Formatting Conventions in JMP Documentation

These conventions help you relate written material to information that you see on your screen:

- Sample data table names, column names, pathnames, filenames, file extensions, and folders appear in Helvetica (or sans-serif online) font.
- Code appears in Lucida Sans Typewriter (or monospace online) font.
- Code output appears in Lucida Sans Typewriter italic (or monospace italic online) font and is indented farther than the preceding code.
- **Helvetica bold** formatting (or bold sans-serif online) indicates items that you select to complete a task:
  - buttons
  - check boxes
  - commands
  - list names that are selectable
  - menus
  - options
  - tab names
  - text boxes

- The following items appear in italics:
  - words or phrases that are important or have definitions specific to JMP
  - book titles
  - variables

- Features that are for JMP Pro only are noted with the JMP Pro icon. For an overview of JMP Pro features, visit [https://www.jmp.com/software/pro](https://www.jmp.com/software/pro).

**Note:** Special information and limitations appear within a Note.

**Tip:** Helpful information appears within a Tip.
JMP Help

JMP Help in the Help menu enables you to search for information about JMP features, statistical methods, and the JMP Scripting Language (or JSL). You can open JMP Help in several ways:

- Search and view JMP Help on Windows by selecting **Help > JMP Help**.
- On Windows, press the F1 key to open the Help system in the default browser.
- Get help on a specific part of a data table or report window. Select the Help tool from the **Tools** menu and then click anywhere in a data table or report window to see the Help for that area.
- Within a JMP window, click the **Help** button.

**Note:** The JMP Help is available for users with Internet connections. Users without an Internet connection can search all books in a PDF file by selecting **Help > JMP Documentation Library**. See “JMP Documentation Library” on page 4 for more information.

JMP Documentation Library

The Help system content is also available in one PDF file called **JMP Documentation Library**. Select **Help > JMP Documentation Library** to open the file. If you prefer searching individual PDF files of each document in the JMP library, download the files from [https://www.jmp.com/documentation](https://www.jmp.com/documentation).

The following table describes the purpose and content of each document in the JMP library.

<table>
<thead>
<tr>
<th>Document Title</th>
<th>Document Purpose</th>
<th>Document Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovering JMP</td>
<td>If you are not familiar with JMP, start here.</td>
<td>Introduces you to JMP and gets you started creating and analyzing data. Also learn how to share your results.</td>
</tr>
<tr>
<td>Using JMP</td>
<td>Learn about JMP data tables and how to perform basic operations.</td>
<td>Covers general JMP concepts and features that span across all of JMP, including importing data, modifying columns properties, sorting data, and connecting to SAS.</td>
</tr>
<tr>
<td>Document Title</td>
<td>Document Purpose</td>
<td>Document Content</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Basic Analysis       | Perform basic analysis using this document.          | Describes these Analyze menu platforms:  
  • Distribution  
  • Fit Y by X  
  • Tabulate  
  • Text Explorer  
  Covers how to perform bivariate, one-way ANOVA, and contingency analyses through Analyze > Fit Y by X. How to approximate sampling distributions using bootstrapping and how to perform parametric resampling with the Simulate platform are also included. |
| Essential Graphing   | Find the ideal graph for your data.                   | Describes these Graph menu platforms:  
  • Graph Builder  
  • Scatterplot 3D  
  • Contour Plot  
  • Bubble Plot  
  • Parallel Plot  
  • Cell Plot  
  • Scatterplot Matrix  
  • Ternary Plot  
  • Treemap  
  • Chart  
  • Overlay Plot  
  The book also covers how to create background and custom maps.                                                                                                                                                                                                                                                                               |
<p>| Profilers            | Learn how to use interactive profiling tools, which enable you to view cross-sections of any response surface. | Covers all profilers listed in the Graph menu. Analyzing noise factors is included along with running simulations using random inputs.                                                                                                                                                                                                                     |</p>
<table>
<thead>
<tr>
<th>Document Title</th>
<th>Document Purpose</th>
<th>Document Content</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Design of Experiments Guide</em></td>
<td>Learn how to design experiments and determine appropriate sample sizes.</td>
<td>Covers all topics in the DOE menu.</td>
</tr>
</tbody>
</table>
| *Fitting Linear Models*          | Learn about Fit Model platform and many of its personalities.                   | Describes these personalities, all available within the Analyze menu Fit Model platform:  
  • Standard Least Squares  
  • Stepwise  
  • Generalized Regression  
  • Mixed Model  
  • MANOVA  
  • Loglinear Variance  
  • Nominal Logistic  
  • Ordinal Logistic  
  • Generalized Linear Model |

| *Multivariate Methods* | Read about techniques for analyzing several variables simultaneously. | Describes these Analyze > Multivariate Methods menu platforms:  
- Multivariate  
- Principal Components  
- Discriminant  
- Partial Least Squares  
- Multiple Correspondence Analysis  
- Structural Equation Models  
- Factor Analysis  
- Multidimensional Scaling  
- Item Analysis  

Describes these Analyze > Clustering menu platforms:  
- Hierarchical Cluster  
- K Means Cluster  
- Normal Mixtures  
- Latent Class Analysis  
- Cluster Variables |

| *Quality and Process Methods* | Read about tools for evaluating and improving processes. | Describes these Analyze > Quality and Process menu platforms:  
- Control Chart Builder and individual control charts  
- Measurement Systems Analysis  
- Variability / Attribute Gauge Charts  
- Process Capability  
- Model Driven Multivariate Control Chart  
- Legacy Control Charts  
- Pareto Plot  
- Diagram  
- Manage Spec Limits  
- OC Curves |
<table>
<thead>
<tr>
<th>Document Title</th>
<th>Document Purpose</th>

</thead>
</table>
| Reliability and Survival Methods | Learn to evaluate and improve reliability in a product or system and analyze survival data for people and products. | Describes these Analyze > Reliability and Survival menu platforms:  
  - Life Distribution  
  - Fit Life by X  
  - Cumulative Damage  
  - Recurrence Analysis  
  - Degradation  
  - Destructive Degradation  
  - Reliability Forecast  
  - Reliability Growth  
  - Reliability Block Diagram  
  - Repairable Systems Simulation  
  - Survival  
  - Fit Parametric Survival  
  - Fit Proportional Hazards |
| Consumer Research               | Learn about methods for studying consumer preferences and using that insight to create better products and services. | Describes these Analyze > Consumer Research menu platforms:  
  - Categorical  
  - Choice  
  - MaxDiff  
  - Uplift  
  - Multiple Factor Analysis |
| Scripting Guide                 | Learn about taking advantage of the powerful JMP Scripting Language (JSL).        | Covers a variety of topics, such as writing and debugging scripts, manipulating data tables, constructing display boxes, and creating JMP applications. |
| JSL Syntax Reference            | Read about many JSL functions on functions and their arguments, and messages that you send to objects and display boxes. | Includes syntax, examples, and notes for JSL commands. |
Additional Resources for Learning JMP

In addition to reading JMP help, you can also learn about JMP using the following resources:

- “JMP Tutorials”
- “Sample Data Tables”
- “Learn about Statistical and JSL Terms”
- “Learn JMP Tips and Tricks”
- “JMP Tooltips”
- “JMP User Community”
- “Free Online Statistical Thinking Course”
- “JMP New User Welcome Kit”
- “Statistics Knowledge Portal”
- “JMP Training”
- “JMP Books by Users”
- “The JMP Starter Window”

JMP Tutorials

You can access JMP tutorials by selecting Help > Tutorials. The first item on the Tutorials menu is Tutorials Directory. This opens a new window with all the tutorials grouped by category.

If you are not familiar with JMP, start with the Beginners Tutorial. It steps you through the JMP interface and explains the basics of using JMP.

The rest of the tutorials help you with specific aspects of JMP, such as designing an experiment and comparing a sample mean to a constant.

Sample Data Tables

All of the examples in the JMP documentation suite use sample data. Select Help > Sample Data Library to open the sample data directory.

To view an alphabetized list of sample data tables or view sample data within categories, select Help > Sample Data.

Sample data tables are installed in the following directory:

On Windows: C:\Program Files\SAS\JMP\16\Samples\Data

On macOS: \Library\Application Support\JMP\16\Samples\Data
In JMP Pro, sample data is installed in the JMPPRO (rather than JMP) directory.

To view examples using sample data, select Help > Sample Data and navigate to the Teaching Resources section. To learn more about the teaching resources, visit https://jmp.com/tools.

Learn about Statistical and JSL Terms

For help with statistical terms, select Help > Statistics Index. For help with JSL scripting and examples, select Help > Scripting Index.

Statistics Index  Provides definitions of statistical terms.

Scripting Index  Lets you search for information about JSL functions, objects, and display boxes. You can also edit and run sample scripts from the Scripting Index and get help on the commands.

Learn JMP Tips and Tricks

When you first start JMP, you see the Tip of the Day window. This window provides tips for using JMP.

To turn off the Tip of the Day, clear the Show tips at startup check box. To view it again, select Help > Tip of the Day. Or, you can turn it off using the Preferences window.

JMP Tooltips

JMP provides descriptive tooltips (or hover labels) when you hover over items, such as the following:

- Menu or toolbar options
- Labels in graphs
- Text results in the report window (move your cursor in a circle to reveal)
- Files or windows in the Home Window
- Code in the Script Editor

Tip: On Windows, you can hide tooltips in the JMP Preferences. Select File > Preferences > General and then deselect Show menu tips. This option is not available on macOS.
**JMP User Community**

The JMP User Community provides a range of options to help you learn more about JMP and connect with other JMP users. The learning library of one-page guides, tutorials, and demos is a good place to start. And you can continue your education by registering for a variety of JMP training courses.

Other resources include a discussion forum, sample data and script file exchange, webcasts, and social networking groups.

To access JMP resources on the website, select **Help > JMP User Community** or visit [https://community.jmp.com](https://community.jmp.com).

**Free Online Statistical Thinking Course**

Learn practical statistical skills in this free online course on topics such as exploratory data analysis, quality methods, and correlation and regression. The course consists of short videos, demonstrations, exercises, and more. Visit [https://www.jmp.com/statisticalthinking](https://www.jmp.com/statisticalthinking).

**JMP New User Welcome Kit**

The JMP New User Welcome Kit is designed to help you quickly get comfortable with the basics of JMP. You’ll complete its thirty short demo videos and activities, build your confidence in using the software, and connect with the largest online community of JMP users in the world. Visit [https://www.jmp.com/welcome](https://www.jmp.com/welcome).

**Statistics Knowledge Portal**

The Statistics Knowledge Portal combines concise statistical explanations with illuminating examples and graphics to help visitors establish a firm foundation upon which to build statistical skills. Visit [https://www.jmp.com/skp](https://www.jmp.com/skp).

**JMP Training**

SAS offers training on a variety of topics led by a seasoned team of JMP experts. Public courses, live web courses, and on-site courses are available. You might also choose the online e-learning subscription to learn at your convenience. Visit [https://www.jmp.com/training](https://www.jmp.com/training).
JMP Books by Users

Additional books about using JMP that are written by JMP users are available on the JMP website. Visit https://www.jmp.com/books.

The JMP Starter Window

The JMP Starter window is a good place to begin if you are not familiar with JMP or data analysis. Options are categorized and described, and you launch them by clicking a button. The JMP Starter window covers many of the options found in the Analyze, Graph, Tables, and File menus. The window also lists JMP Pro features and platforms.

- To open the JMP Starter window, select **View (Window on macOS) > JMP Starter**.
- To display the JMP Starter automatically when you open JMP on Windows, select **File > Preferences > General**, and then select **JMP Starter** from the Initial JMP Window list. On macOS, select **JMP > Preferences > Initial JMP Starter Window**.

JMP Technical Support

JMP technical support is provided by statisticians and engineers educated in SAS and JMP, many of whom have graduate degrees in statistics or other technical disciplines.

Many technical support options are provided at https://www.jmp.com/support, including the technical support phone number.

Get the Most from JMP

Whether you are a first-time or a long-time user, there is always something to learn about JMP.

Visit JMP.com to find the following:

- live and recorded webcasts about how to get started with JMP
- video demos and webcasts of new features and advanced techniques
- details on registering for JMP training
- schedules for seminars being held in your area
- success stories showing how others use JMP
- the JMP user community, resources for users including examples of add-ins and scripts, a forum, blogs, conference information, and so on

### 2 Introducing JMP

47

#### Basic Concepts

49

- JMP Concepts That You Should Know ...................................................... 49
- How Do I Get Started with JMP? .............................................................. 49
  - Starting JMP ........................................................................................... 50
  - Using Sample Data .................................................................................. 52
- Understand Data Tables ........................................................................... 53
- Understand the JMP Workflow ................................................................. 54
  - Step 1: Launch a JMP Platform and View Results ................................ 55
  - Step 2: Remove the Box Plot from a JMP Report ................................. 57
## Contents

- Step 3: Request Additional JMP Output .......................................................... 57
- Step 4: Interact with JMP Platform Results ..................................................... 58
- How is JMP Different from Excel? .................................................................. 59
- Structure of a Data Table ................................................................................. 59
- Formulas in JMP .............................................................................................. 60
- JMP Analysis and Graphing ............................................................................. 61

### 3 Work with Your Data ............................................................................... 63

**Prepare Your Data for Graphing and Analyzing**

- Get Your Data into JMP .................................................................................. 65
  - Copy and Paste Data into a Data Table ......................................................... 65
  - Import Data into a Data Table ...................................................................... 65
  - Enter Data in a Data Table ......................................................................... 68
  - Transfer Data from Excel to JMP ................................................................. 70
- Work with Data Tables .................................................................................... 72
  - Edit Data in a Data Table ........................................................................... 72
  - Select, Deselect, and Find Values in a Data Table .................................... 74
  - View or Change Column Information in a Data Table ............................. 78
  - Example of Calculating Values with Formulas .......................................... 80
  - Example of Filtering Data in a Report ......................................................... 82
- Examples of Reshaping Data .......................................................................... 83
  - Examples of Viewing Summary Statistics .................................................. 84
  - Examples of Creating Subsets .................................................................... 88
  - Example of Joining Data Tables .................................................................. 90
  - Example of Sorting Data ............................................................................ 92

### 4 Visualize Your Data .............................................................................. 95

**Common Graphs**

- Analyze Single Variables in Univariate Graphs ............................................. 97
  - Use Histograms for Continuous Variables .................................................. 97
  - Use Bar Charts for Categorical Variables .................................................... 100
- Compare Multiple Variables ......................................................................... 102
  - Compare Multiple Variables Using Scatterplots ....................................... 103
  - Compare Multiple Variables Using a Scatterplot Matrix .......................... 107
  - Compare Multiple Variables Using Side-by-Side Box Plots ..................... 110
  - Compare Multiple Variables Using Graph Builder .................................. 113
  - Compare Multiple Variables Using Bubble Plots ....................................... 119
  - Compare Multiple Variables Using Overlay Plots .................................... 124
  - Compare Multiple Variables Using a Variability Chart ............................ 129
## Analyze Your Data

**Distributions, Relationships, and Models**

### A Technology Notices ................................................................. 227
Discovering JMP provides a general introduction to the JMP software. This guide assumes that you have no knowledge of JMP. Whether you are an analyst, researcher, student, professor, or statistician, this guide gives you a general overview of JMP’s user interface and features.

This guide introduces you to the following information:

- Starting JMP
- The structure of a JMP window
- Preparing and manipulating data
- Using interactive graphs to learn from your data
- Performing simple analyses to augment graphs
- Customizing JMP and special features
- Sharing your results

This guide contains six chapters. Each chapter contains examples that reinforce the concepts presented in the chapter. All of the statistical concepts are at an introductory level. The sample data used in Discovering JMP are included with the software. Here is a description of each chapter:

- **Chapter 2, “Introducing JMP”** provides an overview of the JMP application. You learn how content is organized and how to navigate the software.
- **Chapter 3, “Work with Your Data”** describes how to import data from a variety of sources, and prepare it for analysis. There is also an overview of data manipulation tools.
- **Chapter 4, “Visualize Your Data”** describes graphs and charts that you can use to visualize and understand your data. The examples range from simple analyses involving a single variable, to multiple-variable graphs that enable you to see relationships between many variables.
- **Chapter 5, “Analyze Your Data”** describes many commonly used analysis techniques. These techniques range from simple techniques that do not require the use of statistical methods, to advanced techniques, where knowledge of statistics is useful.
- **Chapter 6, “The Big Picture”** shows you how to analyze distributions, patterns, and similar values in several platforms.
• **Chapter 7, “Save and Share Your Work”** describes sharing your work with non JMP users in PowerPoint presentations and interactive HTML. Saving analyses as scripts and saving work in journals and projects for JMP users are also covered.

• **Chapter 8, “Special Features”** describes how to automatically update graphs and analyses as data changes, how to use preferences to customize your reports, and how JMP interacts with SAS.

After reviewing this guide, you will be comfortable navigating and working with your data in JMP.

JMP is available for both Windows and macOS operating systems. However, the material in this guide is based on a Windows operating system.
Here are pictures of many of the graphs that you can create with JMP. Each picture is labeled with the platform used to create it. For more information about the platforms and these and other graphs, see the documentation on the Help > Books menu.

JMP (pronounced *jump*) is a powerful and interactive data visualization and statistical analysis tool. Use JMP to learn more about your data by performing analyses and interacting with the data using data tables, graphs, charts, and reports.

JMP enables researchers to perform a wide range of statistical analyses and modeling. JMP is equally useful to the business analyst who wants to quickly uncover trends and patterns in data. With JMP, you do not have to be an expert in statistics to get information from your data.

For example, you can use JMP to do the following:

- Create interactive graphs and charts to explore your data and discover relationships.
- Discover patterns of variation across many variables at once.
- Explore and summarize large amounts of data.
- Develop powerful statistical models to predict the future.

JMP Concepts That You Should Know

Before you begin using JMP, you should be familiar with these concepts:

- Enter, view, edit, and manipulate data using JMP data tables.
- Select a platform from the Analyze, Graph, or DOE menus. Platforms contain interactive windows that you use to analyze data and work with graphs.
- Platforms use these windows:
  - Launch windows where you set up and run your analysis.
  - Report windows showing the output of your analysis.
- Report windows normally contain the following items:
  - A graph of some type (such as a scatterplot or a chart).
  - Specific reports that you can show or hide using the disclosure icon.
  - Platform options that are located within red triangle menus.

How Do I Get Started with JMP?

The general workflow in JMP is simple:

1. Get your data into JMP.
2. Select a platform and complete its launch window.
3. Explore your results and discover where your data takes you.

This workflow is described in more detail in “Understand the JMP Workflow” on page 54.

Typically, you start your work in JMP by using graphs to visualize individual variables and relationships among your variables. Graphs make it easy to see this information, and to see the deeper questions to ask. Then you use analysis platforms to dig deeper into your problems and find solutions.

- The “Work with Your Data” chapter on page 63 shows you how to get data into JMP.
- The “Visualize Your Data” chapter on page 95 shows you how to use some of the useful graphs JMP provides to look more closely at your data.
- The “Analyze Your Data” chapter on page 133 shows you how to use some of the analysis platforms.
- The “The Big Picture” chapter on page 171 shows you how to analyze distributions, patterns, and similar values in several platforms.
Each chapter teaches through examples. The following sections in this chapter describe data tables and general concepts for working in JMP.

**Starting JMP**

Start JMP in two ways:

- Double-click the JMP icon, normally found on your desktop. This starts JMP but does not open any existing JMP files.
- Double-click an existing JMP file. This starts JMP and opens the file.

The initial view of JMP includes the Tip of the Day window and the Home Window on Windows; on macOS, the Tip of the Day and JMP Starter, and Home Window initially appear. The JMP Starter window classifies actions and platforms using categories.

**Figure 2.2 The JMP Starter**
On the left is a list of categories. Click a category to see the features and the commands related to that category. The JMP Starter also lists JMP Pro features and platforms.

The Home Window helps you organize and access files in JMP.

