delete All Result Files()

Function

Deletes all files created by the SAS Submit or Stored Process execution. Note that any result files that are still in use are not deleted.

Returns

1 if the deletion was successful; 0 if some of the files could not be deleted.

results<<Get Directory()

Function

Gets the directory where the results generated by the stored process or SAS submit are located.

Returns

String.

results<<Get Log()

Function

Get the SAS Log from the execution of the stored process or SAS submit.

Returns

String.

results<<Get Main Result File Name(<named arguments>)

Function

Gets the full path of the main result file generated by the stored process or SAS submit.

Returns

String.

Arguments

FullPath(0|1) Optional, Boolean. If True, the main result filename is returned as a full path. The default value is False.

results<<Get Output()

Function

Gets the SAS Listing output from the execution of the stored process or SAS submit.

Returns

String.

results<<Get Output Datasets()

Function

Get a list of output data set generated by the SAS Submit that created this SAS Results object.

Returns

A list of data set names in the form "libname.membername".

results<<Get Result File Info(<MIMEType("mime-type")>, <FullPath>)

Function

Get information about result files that were generated by the execution of the stored process or SAS submit.

Returns

List of two lists of strings. The first list is filenames, and the second list is the MIME-type of the corresponding file from the first list.

Arguments

MIMEType("mime_type") Optional, quoted string that restricts the set of files for which information is returned to only those files with the specified MIME-type. If not specified, information about all generated files is returned.

FullPath Optional, Boolean. If True, the filename returned for each result file is returned as a full path; if False, only the name of the file is returned. The default value is False.

results<<Make JMP Report()

Function

Parses the ODS XML results and creates a JMP report.

Returns

The display box for the report.

results<<Open All Results()

Function

Opens all results generated by the execution of the stored process or SAS submit.

Returns

Void.

results<<Open Result File("filename", <named arguments>)

Function

Attempts to open the result file with the given name.

Returns

JMP Data Table if one was opened.

Arguments

filename Quoted string that contains the name of the file from the generated results to open. filename should just be the name of the file, not the full path. If *filename* is a filename with no extension, both JMP data tables and JSL scripts in the results are searched for a match, and if both exist, both are opened.

RunScript(0|1) Optional, Boolean. If True, and if *filename* is a JSL script, the script is executed. If False, *filename* is just opened, even if it is JSL.

```
results<<Run Script("filename")
```

Function

Looks for a JSL file in the results with the given filename and runs it if it finds it.

Returns

Void.

Arguments

filename Quoted string that contains the name of the JSL file from the generated results to open. *Filename* should just be the name of the file, not the full path, and it does not need to include the .jsl extension.

Schedule

For more information about scheduling actions, see the Programming chapter in the *Scripting Guide*.

See also "Schedule(n, script)" on page 329 in the "JSL Functions" chapter.

```
sch<<Clear Schedule()
```

Cancels all scheduled events.

```
sch<<Close()
```

Closes the scheduler.

```
sch<<Restart()
```

Restarts the scheduler after it was stopped from running all scheduled events.

sch<<Show Schedule()

Shows a list of all scheduled events.

sch<<Stop()

Stops the scheduler from running all scheduled events.

Sockets

skt<<Accept(<callback, timeout>)

Function

Tells the server socket to accept a connection and return a new connected socket.

Returns

A list of up to four items. The first is a string that echoes the command (`"accept"`). The second is a string, either `"ok"` or an error. The third is a string that specifies the name of the machine that just connected. The fourth is a reference to the socket that you can send more messages.

Arguments

callback　an optional argument that specifies the name of a function to receive the data.

timeout　if you use a *callback, timeout* specifies how long the function should wait for an answer. For a server socket, 0 is an acceptable value because a server should not shut down because no one has connected to it recently.

skt<<bind("localhost", port)

Function

Associates a port on the local machine with the socket.

Returns

A list of two strings. The first string is the command name ("bind") and the second is "ok" if successful or an error.

Argument

localhost　Specifies the local machine. You cannot bind to another machine.

port　The port that should be used.

skt<<Close()

Function

Closes a socket.

Returns

A list of two strings. The first string is the command name ("close") and the second is "ok" if successful.

skt<<Connect(socketname, port)

Function

Connects to a listening socket.

Returns

A list of two strings. The first string is the command name ("connect") and the second is "ok" for a successful connection or an error sent back by the other socket.

Arguments

socketname the name of the other socket. If you are connecting to a web server, this is the web address (the name is preferred to the IP address).

port the port of the other socket to connect through.

skt<<GetPeerName()

Function

Retrieves the address and port of the socket at the other end of the connection.