**Figure 2.3** The Home Window on Windows

![JMP Home Window on Windows](image)

To open the Home Window on Windows, select **View > Home Window**. On macOS, select **Window > JMP Home**. The Home Window includes links to the following:

- the data tables and report windows that are currently open
- files that you have opened recently

For more information about the Home Window, see *Using JMP*.

Almost all JMP windows contain a menu bar and a toolbar. You can find most JMP features in three ways:

- using the menu bar
- using the toolbar buttons
- using the buttons on the JMP Starter window

**About the Menu Bar and Toolbars**

The menus and toolbars are hidden in many windows. To see them, hover over the blue bar under the window’s title bar. The menus in the JMP Starter window, the Home Window, and all data tables are always visible.
Using Sample Data

The examples in Discovering JMP and other JMP documentation use sample data tables. The default location on Windows for the sample data is:

C:/Program Files/SAS/JMP/16/Samples/Data
C:/Program Files/SAS/JMPPro/16/Samples/Data

The Sample Data Index groups the data tables by category. Click a disclosure icon to see a list of data tables for that category, and then click a link to open a data table.

macOS sample data is installed in /Library/Application Support/JMP/16/Samples/Data.

Opening a JMP Sample Data Table

1. From the Help menu, select Sample Data.
2. Open the Data Tables used in Discovering JMP list by clicking on the disclosure icon next to it.
3. Click the name of the data table to use it in the examples in Discovering JMP.

Sample Import Data

Use files from other applications to learn how to import data into JMP.

The default location on Windows for the sample import data is:

C:/Program Files/SAS/JMP/16/Samples/Import Data
C:/Program Files/SAS/JMPPro/16/Samples/Import Data
Understand Data Tables

A JMP data table is a collection of data organized in rows and columns. A data table might also contain other information like notes, variables, and scripts. These supplementary items are discussed in later chapters.

Open the VA Lung Cancer data table to see the data table described here.

Figure 2.4 A Data Table

A data table contains the following parts:

**Data grid**  The data grid contains the data arranged in rows and columns. Generally, each row in the data grid is an observation, and the columns (also called variables) give information about the observations. In Figure 2.4, each row corresponds to a test subject, and there are twelve columns of information. Although all twelve columns cannot be shown in the data grid, the Columns panel lists them all. The information given about
each test subject includes the time, cell type, treatment, and more. Each column has a header, or name. That name is not part of the table’s total count of rows.

**Table panel**  The table panel can contain table variables or table scripts. In Figure 2.4, there is one saved script called **Model** that can automatically re-create an analysis. This table also has a variable named **Notes** that contains information about the data. Table variables and table scripts are discussed in a later chapter.

**Columns panel**  The columns panel shows the total number of columns, whether any columns are selected, and a list of all the columns by name. The numbers in parentheses (12/0) show that there are twelve columns, and that no columns are selected. An icon to the left of each column name shows that column’s modeling type. Modeling types are described in “Understand Modeling Types” on page 138 in the “Analyze Your Data” chapter. Icons to the right show any attributes assigned to the column. See “View or Change Column Information in a Data Table” on page 78 in the “Work with Your Data” chapter for more information about these icons.

**Rows panel**  The rows panel shows the number of rows in the data table, and how many rows are selected, excluded, hidden, or labeled. In Figure 2.4, there are 137 rows in the data table.

**Thumbnail links to report windows**  This area shows thumbnails of all reports based on the data table. Hover over a thumbnail to see a larger preview of the report window. Double-click a thumbnail to bring the report window to the front.

Interacting with the data grid, which includes adding rows and columns, entering data, and editing data, is discussed in the “Work with Your Data” chapter on page 63. If you open multiple data tables, each one appears in a separate window.

For more information about how a JMP data table differs from an Excel spreadsheet, see “How is JMP Different from Excel?” on page 59.

---

**Understand the JMP Workflow**

Once your data is in a data table, you can create graphs or plots, and perform analyses. All features are located in platforms, which are found primarily on the **Analyze** or **Graph** menus. They are called platforms because they do not just produce simple static results. Platform results appear in report windows, are highly interactive, and are linked to the data table and to each other.

The platforms under the **Analyze** and **Graph** menus provide a variety of analytical features and data exploration tools.
Here are the general steps to produce a graph or analysis:

1. Open a data table.
2. Select a platform from the Graph or Analyze menu.
3. Complete the platform launch window to set up your analysis.
4. Click OK to create the report window that contains your graphs and statistical analyses.
5. Customize your report by using report options.
6. Save, export, and share your results with others.

Later chapters discuss these concepts in greater detail.

The following example shows you how to perform a simple analysis and customize it in four steps. This example uses the Companies.jmp file sample data table to show a basic analysis of the variable Profits ($M).

**Step 1: Launch a JMP Platform and View Results**

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution to open the Distribution launch window.
3. Select Profits ($M) in the Select Columns box and click the Y, Columns button.
   
   The variable Profits ($M) appears in the Y, Columns role.
   
   Another way to assign variables is to click and drag columns from the Select Columns box to any of the roles boxes.

![Figure 2.5 Assign Profits ($M)](image)

4. Click OK.
   
   The Distribution report window appears.
Figure 2.6 Distribution Report Window on Windows

The report window contains basic plots or graphs and preliminary analysis reports. The results appear in an outline format, and you can show or hide any report by clicking on the disclosure icon.

Red triangle menus contain options and commands to request additional graphs and analyses at any time.

- On Windows, hover over the blue bar at the top of the window to see the menu bar and the toolbars.
- On Windows, click the data table button in the lower right corner to view the data table that was used to create this report. On macOS, click the Show Data Table button in the upper right corner of the report window.
- On Windows, click the JMP Home Window button in the lower right corner to view the Home Window. On macOS, select Window > JMP Home.
Step 2: Remove the Box Plot from a JMP Report

Continue using the Distribution report that you created earlier.

1. Click the red triangle next to Profits ($M) to see a menu of report options.
2. Deselect Outlier Box Plot to turn the option off.

The outlier box plot is removed from the report window.

Figure 2.7 Removing the Outlier Box Plot

Step 3: Request Additional JMP Output

Continue to use the same report window that you created in Step 2: Remove the Box Plot from a JMP Report.

1. Click the red triangle next to Profits ($M) and select Test Mean.
   The Test Mean window appears.
2. Enter 500 in the Specify Hypothesized Mean box.
3. Click OK.
   The test for the mean is added to the report window.
Step 4: Interact with JMP Platform Results

All platforms produce results that are interactive, for example, the following results:

- Reports can be shown or hidden.
- Additional graphs and statistical details can be added or removed to suit your purposes.
- Platform results are connected to the data table and to each other.

For example, to close the Quantiles report, click the disclosure icon next to Quantiles.

Figure 2.9 Close the Quantiles Report
Platform results are connected to the data table. The histogram in Figure 2.10 shows that a group of companies makes a much higher profit than the others. To quickly identify that group, click the histogram bar for them. The corresponding rows in the data table are selected.

**Figure 2.10** Connection between Platform Results and Data Table

Click the bar to select the corresponding rows

In this case, the group includes only one company, and that one row is selected.

---

**How is JMP Different from Excel?**

JMP is a statistical analysis program that uses data tables. Excel is a spreadsheet application. Data tables and spreadsheets have different structures.

- “Structure of a Data Table”
- “Formulas in JMP”
- “JMP Analysis and Graphing”

**Structure of a Data Table**

A data table has fixed rows and columns, while a spreadsheet is cell based. In a spreadsheet, data, headings, or formulas can be placed in any cell. In a data table, the structure organizes data for analysis. This structure is used by JMP analysis and graphing platforms.

**Column Headings** Column names are column headings.

**Columns** Columns contain data and are assigned one data type. Basic columns are either numeric or character. If a column contains both character and numeric data, the entire
column’s data type is character, and the numbers are treated as character data. JMP also has specialized column types for capturing things such as images. JMP uses the column’s data type to determine analysis options and results. For more information about data types, see “Understand Modeling Types” on page 138 in the “Analyze Your Data” chapter.

**Rows**
Rows contain observations. If there is no observation for a row, that cell is left empty. In JMP a dot signifies a missing numeric value, and a blank signifies a missing character value.

For more information about JMP data tables, see “Understand Data Tables” on page 53. For more information about JMP column properties, see the Using JMP book.

JMP data tables cannot be arranged in a workbook such as in Excel. Each JMP data table is a separate file and appears in its own window. To combine multiple tables, see the Using JMP book. For organizing JMP tables and output see “Save and Run Scripts” on page 202 in the “Save and Share Your Work” chapter.

**Tip:** To use data from two or more tables in a single analysis, use Virtual Join. For more information, see the Using JMP book.

### Formulas in JMP

In spreadsheets, formulas apply to a single cell and can utilize data from any cell in the spreadsheet, including cells on different tabs of the workbook. In data tables, formulas apply to an entire column. A formula can use data from any other column in the data table. Each row in the column will have the same calculation applied to it based on the data in the row.

For example, consider a data table with a simple sum as shown in Figure 2.11. The column height + weight has a formula. The formula adds height and weight by row for all rows in the data table.

**Figure 2.11** Data Table with Formula Column

For more information about JMP formulas, see the Using JMP book.

**Tip:** For basic column summary statistics, use the Distribution platform. See the Basic Analysis book.
JMP Analysis and Graphing

JMP uses platforms to drive data analysis. To launch an analysis, go to the Analyze menu. Select the variables for your analysis in the platform launch window, and the analysis results appear in a report window that is separate from the data table. This differs from Excel, where an analysis is inserted on the spreadsheet.

Graphing choices are found in the Graph menu. Graph Builder is a great place to start. Use Graph Builder to drag and drop your columns and quickly build a graph to explore your data. For more information about Graph Builder, see the Essential Graphing book.
Before graphing or analyzing your data, the data has to be in a data table and in the proper format. This chapter shows some basic data management tasks, including the following:

- Creating new data tables
- Opening existing data tables
- Importing data from other applications into JMP
- Managing your data

**Figure 3.1  Example of a Data Table**

Get Your Data into JMP

JMP provides many ways to get your data into JMP.

• To copy and paste data from another application, see “Copy and Paste Data into a Data Table” on page 65.
• To import data from another application, see “Import Data into a Data Table” on page 65.
• To enter data directly into a data table, see “Enter Data in a Data Table” on page 68.

You can also import data into JMP from a database. See Using JMP.

This chapter uses sample data tables and sample import data that is installed with JMP. To find these files, see “Using Sample Data” on page 52 in the “Introducing JMP” chapter.

Copy and Paste Data into a Data Table

You can move data into JMP by copying and pasting from another application, such as Microsoft Excel or a text file.

1. Open the VA Lung Cancer.xlsx file in Microsoft Excel. This file is located in the Sample Import Data folder.
2. Select all of the rows and columns, including the column names. There are 12 columns and 138 rows.
3. Copy the selected data.
4. In JMP, select File > New > Data Table to create an empty table.
5. Select Edit > Paste with Column Names to paste the data and column headings.
   If the data that you are pasting into JMP does not have column names, then you can use Edit > Paste.

Import Data into a Data Table

You can move data into a JMP data table by importing data from another application, such as Microsoft Excel, SAS, or text files. Here are the basic steps to import data:

1. Select File > Open.
2. Navigate to your file’s location.
3. If your file is not listed in the Open Data File window, select the correct file type from the Files of type menu.
4. Click Open.
Example of Importing a Microsoft Excel File

1. Select **File > Open**.
2. Navigate to the Samples/Import Data folder.
3. Select Team Results.xlsx.
   
   Note the rows and columns on which the data begin. The spreadsheet also contains two worksheets. In this example, you import the Ungrouped Team Results worksheet.
4. Click **Open**.
   
   The spreadsheet opens in the Excel Import Wizard, where a preview of the data appears along with import options.
   
   Text from the first row of the spreadsheet are column headings. However, you want text in row 3 of the spreadsheet to be converted to column headings.
5. Next to **Column headers start on row**, type 3, and press Enter. The column headings are updated in the data preview. The value for the first row of data is updated to 4.
6. Save the settings only for this worksheet:
   
   – Deselect **Use for all worksheets** in the lower left corner of the window.
   
   – Select **Ungrouped Team Results** in the upper right corner of the window.
7. Click **Import** to convert the spreadsheet as you specified.

When you import Excel files, JMP predicts whether columns headings exist, and if the column names are on row one. The copy and paste method is recommended for the following situations:

- If the column names are located in a row other than row one
- If the file does not include column names and the data does not start in row one
- If the file contains column names and the data does not start in row two

See “Copy and Paste Data into a Data Table” on page 65 and *Using JMP* for more information about importing Excel files.

Example of Importing a Text File

One way to import a text file is to let JMP assume the data’s format and place the data in a data table. This method uses settings that you can specify in Preferences. See *Using JMP* for information about setting text import preferences.

Another way to import a text file is to use a Text Preview window to see what your data table will look like after importing, and make adjustments. The following example shows you how to use Text Import Preview window.

1. Select **File > Open**.
2. Navigate to the Samples/Import Data folder.
4. At the bottom of the Open window, select Data with Preview.
5. Click Open.

**Figure 3.2** Initial Preview Window

This text file has a title on the first line, column names on the third line, and the data starts on line four. If you opened this directly in JMP, the Animals Data line would be the first column name, and all the column names and data afterward would be out of sync. The Preview window lets you adjust the settings before you open the file, and see how your adjustments affect the final data table.

6. Enter 3 in the **File contains column names on line** field.
7. Enter 4 in the **Data starts on line** field.
8. Click **Next**.

   In the second window, you can exclude columns from the import and change the data modeling of the columns. For this example, use the default settings.

9. Click **Import**.

The new data table has columns named species, subject, miles, and season. The species and season columns are character data. The subject and miles columns are continuous numeric data.
Enter Data in a Data Table

You can enter data directly in a data table. The following example shows you how to enter data that was collected over several months into a data table.

Scenario

Table 3.1 shows the data from a study that investigated a new blood pressure medication. Each individual’s blood pressure was measured over a six-month period. Two doses (300mg and 450mg) of the medication were used, along with a control and placebo group. The data shows the average blood pressure for each group.

Table 3.1  Blood Pressure Data

<table>
<thead>
<tr>
<th>Month</th>
<th>Control</th>
<th>Placebo</th>
<th>300mg</th>
<th>450mg</th>
</tr>
</thead>
<tbody>
<tr>
<td>March</td>
<td>165</td>
<td>163</td>
<td>166</td>
<td>168</td>
</tr>
<tr>
<td>April</td>
<td>162</td>
<td>159</td>
<td>165</td>
<td>163</td>
</tr>
<tr>
<td>May</td>
<td>164</td>
<td>158</td>
<td>161</td>
<td>153</td>
</tr>
<tr>
<td>June</td>

</tr>
<tr>
<td>August</td>
<td>163</td>
<td>158</td>
<td>157</td>
<td>150</td>
</tr>
</tbody>
</table>

Enter Data in a New Data Table

1. Select File > New > Data Table to create an empty data table. A new data table has one column and no rows.
2. Select the column name and change the name to Month.

Note: To rename a column, you can also double-click the column name or select the column and press Enter.
3. Select **Rows > Add Rows**.

   The Add Rows window appears.

4. Since you want to add six rows, type 6.

5. Click **OK**. Six empty rows are added to the data table.

6. Enter the **Month** information by clicking in a cell and typing.

**Figure 3.4 Month Column Completed**

In the columns panel, look at the modeling type icon to the left of the column name. It has changed to reflect that **Month** is now nominal (previously it was continuous). Compare the modeling type shown for Column 1 in Figure 3.3 and for **Month** in Figure 3.4. This difference is important and is discussed in “**View or Change Column Information in a Data Table**” on page 78.

7. Double-click in the space on the right side of the **Month** column to add the **Control** column.

8. Change the name to **Control**.

9. Enter the **Control** data as shown in Table 3.1. Your data table now consists of six rows and two columns.

10. Continue adding columns and entering data as shown in Table 3.1 to create the final data table with six rows and five columns.
Change the Data Table Name

1. Double-click the data table name (Untitled) in the Table Panel.
2. Type the new name (Blood Pressure).

**Figure 3.5** Changing the Data Table Name

Double-click here. Type the new name.

---

Transfer Data from Excel to JMP

You can use the JMP Add In for Excel to transfer a spreadsheet from Excel to JMP:

- a data table
- Graph Builder
- Distribution platform
- Fit Y by X platform
- Fit Model platform
- Time Series platform
- Control Chart platform

---

Set JMP Add In Preferences in Excel

To configure JMP Add In Preferences:

1. In Excel, select **JMP > Preferences**.
   The JMP Preferences window appears.
Figure 3.6 JMP Add In Preferences

2. Accept the default **Data Table Name** (File name_Worksheet name) or type a name.
3. Select to **Use the first rows as column names** if the first row in the worksheet contains column headers.
4. If you selected to use the first rows a column headers, type the number of rows used.
5. Select to **Transfer Hidden Rows** if the worksheet contains hidden rows to be included in the JMP data table.
6. Select to **Transfer Hidden Column** if the worksheet contains hidden columns to be included in the JMP data table.
7. Click **OK** to save your preferences.

Transfer to JMP

To transfer an Excel worksheet to JMP:

1. Open the Excel file.
2. Select the worksheet to transfer.
3. Select **JMP** and then select the JMP destination:
   - Data Table
   - Graph Builder
   - Distribution platform
   - Fit Y by X platform
   - Fit Model platform
   - Time Series platform
   - Control Chart platform

The Excel worksheet is opened as a data table in JMP and the selected platform’s launch window appears.
Work with Data Tables

This section describes the basic concepts for working with data tables.

- Edit Data in a Data Table
- Select, Deselect, and Find Values in a Data Table
- View or Change Column Information in a Data Table
- Example of Calculating Values with Formulas
- Example of Filtering Data in a Report

**Tip:** Consider setting the *Autosave timeout* value in the General preferences to automatically save open data tables at the specified number of minutes. This autosave value also applies to journals, scripts, projects, and reports.

Edit Data in a Data Table

You can enter or change data, either a few cells at a time or for an entire column. This section contains the following information:

- Change Values in a Data Table Cell
- Recode Values
- Create Patterned Data

**Change Values in a Data Table Cell**

To change a value, select a cell and type the change. You can also double-click a cell to edit it.

**Note:** Double-clicking in a cell is not the same as selecting a cell. A single click selects a cell. You can select more than one cell at the same time, and you can perform certain actions on selected cells. Double-clicking only lets you edit a cell. For more information about selecting rows, columns, and cells, see “Select, Deselect, and Find Values in a Data Table” on page 74.
Recode Values

Use the recoding tool to change all of the values in a column at once. For example, suppose that you are interested in comparing the sales of computer and pharmaceutical companies. Your current company labels are Computer and Pharmaceutical. You want to change them to Technical and Drug. Going through all 32 rows of data and changing all the values would be tedious, inefficient, and error-prone, especially if you had many more rows of data. Recode is a better option.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select the Type column by clicking once on the column heading.
5. Select In Place from the New Column list.
6. Click Recode.

All cells are updated automatically to the new values.
Create Patterned Data

Use the Fill options to populate a column with patterned data. The Fill options are especially useful if your data table is large, and typing in the values for each row would be cumbersome.

Example of Filling a Column with the Pattern

1. Add a new column.
2. Enter 1 in the first cell, 2 in the second cell, and 3 in the third cell.
3. Select the three cells, and right-click anywhere in the selected cells to see a menu.
4. Select **Fill > Repeat sequence to end of table**.
   
The rest of the column is filled with the sequence (1, 2, 3, 1, 2, 3, ...).

To continue a pattern instead of repeating it (1, 2, 3, 4, 5, 6, ...), select **Continue sequence to end of table**. This command can also be used to generate patterns like (1, 1, 2, 2, 2, 3, 3, 3, ...).

The Fill options can recognize simple arithmetic and geometric sequences. For character data, the Fill options only repeat the values.

Select, Deselect, and Find Values in a Data Table

You can select rows, columns, or cells within a data table. For example, to create a subset of an existing data table, you must first select the parts of the table that you want to subset. Also, selecting rows can make data points stand out on a graph. Select rows and columns manually by clicking, or select rows that meet certain search criteria. This section contains the following information:

- “Select and Deselect Rows” on page 74
- “Select and Deselect Columns” on page 75
- “Select and Deselect Cells” on page 76
- “Search for Values” on page 77

Select and Deselect Rows

Discovering JMP Work with Data Tables

Search for Values

In a data table that has thousands or tens of thousands of rows, it can be difficult to locate a particular cell by scrolling through the table. If you are looking for specific information, use the Search feature to find it. If data match the search criteria, the cell is selected and the data grid scrolls to show it in the window. For example, the Companies.jmp data table contains information about a company that has total sales of $11,899. Use the Search feature to find that cell.

Example of Searching for a Value

1. Select Edit > Search > Find to launch the Search window.
2. In the Find what box, enter 11899.
3. Click Find. JMP finds the first cell that has 11,899 in it, and selects it.

If multiple cells meet the search criteria, click Find again to find the next cell that matches the search term.

You can also search for multiple rows at once, with each row matching some criteria.

Example of Select All Rows That Correspond to Medium-Sized Companies

1. Select Rows > Row Selection > Select Where to open the Select rows window.
2. In the column list box on the left, select Size Co.
3. In the text box on the right, enter medium.
4. Click OK.
Figure 3.10 Select Rows Window

JMP selects all of the rows that have Size Co equal to medium. There are seven.

View or Change Column Information in a Data Table

Information about a data table column is not limited to the data in the column. Data type, modeling type, format, and formulas can also be set.

To view or change column characteristics, double-click the column heading. Or, right-click the column heading and select Column Info. The Column Info window appears.
Figure 3.11 Column Info Window

**Column Name**  Enter or change the column name. No two columns can have the same column name.

**Data Type**  Select one of the following data types:

- **Numeric**  Specifies the column values as numbers.
- **Character**  Specifies the column values as non-numeric, such as letters or symbols.
- **Row State**  Specifies the column values as row states. This is an advanced topic. See *Using JMP*.

**Modeling Type**  Modeling types define how values are used in analyses. Select one of the following modeling types:

- **Continuous**  Numeric only
- **Ordinal**  Either numeric or character, and are ordered categories
- **Nominal**  Either numeric or character, but not ordered

**Format**  Select a format for numeric values. This option is not available for character data. Here are a few of the most common formats:
Best  Lets JMP choose the best display format.

Fixed Dec  Specifies the number of decimal places that appear.

Date  Specifies the syntax for date values.

Time  Specifies the syntax for time values.

Currency  Specifies the type of currency and decimal points that are used for currency values.

Column Properties  Set special column properties such as formulas, notes, and value orders. See Using JMP.

Lock  Lock a column, so that the values in the column cannot be changed.

Example of Calculating Values with Formulas

Use the Formula Editor to create columns that contain calculated values.

Scenario

The sample data table On-Time Arrivals.jmp reflects the percent of on-time arrivals for several airlines. The data was collected for March, June, and August of 1999.

Create the Formula

Suppose that you want to create a new column containing the average on-time percentage for each airline.

1. Add a new column.

2. Right-click the column heading of the new column and select Formula. The Formula Editor window appears.
Create the formula for the average on-time percentage of each airline:

3. From the Columns list, select March 1999.
4. Click the + button on the keypad.
5. Select June 1999, followed by another + sign.

**Figure 3.13** Sum of the Months

March 1999 + June 1999 + August 1999

Notice that only August 1999 is selected (has the blue box around it).

7. Click the box surrounding the entire formula.

**Figure 3.14** Entire Formula Selected

March 1999 + June 1999 + August 1999
8. Click the button.
9. Type a 3 in the denominator box, and then click outside of the formula in any of the white space.

**Figure 3.15** Completed Formula

<table>
<thead>
<tr>
<th>March 1999 + June 1999 + August 1999</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

10. Click **OK**

The new column contains the averages.

The Formula Editor has many built-in arithmetic and statistical functions. For example, another way to calculate the average on-time arrival percentage is to use the Mean function in the Statistical functions list. For more information about all of the Formula Editor functions, see *Using JMP*.

### Example of Filtering Data in a Report

Use the **Data Filter** to interactively select complex subsets of data, hide these subsets in plots, or exclude them from analyses. For example, look at profit per employee for computer and pharmaceutical companies.

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. Select **Analyze > Distribution**.
3. Select profit/emp and click **Y, Columns**.
4. Click **OK**.
5. Click the red triangle next to profit/emp and select **Display Options > Horizontal Layout**.

**Figure 3.16** Distribution of profit/emp
6. Turn on Automatic Recalc by selecting **Redo > Automatic Recalc** from the Distributions red triangle.

   When this option is on, every change that you make (for example, hiding or excluding points) causes your report window to automatically update itself.

7. In the data table, select **Rows > Data Filter**.

8. Select Type and click **Add**.

9. Make sure that Select is selected.

10. To filter out the Pharmaceutical companies from the Distribution results, and include only the Computer companies, click the **Computer** box in the Data Filter window.

    The distribution results update to only include Computer companies.

**Figure 3.17** Filter for Computer Companies

Click the Computer box to include only computer companies in the Distribution results.

The graph and the statistics report automatically reflect only the rows that are selected.

Conversely, to change the Distribution results to include only the Pharmaceutical companies, click the **Pharmaceutical** box on the Data Filter window.

**Examples of Reshaping Data**

The commands on the **Tables** menu (and Tabulate on the **Analyze** menu) summarize and manipulate data tables into the format that you need for graphing and analyzing. This section describes five of these commands:

**Summary**  Creates a table that contains summary statistics that describe your data.
Tabulate  Provides a drag and drop workspace to create summary statistics.

Subset   Creates a table that contains a subset of your data.

Join     Joins the data from two data tables into one new data table.

Sort     Sorts your data by one or more columns.

For more information about these and the other Tables menu commands, see Using JMP.

Examples of Viewing Summary Statistics

Summary statistics, such as sums and means, can instantly provide useful information about your data. For example, if you look at the annual profit of each company out of thirty-two companies, it’s difficult to compare the profits of small, medium, and large companies. A summary shows that information immediately.

Create summary tables by using either the Summary or Tabulate commands. The Summary command creates a new data table. As with any data table, you can perform analyses and create graphs from the summary table. The Tabulate command creates a report window with a table of summary data. You can also create a table from the Tabulate report.

Summary Table Example

A summary table contains statistics for each level of a grouping variable. For example, look at the financial data for computer and pharmaceutical companies. Suppose that you want to calculate the mean of sales and the mean of profits, for each combination of company type and size.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Tables > Summary.
3. Select Type and Size Co and click Group.
4. Select Sales ($M) and Profits ($M) and click Statistics > Mean.
Figure 3.18  Completed Summary Window

5. Click **OK**.

JMP calculates the mean of Sales ($M) and the mean of Profit ($M) for each combination of Type and Size Co.

Figure 3.19  Summary Table

The summary table contains the following:

- There are columns for each grouping variable (in this example, Type, and Size Co).
• The N Rows column shows the number of rows from the original table that correspond to each combination of grouping variables. For example, the original data table contains 14 rows corresponding to small computer companies.

• There is a column for each summary statistic requested. In this example, there is a column for the mean of Sales ($M) and a column for the mean of Profits ($M).

The summary table is linked to the source table. Selecting a row in the summary table also selects the corresponding rows in the source table.

**Tabulate Example**

Use the Tabulate command to drag columns into a workspace, creating summary statistics for each combination of grouping variables. This example shows you how to use Tabulate to create the same summary information that you just created using Summary.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Tabulate.

**Figure 3.20** Tabulate Workspace
3. Select both Type and Size Co.
4. Drag and drop them into the **Drop zone for rows**.

**Figure 3.21** Dragging Columns to the Row Zone

5. Right-click a heading and select **Nest Grouping Columns**.
   
The initial tabulation shows the number of rows per group.

**Figure 3.22** Initial Tabulation

6. Select both Sales ($M) and Profits ($M), and drag and drop them over the **N** in the table.

**Figure 3.23** Adding Sales and Profit

The tabulation now shows the sum of Sales ($M) and the sum of Profits ($M) per group.
Figure 3.24 Tabulation of Sums

<table>
<thead>
<tr>
<th>Type</th>
<th>Size Co</th>
<th>Sales ($M)</th>
<th>Profits ($M)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer</td>
<td>big</td>
<td>82389.9</td>
<td>4359.7</td>
</tr>
<tr>
<td></td>
<td>medium</td>
<td>6037.7</td>
<td>-174.5</td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>24612.8</td>
<td>629.1</td>
</tr>
<tr>
<td>Pharmaceutical</td>
<td>big</td>
<td>37370.2</td>
<td>4472.1</td>
</tr>
<tr>
<td></td>
<td>medium</td>
<td>21305.3</td>
<td>3494.9</td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>2167.5</td>
<td>313.9</td>
</tr>
</tbody>
</table>

7. The final step is to change the sums to means. Right-click **Sum** (either of them) and select **Statistics > Mean**.

Figure 3.25 Final Tabulation

<table>
<thead>
<tr>
<th>Type</th>
<th>Size Co</th>
<th>Sales ($M)</th>
<th>Profits ($M)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer</td>
<td>big</td>
<td>20597.48</td>
<td>1089.9</td>
</tr>
<tr>
<td></td>
<td>medium</td>
<td>3018.85</td>
<td>-85.75</td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>1758.06</td>
<td>44.94</td>
</tr>
<tr>
<td>Pharmaceutical</td>
<td>big</td>
<td>747.40</td>
<td>894.42</td>
</tr>
<tr>
<td></td>
<td>medium</td>
<td>4261.06</td>
<td>698.98</td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>1082.75</td>
<td>155.95</td>
</tr>
</tbody>
</table>

The means are the same as those obtained using the Summary command. Compare Figure 3.25 to Figure 3.19.

Examples of Creating Subsets

If you want to look closely at only part of your data table, you can create a subset. For example, suppose that you have already compared the sales and profits of big, medium, and small computer and pharmaceutical companies. Now you want to look at the sales and profits of only the medium-sized companies.

Creating a subset is a two-step process. First select the target data, and then extract the data into a new table.

Subset with the Subset Command

1. Select **Help > Sample Data Library** and open **Companies.jmp**.

Selecting the Rows and Columns That You Want to Subset

2. Select **Rows > Row Selection > Select Where**.
3. Select **Size Co** in the column list box on the left.
4. Enter medium in the text enter box.
5. Click OK.
6. Press Ctrl and select the Type, Sales ($M), and Profits ($M) columns.

Creating the Subset Table

7. Select Tables > Subset to launch the Subset window.

Figure 3.26 Subset Window

8. Select Selected columns to subset only the columns that you selected. You can also customize your subset table further by selecting additional options.

9. Click OK.

The resulting subset data table has seven rows and three columns. For more information about the Subset command, see Using JMP.

Subset with the Distribution Platform

Another way to create subsets uses the connection between platform results and data tables.

Example of Creating a Subset Using the Distribution Command

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Type and click **Y, Columns**.
4. Click **OK**.
5. Double-click the histogram bar that represents Computer to create a subset table of the Computer companies.

**Caution:** This method creates a *linked* subset table. This means if you make any changes to the data in the subset table, the corresponding value changes in the source table.

---

### Example of Joining Data Tables

Use the Join option to combine information from multiple data tables into a single data table. For example, suppose that you have a data table containing results from an experiment on popcorn yields. In another data table, you have the results of a second experiment on popcorn yields. To compare the two experiments or to analyze the trials using both sets of results, you need to have the data in the same table. Also, the experimental data was not entered into the data tables in the same order. One of the columns has a different name, and the second experiment is incomplete. This means that you cannot copy and paste from one table into another.

### Example of Joining Two Data Tables

1. Select **Help > Sample Data Library** and open Trial1.jmp and Little.jmp.
2. Click **Trial1.jmp** to make it the active data table.
3. Select **Tables > Join**.
4. In the **Join ‘Trial1’ With** box, select **Little**.
5. From the **Matching Specification** menu, select **By Matching Columns** if it’s not already selected.
6. In the **Source Columns** boxes, select popcorn in both boxes, and then click **Match**.
7. In the same way, match batch to batch and oil amt to oil in both boxes.
   
   Your matching columns do not have to have the same name.
8. Select **Include non-matches** for both tables.
   
   Since one experiment is partial, you want to include all rows, including any with missing data.
9. To avoid duplicate columns, select the **Select columns for joined table** option.
10. From Trial1, select all four columns and click **Select**.
11. From Little, select only yield and click **Select**.
Figure 3.27  Completed Join Window

12. Click **OK**.
Example of Sorting Data

Use the Sort command to sort a data table by one or more columns in the data table. For example, look at financial data for computer and pharmaceutical companies. Suppose that you want to sort the data table by Type, then by Profits ($M). Also, you want Profits ($M) to be in descending order within each Type.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Tables > Sort.
3. Select Type and click By to assign Type as a sorting variable.
4. Select Profits ($M) and click By.

At this point, both variables are set to be sorted in ascending order. See the ascending icon next to the variables in Figure 3.29.
5. To change Profits ($M) to sort in descending order, select Profits ($M) and click the descending button.

6. Select the **Replace Table** check box.

   When selected, the **Replace Table** option tells JMP to sort the original data table instead of creating a new table with the sorted values. This option is not available if there are any open report windows created from the original data table. Sorting a data table with open report windows might change how some of the data is displayed in the report window, especially in graphs.
7. Click **OK**.

The data table is now sorted by type alphabetically, and by descending profit totals within type.
Visualizing your data is an important first step. The graphs described in this chapter help you discover important details about your data. For example, histograms show you the shape and range of your data, and help you find unusual data points.

This chapter presents several of the most common graphs and plots that enable you to visualize and explore data in JMP. This chapter is an introduction to some of JMP’s graphical tools and platforms. Use JMP to visualize the distribution of single variables, or the relationships among multiple variables.

Analyze Single Variables in Univariate Graphs

Single-variable graphs, or *univariate* graphs, let you look closely at one variable at a time. When you begin to look at your data, it’s important to learn about each variable before looking at how the variables interact with each other. Univariate graphs let you visualize each variable individually.

This section covers two graphs that show the distribution of a single variable:

- “Use Histograms for Continuous Variables” on page 97
- “Use Bar Charts for Categorical Variables” on page 100

Use the Distribution platform to create both of these graphs. Distribution produces a graphical description and descriptive statistics for each variable.

Use Histograms for Continuous Variables

The histogram is one of the most useful graphical tools for understanding the distribution of a continuous variable. Use a histogram to find the following in your data:

- the average value and variation
- extreme values

**Figure 4.2** Example of a Histogram

![Histogram Example](image)

**Instant Histograms**

You can view a histogram instantly by clicking the histogram icon in the column header. Histograms appear below the column header.
Visualize Your Data
Chapter 4
Analyze Single Variables in Univariate Graphs
Discovering JMP

Figure 4.3 Instant Histograms

Scenario

This example uses the Companies.jmp data table, which contains data on profits for a group of companies.

A financial analyst wants to explore the following questions:

- Generally, how much profit does each company earn?
- What is the average profit?
- Are there any companies that earn either extremely high or extremely low profits compared to the other companies?

To answer these questions, use a histogram of Profits ($M).

Create the Histogram

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Profits ($M) and click Y, Columns.
Figure 4.4 Distribution Window for Profits ($M)

4. Click **OK**.

Figure 4.5 Histogram of Profits ($M)

Interpret the Histogram

The histogram provides these answers:

- Most companies’ profits are between $-1000 and $1500.
  
  All the bars except for one are located in this range. Also, more companies’ profits range from $0 to $500 than any other range. The bar representing that range is much longer than the others.

- The average profit is a little less than $500.
  
  The middle of the diamond in the box plot indicates the mean value. In this case, the mean is slightly lower than the $500 mark.

- One company has significantly higher profits than the others, and might be an **outlier**. An outlier is a data point that is separated from the general pattern of the other data points.
This outlier is represented by a single, very short bar at the top of the histogram. The bar is small and represents a small group (in this case, a single company), and it is widely separated from the rest of the histogram bars.

In addition to the histogram, this report includes the following:

- The box plot, which is another graphical summary of the data. For detailed information about the box plot, see *Essential Graphing*.
- **Quantiles** and **Summary Statistics** reports. These reports are discussed in “Analyze Distributions” on page 143 in the “Analyze Your Data” chapter.

### Interact with the Histogram

Data tables and reports are all connected in JMP. Click a histogram bar to select the corresponding rows in the data table.

### Use Bar Charts for Categorical Variables

Use a bar chart to visualize the distribution of a categorical variable. A bar chart looks similar to a histogram, since they both have bars that correspond to the levels of a variable. A bar chart shows a bar for every level of the variable, whereas the histogram shows a range of values for the variable.

**Figure 4.6  Example of a Bar Chart**

![Bar Chart Example](image)

### Scenario

This example uses the *Companies.jmp* data table, which contains data on the size and type of a group of companies.

A financial analyst wants to explore the following questions:

- What is the most common type of company?
- What is the most common size for a company?
To answer these questions, use bar charts of Type and Size Co.

**Create the Bar Chart**

1. Select **Help > Sample Data Library** and open **Companies.jmp**.
2. Select **Analyze > Distribution**.
3. Select **Type** and **Size Co** and click **Y, Columns**.
4. Click **OK**.

**Figure 4.7 Bar Charts of Type and Size Co**

**Interpret the Bar Charts**

The bar charts provide these answers:

- There are more computer companies than pharmaceutical companies.
  The bar that represents computer companies is larger than the bar that represents pharmaceutical companies.

- The most common company size is small.
  The bar that represents small companies is larger than the bars that represent medium and big companies.

The additional summary output gives detailed frequencies. This report is discussed in “Distributions of Categorical Variables” on page 146 in the “Analyze Your Data” chapter.
Interact with the Bar Charts

As is the case with histograms, click individual bars to highlight rows of the data table. If more than one graph is created, clicking on a bar in one bar chart highlights the corresponding bar or bars in the other bar chart.

For example, suppose that you want to see the distribution of company size for the pharmaceutical companies. Click the Pharmaceutical bar in the Type bar chart, and the pharmaceutical companies are highlighted on the Size Co bar chart. Figure 4.8 shows that although most companies in this data table are small, most of the pharmaceutical companies are medium or big.

Also, the corresponding rows in the data table are selected.

Figure 4.8 Clicking Bars

Click this bar to select the corresponding data in the other chart.

---

Compare Multiple Variables

Use multiple-variable graphs to visualize the relationships and patterns between two or more variables. This section covers the following graphs:

Table 4.1 Multiple-Variable Graphs

| Use scatterplots to compare two continuous variables. |
| “Compare Multiple Variables Using Scatterplots” on page 103 |
### Table 4.1 Multiple-Variable Graphs (Continued)

<table>

</tr>
</tbody>
</table>

### Compare Multiple Variables Using Scatterplots

The scatterplot is the simplest of all the multiple-variable graphs. Use scatterplots to determine the relationship between two continuous variables and to discover whether two continuous variables are *correlated*. Correlation indicates how closely two variables are related. When you have two variables that are highly correlated, one might influence the other. Or, both might be influenced by other variables in a similar way.
**Scenario**

This example uses the Companies.jmp data table, which contains sales figures and the number of employees of a group of companies.

A financial analyst wants to explore the following questions:

- What is the relationship between sales and the number of employees?
- Does the amount of sales increase with the number of employees?
- Can you predict average sales from the number of employees?

To answer these questions, use a scatterplot of Sales ($M) versus # Employ.

**Create the Scatterplot**

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select Sales ($M) and **Y, Response**.
4. Select # Employ and **X, Factor**.
Figure 4.10  Fit Y by X Window

5. Click **OK**.

Figure 4.11  Scatterplot of Sales ($M) versus # Employ

Interpret the Scatterplot

One company has a large number of employees and high sales, represented by the single point at the top right of the plot. The distance between this data point and all the rest makes it difficult to visualize the relationship between the rest of the companies. Remove the point from the plot and re-create the plot by following these steps:

1. Click the point to select it.
2. Select **Rows > Hide and Exclude**. The data point is hidden and no longer included in calculations.