Returns

A list of four strings. The first echoes the command ("getpeername"). The second is either "ok" or an error. The third and fourth are the address and the port.

skt<<GetSockName()

Function

Retrieves the address and port of the socket at this end of the connection.

Returns

A list of four strings. The first echoes the command ("getsockname"). The second is either "ok" or an error. The third and fourth are the address and the port.

skt<<ioctl(FIONBIO, 1)

Function

Controls the socket's blocking behavior.

Returns

A list of two strings. The first string is the command name ("ioctl") and the second is "ok" if successful or an error.

Arguments

FIONBIO, 1 FIONBIO means Non-Blocking I/O. 1 turns on the behavior and the argument.

skt<<Listen()

Function

Tells the server socket to listen for connections.

Returns

A list of two strings. The first echoes the command ("listen") and the second is "ok" or an error message.

skt<<recv(n, <callback, timeout>)

skt<<recvfrom(n, <callback, timeout>)

Function

Receives either a stream message (recv) or a datagram message (recvfrom) from the other socket. If the two optional arguments are used, the data is not received immediately. Instead, the data is received when the function *callback* is called.

Returns

A list of three strings. The first string is the command name ("recv" or "recvto"). The second is "ok" if successful or an error message if not. The third string is the data that was received. If a callback function is used, a fourth element is the socket that was used in the original recv or recvfrom message.

Arguments

n specifies the number of bytes to receive from the other socket.

callback an optional argument that specifies the name of a function to receive the data.

timeout if you use a *callback, timeout* specifies how long the function should wait for an answer.

skt<<Send(stream)

skt<<SendTo(dgram)

Function

Sends the data in the argument to the other socket. Send sends a stream and sendto sends a datagram.

Returns

A list of three strings. The first string is the command name ("send" or "sendto"). The second is "ok" if successful or an error message if not. The third string is any portion of the stream that could not be sent, or empty if all the data was sent correctly.

Arguments

stream the command to send to the other socket.

dgram the command to send to the other socket.

Note

Either argument might need to contain binary data. JMP represents non-printable ASCII characters with a tilde (~) followed by the hexadecimal number. For example,

```
 skt<<send(("GET / HTTP/1.0~0d~0a~0d~0a");
```

sends a "get request" to an HTTP server.

SQL

```
obj<<Custom SQL(sql)
```

Changes the query to a custom SQL query and sets the SQL.

```
obj<<Generate SQL
```

Returns the SQL that the query generates when you run it.

```
obj<<Modify
```

Opens the query in Query Builder.

```
obj<<PostQueryScript(script_as_text)
```

Sets a JSL script that runs after the query finishes executing.

```
obj<<Query Name(<newName>)
```

Gets (without the newName argument) or sets (with the newName argument) the name of the query. The name of the query is used as the name of the data table that results from running the query.

```
obj<<Run(<private|invisible>, <UpdateTable(table)>,
<OnRunComplete(script)>, <OnRunCanceled(script)>, <OnError(script)>
```

Description

Runs the SQL query in the background or foreground depending on the Query Builder preference "Run queries in the background when possible".

Returns

Null (if the query runs in the background) or a data table (if the query runs in the foreground).

Arguments

`private` Optional. Opens the data table that the query produces without displaying it in a data table window.

`invisible` Optional. Hides the data table that the query produces. Use this argument to keep the query result hidden but use it in a subsequent query. The data table is displayed in the Home Window's Window List and the Window > Unhide list.

`UpdateTable` Optional. Updates the specified data table. Runs the query in the foreground.

`OnRunComplete` Optional. Specifies a script to run after the query is complete.

`OnRunCanceled` Optional. Specifies a script to run after the user cancels the query.

`OnError` Optional. Specifies a script to run if an error occurs.

Notes

If you want the data table that results from the background query, use the `OnRunComplete` optional argument. You can include a script that runs when the query completes and then assigns a data table reference to the resulting data table. Or you might pass the name of a function that accepts a data table as its first argument. That function is called when the query completes.