**Note:** The difference between hiding and excluding is important. Hiding a point removes it from any graphs but statistical calculations continue to use the point. Excluding a point removes it from any statistical calculations but does not remove it from graphs. When you both hide and exclude a point, you remove it from all calculations and from all graphs.

3. To re-create the plot without the outlier, click the Bivariate red triangle and select **Redo > Redo Analysis**. You can close the original report window.

**Figure 4.12** Scatterplot with the Outlier Removed

The updated scatterplot provides these answers:

- There is a relationship between the sales and the number of employees.
  The data points have a discernible pattern. They are not scattered randomly throughout the graph. You could draw a diagonal line that would be near most of the data points.

- Sales do increase with the number of employees, and the relationship is linear.
  If you drew that diagonal line, it would slope from bottom left to top right. This slope shows that as the number of employees increases (left to right on the bottom axis), sales also increases (bottom to top on the left axis). A straight line would be near most of the data points, indicating a linear relationship. If you would have to curve your line to be near the data points, there would still be a relationship (because of the pattern of the points). However, that relationship would not be linear.

- You can predict average sales from the number of employees.
  The scatterplot shows that sales generally increase as the number of employees does. You could predict the sales for a company if you knew only the number of employees of that company. Your prediction would be on that imaginary line. It would not be exact, but it would approximate the real sales.
Interact with the Scatterplot

As with other JMP graphics, the scatterplot is interactive. Hover over the point in the bottom right corner with the mouse to reveal the row number and the x and y values.

Figure 4.13 Hover Over a Point

Click a point to highlight the corresponding row in the data table. Select multiple points by doing one of the following:

- Click and drag with the cursor around the points. This selects points in a rectangular area.
- Select the lasso tool, and then click and drag around multiple points. The lasso tool selects an irregularly shaped area.

Compare Multiple Variables Using a Scatterplot Matrix

A scatterplot matrix is a collection of scatterplots organized into a grid (or matrix). Each scatterplot shows the relationship between a pair of variables.
**Figure 4.14 Example of a Scatterplot Matrix**

![Scatterplot Matrix](image)

**Scenario**

This example uses the Solubility.jmp data table, which contains data for solubility measurements for 72 different solutes.

A lab technician wants to explore the following questions:

- Is there a relationship between any pair of chemicals? (There are six possible pairs.)
- Which pair has the strongest relationship?

To answer these questions, use a scatterplot matrix of the four solvents.

**Create the Scatterplot Matrix**

1. Select Help > Sample Data Library and open Solubility.jmp.
2. Select Graph > Scatterplot Matrix.
3. Select Ether, Chloroform, Benzene, and Hexane, and click Y, Columns.
4. Click **OK**.

**Figure 4.15  Scatterplot Matrix Window**

**Figure 4.16  Scatterplot Matrix**

**Interpret the Scatterplot Matrix**

The scatterplot matrix provides these answers:

- All six pairs of variables are positively correlated.
  
  As one variable increases, the other variable increases too.
• The strongest relationship appears to be between Benzene and Chloroform. The data points in the scatterplot for Benzene and Chloroform are the most tightly clustered along an imaginary line.

Interact with the Scatterplot Matrix

If you select a point in one scatterplot, it is selected in all the other scatterplots. For example, if you select a point in the Benzene versus Chloroform scatterplot, the same point is selected in the other five plots.

Figure 4.17 Selected Points

Compare Multiple Variables Using Side-by-Side Box Plots

Side-by-side box plots show the following:

• the relationship between one continuous variable and one categorical variable
• differences in the continuous variable across levels of the categorical variable
Scenario

This example uses the Analgesics.jmp data table, which contains data on pain measurements taken on patients using three different drugs.

A researcher wants to explore the following questions:

- Are there differences in the average amount of pain control among the drugs?
- Does the variability in the pain control given by each drug differ? A drug with high variability would not be as reliable as a drug with low variability.

To answer these questions, use a side-by-side box plot for the pain levels and the drug categories.

Create the Side-by-Side Box Plots

1. Select Help > Sample Data Library and open Analgesics.jmp.
2. Select Analyze > Fit Y by X.
4. Select drug and click X, Factor.

Figure 4.18 Example of Side-by-Side Box Plots
Figure 4.19 Fit Y by X Window

5. Click OK.

6. Click the red triangle next to Oneway Analysis of pain By drug and select Display Options > Box Plots.

Figure 4.20 Side-by-Side Box Plots

Interpret the Side-by-Side Box Plots

Box plots are designed according to the following principles:

- The line through the box represents the median.
- The middle half of the data is within the box.
- The majority of the data falls between the ends of the whiskers.
• A data point outside the whiskers might be an outlier.

The box plots in Figure 4.20 show these answers:

• There is evidence to believe that patients on drug A feel less pain, since the box plot for drug A is lower on the pain scale than the others.

• Drug B appears to have higher variability than Drugs A and C, since the box plot is taller.

There is one point for drug C that is a lot lower than the other points for drug C. Hover over the lower point to see that it is row 26 of the data table. That point looks like it is more similar to the data in drug group A or B. The information in row 26 deserves investigation. There might have been a typographical error when the data was recorded.

**Compare Multiple Variables Using Graph Builder**

Use Graph Builder to interactively create and modify graphs. Most graphs in JMP are created by launching a platform and specifying variables. If you want to create a different type of graph, you launch a specific platform from the Graph menu. However, with Graph Builder, you can change the variables and change the type of graph at any time.

Use Graph Builder to accomplish the following tasks:

• Change variables by dragging and dropping them in and out of the graph.

• Create a different type of graph with a few mouse clicks.

• Partition the graph horizontally or vertically.
Figure 4.21  Example of a Graph That Was Created with Graph Builder

Note: Only some of the Graph Builder features are covered here. See Essential Graphing.

Scenario

This example uses the Profit by Product.jmp data table, which contains profit data for multiple product lines.

A business analyst wants to explore the following question:

- How is the profitability different between product lines?

To answer this question, use a line plot that displays revenue, product cost, and profit data across different product lines.

Create the Graph

1. Select Help > Sample Data Library and open Profit by Product.jmp.
2. Select Graph > Graph Builder.
3. Click *Quarter* and then drag and drop it onto the X zone to assign *Quarter* as the X variable.

4. Click *Revenue*, *Product Cost*, and *Profit*, and drag and drop them onto the Y zone to assign all three variables as Y variables.

The X and Y zones are now axes.

**Note:** You can also click variables and then click a zone to assign them. However, after a zone becomes an axis, drag and drop additional variables onto the axis rather than clicking on the variables and axis.
Figure 4.23 After Adding Y and X Variables

Based on the variables that you are using, Graph Builder shows side-by-side box plots.

5. To change the box plots to a line plot, click the Line icon.
6. To create a separate chart for each product, click **Product Line**, and drag and drop it into the **Wrap** zone.

A separate line plot is created for each product.
Interpret the Graph

Figure 4.25 shows revenue, cost, and profit broken down by product line. The business analyst was interested in seeing the difference in profitability between product lines. The line plots in Figure 4.25 can provide some answers:

- Credit products, deposit products, and revolving credit products produce more revenue than fee-based products, third-party products, and other products.
- However, the profits of all the product lines are similar.

The data table also includes data on sales channels. The business analyst wants to see how revenue, product cost, and profit differ between different sales channels.

1. To remove Product Line from the graph, click the title of the graph (Product Line) and drag and drop it into any empty area within Graph Builder.

2. To add Channel as the wrap variable, click Channel and drag and drop it into the Wrap zone.
Figure 4.26 provides this answer: revenue and product cost for ATMs are the highest and are growing the most quickly.

**Compare Multiple Variables Using Bubble Plots**

A bubble plot is a scatterplot that represents its points as bubbles. You can change the size and color of the bubbles, and even animate them over time. With the ability to represent up to five dimensions (x position, y position, size, color, and time), a bubble plot can produce dramatic visualizations and make data exploration easy.
**Scenario**

This example uses the PopAgeGroup.jmp data table, which contains population statistics for 116 countries or territories between the years 1950 to 2004. Total population numbers are broken out by age group, and not every country has data for every year.

A sociologist wants to explore the following question:

- Is the age of the population of the world changing?

To answer this question, look at the relationship between the oldest (more than 59) and the youngest (younger than 20) portions of the population. Use a bubble plot to determine how this relationship changes over time.

**Create the Bubble Plot**

1. Select Help > Sample Data Library and open PopAgeGroup.jmp.
2. Select Graph > Bubble Plot.
3. Select Portion60+ and click **Y**.
   This corresponds to the **Y** variable on the bubble plot.
4. Select Portion 0-19 and click **X**.
This corresponds to the X variable on the bubble plot.

5. Select Country and click **ID**.
Each unique level of the ID variable is represented by a bubble on the plot.

6. Select Year and click **Time**.
This controls the time indexing when the bubble plot is animated.

7. Select Pop and click **Sizes**.
This controls the size of the bubbles.

8. Select Region and click **Coloring**.
Each level of the Coloring variable is assigned a unique color. So in this example, all the bubbles for countries located in the same region have the same color. The bubble colors that appear in Figure 4.29 are the JMP default colors.

**Figure 4.28  Bubble Plot Launch Window**

9. Click **OK**.
Figure 4.29 Initial Bubble Plot

Interpret the Bubble Plot

Because the time variable (in this case, year) starts in 1950, the initial bubble plot shows the data for 1950. Animate the bubble plot to cycle through all the years by clicking the play/pause button. Each successive bubble plot shows the data for that year. The data for each year determines the following:

- The X and Y coordinates
- The bubble’s sizes
- The bubble’s coloring
- Bubble aggregation

**Note:** For detailed information about how the bubble plot aggregates information across multiple rows, see *Essential Graphing.*

The bubble plot for 1950 shows that if a country’s proportion of people younger than 20 is high, then the proportion of people more than 59 is low.
Click the play/pause button to animate the bubble plot through the range of years. As time progresses, the Portion 0-19 decreases and the Portion 60+ increases.

- plays the animation, turns to a pause button after you click it.
- pauses the animation.
- manually controls the animation back one unit of time.
- manually controls the animation forward one unit of time.

**Year**  Changes the time index manually.

**Speed**  Controls the speed of the animation.

**Bubble Size**  Controls the absolute sizes of the bubbles, while maintaining the relative sizes

The sociologist wanted to know how the age of the world’s population is changing. The bubble plot indicates that the population of the world is getting older.

**Interact with the Bubble Plot**

Click to select a bubble to see the trend for that bubble over time. For example, in the 1950 plot, the large bubble in the middle is Japan.

**To See the Pattern of Population Changes in Japan through the Years**

1. Click in the middle of the Japan bubble to select it.
2. Click the Bubble Plot red triangle and select **Trail Bubbles > Selected**.
3. Click the play button.

As the animation progresses through time, the Japan bubble leaves a trail of bubbles that illustrates its history.
Focusing on the Japan bubble, you can see the following over time:

- The proportion of the population 19 years old or less decreased.
- The proportion of the population 60 years old or more increased.

**Compare Multiple Variables Using Overlay Plots**

Like scatterplots, overlay plots show the relationship between two or more variables. However, if one of the variables is a time variable, an overlay plot shows trends across time better than scatterplots do.
Chapter 4 Visualize Your Data

Discovering JMP Compare Multiple Variables

**Figure 4.31** Example of an Overlay Plot

![Overlay Plot](image)

**Note:** To plot data over time, you can also use bubble plots, control charts, and variability charts. For more information about Graph Builder and bubble plots, see *Essential Graphing*. See and *Quality and Process Methods* for information about control charts and variability charts.

**Scenario**

This example uses the *Stock Prices.jmp* data table, which contains data on the price of a stock over a three-month period.

A potential investor wants to explore the following questions:

- Has the stock’s closing price changed over the past three months?
  
  To answer this question, use an overlay plot of the stock’s closing price over time.

- How do the stock’s high and low prices relate to each other?
  
  To answer this question, use another overlay plot of the stock’s high and low prices over time.

Create the first overlay plot to answer the first question, and then create a second overlay plot to answer the second question.
Create the Overlay Plot of the Stock’s Price over Time

1. Select Help > Sample Data Library and open Stock Prices.jmp.
2. Select Graph > Graph Builder.
3. Select Close and click Y.
4. Select Date and click X.

Figure 4.32 Overlay Plot with Smoother

5. Press Ctrl and click the Smoother icon above the graph to remove the smoother line.
Interpret and Interact with the Overlay Plot

The overlay plot shows that the closing stock price has been decreasing over the last several months. To see the trend more clearly, connect the points.

1. Press Shift and click the Line icon above the graph.
The potential investor can see that although the stock price has gone up and down over the past three months, the overall trend has been downward.

**Create the Overlay Plot of the Stock’s High and Low Prices**

Use an overlay plot to plot more than one Y variable. For example, suppose that you want to see both the high and the low prices on the same plot.

1. Follow the steps in “Create the Overlay Plot of the Stock’s Price over Time” on page 126, this time assigning both High and Low to the Y role.

2. Connect the points and add grid lines as shown in “Interpret and Interact with the Overlay Plot” on page 127.
The legend at the bottom of the plot shows the colors and markers used for the High and Low variables in the graph. The overlay plot shows that the High price and Low price track each other very closely.

**Answer the Questions**

Both of the overlay plots answer the two questions asked at the beginning of this example.

- The first plot shows that the price of this stock has not remained the same, but has been decreasing.
- The second plot shows that the high and low prices of this stock are not very different from each other. The stock price does not vary wildly on any given day.

**Compare Multiple Variables Using a Variability Chart**

In the graphs described so far, you specified only a single X variable. Use a variability chart to specify multiple X variables and see differences in means and variability across all of your variables at once.
Figure 4.36  Example of a Variability Chart

Scenario

This example uses the Popcorn.jmp data table with data from a popcorn maker. The yield (the volume of popcorn for a given measure of kernels) was measured for each combination of popcorn style, batch size, and amount of oil used.

The popcorn maker wants to explore the following question:

- Which combination of factors results in the highest popcorn yield?

To answer this question, use a variability chart of the yield versus the style, batch size, and oil amount.

Create the Variability Chart

1. Select Help > Sample Data Library and open Popcorn.jmp.
2. Select Analyze > Quality and Process > Variability/Attribute Gauge Chart.
4. Select popcorn and click X, Grouping.
5. Select batch and click X, Grouping.
6. Select oil amt and click X, Grouping.

Note: The order in which you assign the variables to the X, Grouping role is important, because the order in this window determines their nesting order in the variability chart.
Figure 4.37 Variability Chart Window

7. Click **OK**.

The top chart is the variability chart, showing the yield broken down by each combination of the three variables. The bottom chart shows the standard deviation for each combination of the three variables. Since the bottom chart does not show the yield, hide it.

8. Click the Variability Gauge red triangle and deselect **Std Dev Chart**.

Figure 4.38 Results Window
Interpret the Variability Chart

The variability chart for yield indicates that small, gourmet batches produce the highest yield.

To be more specific, the popcorn maker might ask this additional question: Is the yield high because those batches are small, or because those batches are gourmet?

The variability chart shows the following:

- The yield from small, plain batches is low.
- The yield from large, gourmet batches is low.

Given this information, the popcorn maker can conclude that only the combination of small and gourmet at the same time results in batches with high yield. It would have been impossible to reach this conclusion with a chart that only allowed a single variable.
Analyzing your data in JMP helps you make informed decisions. Data analysis often involves these actions:

- Examining distributions
- Discovering relationships
- Hypothesis testing
- Building models

About This Chapter

Before you analyze your data, review the following information about basic concepts:

- “The Importance of Graphing Your Data” on page 135
- “Understand Modeling Types” on page 138

The rest of this chapter shows you how to use some basic analytical methods in JMP:

- “Analyze Distributions” on page 143
- “Analyze Relationships” on page 149

For a description of advanced modeling and analysis techniques, refer to the following JMP documentation:

- Fitting Linear Models
- Multivariate Methods
- Predictive and Specialized Modeling
- Consumer Research
- Reliability and Survival Methods
- Quality and Process Methods

The Importance of Graphing Your Data

Graphing, or visualizing, your data is important to any data analysis, and should always occur before the use of statistical tests or model building. To illustrate why data visualization should be an early step in your data analysis process, consider the following example:

   This data consists of four pairs of X and Y variables.

2. In the Table panel, click the green triangle next to the The Quartet script.
   The script creates a simple linear regression on each pair of variables using Fit Y by X. The Show Points option is turned off, so that none of the data can be seen on the scatterplots. Figure 5.2 shows the model fit and other summary information for each regression.
Notice that all four models and the RSquare values are nearly identical. The fitted model in each case is essentially $Y = 3 + 0.5X$, and the RSquare value in each case is essentially 0.66. If your data analysis took into account only the above summary information, you would likely conclude that the relationship between X and Y is the same in each case. However, at this point, you have not visualized your data. Your conclusion might be wrong.

**To Visualize the Data, Add the Points to All Four Scatterplots**

1. Press Ctrl.
2. Click the red triangle next to any one of the Bivariate Fits and select **Show Points**.
Figure 5.3 Scatterplots with Points Added

The scatterplots show that the relationship between $X$ and $Y$ is not the same for the four pairs, although the lines describing the relationships are the same:

- Plot 1 represents a linear relationship.
- Plot 2 represents a non-linear relationship.
- Plot 3 represents a linear relationship, except for one outlier.
- Plot 4 has all the data at $x = 8$, except for one point.

This example illustrates that conclusions that are based on statistics alone can be inadequate. A visual exploration of the data should be an early part of any data analysis.
Understand Modeling Types

In JMP, data can be of different types. JMP refers to this as the modeling type of the data. Table 5.1 describes the three modeling types in JMP.

Table 5.1  Modeling Types

<table>
<thead>
<tr>
<th>Modeling Type and Description</th>

</table>
Example of Viewing Modeling Type Results

Different modeling types produce different results in JMP. To see an example of the differences, follow these steps:

1. Select **Help > Sample Data Library** and open Linnerud.jmp.
2. Select **Analyze > Distribution**.
3. Select Age and Weight and click **Y, Columns**.
4. Click **OK**.
Although Age and Weight are both numeric variables, they are not treated the same. Table 5.2 compares the differences between the results for weight and age.

**Table 5.2  Results for weight and age**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Modeling Type</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight</td>
<td>Continuous</td>
<td>Histogram, Quantiles, and Summary Statistics</td>
</tr>
<tr>
<td>Age</td>
<td>Ordinal</td>
<td>Bar chart and Frequencies</td>
</tr>
</tbody>
</table>
Change the Modeling Type

To treat a variable differently, change the modeling type. For example, in Figure 5.4, the modeling type for Age is ordinal. Remember that for an ordinal variable, JMP calculates frequency counts. Suppose that you wanted to find the average age instead of frequency counts. Change the modeling type to continuous, which shows the mean age.

1. Double-click the Age column heading. The Column Info window appears.
2. Change the Modeling Type to Continuous.

Figure 5.5 Column Info Window

3. Click OK.
4. Repeat the steps in the example (see “Example of Viewing Modeling Type Results” on page 139) to create the distribution. Figure 5.6 shows the distribution results when Age is ordinal and continuous.
When age is ordinal, you can see the frequency counts for each age. For example, age 48 appears two times. When age is continuous, you can find the mean age, which is nearly 48 (47.677)
Analyze Distributions

To analyze a single variable, you can examine the distribution of the variable, using the Distribution platform. Report content for each variable varies, depending on whether the variable is categorical (nominal or ordinal) or continuous.

Note: For more information about the Distribution platform, see Basic Analysis.

Distributions of Continuous Variables

Analyzing a continuous variable might include questions such as the following:

- Does the shape of the data match any known distributions?
- Are there any outliers in the data?
- What is the average of the data?
- Is the average statistically different from a target or historical value?
- How spread out are the data? In other words, what is the standard deviation?
- What are the minimum and maximum values?

You can answer these and other questions with graphs, summary statistics, and simple statistical tests.

Scenario

This example uses the Car Physical Data.jmp data table, which contains information about 116 different car models.

A planning specialist has been asked by a railroad company to determine the possible issues involved in transporting cars by train. Using the data, the planning specialist wants to explore the following questions:

- What is the average car weight?
- How spread out are the cars’ weights (standard deviation)?
- What are the minimum and maximum weights of cars?
- Are there any outliers in the data?

Use a histogram of weight to answer these questions.

Create the Histogram

1. Select Help > Sample Data Library and open Car Physical Data.jmp.
2. Select **Analyze > Distribution**.
3. Select Weight and click **Y, Columns**.
4. Click **OK**.
5. To rotate the report window, click the Weight red triangle and select **Display Options > Horizontal Layout**.

**Figure 5.7** Distribution of Weight

The report window contains three sections:
- A histogram and a box plot to visualize the data.
- A Quantiles report that shows the percentiles of the distribution.
- A Summary Statistics report that shows the mean, standard deviation, and other statistics.

**Interpret the Distribution Results**

Using the results presented in Figure 5.7, the planning specialist can answer the questions.

**What is the average car weight?** The Histogram shows a weight of around 3,000 lbs.

**How spread out are the weights (standard deviation)?** The Summary Statistics show a weight of around 2,958 lbs. The Summary Statistics show a standard deviation of around 536 lbs.

**What are the minimum and maximum weights?** The Histogram shows a minimum of around 1,500 lbs. and a maximum of around 4,500 lbs. The Quantiles show a minimum of around 1,695 lbs. and a maximum of around 4,285 lbs.

**Are there any outliers?** No.

The default report window in Figure 5.7 provides a minimal set of graphs and statistics. Additional graphs and statistics are available on the red triangle menu.
**Draw Conclusions**

Based on other research, the railroad company has determined that an average weight of 3000 pounds is the most efficient to transport. Now, the planning specialist needs to find out whether the average car weight in the general population of cars that they might transport is 3000 pounds. Use a *t* test to draw inferences about the broader population based on this sample of the population.

**Test Conclusions**

1. Click the Weight red triangle and select **Test Mean**.
2. In the window that appears, type 3000 in the Specify Hypothesized Mean box.
3. Click **OK**.

![Figure 5.8 Test Mean Results](image)

**Interpret the *t* Test**

The primary result of a *t* test is the *p*-value. In this example, the *p*-value is 0.396 and the analyst is using a significance level of 0.05. Since 0.396 is greater than 0.05, you cannot conclude that the average weight of car models in the broader population is significantly different from 3000 pounds. Had the *p*-value been lower than the significance level, the planning specialist would have concluded that the average car weight in the broader population *is* significantly different from 3000 pounds.
Distributions of Categorical Variables

Analyzing a categorical (ordinal or nominal) variable might include questions such as the following:

- How many levels does the variable have?
- How many data points does each level have?
- Is the data uniformly distributed?
- What proportions of the total do each level represent?

Scenario

See the scenario in “Distributions of Continuous Variables” on page 143.

Now that the railroad company has determined that the average weight of the cars is not significantly different from the target weight, there are more questions to address.

The planning specialist wants to answer these questions for the railroad company:

- What are the types of cars?
- What are the countries of origin?

To answer these questions, look at the distribution for Type and Country.

Create the Distribution

1. Select Help > Sample Data Library and open Car Physical Data.jmp.
2. Select Analyze > Distribution.
3. Select Country and Type and click Y, Columns.
4. Click OK.
**Figure 5.9 Distribution for Country and Type**

The report window includes a bar chart and a Frequencies report for Country and Type. The bar chart is a graphical representation of the frequency information provided in the Frequencies report. The Frequencies report contains the following:

- Categories of data. For example, Japan is a category of Country, and Sporty is a category of Type.
- Total counts for each category.
- Proportion of the total each category represents.

For example, there are 22 compact cars, or about 19% of the 116 observations.

**Interact with the Distribution Results**

Selecting a bar in one chart also selects the corresponding data in the other chart. For example, select the Japan bar in the Country bar chart to see that a large number of Japanese cars are sporty.
Select the Other category to see that a majority of these cars are small or compact, and almost none are large.

Figure 5.11 Other Cars
Analyze Relationships

Scatterplots and other such graphs can help you visualize relationships between variables. Once you have visualized relationships, the next step is to analyze those relationships so that you can describe them numerically. That numerical description of the relationship between variables is called a model. Even more importantly, a model also predicts the average value of one variable (Y) from the value of another variable (X). The X variable is also called a predictor. Generally, this model is called a regression model.

With JMP, the **Fit Y by X** platform and the **Fit Model** platform creates regression models.

**Note:** Only the basic platforms and options are covered here. For explanations of all platform options, see *Basic Analysis*, *Essential Graphing*, and the documentation listed in “About This Chapter” on page 135.

Table 5.3 shows the four primary types of relationships.

**Use Regression with One Predictor**

**Scenario**

This example uses the Companies.jmp data table, which contains financial data for 32 companies from the pharmaceutical and computer industries.
Intuitively, it makes sense that companies with more employees can generate more sales revenue than companies with fewer employees. A data analyst wants to predict the overall sales revenue for each company based on the number of employees.

To accomplish this task, do the following:

- “Discover the Relationship” on page 150
- “Fit the Regression Model” on page 150
- “Predict Average Sales” on page 152

Discover the Relationship

First, create a scatterplot to see the relationship between the number of employees and the amount of sales revenue. This scatterplot was created in “Create the Scatterplot” on page 104 in the “Visualize Your Data” chapter. After hiding and excluding one outlier (a company with significantly more employees and higher sales), the plot in Figure 5.12 shows the result.

Figure 5.12 Scatterplot of Sales ($M) versus # Employ

This scatterplot provides a clearer picture of the relationship between sales and the number of employees. As expected, the more employees a company has, the higher sales that it can generate. This visually confirms the data analyst’s guess, but it does not predict sales for a given number of employees.

Fit the Regression Model

To predict the sales revenue from the number of employees, fit a regression model. Click the Bivariate Fit red triangle and select Fit Line. A regression line is added to the scatterplot and reports are added to the report window.
Within the reports, look at the following results:

- the \( p \)-value of <.0001
- the RSquare value of 0.618

From these results, the data analyst can conclude the following:

- The \( p \)-value for the \#Employ model term is small. This supports that at the 0.05 significance level the coefficient for \#Employ is not zero. Therefore, including the number of employees in the prediction model significantly improves the ability to predict average sales over a model without the number of employees.

- The RSquare value of 0.618 indicates that this model explains about 62% of the variability in sales. The RSquare value is the coefficient of determination and indicates the proportion of the variance in the dependent (response) variable that is explained by your model. RSquare can range from 0 to 1. A model with an RSquare of 0 has no explanatory power. A model with an RSquare of 1 predicts the response perfectly.
Predict Average Sales

Use the regression model to predict the average sales a company might expect if they have a certain number of employees. The prediction equation for the model is included in the report:

\[
\text{Average sales} = 1059.68 + 0.092\times \text{employees}
\]

For example, in a company with 70,000 employees sales are predicted to be about $7,500:

\[
7,499.68 = 1059.68 + 0.092\times 70,000
\]

In the lower right area of the current scatterplot, there is an outlier that does not follow the general pattern of the other companies. The data analyst wants to know whether the prediction model changes when this outlier is excluded.

Exclude the Outlier

1. Click the outlier.
2. Select **Rows > Exclude/Unexclude**.
3. To fit this model, click red triangle next to Bivariate Fit of Sales (SM) By # Employ and select **Fit Line**.

The following are added to the report window (Figure 5.14):

- a new regression line
- a new Linear Fit report, which includes:
  - a new prediction equation
  - a new RSquare value
Interpret the Results

Using the results in Figure 5.14, the data analyst can make the following conclusions:

- The outlier was pulling down the regression line for the larger companies, and pulling the line up for the smaller companies.
- The new model for the data without the outlier is a stronger model than the first model. The new RSquare value of 0.88 is higher and closer to 1 than the initial analysis.
Draw Conclusions

Using the new prediction equation, the predicted average sales for a company with 70,000 employees can be calculated as follows:

$$8961.37 = 631.37 + 0.119 \times 70,000$$

The prediction from the first model was about $7500. The second model predicts a sales total of about $8960 or an increase of $1460 as compared to the first model.

The second model, after removing the outlier, describes and predicts sales totals based on the number of employees better than the first model. The data analyst now has a good model to use.

Compare Averages for One Variable

If you have a continuous Y variable, and a categorical X variable, you can compare averages across the levels of the X variable.

Scenario

This example uses the Companies.jmp data table, which contains financial data for 32 companies from the pharmaceutical and computer industries.

A financial analyst wants to explore the following question:

- How do the profits of computer companies compare to the profits of pharmaceutical companies?

To answer this question, fit Profits ($M) by Type.

Discover the Relationship

1. Select Help > Sample Data Library and open Companies.jmp.
2. If you still have the Companies.jmp sample data table open, you might have rows that are excluded or hidden. To return the rows to the default state (all rows included and none hidden), select Rows > Clear Row States.
3. Select Analyze > Fit Y by X.
4. Select Profits ($M) and click Y, Response.
5. Select Type and click X, Factor.
6. Click OK.
Figure 5.15  Profits by Company Type

There is an outlier in the Computer Type. The outlier is stretching the scale of the plot and making it difficult to compare the profits. Exclude and hide the outlier:

1. Click the outlier.
2. Select **Rows > Exclude/Unexclude**. The data point is no longer included in calculations.
3. Select **Rows > Hide/Unhide**. The data point is hidden from all graphs.
4. To re-create the plot without the outlier, click the Oneway Analysis of Profits ($M) By Type and select **Redo > Redo Analysis**. You can close the original Scatterplot window.

Figure 5.16  Updated Plot
Removing the outlier gives the financial analyst a clearer picture of the data.

5. To continue analyzing the relationship, select these options from the red triangle next to Oneway Analysis of Profits ($M) By Type:

- **Display Options > Mean Lines.** This adds mean lines to the scatterplot.
- **Means and Std Dev.** This displays a report that provides averages and standard deviations.

**Figure 5.17 Mean Lines and Report**

**Interpret the Results**

The financial analyst wanted to know how the profits of computer companies compared to the profits of pharmaceutical companies. The updated scatterplot shows that pharmaceutical companies have higher average profits than computer companies. In the report, if you subtract one mean value from the other, the difference in profit is about $635 million. The plot also shows that some of the computer companies have negative profits and all of the pharmaceutical companies have positive profits.
Perform the t Test

The financial analyst has looked at only a sample of companies (the companies in the data table). The financial analyst now wants to examine these questions:

- Does a difference exist in the broader population, or is the difference of $635 million due to chance?
- If there is a difference, what is it?

To answer these questions, perform a two-sample t test. A t test lets you use data from a sample to make inferences about the larger population.

To perform the t test, click the Oneway Analysis red triangle and select Means/Anova/Pooled t.

Figure 5.18 t Test Results

The p-value of 0.0001 is less than the significance level of 0.05, which indicates statistical significance. Therefore, the financial analyst can conclude that the observed difference in average profits for the sample data is statistically significant. This means that in the larger population, the average profits for pharmaceutical companies are different from the average profits for computer companies.

Draw Conclusions

Use the confidence interval limits to determine how much difference exists in the profits of both types of companies. Look at the Upper CL Dif and Lower CL Dif values in Figure 5.18. The financial analyst concludes that the average profit of pharmaceutical companies is between $343 million and $926 million higher than the average profit of computer companies.

Compare Proportions

If you have categorical X and Y variables, you can compare the proportions of the levels within the Y variable to the levels within the X variable.
**Scenario**

This example continues to use the Companies.jmp data table. In “Compare Averages for One Variable” on page 154, a financial analyst determined that pharmaceutical companies have higher profits on average than do computer companies.

The financial analyst wants to know whether the size of a company affects profits more for one type of company than the other? However, before examining this question, the financial analyst needs to know whether the populations of computer and pharmaceutical companies consist of the same proportions of small, medium, and big companies.

**Discover the Relationship**

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. If you still have the Companies.jmp data file open from the previous example, you might have rows that are excluded or hidden. To return the rows to the default state (all rows included and none hidden), select **Rows > Clear Row States**.
3. Select **Analyze > Fit Y by X**.
4. Select Size Co and click **Y, Response**.
5. Select Type and click **X, Factor**.
6. Click **OK**.
Figure 5.19 Company Size by Company Type

The Contingency Table contains information that is not applicable for this example. Click the Contingency Table red triangle and deselect Total % and Col % to remove that information. Figure 5.20 shows the updated table.

Figure 5.20 Updated Contingency Table
Interpret the Results

The statistics in the Contingency Table are graphically represented in the Mosaic Plot. Together, the Mosaic Plot and the Contingency Table compare the percentages of small, medium, and big companies between the two industries. For example, the Mosaic Plot shows that the computer industry has a higher percentage of small companies compared to the pharmaceutical industry. The Contingency Table shows the exact statistics: 70% of computer companies are small, and about 17% of pharmaceutical companies are small.

Interpret the Test

The financial analyst has looked at only a sample of companies (the companies in the data table). The financial analyst needs to know whether the percentages differ in the broader populations of all computer and pharmaceutical companies.

To answer this question, use the $p$-value from the Pearson test in the Tests report (Figure 5.19 on page 159). Since the $p$-value of 0.011 is less than the significance level of 0.05, the financial analyst concludes the following:

- The differences in the sample data are statistically significant.
- The percentages differ in the broader population.

Now the financial analyst knows that the proportions of small, medium, and big companies are different, and can answer the question: Does the size of company affect profits more for one type of company than the other?

Compare Averages for Multiple Variables

The section “Compare Averages for One Variable” on page 154, compared averages across the levels of a categorical variable. To compare averages across the levels of two or more variables at once, use the Analysis of Variance technique (or ANOVA).

Scenario

The financial analyst can answer the question that we started to work through in the Comparing Proportions section, which is: Does the size of the company have a larger effect on the company’s profits, based on type (pharmaceutical or computer)?

To answer this question, compare the company profits by these two variables:

- Type (pharmaceutical or computer)
- Size (small, medium, big)
Discover the Relationship

To visualize the differences in profit for all of the combinations of type and size, use a graph:

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Graph > Graph Builder. The Graph Builder window appears.
3. Click Profits ($M) and drag and drop it into the Y zone.
4. Click Size Co and drag and drop it into the X zone.
5. Click Type and drag and drop it into the Group X zone.

Figure 5.21 Graph of Company Profits

The graph shows that one big computer company has very large profits. That outlier is stretching the scale of the graph, making it difficult to compare the other data points.

6. Select the outlier, then right-click and select Rows > Row Exclude. The point is removed, and the scale of the graph automatically updates.
7. Click the Bar icon. Comparing mean profits is easier with bar charts than with points.
The updated graph shows that pharmaceutical companies have higher average profits. The graph also shows that profits differ between company sizes for only the pharmaceutical companies. When the effect of one variable (company size) changes for different levels of another variable (company type), this is called an interaction.

**Quantify the Relationship**

Because this data is only a sample, the financial analyst needs to determine the following:

- if the differences are limited to this sample and due to chance
- or
- if the same patterns exist in the broader population

1. Return to the Companies.jmp sample data table that has the data point excluded. See “Discover the Relationship” on page 161.
2. Select **Analyze > Fit Model**.
3. Select Profits ($M) and click **Y**.
4. Select both Type and Size Co.
5. Click the **Macros** button and select **Full Factorial**.
6. From the Emphasis menu, select **Effect Screening**.
7. Select the **Keep dialog open** option.

**Figure 5.23** Completed Fit Model Window

8. Click **Run**. The report window shows the model results.

To decide whether the differences in profits are real, or due to chance, examine the **Effect Tests** report.

**Note:** For more information about all of the Fit Model results, see *Fitting Linear Models*.

**View Effect Tests**

The Effect Tests report (Figure 5.24) shows the results of the statistical tests. There is a test for each of the effects included in the model on the Fit Model window: Type, Size Co, and Type*Size Co.
Figure 5.24  Effect Tests Report

First, look at the test for the interaction in the model: the Type*Size Co effect. Figure 5.22 showed that the pharmaceutical companies appeared to have different profits between company sizes. However, the effect test indicates that there is no interaction between type and size as it relates to profit. The $p$-value of 0.218 is large (greater than the significance level of 0.05). Therefore, remove that effect from the model, and re-run the model.

1. Return to the Fit Model window.
2. In the Construct Model Effects box, select the **Type*Size Co** effect and click **Remove**.
3. Click **Run**.

Figure 5.25  Updated Effect Tests Report

The $p$-value for the Size Co effect is large, indicating that there are no differences based on size in the broader population. The $p$-value for the Type effect is small, indicating that the differences that you saw in the data between computer and pharmaceutical companies is not due to chance.

**Draw Conclusions**

The financial analyst wanted to know whether the size of the company has a larger effect on the company’s profits, based on type (pharmaceutical or computer). The financial analyst can now answer this question:

- There is a real difference in profits between computer and pharmaceutical companies in the broader population.
- There is no correlation between the company’s size and type and its profits.
Use Regression with Multiple Predictors

The section “Use Regression with One Predictor” on page 149 showed you how to build simple regression models consisting of one predictor variable and one response variable. *Multiple regression* predicts the average response variable using two or more predictor variables.

**Scenario**

This example uses the Candy Bars.jmp data table, which contains nutrition information for candy bars.

A dietitian wants to predict calories using the following information:

- Total fat
- Carbohydrates
- Protein

Use *multiple regression* to predict the average response variable using these three predictor variables.

**Discover the Relationship**

To visualize the relationship between calories and total fat, carbohydrates, and protein, create a scatterplot matrix:

1. Select Help > Sample Data Library and open Candy Bars.jmp.
2. Select Graph > Scatterplot Matrix.
4. Select Total fat g, Carbohydrate g, and Protein g, and click X.
5. Click OK.
Figure 5.26  Scatterplot Matrix Results

The scatterplot matrix shows that there is a positive correlation between calories and all three variables. The correlation between calories and total fat is the strongest. Now that the dietitian knows that there is a relationship, the dietitian can build a multiple regression model to predict average calories.

Build the Multiple Regression Model

Continue to use the Candy Bars.jmp sample data table.

1. Select Analyze > Fit Model.
2. Select Calories and click Y.
3. Select Total Fat g, Carbohydrate g, and Protein g and click Add.
4. Next to Emphasis, select Effect Screening.
Chapter 5 Analyze Your Data

Discovering JMP Analyze Relationships

Figure 5.27  Fit Model Window

5. Click Run.

The report window shows the model results. To interpret the model results, focus on these areas:

- “View the Actual by Predicted Plot” on page 167
- “Interpret the Parameter Estimates” on page 168
- “Use the Prediction Profiler” on page 169

**Note:** For more information about all of the model results, see *Fitting Linear Models.*

**View the Actual by Predicted Plot**

The Actual by Predicted Plot shows the actual calories versus the predicted calories. As the predicted values come closer to the actual values, the points on the scatterplot fall closer around the red line (Figure 5.28). Because the points are all very close to the line, you can see that the model predicts calories based on the chosen factors well.
Another measure of model accuracy is the RSq value (which appears below the plot in Figure 5.28). The RSq value measures the percentage of variability in calories, as explained by the model. A value closer to 1 means a model is predicting well. In this example, the RSq value is 0.99.

Interpret the Parameter Estimates

The Parameter Estimates report shows the following information:

- The model coefficients
- $p$-values for each parameter

In this example, the $p$-values are all very small (<.0001). This indicates that all three effects (fat, carbohydrate, and protein) contribute significantly when predicting calories.
You can use the model coefficients to predict the value of calories for particular values of fat, carbohydrate, and protein. For example, suppose that you want to predict the average calories for any candy bar that has these characteristics:

- Fat = 11 g
- Carbohydrate = 43 g
- Protein = 2 g

Using these values, you can calculate the predicted average calories as follows:

\[ 277.92 = -5.9643 + 8.99 \times 11 + 4.0975 \times 43 + 4.4013 \times 2 \]

The characteristics in this example are the same as the Milky Way candy bar (on row 59 of the data table). The actual calories for the Milky Way are 280, showing that the model predicts well.