Examples

The following example opens a query that you previously saved from Query Builder. The query opens privately, that is, without opening Query Builder. The query runs, and the resulting data table opens.

```
query = Open( "c:/My Data/Movies.jmpquery", private);
dt = query << Run();
```

You can include a .jmpquery file in a script and run the query in the background using the `<<Run Background` message.

```
query = Include( "C:/Queries/movies.jmpquery");
query <<Run Background();
```

The following example queries the database, opens the resulting data table, and prints the number of data table rows to the log.

```
confirmation = Function( {dtResult},
   Write( "\!NNumber of rows in query result: ", N Rows( dtResult ) )
);
query = New SQL Query(
   Connection(
      "ODBC:DSN=SQL
   Databases;APP=MYAPP;TrustedConnection=yes;WSID=D79255;DATABASE=SQB;"
   ),
```

```
    QueryName( "movies_to_update" ),
    Select( Column( "YearMade", "t1" ), Column( "Rating", "t1" ) ),
    From( Table( "g6_Movies", Schema( "SQB" ), Alias( "t1" ) ) ),

);
query << Run( OnRunComplete( confirmation ) );
```

Run Background(<OnRunComplete(script), <private|invisible>>, <OnRunCanceled(script)>, <OnError(script)>

Description

Runs the SQL query in the background. The running query is not displayed.

Returns

Null (or the data table object, if `OnRunComplete` is included).

Arguments

`OnRunComplete` Optional. Specifies a script to run after the query is complete. To get the resulting data table, include `OnRunComplete`.

`private` Optional. Does not open the resulting data table. Specify only with `OnRunComplete`. If you include `private` in a background query, JMP opens the data table as invisible instead.

`invisible` Optional. Hides the data table. Use this argument to keep the query result hidden but use it in a subsequent query. The data table is displayed in the Home Window's Window List and the Window > Unhide list.

`OnRunCanceled` Optional. Specifies a script to run after the user cancels the query.

`OnError` Optional. Specifies a script to run if an error occurs.

Notes

All queries except for SAS queries run in the background based on the Query Builder preference "Run the queries in the background when possible", which is selected by default. For SAS queries, `Run Background()` is ignored.

You can include a .jmpquery file in a script and run the query in the background using the `<<Run Background` message.

```
query = Include( "C:/Queries/movies.jmpquery");
query <<Run Background();
```

Run Foreground(<OnRunComplete(script), <private|invisible>>, <OnRunCanceled(script)>, <OnError(script)>

Description

Runs the SQL query in the foreground.

Returns

A data table that opens when the query is finished.

See for details about the arguments.

obj<<Save

Saves the query to its associated file. The save fails if the query does not yet have an associated file.

obj<<Save As(path, <ReplaceExisting(Boolean))

Saves the query to the specified file. If the file already exists, the save fails unless `Replace Existing` is true.

Other Objects

Zip Archives

list = za<<dir

Returns a list of member names

data = za<<read(membername, <format(blob)>)

Returns a string that contains the entire member data. If the optional argument is specified, the message returns a blob.

Note

For remote files, JMP copies the URL data to the local disk. When the zip archive is no longer accessible, the local data file is deleted.

actualname = za<<write(membername, textstring|blobdata)

Writes a text or blob to a zip archive member file. If the specified `membername` isn't in the current zip file, the returned `actualname` is the same as `membername`. This member name will be changed to prevent overwriting an existing member; the name actually used is returned. For example,

```
 name1 = za<<write(name, blobdata)
```

Journals

`jnl<<Save HTML(<"path">, <"format">)`

Saves the journal as HTML.

path A quoted string that contains the filepath for the saved HTML file (for example, `"c:/myFile.html"`).

format The quoted graphic file format. JPG, PNG, and TIFF formats are supported. The graphics are saved in a subdirectory named gfx.

`jnl<<Save RTF(<"path">, <"format">)`

Saves the journal as an RTF file.

Arguments

path A quoted string that contains the filepath for the saved RTF file (for example, `"c:/myFile.rtf"`).

format The quoted file format for the embedded graphics. JPG, PNG, and TIF formats are supported.

`jnl<<Save PDF(<"path">, <Show Page Setup(0|1)>, <Portrait(0|1)>)`

Saves the journal as a PDF file.

Arguments

path A quoted string that contains the filepath for the saved PDF file (for example, `"c:/myFile.pdf"`).

Show Page Setup If set to true, opens the Page Setup window to let the user change the margin, magnification level, and other page layout options.

Portrait Determines whether the page orientation is portrait or landscape. Overrides the user's selection in the Show Page Setup window.