**Use the Prediction Profiler**

Use the Prediction Profiler to see how changes in the factors affect the predicted values. The profile lines show the magnitude of change in calories as the factor changes. The line for Total fat g is the steepest, meaning that changes in total fat have the largest effect on calories.

**Figure 5.30 Prediction Profiler**

Click and drag the vertical line for each factor to see how the predicted value changes. You can also click the current factor values and change them. For example, click the factor values and type the values for the Milky Way candy bar (row 59).
**Figure 5.31** Factor Values for the Milky Way

![Prediction Profiler](image)

Predicted calories

Milky Way values

**Note:** For more information about the Prediction Profiler, see *Profilers*.

**Draw Conclusions**

The dietitian now has a good model to predict calories of a candy bar based on its total fat, carbohydrates, and protein.
JMP provides a host of statistical discovery platforms to help you explore different aspects of your data. You might start with a simple look at individual variables in histograms and then progress to multivariate and cluster analyses to get a deeper look. Each step of the way, you learn more about your data.

This chapter steps through an analysis of the Cereal.jmp sample data table that is installed with JMP. You learn how to explore the data in the Distribution, Multivariate, and Hierarchical Clustering platforms.

**Figure 6.1  Linked Analyses in JMP**
Contents

Fun Fact: Linked Analyses ................................................................. 173
Explore Data in Multiple Platforms .................................................. 173
  Analyze Distributions in the Distribution Platform ......................... 173
  Analyze Patterns and Relationships in the Multivariate Platform .... 177
  Analyze Similar Values in the Clustering Platform ......................... 181
Fun Fact: Linked Analyses

One of the powerful features in JMP is its linked analyses. The graphs and reports that you create are linked to each other through the data table. As shown in Figure 6.1, data that are selected in the data table are also selected in the three report windows. The linked analyses enable you to select data in one window and see where it occurs in the other windows. As you work through the examples in this chapter, keep the JMP windows open to see these interactions yourself.

Explore Data in Multiple Platforms

Which cereals are part of a healthy diet? The Cereal.jmp sample data (real data gathered from boxes of popular cereals) provides statistics on fiber content, calories, and other nutritional information. To identify the most healthful cereals, you step through interpreting histograms and descriptive statistics, correlations and outlier detection, scatterplots, and cluster analysis.

Analyze Distributions in the Distribution Platform

The Distribution platform illustrates the distribution of a single variable (univariate analysis) using histograms, additional graphs, and reports. The word univariate simply means involving one variable instead of two (bivariate) or many (multivariate). However, you can examine the distribution of several individual variables within a single report. The report content for each variable changes depending on whether the variable is categorical (nominal or ordinal) or continuous.

- For categorical variables, the initial graph is a histogram. The histogram shows a bar for each level of the ordinal or nominal variable. The reports show counts and proportions.
- For continuous variables, the initial graphs show a histogram and an outlier box plot. The histogram shows a bar for grouped values of the continuous variable. The reports show selected quantiles and summary statistics.

Once you know how your data are distributed, you can plan the appropriate type of analysis going forward.

Note: For more information about the Distribution platform, see Basic Analysis.
Scenario

You want to view the nutritional values of cereals so that you can eat a more healthful diet. Analyzing distributions of cereal data reveals answers to the following questions:

- Which cereals are highest in fiber?
- What is the average, minimum, and maximum number of calories?
- What is the median amount of fat?
- Which cereal contains the most fat?
- Are there any outliers in the data?

Create the Distributions

1. Select Help > Sample Data Library and open Cereal.jmp.
2. Select Analyze > Distribution.
3. Press Ctrl and click Manufacturer, Calories, Fat, and Fiber.
4. Click Y, Columns and then click OK.

Figure 6.2  Distributions for Manufacturer, Calories, Fat, and Fiber
In the Fiber distributions, notice the following:

- Fiber One and All-Bran with Extra Fiber contain the most fiber as shown in the Fiber box plot. These cereals are outliers in terms of fiber content.

  The row that contains Fiber One in Cereal.jmp is labeled. This label shows the name of the cereal next to a data point in graphs. To see the entire label, drag the right-most vertical border to the right. Hover over the unlabeled data point to see “All Bran with Extra Fiber”.

In the Fat distributions, notice the following:

- Hover over the top data point (the x marker) in the Fat box plot to see that 100% Nat. Bran Oats & Honey is the highest in fat.
- In the Fat Quantiles report, the median amount of fat is 1 gram.

In the Calories Quantiles report, notice the following:

- The maximum number of calories is 250.
- The minimum number of calories is 50.

5. In the Manufacturer histogram, click the bar for Nabisco.

**Figure 6.3 Distributions for Nabisco Cereals**

The Calories, Fat, and Fiber distributions for Nabisco cereals are highlighted in the other histograms. You can view the Calories, Fat, and Fiber distributions for the Nabisco cereals relative to the Calories, Fat, and Fiber distributions for the overall data. For example, the Fat distribution of Nabisco cereals seems to be lower than the Fat distribution for the overall data.

6. Click below the last Fiber bar to deselect all bars.

7. Press Shift and, in the Fiber histogram, click all histogram bars with a value above 8.
Figure 6.4 High-Fiber Cereals

The highest-fiber cereals are highlighted in the Calories and Fat histograms. Because the histograms are linked, note that some of the high-fiber cereals are also low in fat.

8. Press Ctrl and Shift and deselect the two Calories histogram bars that are at or near 200. High calorie cereals are eliminated from the histograms.

Figure 6.5 High-Fiber and Low-Calorie Cereals

Tip: Leave the Distributions report open. You will use it later in a cluster analysis. See “Analyze Similar Values in the Clustering Platform” on page 181.

Interpret the Results

Looking at the results, you can answer the following questions:

Which cereals are highest in fiber? The Fiber box plot shows that All-Bran with Extra Fiber and Fiber One have the highest amount of fiber. These two cereals are outliers.
What is the average, minimum, and maximum number of calories? The Calories histogram shows that the number of calories ranges from 50 to 275. The Calories Quantiles show that the number of calories ranges from 50 to 250, and the median number of calories is 120. The distribution is not uniform.

What is the median amount of fat? The Fat Quantiles report shows that the median amount of fat is 1 gram.

Which cereal contains the most fat? The Fat box plot shows that 100% Nat. Bran Oats & Honey is the highest in fat. This cereal is an outlier.

Draw Conclusions

To increase the amount of fiber in your diet, you decide to try All-Bran with Extra Fiber and Fiber One. These cereals are lower in calories and fat. Most cereals do not greatly increase the amount of fat in your diet, but you plan to avoid the high fat 100% Nat. Bran Oats & Honey. And although most cereals are relatively low in fat, they are not necessarily low in calories.

Analyze Patterns and Relationships in the Multivariate Platform

Now that you have identified which cereals to eat or avoid, you want to see how the cereal variables relate to each other. The Multivariate platform enables you to observe patterns and relationships between variables. From the Multivariate report, you can do the following:

• summarize the strength of the linear relationships between each pair of response variables using the Correlations table
• identify dependencies, outliers, and clusters using the Scatterplot Matrix
• use other techniques to examine multiple variables, such as partial, inverse, and pairwise correlations, covariance matrices, and principal components

Note: For more information about the Multivariate platform, see Multivariate Methods.

Scenario

You want to see the relationships between variables such as fat and calories. Analyzing the cereal data in the Multivariate platform reveals answers to the following questions:

• Which pairs of variables are highly correlated?
• Which pairs of variables are not correlated?
Create the Multivariate Report

1. In the Cereal.jmp data table, click the bottom triangle at the top of the Columns panel to deselect the rows.

Figure 6.6 Deselecting Rows

2. Select **Analyze > Multivariate Methods > Multivariate**.

3. Select Calories through Potassium, click **Y, Columns**, and then click **OK**.

   The Multivariate report appears. The report contains the Correlations report and Scatterplot Matrix by default. The Correlations report is a matrix of correlation coefficients that summarizes the strength of the linear relationships between each pair of response (Y) variables. The dark numbers indicate a lower degree of correlation.

Figure 6.7 Correlations Report

Note the following:

- In the Calories column, the number of calories is highly correlated with all variables except for sodium and fiber.
- In the Fiber column, fiber and potassium appear to be highly correlated.
- In the Sodium column, sodium is not highly correlated with the other variables.
The density ellipses in the Scatterplot Matrix further illustrates relationships between variables.

**Figure 6.8 Portion of the Scatterplot Matrix**

By default, a 95% bivariate normal density ellipse is in each scatterplot. Assuming that each pair of variables has a bivariate normal distribution, this ellipse encloses approximately 95% of the points. If the ellipse is fairly round and is not diagonally oriented, the variables are uncorrelated. If the ellipse is narrow and diagonally oriented, the variables are correlated.

Note the following:

- The ellipses are fairly round in the Sodium row. This shape indicates that Sodium is uncorrelated with other variables.

- The blue x markers, which represent Nat. Bran Oats & Honey, Cracklin’ Oat Bran, and Banana Nut Crunch, appear outside the ellipses in the Fat row. This placement indicates that the datum is an outlier (because of the amount of fat in the cereal).

You will further explore a scatterplot matrix later.

4. Click the Multivariate red triangle and select *Pairwise Correlations* to show the Pairwise Correlations report.
Figure 6.9 Portion of the Pairwise Correlations Report

The Pairwise Correlations report lists the Pearson product-moment correlations for each pair of Y variables. The report also shows significance probabilities and compares the correlations in a bar chart.

5. To quickly see which pairs are highly correlated, right-click in the report and select the Sort by Column, Signif Prob, Ascending check box, and then click OK.

The most highly correlated pairs appear at the top of the report. The small *p*-values for the pairs indicate evidence of correlation. The most significant correlation is between Tot Carbo (total carbohydrates) and Calories.

Figure 6.10 Small *p*-values for Pairs

Interpret the Results

Looking at the results, you can answer the following questions:

**Which pairs of variables are highly correlated?** The Correlations report and Scatterplot Matrix show that the number of calories is highly correlated with all variables except for sodium and fiber. The Pairwise Correlations report shows that Tot Carbo (total carbohydrates) and Calories is the most correlated pair of variables.

**Which pairs of variables are not correlated?** The Correlations report and Scatterplot Matrix show that Sodium is not correlated with the other variables.
Draw Conclusions

You confirm the previous decision to avoid the high fat 100% Nat. Bran Oats & Honey. Trying All-Bran with Extra Fiber and Fiber One was also a smart decision. These two high-fiber cereals have the added benefit of contributing a lower number of calories, fat, and sugars and a higher amount of potassium. You also decide to avoid high-carbohydrate cereals because they likely contain a large number of calories.

Analyze Similar Values in the Clustering Platform

Clustering is a multivariate technique that groups observations together that share similar values across a number of variables. Hierarchical clustering combines rows in a hierarchical sequence that is portrayed as a tree. Cereals with certain characteristics, such as high fiber, are grouped in clusters so that you can view similarities among cereals.

Note: For more information about hierarchical clustering, see *Multivariate Methods*.

Scenario

You want to know which cereals are similar to each other and which ones are dissimilar. Analyzing clusters of cereal data reveals answers to the following questions:

- Which cluster of cereals provides little nutritional value?
- Which cluster of cereals is high in vitamins and minerals and contains a low amount of sugar and fat?
- Which cluster of cereals is high in fiber and low in calories?

Create the Hierarchical Cluster Graph

1. With Cereal.jmp displayed, select Analyze > Clustering > Hierarchical Cluster.
2. Select Calories through Enriched, click Y, Columns, and then click OK.
   
   The Hierarchical Clustering report appears. The clusters are colored according to the data table row states.
Figure 6.11 Portion of the Hierarchical Clustering Report

3. Click the Hierarchical Clustering red triangle and select **Color Clusters**.

The clusters are colored according to their relationships in the dendrogram.
The cereals have similar characteristics within each cluster. For example, judging by the names of the cereals in cluster one, you guess that the cereals are high in fiber.

Notice how All-Bran with Extra Fiber and Fiber One are grouped in cluster one. These cereals are more similar to each other than the other two cereals in the cluster.

4. To select cluster one, click the red horizontal line on the right.

The four cereals are highlighted in red.
Figure 6.14  Selecting a Cluster

5. To see the similar characteristics in the cluster, click the Hierarchical Clustering red triangle and select **Cluster Summary**.

The Cluster Summary graph at the bottom of the report shows the mean value of each variable across each cluster. For example, the cereals in this cluster contain more fiber and potassium than cereals in other clusters.

Figure 6.15  Cluster Summary

6. Click the Hierarchical Clustering red triangle and select **Scatterplot Matrix**.

This option is an alternative to creating a scatterplot matrix in the Multivariate platform.

Note the Fiber plot in the Potassium row. The selected cereals are located on the right side of the plot between 8 and 13 grams. This location indicates that the cereals in cluster one are high in fiber and potassium.

Figure 6.16  Cluster One Characteristics
Interpret the Results

Clicking through the clusters and looking at the Cluster Summary report, you can see the following characteristics:

- Cluster one cereals, such as Fiber One and All-Bran, contain high fiber and potassium and low calories.
- Cluster two cereals, which contain many favorite children’s cereals, are high in sugar and low in fiber, complex carbohydrates, and protein.
- Cluster three cereals (Puffed Rice and Puffed Wheat) are low in calories but provide little nutritional value.
- Cluster four cereals, such as Total Corn Flakes and Multi-Grain Cheerios, provide 100% of your daily requirement of vitamins and minerals. They are low in fat, fiber, and sugar.
- Cluster five cereals are high in protein and fat and low in sodium. The cluster consists of cereals such as Banana Nut Crunch and Quaker Oatmeal.
- Cluster six cereals are low in fat and high in sodium and carbohydrates. Traditional cereals such as Wheaties and Grape-Nuts are in this cluster.
- Cluster seven cereals are high in calories and low in fiber. Many cereals that include dried fruit are in this cluster (Mueslix Healthy Choice, Low Fat Granola w Raisins, Oatmeal Raisin Crisp, Raisin Nut Bran, and Just Right Fruit & Nut).
- Cluster eight cereals are low in sodium and sugar, and high in complex carbohydrates, protein, and potassium. Shredded Wheat and Mini-Wheat cereals are in this cluster.

By looking at the joins in the dendrogram, you can see which cereals in each cluster are most similar.

- In cluster one, Fiber One is similar in nutritional value to All-Bran with Extra Fiber. 100% Bran and All-Bran are also similar. Each pair of similar cereals are made by different companies, so the cereals are competing against each other.
- In cluster two, Frosted Flakes and Honey Frosted Wheaties are similar even though one is a corn flake and the other is a wheat flake. Lucky Charms and Frosted Cheerios are similar. Cap’n’Crunch and Trix are also similar.
**Draw Conclusions**

Based on your desire to eat more fiber and fewer calories, you decide to try the cereals in cluster one. You will avoid cereals in cluster three, which consists of puffed wheat and puffed rice and have little nutritional value. And you will try cereals in the highly nutritious cluster four.
Once you have generated results from your data, JMP provides you with multiple ways to share your work with others. Here are some of the ways that you can share your work:

- Saving platform results as journals, projects, or web reports
- Saving results, data tables, and other files in projects
- Saving scripts to reproduce results in data tables
- Saving results as Interactive HTML (.htm, html)
- Saving results as a PowerPoint presentation (.pptx)
- Sharing results in a dashboard

Work with Projects

With JMP projects, you can do the following:

- Explore your data more efficiently with a single, tabbed JMP window
- Quickly save and reopen a set of related files and reports
- Easily share your work by embedding your tables and scripts in a self-contained project file

Figure 7.2 Project File with Data Tables and Reports
This section contains the following information:

- “Create a New Project”
- “Open Files in a Project”
- “Rearrange Files in Projects”
- “Save a Project”
- “Project Workspace”
- “Project Bookmarks”
- “Project Contents”
- “Recent Files in Projects”
- “Project Log”
- “Move Files into Projects”
- “Write a Project On Open Script”
- “Example of Creating a New Project”

Create a New Project

To create a new, empty JMP project, select **File > New > Project** (Windows) or **File > New > New Project** (macOS).

Open Files in a Project

In a JMP project, you can open data tables and then run analyses on the data. Each data table and analysis report opens in a new tab.

1. From a project window, select **File > Open** and navigate to the data tables that you want to open.
2. From a data table, run an analysis.

If a data table is updated on your computer, any associated reports in your project update when you reopen the project.
Discovering JMP Work with Projects

Tip: You can use JMP keyboard shortcuts in projects, such as Ctrl+S to save a file, or Ctrl+W to close the active window pane. For a full list, select Help > Quick Reference Card.

Rearrange Files in Projects

In a JMP project, data tables and reports appear in individual tabs. You can rearrange tabs by dragging them into a dock zone.

Tip: To undo or redo a docked item, select Project > Undo Layout or Project > Redo Layout. To return all tables and reports to individual tabs, select Project > Reset Layout.

Example of Rearranging Project Files

1. Select File > New > Project (Windows) or File > New > New Project (macOS).
2. Select Help > Sample Data Library and open Car Physical Data.jmp and Car Poll.jmp.
3. In the Car Poll.jmp data table, run the Distribution script.
4. In the Car Physical Data.jmp data table, run the Contingency script.
5. Drag the Car Poll - Distribution report tab to the right and drop it into the Dock right zone. The Distribution report pane appears at the right of the project window. The report is docked and stays visible when you switch between tabs.
6. Drag the Car Physical Data - Contingency tab to the middle of the Car Poll - Distribution report and drop it into the Dock tab zone.
Tip: You can adjust the size of the data table window to fully show both reports.

Figure 7.4 Reports and Data Tables Grouped into Tabs

The Distribution and Contingency reports are now tabbed together, as are the two data tables.

Save a Project

If you want to share, distribute, or archive your project, create a self-contained project by saving all your data tables and scripts to the project contents. This embeds all project files and folders into a single project file that you can share with other JMP users.

1. (Optional) To save the project as a self-contained project, save each data table and script in the project by selecting File > Save As and then select Project Contents. You can click New Folder to create a folder in the project contents.

Note: You do not need to save reports as these are automatically saved to the project.
Figure 7.5  Save a Data Table to the Project Contents

2. Select **File > Save Project** to save the project file.

Figure 7.6  Save a Project File

**Project Workspace**

In a JMP project, you can see all currently open files in the Workspace tool pane. Reports appear under the corresponding data table. The active data table appears in bold.

**Tip:** To hide or show the Workspace tool pane, select **Project > Show Workspace**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.

In the Workspace tool pane, you can do the following:

- Double-click a file to make it active.
- Right-click a file to close it, hide it (removes the tab and dims the file name), bookmark it, and more.

**Project Bookmarks**

In a JMP project, you can create a shortcut to a file or folder in the Bookmarks tool pane. You can also organize your bookmarked files and folders by creating a bookmark group.
Tip: To hide or show the Bookmarks tool pane, select Project > Show Bookmarks. To specify which tool panes appear by default when you create a project, select File > Preferences > Projects and choose the initial tool panes.

Bookmark an open file in the project

- Right-click a tab and select Bookmark.
- To bookmark all open files, right-click a tab and select Bookmark All.

Bookmark a file or folder on your computer

Drag a file or folder from your computer into the Bookmarks tool pane, or click the Bookmarks red triangle menu and select Add Files or Add Folder.

Note: If you add or remove files from a bookmarked folder on your computer, the folder contents automatically update in the project.

Open a bookmarked file

In the Bookmarks tool pane, double-click a file.

Remove a bookmark

In the Bookmarks tool pane, right-click a file and select Remove Bookmark.

Create a bookmark group

1. Click the Bookmarks red triangle menu and select New Group.
2. Name the group and click OK.
3. Drag new or existing bookmarks into the group, or in the Bookmarks tool pane, right-click the group and select Add Files or Add Folder.

Project Contents

In a self-contained JMP project, any files you save to the project contents appear in the Contents tool pane.

Tip: To hide or show the Contents tool pane, select Project > Show Contents. To specify which tool panes appear by default when you create a project, select File > Preferences > Projects and choose the initial tool panes.
Open a file from the project contents
In the Contents tool pane, double-click a file.

Create a folder in the project contents
1. Click the Contents red triangle menu and select **New Folder**.
2. Name the folder and click **OK**.

Move files into folders
In the Contents tool pane, drag a file into a folder.

Copy a file or folder from your computer into the project contents
1. Click the Contents red triangle menu and select **Copy Files into Project** or **Copy Folder into Project**.
2. Navigate to the file and click **Open**, or navigate to the folder and click **Select**.

Rename a file in the project contents
In the Contents tool pane, right-click a file and select **Rename**.

Delete a file in the project contents
In the Contents tool pane, right-click a file and select **Delete**.

Recent Files in Projects
In a JMP Project, you can open a file from the Recent Files tool pane.

**Tip:** To hide or show the Recent Files tool pane, select **Project > Show Recent Files**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.

Open a file
In the Recent Files tool pane, double-click on a file or drag it into a project.

**Note:** Open files that are saved to the project contents do not appear in the Recent Files tool pane.
Project Log

In a JMP Project, you can see log messages in the Log tool pane.

**Tips:**
- To hide or show the Log tool pane, select **Project > Show Log**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.
- By default, log messages that occur in projects appear only in the project log, not in the main JMP log. To change this setting, select **File > Preferences > Projects** and update **Use Project Log Pane to If Open or Never**.

Move Files into Projects

In JMP, you can move files into a project, out of a project, or between projects.

1. Select **Help > Sample Data Library** and open **Big Class Families.jmp**.
2. Run the Distribution, Text Explorer, and Graph Builder scripts.
3. From any window, select **Window > Move to/from Project**.
4. Leave the Source Project as **(None)** to see files that are not open in any project.
5. Leave the Destination Project as **(New Project)** to move the selected files into a newly created project.
6. Select the check box next to **Big Class Families.jmp**. The graphs associated with the data table are also selected.

**Figure 7.7** Move Windows To/From Project

![Move Windows To/From Project](image)

7. Click **OK**. A new project is created with the selected table and reports.
Write a Project On Open Script

In the Project On Open Script box, you can add a JSL script that will run each time this specific project is opened. For example, you can create a script that creates or modifies reports, prompts the user for information, or writes usage information to the log window.

1. Select **Project > Project Settings**.
2. Paste the JSL script and click **OK**.

**Tips:**
- See the *Scripting Guide*, which explains how to create a start-up script when *any* project is opened (instead of a specific project).
- To use an existing project as a template for new projects, specify the existing project as a new project template under **File > Preferences > Projects**.

Example of Creating a New Project

In this example, you create a project, import data, generate an analysis and dock the report in the project window, create a subset table, and then save, close, and reopen the project.

1. Select **File > New > Project** (Windows) or **File > New > New Project** (macOS).
2. From the project window, select **File > Open**.
3. Open the *sandwiches.xlsx* file, located here by default:
   
   C:/Program Files/SAS/JMP/16/Samples/Import Data

   **Tip:** At the bottom, you might need to change All JMP Files to Excel Files.

4. Click **Import**.
5. Select **File > Save**.
6. Make sure **Project Contents** is selected.
7. Change the file name to *Sandwiches.jmp* and click **Save**.
8. Select **Analyze > Fit Y by X**.
9. Select Calories and click **Y, Response**.
10. Select Weight and click **X, Factor**.
11. Click **OK**.
12. Drag the **Sandwiches - Fit Y by X** tab to the right and drop it into the *Dock right* zone.

**Tip:** To show the entire report, you can drag the line between the data table and the report to the left.
13. Select **Tables > Subset**.
14. Under Rows, select **Random: sampling rate 0.5**.
15. Click **OK**.

**Figure 7.10** Project with Unsaved Subset Table

16. Select **File > Save Project**.
17. Navigate to the folder where you want to save your project, name the project file, and click **Save**.
18. Close the project.
19. Select **File > Open** and open your project file.
Notice that the subset table that you did not save has been saved automatically to the project file.

Save Platform Results in Journals

Save platform reports for future viewing by creating a journal of the report window. The journal is a copy of the report window. You can edit or append additional reports to an existing journal. The journal is not connected to the data table. A journal is an easy way to save the results from several report windows in a single report window that you can share with others.

This section contains the following information:

- “Example of Creating a Journal”
- “Add Analyses to a Journal”

Example of Creating a Journal

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select both Type and Size Co and click Y, Columns.
4. Click OK.
5. Click the Type red triangle and select Histogram Options > Show Counts.
6. Click the Size Co red triangle and select Mosaic Plot.
7. Select Edit > Journal to journal these results. The results are duplicated in a journal window.
Figure 7.11 Journal of Distribution Results

The results in the journal are not connected to the data table. In the Type bar chart, if you click the Computer bar, no rows are selected in the data table.

Since the journal is a copy of your results, most of the red triangle menus do not exist. A journal does have a red triangle menu for each new report that you add to the journal. This menu has two options:

Rerun in new window  If you have the original data table that was used to create the original report, this option runs the analysis again. The result is a new report window.

Edit Script  This option opens a script window that contains a JSL script to re-create the analysis. JSL is a more advanced topic that is covered in the Scripting Guide and JSL Syntax Reference.

Add Analyses to a Journal

If you perform another analysis, you can add the results of the analysis to the existing journal.

1. With a journal open, select Analyze > Distribution.
2. Select profit/emp and click Y, Columns.
3. Click OK.
4. Select Edit > Journal. The results are appended to the bottom of the journal.
Save and Run Scripts

Most platform options in JMP are scriptable, meaning that most actions that you perform can be saved as a JMP Scripting Language (JSL) script. You can use a script to reproduce your actions or results at any time.

This section contains the following information:

- “Example of Saving and Running a Script”
- “About Scripts and JSL”

Example of Saving and Running a Script

Create a Report

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Type and profit/emp and click Y, Columns.
4. Click OK.
5. Click the Type red triangle and select these options:
   - Histogram Options > Show Counts
   - Confidence Interval > 0.95
6. Click the profit/emp red triangle and select these options:
   - Outlier Box Plot, to remove the outlier box plot
   - CDF Plot
7. Click the Distributions red triangle and select Stack.

Save the Script to the Data Table and Run It

1. To save this analysis, click the Distributions red triangle and select Save Script > To Data Table. The new script appears in the Table panel.

Figure 7.12  Distribution Script

2. Close the Distribution report window.
3. To re-create the analysis, click the green triangle next to the Distribution script.

**Figure 7.13** Running the Distribution Script

Tip: Right-click the table script to view more options.

**About Scripts and JSL**

The script that you saved in this section contains JMP Scripting Language (JSL) commands. JSL is a more advanced topic that is covered in the *Scripting Guide* and *JSL Syntax Reference*.
Save Reports as Interactive HTML

Interactive HTML enables JMP users to share reports that contain dynamic graphs so that even non JMP users can explore the data. The JMP report is saved as a web page in HTML 5 format, which you can email to users or publish on a website. Users then explore the data as they would in JMP.

Interactive HTML provides a subset of features from JMP:

- Explore interactive graph features, such as selecting histogram bars and viewing data values.
- View data by brushing.
- Show or hide report sections.
- Hover over the report for tooltips.
- Increase the marker size.

**Figure 7.14** Brushing Data in Interactive HTML

![Bivariate Fit of Petal length By Petal width](image)

![Actual by Predicted Plot](image)
Many changes that you make to the graphs, such as ordered variables, horizontal histograms, background colors, and colored data points, are saved in the web page. Graphs and tables that are closed when you save the content remain closed on the web page until the user opens them.

**Interactive HTML Contains Data**

When you save reports as interactive HTML in JMP, your data are embedded in the HTML. The content is unencrypted, because web browsers cannot read encrypted data. To avoid sharing sensitive data, save your results as a non-interactive web page. (Select **File > Export > Interactive HTML File with Data**.)

**Example of Creating Interactive HTML**

**Create a Report**

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Distribution**.
3. Select height and click **Y, Columns**.
4. Click **OK**.

**Save as Interactive HTML**

1. (Windows) Select **File > Export** , select **Interactive HTML with Data**, and then click **OK**.
2. (macOS) Select **File > Export**, select **Interactive HTML with Data**, and then click **Next**.
3. On the Export window, select **Open the file after saving** if it’s not already selected.
4. Name and save the file.
   The output appears in your default browser.
**Figure 7.15** Interactive HTML Output

For information about exploring interactive HTML output, visit [https://www.jmp.com/interactive](https://www.jmp.com/interactive).

**Share Reports as Interactive HTML**

Interactive HTML enables you to share JMP reports that contain dynamic graphs so that even non JMP users can explore the data. JMP reports are saved as an interactive web page that you can share with others (for example, on a shared network drive, by email, or on a website). Users then explore the data as they would in JMP.

**Interactive HTML Contains Data**

When you export or publish a report as interactive HTML, your data are embedded in the HTML. The content is unencrypted, because web browsers cannot read encrypted data. To avoid sharing sensitive data, export your results as a non-interactive web page instead by selecting **File > Export > HTML.**
Which Features Are Supported Interactively

Interactive HTML provides a subset of features from JMP:

- If the features in your report are fully supported, the web page is created with no warnings.
- If your report contains unsupported features, you see a message in the export or publish window that interactive HTML is partially implemented. For details, see the JMP log (View > Log).
- Partially or unsupported features appear static in the web page. If you hover over an unsupported feature in the web page, a tooltip says that the feature is not yet interactive.

For information about exploring interactive HTML output, visit https://www.jmp.com/interactive.

Export a Single Report as Interactive HTML

To export a single JMP report as interactive HTML, use the Export as Interactive HTML with Data option to create a single web page.

1. In JMP, create the report and make it the active window.

   **Note:** If a report contains a Local Data Filter, it is static in the web report and users cannot change the selections. To make the Local Data Filter interactive, deselect the Include mode. (In Graph Builder, to see the Include mode, select Show Modes from the Local Data Filter red triangle menu.)

2. Select **File > Export**, select **Interactive HTML with Data** and click **Next**.
3. Name the file.
4. (Optional) To open the HTML file in your default browser after exporting it, select **Open the file after saving**.
5. Click **Save**.

   The output is saved in the selected folder.
Publish Multiple Reports as Interactive HTML

To publish multiple JMP reports as interactive HTML, use the Publish to File option, which creates an index page that contains the reports.

**Tip:** When you publish multiple JMP reports, you specify where to save the index page and report files. You can choose a shared network folder and provide the location to others, or choose a folder on your computer and zip the files before sharing. This is particularly helpful if you are sharing with non JMP users.

1. In JMP, create the reports.

   **Note:** If a report contains a Local Data Filter, it is static in the web report and users cannot change the selections. To make the Local Data Filter interactive, deselect the **Include** mode. (In Graph Builder, to see the **Include** mode, select **Show Modes** from the Local Data Filter red triangle menu.)

2. From a report window, select **File > Publish > Publish to File**.

3. Select the reports that you want to publish.
4. (Optional) Change where the parent folder resides or change the name of the subfolder that will contain the reports.

5. Click **Next**.

6. Enter a title for the index page. You can also update the report titles.

8. Click **Publish**.

**Figure 7.17** Index Page for Multiple Interactive HTML Reports

9. Click a thumbnail to open a report.

For details about working with interactive reports, from an HTML report, click ➕ > **Help**. This opens the help at https://www.jmp.com/interactive.

**Interactive HTML Report Options**

- **Title**  Add a title for the index page (multiple reports only) or the reports.

- **Description** (Optional) Add a description to the index page or the reports. The description will appear under the titles.

- **Customize** (Appears for multiple reports only) Change the appearance of the web page. You can change the style, theme, font, logo, and whether the date or time appears. See Customize Index Page Options.
Publish Data  Select this for interactive reports. If you deselect this option, the reports are static.

Note: To avoid sharing sensitive data, save your results as a non-interactive web page. (Select File > Export > HTML.)

Add Image  Adds an image to the bottom of the web page.

Open published web report  Opens the web page in a browser once you click Publish.

Close reports after running  Closes the reports in JMP once you publish the web report.

Delete icon (Appears for multiple reports only) Deletes a report.

Arrow icons (Appears for multiple reports only) Changes the order of reports.

Customize Index Page Options

Style Format  Determines the layout of the reports.

Large List  Shows the reports in a column with large thumbnail graphics.

Small List  Shows the reports in a column with small thumbnail graphics.

Grid  Shows the reports in rows.

Custom CSS  Enables you to specify a CSS file to format the web page. The CSS file is copied into a subfolder called _css. The link to the CSS file is relative so that you can send the report and support files to another user and maintain the CSS formatting.

Color Theme  Specifies the color of the web page, headings, and borders. The default web page has a white background, orange headings, and blue borders.

Change Font  Change the font applied in the reports.

Change Logo  Specifies an image to display along with the reports. Click the up or down arrow next to the image to move it above or below the reports.

Show date/time  Shows or hides the date and time at which the web page was generated.

Save a Report as a PowerPoint Presentation

Create a presentation by saving JMP results as a PowerPoint presentation (.pptx). Rearrange JMP content and edit text in PowerPoint after saving as a .pptx file. Sections of a JMP report are exported into PowerPoint differently.

•  Report headings are exported as editable text boxes.
• Graphs are exported as images. Certain graphical elements, such as legends, are exported as separate images. Images resize to fit the slide in PowerPoint.

Use the selection tool to select the sections that you want to save in your presentation. Delete unwanted content once after you open the file in PowerPoint.

**Note:** On Windows, PowerPoint 2007 is the minimum version required to open .pptx files created in JMP. On macOS, at least PowerPoint 2011 is required.

1. In JMP, create the report.
2. Select File > Export, select Microsoft PowerPoint, and then click Next.
3. Select a graphic file format from the list.
   - On Windows, EMF is the default format. On macOS, PDF is the default format.
4. Name and save the file. (On macOS, name the file and click Export.
   - The file opens in Microsoft PowerPoint because Open the file after saving is selected by default.

**Note:** The native EMF graphics produced on Windows are not supported on macOS. The native PDF graphics produced on macOS are not supported on Windows. For cross-platform compatibility, change the default graphics file format by selecting File > Preferences > General. Then, change the Image Format for PowerPoint to either PNG or JPEG.

### Create Dashboards

A dashboard is a visual tool that lets you run and present reports on a regular basis. You can show reports, data filters, selection filters, data tables, and graphics on a dashboard. The content shown on the dashboard is updated when you open the dashboard.

This section contains the following information:

- “Example of Combining Windows”
- “Example of Creating a Dashboard with Two Reports”

### Example of Combining Windows

You can quickly create dashboards by merging several open windows in JMP. Combining windows provides options to view a summary of statistics and include a selection filter.

1. Select Help > Sample Data Library and open Birth Death.jmp.
2. Run the Distribution and Bivariate table scripts.
3. From one of the report windows, select **Window > Combine Windows**. The Combine Windows window appears.

   **Tip:** On Windows, you can also select Combine Windows from the Arrange Menu option in the lower right corner of JMP windows.

4. Select **Summary Report View** to display the graphs and omit the statistical reports.

5. In the Combine column, select **Birth Death - Bivariate of death by birth** and **Birth Death - Distribution**.

6. In the Filter By column, select **Birth Death - Distribution**.

**Figure 7.18** Combine Windows Options

7. Click **OK**.

   The two reports are combined into one window. Notice the filter icon 🔄 at the top of the Distribution report. When you select a bar in one of the histograms, the corresponding data in the Bivariate graph are selected.

**Notes:**

- To combine reports on Windows, you can also select Combine Windows from the Arrange Menu option in the lower right corner of JMP windows.

- In the Combine Windows window, select **Summary Report View** to see only the graphs in a report and omit the statistics.
Example of Creating a Dashboard with Two Reports

Suppose that you created two reports and want to run the reports again the next day against an updated set of data. This example shows how to create a dashboard from the reports in Dashboard Builder.

2. Run the table scripts named “Distribution: Profitability by Lead Studio and Genre” and “Graph Builder: World and Domestic Gross by Genre”.
3. From any window, select File > New > Dashboard.
   Templates for common layouts appear.
4. Select the 2x1 Dashboard template.
   A box with room for two reports appears on the workspace.
5. In the Reports list, double-click the report thumbnails to put them on the dashboard.
6. Click the Dashboard Builder red triangle and select Preview Mode.
   A preview of the dashboard appears. Notice that the graphs are linked to each other and the data table. They also have the same red triangle options as the Distribution and Graph Builder platforms.
7. Click Close Preview.
For more information about creating dashboards, see *Using JMP*. 
Using some of the special features in JMP, you can do the following:

- Update analyses or graphs automatically
- Customize platform results
- Integrate with SAS to use advanced analytical features