Appendix A

SQL Functions Available for JMP Queries

The `Query()` JSL function performs a SQL query on selected tables and exports the data to a data table. The following example first assigns the t1 alias to Big Class.jmp. name, age greater than 13, and height are then selected from the t1 table.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Query( Table( dt, "t1" ),
        "SELECT t1.name, t1.age, t1.height FROM t1
        WHERE t1.age > 13" );
```

You can use SQL functions in a query. For example, SELECT CURRENT_TIMESTAMP returns the current UTC/GMT time stamp as a SQLite time string:

```
Query( Scalar, "SELECT CURRENT_TIMESTAMP;" );
```

This appendix lists the numeric, date-time, string, system SQL, and aggregate functions that you can use in SQL queries. "Yes" in the SQLite column indicates native SQLite functions. See the Online SQLite documentation at https://www.sqlite.org/lang.html for details.

Contents

Numeric SQL Functions

Numeric Function	Native SQLite	Description
ABS(*number*)		Returns the absolute value of the specified number.
ACOS(*cosine*)		Returns the angle in radians for the specified cosine.
ASIN(*sin*)		Returns the angle in radians for the specified sine.
ATAN(*tangent*)		Returns the angle in radians for the specified tangent.
ATAN2(*x, y*)		Two-argument arctangent function.
CEILING(*number*) CEIL(*number*)		Returns the smallest integer larger than the specified number.
COS(*radians*)		Returns the cosine of the specified angle in radians.
COT(*radians*)		Returns the cotangent of the specified angle in radians.
DEGREES(*radians*)		Converts an angle in radians to an angle in degrees.
EXP(*number*)		Returns the constant e raised to the specified power.
FLOOR(*number*)		Returns the largest integer smaller than the specified number.
LN(*number*) LOG(*number*)		Returns the natural logarithm of the specified number.
LOG10(*number*)		Returns the common logarithm of the specified number.
MAX(*n1, n2, ...*)	Yes	Returns the largest of the specified numbers. A minimum of two numbers must be specified.
MIN(*n1, n2, ...*)	Yes	Returns the smallest of the specified numbers. A minimum of two numbers must be specified.
MOD(*dividend, divisor*)		Returns the remainder when *dividend* is divided by *divisor*. Floating-point values are truncated to integers before the modulus operation is performed.
PI()		Returns the value of the constant pi (π).
POWER(*number, power*) POW(*number, power*)		Raises *number* to the specified *power*.

Numeric Function	Native SQLite	Description
RADIANS(*degrees*)		Converts an angle in degrees to an angle in radians.
RANDOM() RANDOM(*max*) RANDOM(*min, max*)		Returns a random number. RANDOM() returns a number between 0 and 1. RANDOM(max) returns a number between 0 and *max*. RANDOM(min, max) returns a number between *min* and *max*. This function is equivalent to the Random Uniform() JSL function, and its seed can be controlled using the Random Reset() JSL function. RANDOM can be shortened to RAND.
RANDOMBLOB(*length*)	Yes	Returns an N-byte blob that contains pseudo-random bytes. See the SQLite Online documentation at https://www.sqlite.org/lang.html for details.
ROUND(*number*, *<precision>*)		Rounds *number* to the number of decimal places given by *precision*. The default value of *precision* is 0, and *precision* can be negative.
SIGN(*number*)		Returns 1 if *number* is positive, -1 if *number* is negative, or 0 if *number* is zero.
SIN(*radians*)		Returns the sin of the specified angle in radians.
SQRT(*number*)		Returns the square root of *number*.
TAN(*radians*)		Returns the tangent of the specified angle in radians.
TRUNCATE(*number*, *<precision>*)		Truncates *number* at the number of decimal places given by *precision*. The default value of *precision* is 0, and *precision* can be negative. TRUNCATE() can be shortened to TRUNC().

Date-Time SQL Functions

Using date-time functions in JMP queries is complicated by the fact that the SQL engine that handles JMP queries (SQLite) uses different formats for storing dates than JMP does. SQLite stores date-times as strings. However, JMP stores date-times as the number of seconds since January 1, 1904. When you have columns in your table that contain date-times, the conversions are handled automatically. However, when you use functions that return date-times, you might need to let JMP know when a conversion is required.

Consider the CURRENT_TIMESTAMP function. CURRENT_TIMESTAMP is a built-in SQLite function that returns the current UTC/GMT time stamp as a SQLite time string:

```
Query( Scalar, "SELECT CURRENT_TIMESTAMP;" );
```

returns:

"2016–02–16 15:44:42"

The string could perhaps be parsed as a date to return it as a JMP date. To prevent the need to do so, wrap the CURRENT_TIMESTAMP function in the JMPDATE() function:

```
Query( Scalar, "SELECT JMPDATE( CURRENT_TIMESTAMP );" );
```

returns:

3538482531

The string is an unformatted JMP date. However, if you pass a SQLite time string to another SQL date-time function, you do not need to use JMPDate(); the value will be converted to a JMP date automatically. Here is an example:

```
Query( Scalar, "SELECT EXTRACT('YEAR', CURRENT_TIMESTAMP);" );
```

Using native SQLite date-time functions (date(), time(), datetime(), julianday(), strftime()) in JMP queries is not recommended because JMP date-time values are not compatible with those functions.

Date-Time Function	Naive SQLite	Description
CURRENT_DATE	Yes	Returns the current date (UTC/GMT) as a SQLite time string.
CURRENT_TIME	Yes	Returns the current time (UTC/GMT) as a SQLite time string.
CURRENT_TIMESTAMP	Yes	Returns the current date and time (UTC/GMT) as a SQLite time string.
DATEDIFF(*date1*, *date2*, *interval*, *<alignment = "Start">*)		Computes the difference between two dates in units specified by *interval*, based on *alignment*. This function works the same as the Date Difference() JSL function. Valid values for *interval* are: "Year", "Quarter", "Month", "Week", "Day", "Hour", "Minute" and "Second". Valid values for *alignment* are "Start", "Actual" and "Fractional". If *alignment* is not specified, "Start" is used.

Date-Time Function	Naive SQLite	Description
EXTRACT(*datepart*, *datetime*, *<use_locale = 1>*)		Extracts a specific part of a date or date-time value. *Datetime* is a JMP date-time value or a SQLite time string. *Use_locale* is optional and applies only to date name parts such as "MonthName" and "DayName" and determines whether values from the current language or English are returned. The following values of *datepart* are supported:
		"Year" — Returns the year as a number.
		"Month" — Returns the numeric month (1-12).
		"MonthName" — Returns the full name of the month in the current language (*use_locale = 1*) or English (*use_locale = 0*).
		"Mon", "MMM" — Returns the abbreviated name of the month.
		"Day" — Returns the day of the month (1-31).
		"DayName" — Returns the name of the day of the week.
		"DayOfWeek" — Returns the numeric day of the week (1-7).
		"DayOfYear" — Returns the numeric day of the year (1-366).
		"Quarter" — Returns the numeric quarter (1-4).
		"Hour" — Returns the hour (0-23).
		"Minute" — Returns the minute (0-59).
		"Second" — Returns the seconds, including any fractional part.
		"Date" — Returns just the date portion of a date-time value as a JMP date-time value.
		"Time" — Returns just the time portion of a date-time value as a JMP date-time value.
JMPDATE(*SQLite time string*)		Converts a SQLite time string to the equivalent JMP date-time value.
NOW()		A synonym for TODAY().
TODAY()		Returns the JMP date-time value of the current moment in *local* time, which matches the JMP Today() function.

String SQL Functions

Function	Native SQLite	Description
HEX(*binary*)	Yes	SQLite built-in function that converts a BLOB to a string of hexadecimal characters. Useful when paired with the RANDOMBLOB() function.
JLEFT(*string*, *len*, *<pad>*)		Like the JSL Left() function. Returns *len* characters from the beginning of *string*. If *pad* is specified and fewer than *len* characters are present in *string,* the result is padded with *pad* out to length *len*.
JRIGHT(*string*, *len*, *<pad>*)		Like the JSL Right() function. Returns *len* characters from the end of *string*. If *pad* is specified and fewer than *len* characters are present in *string,* the result is padded with *pad* at the front out to length *len*.
LENGTH(*string*)	Yes	SQLite equivalent of the ANSI standard CHAR_LENGTH() function. Returns the length of its string argument in characters.
LOCATE(*string1*, *string2*) POSITION(*string1*, *string2*)		Returns the (1-based) starting position of *string1* within *string2*, returning 0 if *string1* is not found within *string2*.
LOWER(*string*)		Returns a copy of *string* with all uppercase characters converted to lowercase.
LTRIM(*string*, *<trimchars>*)	Yes	Trims any characters contained in *trimchars* from the beginning of *string* and returns the result. If *trimchars* is omitted, spaces are trimmed.
PRINTF(*format*, *<arg1, ..., argN>*)	Yes	Allows constructing strings using placeholders and arguments. See the SQLite Online documentation at https://www.sqlite.org/lang.html for details.
REPLACE(*string*, *find*, *replace*)	Yes	Replaces all instances of *find* in *string* with *replace* and returns the result. If *replace* is numeric, it is converted to a string.
REVERSE(*string*)		Returns a copy of *string* with the order of the characters reversed.

Function	Native SQLite	Description
RTRIM(*string*, *<trimchars>*)	Yes	Trims any characters contained in *trimchars* from the end of *string* and returns the result. If *trimchars* is omitted, spaces are trimmed.
SPACE(*length*)		Returns a string consisting of *length* space characters.
SUBSTR(*string*, *start*, *<length>*)	Yes	Returns the substring of *string* starting at *start* (1-based) that is *length* characters long. If *length* is omitted, the substring starting at *start* and continuing to the end of *string* is returned.
TRIM(*string*, *<trimchars>*)		Trims any characters contained in *trimchars* from the end of *string* and returns the result. If *trimchars* is omitted, spaces are trimmed.
UPPER(*string*)		Returns a copy of *string* with all lowercase characters converted to uppercase.

System SQL Functions

Function	SQLite	Description
COALESCE(*arg1*,..., *argN*)	Yes	Returns the first argument passed to it that is non-NULL. Returns NULL if all arguments are NULL. Requires at least two arguments.
IFNULL(*arg1*, *arg2*)	Yes	Returns *arg1* if not NULL, otherwise *arg2*. Basically, IFNULL is a two-argument version of COALESCE().
NULLIF(*arg1*, *arg2*)	Yes	Returns *arg1* if *arg1* and *arg2* are different and returns NULL if the arguments are equal. Used when you have non-NULL values in your database that you want to treat as NULL.

Aggregate SQL Functions

When passing a single argument to an aggregate function, that argument can be preceded by the keyword DISTINCT, which filters out duplicate values.

For all aggregations other than COUNT(*), NULL and missing values are ignored.

Function	SQLite	Description
AVG(*num_expr*)		Computes the average of *num_expr* for the rows in the group. *Num_expr* must be numeric.
COUNT(*expr*) COUNT(*)		Counts the number of times *expr* is not NULL in the group. COUNT(*) returns the total number of rows in the group.
GROUP_CONCAT(*expr*, *<separator = ','>*)	Yes	Concatenates all non-NULL values of *expr* and returns them as a string. Numeric values of *expr* are converted to character. If *separator* is present, it is placed between the values. The default separator is a comma. DISTINCT can be used only with GROUP_CONCAT() if *separator* is not specified.
MAX(*expr*)		Returns the maximum value of *expr* in the group. *Expr* can be character or numeric.
MIN(*expr*)		Returns the minimum value of *expr* in the group. *Expr* can be character or numeric.
STDDEV_POP(*num_expr*)		Computes the population standard deviation of *num_expr* for the group.
STDDEV_SAMP(*num_expr*)		Computes the sample standard deviation of all *num_expr* for the group.
SUM(*num_expr*)		Returns the sum of *num_expr* for the group. If no non-NULL values are found, SUM() returns NULL.
TOTAL (*num_expr*)	Yes	Same as SUM(*num_expr*), except TOTAL() returns 0.0 if no non-NULL values are found.
VAR_POP(*num_expr*)		Computes the population variance of *num_expr* for the group.
VAR_SAMP(*num_expr*)		Computes the sample variance of *num_expr* for the group.

Appendix B

JMP Icon Names

This appendix provides the names of all icons used in JMP. Specify the quoted icon name in the Icon Box() function to create a display box that contains the icon. For example, the following example constructs a display box that contains the Nominal icon.

Icon Box("Nominal") constructs a display box that contains the Nominal icon.

Icon names can also be used in Button Box(), Tree Node(), Tree Box(), Tab Page Box(), command menu items in an add-in, and window objects.

```
nw = New Window( "Icon Example",
    Icon Box( "Nominal" ),
    bb = Button Box( "Example Text", ),
    Tree Box( {tn = Tree Node( "Example" )} ),
    Tab Page Box( Title( "Example Text" ), Icon( "Nominal" ), Text Box(
   "Example Text" ) ),
    List Box( {{"Example Text", "Nominal"}} )
);
bb << Set Icon( "Nominal" );
tn << Set Icon( "Nominal" );
nw << Set Window Icon( "Nominal" );
```

Caution: JMP might rename an icon. Scripts that rely on icon names will then break.

Notes:

- Some icons are used in both Windows and Macintosh. Other icons are platform specific.

- Consider installing the Built-In JMP Icons add-in. The add-in lets you view icons interactively and see what they look like in different contexts. Download the add-in from https://community.jmp.com/t5/JMP-Add-Ins/Built-In-JMP-Icons/ta-p/42251.