**Figure 8.1** Examples of Special Features

```plaintext

Automatically Update Analyses and Graphs

When you make a change to a data table, you can use the Automatic Recalc feature to automatically update analyses and graphs that are associated with the data table. For example, if you exclude, include, or delete values in the data table, that change is instantly reflected in the associated analyses or graphs. Note the following information:

- Some platforms do not support Automatic Recalc. See Using JMP.
- For the supported platforms in the Analyze menu, Automatic Recalc is turned off by default. However, for the supported platforms in the Quality and Process menu, Automatic Recalc is turned on by default, except for the Variability/Attribute Gauge Chart, Capability, and Control Chart.
- For the supported platforms in the Graph menu, Automatic Recalc is turned on by default.

Example of Using Automatic Recalc

This example uses the Companies.jmp sample data table, which contains financial data for 32 companies from the pharmaceutical and computer industries.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Fit Y by X.
3. Select Sales ($M) and click Y, Response.
4. Select # Employ and click X, Factor.
5. Click OK.

Figure 8.2  Initial Scatterplot
The initial scatterplot shows that one company has significantly more employees and sales than the other companies. You decide that this company is an outlier, and you want to exclude that point. Before you exclude the point, turn on Automatic Recalc so that your scatterplot is updated automatically when you make the change.

6. To turn on Automatic Recalc, click the red triangle next to Bivariate Fit of Sales ($M) By # Employ and select **Redo > Automatic Recalc**.

7. Click the outlier to select it.

8. Select **Rows > Exclude/Unexclude**. The point is excluded from the analysis and the scatterplot is automatically updated.

**Figure 8.3** Updated Scatterplot

If you fit a regression line to the data, the point in the lower right corner is an outlier, and influences the slope of the line. If you then exclude the outlier with Automatic Recalc turned on, you can see the slope of the line change.

9. To fit a regression line, click the red triangle next to Bivariate Fit of Sales ($M) By # Employ and select **Fit Line**. Figure 8.4 shows the regression line and analysis results added to the report window.
10. Click the outlier to select it.

11. Select **Rows > Exclude/Unexclude**. The regression line and analysis results are automatically updated, reflecting the exclusion of the point.

**Tip:** When you exclude a point, the analyses are recalculated without the data point, but the data point is not hidden in the scatterplot. To also hide the point in the scatterplot, select the point, and then select **Rows > Hide and Exclude**.
Figure 8.5 Updated Regression Line and Analysis Results
Change Preferences

You can change preferences in JMP using the Preferences window. To open the Preferences window, select File > Preferences (Windows) or JMP > Preferences (macOS).

Figure 8.6 Preferences Window

On the left side of the Preferences window is a list of Preference groups. On the right side of the window are all of the preferences that you can change for the selected category.
Example of Changing Preferences

Every platform report window has options that you can turn on or off. However, your changes to these options are not remembered the next time you use the platform. If you want JMP to remember your changes every time you use the platform, change those options in the Preferences window.

This example shows how to set the Distribution platform so that an Outlier Box Plot is not added to the initial report.

Create a Distribution Using the Default Preference Setting

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Profits ($M) and click Y, Columns.
4. Click OK.

Figure 8.7  Distribution Report Window
The histogram is vertical, and the graphs include an outlier box plot. To change the histogram to horizontal and remove the outlier box, select the appropriate options from the red triangle menu for Profits ($M). However, if you want those preferences to be in effect every time you use the platform, then change them in the Preferences window.

**Change the Preference for the Outlier Box Plot and Run Distribution Again**

1. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS).
2. Select **Platforms** from the preference group.
3. Select **Distribution** from the Platforms list.
4. Select the **Horizontal Layout** option to turn it on.
5. Deselect the **Outlier Box Plot** option to turn it off.

**Figure 8.8 Distribution Preferences**

6. Click **OK**.
7. Repeat the Distribution analysis. See “Create a Distribution Using the Default Preference Setting” on page 222.

The histogram is now horizontal and the outlier box plot does not appear. These preferences remain the same until you change them.

For more information about all of the preferences, see *Using JMP*.

---

**Integrate JMP and SAS**

**Note:** You must have access to SAS, either on your local machine or on a server, to use SAS through JMP.

Using JMP, you can interact with SAS in these ways:

- Write or create SAS code in JMP.
- Submit SAS code and view the results in JMP.
- Connect to a SAS Metadata Server or a SAS Server on a remote machine.
- Connect to SAS on your local machine.
- Open and browse SAS data sets.
- Retrieve and view data sets generated by SAS.

For more information about integrating JMP and SAS, see *Using JMP*.

---

**Example of Creating SAS Code**

This example uses the Candy Bars.jmp sample data table, which contains nutrition data for candy bars.

1. Select **Help > Sample Data Library** and open Candy Bars.jmp.
2. Select **Analyze > Fit Model**.
3. Select Calories and click **Y**.
4. Select Total fat g, Carbohydrate g, and Protein g, and click **Add**.
5. Click the Model Specification red triangle and select **Create SAS Job**.

Figure 8.9 shows the SAS code. (Not all of the data is shown.)
Example of Submitting SAS Code

1. Select Help > Sample Data Library and open Candy Bars.jmp.
2. Select Analyze > Fit Model.
3. Select Calories and click Y.
4. Select Total fat g, Carbohydrate g, and Protein g, and click Add.
5. Click the Model Specification red triangle and select Submit to SAS.
6. In the Connect to SAS Server window (Figure 8.10), choose a method to connect to SAS (if you are not already connected). For this example, select Connect to SAS on this machine.
7. Click OK.

JMP connects to SAS. SAS runs the model and sends the results back to JMP. The results can appear as SAS output, HTML, RTF, PDF, or JMP report format (you can choose the format using JMP Preferences). Figure 8.11 shows the results formatted as a JMP report. See Using JMP.

Get the Most from JMP

Whether you are a first-time or a long-time user, there is always something to learn about JMP.

Visit JMP.com to find the following:

- live and recorded webcasts about how to get started with JMP
- video demos and webcasts of new features and advanced techniques
- details on registering for JMP training
- schedules for seminars being held in your area
- success stories showing how others use JMP
- the JMP user community, resources for users including examples of add-ins and scripts, a forum, blogs, conference information, and so on

To get you started with JMP, this chapter covers the following topics:

- learn about the initial windows that appear when you start JMP
- understand data tables
- open data files
- manage open windows
- learn about the anatomy of a typical JMP user session

Figure 2.1 The JMP Home Window on Windows

Anatomy of a JMP Session

JMP consists of platforms that are organized by the type of statistical analysis. For example, the Distribution platform produces a univariate analysis using histograms, additional graphs, and reports. You might analyze data in the Distribution platform and then choose another platform to examine the data more thoroughly. As a result, several windows are open at once: at a minimum, the data table, platform launch windows, and the results of the analyses.

Figure 2.2 shows a typical JMP session. Note that the windows are not maximized so that you can quickly switch from one window to another.

Figure 2.2 Anatomy of a Typical JMP Session on Windows

The following sections describe the windows that you typically work with.
Data Table Features

In JMP, data points are organized into rows and columns referred to as the *data table*. A data table has two parts: the *data table panels* on the left and the *data grid* on the right.

You can enter, view, edit, and manipulate data using data tables. In a data table, each variable is a column, and each observation is a row.

**Figure 2.3 Data Table Features**
The data table has the following characteristics:

- Column names can contain any keyboard character, including spaces, and can be up to 255 characters long.
- The maximum length of the data table’s name depends on your computer’s operating system.
- Consider setting the *Autosave timeout value* in the General preferences to automatically save data tables at the specified number of minutes. This autosave value also applies to journals, scripts, projects, and reports.
- Change the default size and font for names and values selecting **File > Preferences > Fonts**. (On macOS, select **JMP > Preferences > Fonts**.)
- Column names automatically wrap in the column name area to accommodate the column width that you specify.
- Move column boundaries and enlarge the column to view long values. Adjust widths of all selected columns at once by pressing Alt as you drag the double arrow cursor on any of the selected column boundaries.
- The number of rows and columns in a data table is limited only by your computer’s memory.
- Resize rows by dragging one of the row borders. All rows are resized to the same height. Graphics that display inside each cell shrink based on the row height.

  To resize columns to the same width, select the columns and press Alt (Windows) or Option (macOS); drag one of the column borders. All columns are resized to the same width.

**Tip:** To close a report thumbnail in the data table on Windows, press the middle-click button on your mouse.

### Data Table Panels

Data tables contain three panels:

- Table panel
- Columns panel
- Rows panel

These panels are located on the left of the data grid. They contain information about the table and its contents. Each panel has interactive areas.
Figure 2.4 Interacting with the Data Table Panels

Click and drag to adjust the height and width of the panels.

Table Panel in Data Tables

The Table panel contains the following elements:

- Name of the data table
- Icons indicating the table state
- Red triangle menus containing table options
- (Optional) Table variables
- (Optional) Green triangles for table scripts

Figure 2.5 Example of a Table Panel
Table Options

Clicking on the red triangle menu next to the data table name shows these options:

**Tables**  Contains the same options as the Tables menu. See the “Reshape Your Data” chapter on page 335.

**New Table Variable**  Creates a new table variable, which can be text or any other constant character value that you always want to be available in the data table. Table variables are normally used to document tables. See “Use Data Table Variables” on page 283 in the “Enter and Edit Your Data” chapter.

**Note:** To rename a table variable, double-click it and enter a new name in the Name field.

**New Script**  Creates a JSL script to save with the data table. After selecting this command, name the script and type in the value (the JSL commands). After you click **OK**, the new script is listed in the Table panel and you can click its green triangle to run, edit, or delete it. See “Create and Save Scripts in Data Tables” on page 284 in the “Enter and Edit Your Data” chapter.

**Group Scripts**  Moves the selected scripts into a group. Click the group name to rename it. Helpful when you want to organize scripts or minimize a long list of scripts.

**Ungroup Scripts**  Ungroups scripts in the selected group to return them to the top level.

**Suppress Formula Eval**  Turns off the feature that automatically evaluates formulas. You can turn off evaluation and build sections of a formula. To then test the formula, deselect Suppress Formula Eval.

**Lock Data Table**  Locks the data table so that data and column properties cannot be edited or added. You can still run analyses and assign characteristics. See “Lock Data Tables” on page 281 in the “Enter and Edit Your Data” chapter.

**Compress file when saved**  Compresses the data table when it is saved. After the data table is saved, a compressed file icon appears next to the data table name in the table panel. See “Compress Data Tables” on page 282 in the “Enter and Edit Your Data” chapter.

The **Compress file when saved** option only decreases the file size. This command does not affect the memory required to analyze the data. To reduce both the file size and memory required for analyzing, use **Cols > Utilities > Compress Selected Columns**. See “Compress Selected Columns in Data Tables” on page 247 in the “Enter and Edit Your Data” chapter.

**Tip:** You can also configure JMP to always use GZ compression when saving tables by selecting **Preferences > General > Save Data Table Columns GZ Compressed**.
Disable Undo   Removes all actions from the undo history and does not record future actions.
   Undos are disabled only while the data table is open; the setting is not saved with the data
table. This option saves memory, especially when you delete many rows or perform other
tasks on the data table that require a large amount of memory to record the data.

Copy Table Script   Copies the script that re-creates the table. To re-create the table, put the
copied script in a new script and run it. Note that referenced columns in virtually joined
tables are not included in the script.

Copy Table Script (No Data)   Copies the script that re-creates the table but omits the data.

Rerun Formulas   Re-evaluates all columns containing formulas within the data table.

Script Options
To run a script from the data table panel, click the green triangle next to the script name.
Right-clicking the script name or green triangle shows these options:

Run Script   Runs the script.

Tip: Run multiple table scripts at once by pressing Ctrl while selecting the table scripts you
want to run. Then, right-click inside the empty area under the list of table scripts, and select
Run Script.

Edit   Opens most scripts in the script editor so that you can edit it. Opens a JMP application
script in Application Builder.

Edit with Recode   Opens a recode script (which you created by recoding a column and
saving the script) in the script editor.

Delete   Deletes the script.

Group Scripts   Moves the selected scripts into a group. Click the group name to rename it.
   Helpful when you want to organize scripts or minimize a long list of scripts.

Ungroup Scripts   Ungroups scripts in the selected group to return them to the top level.

Copy   Copies the script. You can then paste it into the Table panel of another data table.

Debug Script   Opens the script in the JSL Debugger. See the Scripting Guide.

Paste   Pastes the script from another data table.

Additional Options
In the Table panel, you can also perform the following tasks:
• Double-click a table variable or script name to edit the name and content.
• Drag a table variable or script to rearrange it.

**Columns Panel in Data Tables**

The Columns panel provides a way to view and move columns. The panel contains the following information:

• Column options (contains some of the same options as the Cols menu)
• Total number of columns and number of columns selected in the data table
• A filter box to help you quickly find columns (click the magnifying glass icon to set search filter options and parameters)
• A list of columns found in the data table
• Icons indicating each column’s modeling type (see “About Modeling Types” on page 294 in the “Set JMP Column Properties” chapter)
• Icons representing characteristics and properties assigned to the columns (not shown, see Figure 2.7)

**Figure 2.6  Example of a Columns Panel**

**Icons Representing Column Characteristics and Properties**

Icons to the right of each column name indicate characteristics and properties the columns contain.

**Figure 2.7  Icons Indicating Column Characteristics and Properties**
**Note:** Italics indicate that the column is locked into place. When you scroll horizontally, the column remains visible.

Here are the icons that can appear in the Columns panel:

- ![Icon](image) Indicates that points on plots corresponding to the column are labeled by the value instead of the row number. See “Label Rows and Columns” on page 232 in the “Enter and Edit Your Data” chapter.

- ![Icon](image) Indicates that the column is excluded from the calculations. See “Exclude Rows in Data Tables” on page 216 in the “Enter and Edit Your Data” chapter.

- ![Icon](image) Indicates that the column is not included in graphs. See “Hide Rows in Data Tables” on page 217 in the “Enter and Edit Your Data” chapter.

- ![Icon](image) Can be X or Y. Indicates that the column has been assigned the preselected role of \( x \) or \( y \). See “Assign a Preselected Analysis Role to a Column” on page 334 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the column has been assigned the preselected role of validation. See “Assign a Preselected Analysis Role to a Column” on page 334 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the column contains one or more properties. Click to reveal a list of properties the column contains.

- ![Icon](image) Indicates that the values in the column result from a formula. When formula evaluation is suppressed, the icon appears gray. Double-click to view and edit the formula. See “JMP Formula Editor Options” on page 415 in the “Create Formulas in JMP” chapter.

- ![Icon](image) Indicates that the range check or the list check option is turned on. Click to view and edit the range or list. See “Range Check” on page 305 in the “Set JMP Column Properties” chapter and “List Check” on page 305 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the column has been assigned the preselected role of weight. See “Assign a Preselected Analysis Role to a Column” on page 334 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the column has been assigned the preselected role of frequency. See “Assign a Preselected Analysis Role to a Column” on page 334 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the column values cannot be edited. See “About the Column Info Window” on page 291 in the “Set JMP Column Properties” chapter.

- ![Icon](image) Indicates that the expression column contains images that can be used as markers. See “Use Images as Markers” on page 489 in the “JMP Reports” chapter.
Virtual Join Icons

- Indicates that the column has a Link Reference column property. This property links a column in the current data table to the ID column in the referenced data table. Blue indicates that the referenced data table is linked.
- Indicates that the column has a Link Reference column property. Gray indicates that the referenced data table is not open or not linked properly.
- Indicates that the column has a Link ID column property, which marks a column in the data table as the ID column. That is, the rows of the data table are uniquely identified by the values of the ID column.
- Indicates that the column is linked from the referenced data table.

For more information about virtual join, see “Virtually Join Data Tables” on page 374 in the “Reshape Your Data” chapter.

Search Filter Options

To show search filter options in the columns list, select Show Filter from the columns list’s red triangle menu. This enables you to customize your search for columns, which is particularly helpful with long lists of columns.

Click the down arrow button next to the search box to refine your search.

- **Contains Terms** Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.
- **Contains Phrase** Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).
- **Starts With Phrase** Returns items that start with the search criteria.
- **Ends With Phrase** Returns items that end with the search criteria.
- **Whole Phrase** Returns items that consist of the entire string. A search for “text box” returns entries that contain only “text box”.
- **Regular Expression** Enables you to use the wildcard (*) and period (.) in the search box. Searching for “get.*name” looks for items that contain “get” followed by one or more words. It returns “Get Color Theme Names”, “Get Name Info”, and “Get Effect Names”, and so on.
- **Invert Result** Returns items that do not match the search criteria.
- **Match All Terms** Returns items that contain both strings. A search for “t test” returns elements that contain either or both of the search strings: “Pat Test”, “Shortest Edit Script” and “Paired t test”.
**Ignore Case**   Ignores the case in the search criteria.

**Match Whole Words**   Returns items that contain each word in the string based on the Match All Terms setting. If you search for “data filter”, and Match All Terms is selected, entries that contain both “data” and “filter” are returned.

**Rows Panel in Data Tables**

The Rows panel contains the following information:

- Row options (same options as the **Rows** menu)
- Total number of rows
- Number of selected (highlighted), excluded, hidden, and labeled rows

![Figure 2.8 Example of a Rows Panel](image)

Right-click the categories in the Rows panel to select rows, clear the selection, or to create a data view.

A data view creates a linked subset of the main data table. For example, if several rows are marked hidden, you might want to open a window that shows you only the hidden rows. Right-click **Hidden** in the Rows panel and select **Data View**.
When using a data view, continue to do most of your editing in the main data table. When you make changes in either the main data table or in the data view, the changes are reflected in both. You can make minor changes (such as changing some data or adding a column) in the data view. However, if you want to make major changes (like adding a formula) you must make those changes in the main data table.

**Data Grid in Data Tables**

The data grid is the main part of the data table that contains your data. Figure 2.10 illustrates how to interact with the data grid. See also “Select Rows in Data Tables” on page 198 in the “Enter and Edit Your Data” chapter.
Figure 2.10  Interacting with the Data Grid

<table>

</tbody>
</table>
| 5   | Click to select the column.  
Double-click to view the Column Info window. See “About the Column Info Window” on page 291.  
Right-click for column options. See “Right-Click Options for Columns” on page 47. |
| 6   | Double-click the column name to edit it in the Column Info window, or select the column name and press Enter. |
| 7   | Click and drag to change a column width. To change several column widths, select the columns, press Alt, then click and drag. |
| 8   | Click to select the row.  
Double-click to open the Row Editor. See “Edit Cells in Data Tables” on page 223 in the “Enter and Edit Your Data” chapter.  
Right-click for row options. See “Right-Click Options for Rows” on page 48. |
| 9   | Shows the rows menu. |
| 10  | Click to deselect all selected rows. To select all rows, press Shift and click. Double-click to add rows. |
Right-Click Options for Columns

Right-clicking in a column heading shows these options:

**Column Info**  
Opens the Column Info window. See “About the Column Info Window” on page 291.

**Standardize Attributes**  
Copies attributes (data types, modeling types, numeric formats, and so on) or properties (formulas, notes, list and range checks, and so on) from one column to other columns. Also deletes selected attributes or properties from columns. See “Standardize Attributes and Properties Across Columns” on page 331 in the “Set JMP Column Properties” chapter.

**Column Properties**  
Contains a list of column properties. Select one to open the Column Info window and apply it to the column. This list is also available from the Column Info window. See “Column Properties in JMP” on page 303 in the “Set JMP Column Properties” chapter.

**Formula**  
Opens the Formula Editor. See the “Create Formulas in JMP” chapter on page 393.

**Recode**  
Enables you to change all of the values in a column at once. See “Recode Data in a Column” on page 264 in the “Enter and Edit Your Data” chapter.

**New Formula Column**  
Creates a formula column. See “Make a New Formula Column” on page 254 in the “Enter and Edit Your Data” chapter.

**Insert Columns**  
Inserts one or more columns before the selected column or columns.

**Delete Columns**  
Deletes all selected columns.

**Label/Unlabel**  
Labels or unlabels selected columns in all plots. See “Label Rows and Columns” on page 232 in the “Enter and Edit Your Data” chapter.

**Link ID**  
Used in virtually joined data tables to mark a column in the auxiliary data table as the ID column. That is, the rows of the data table are uniquely identified by the values of the ID column. The Link ID column property checkbox is selected if the column is the ID column for the data table. See “Link Data Tables with Virtual Join Properties” on page 324 in the “Set JMP Column Properties” chapter.

**Link Reference**  
Used in virtually joined data tables to map a column in the main data table to the ID column in the auxiliary data table. The Link Reference column property specifies the path name of the auxiliary data table. See “Link Data Tables with Virtual Join Properties” on page 324 in the “Set JMP Column Properties” chapter.

**Sort**  
Sorts all of the rows in the table by the values in the selected column. You can choose to sort the rows in ascending or descending order. See “Sort Data Tables” on page 340 in the “Reshape Your Data” chapter.
Copy Column Properties  Copies the column properties.

Paste Column Properties  Pastes the column properties.

Copy Columns  Copies the script to recreate the columns. It copies all of the attributes and properties but no data.

Paste Columns  Creates new columns from the script generated by Copy Columns. The column will be placed after the selected column. If no column is selected, the new columns are placed at the end of the data table. The new columns populate (in the destination table) as many rows as there are data in the script.

Right-Click Options for Rows

Right-clicking in a row heading shows these options:

Hide and Exclude  Hides the selected rows in all plots and graphs and excludes them from analyses. See “Hide and Exclude Rows in Data Tables” on page 215 in the “Enter and Edit Your Data” chapter.

Exclude/Unexclude  Excludes or includes selected rows from analyses. See “Exclude Rows in Data Tables” on page 216 in the “Enter and Edit Your Data” chapter.

Hide/Unhide  Hides or shows selected rows in all plots and graphs. See “Hide Rows in Data Tables” on page 217 in the “Enter and Edit Your Data” chapter.

Label/Unlabel  Labels or unlabels selected rows in all plots. See “Label Rows and Columns” on page 232 in the “Enter and Edit Your Data” chapter.

Colors  Provides a color palette. Select a color to apply it to the selected rows. The color is used in plots and graphs. See “Assign a Color to Rows” on page 233 in the “Enter and Edit Your Data” chapter.

Markers  Provides a palette of markers or symbols. Select a marker to apply it to the selected rows. The marker is used in plots and graphs instead of points. See “Add Markers to Rows” on page 234 in the “Enter and Edit Your Data” chapter.

Color Rows by Row State  Colors the row the same as the current row state color. See “Assign Colors or Markers to Rows Based on Column Values” on page 234 in the “Enter and Edit Your Data” chapter.

Select Matching Cells  Selects rows in the active data table with values that match the selected row(s). See “Resize Rows and Columns” on page 210 in the “Enter and Edit Your Data” chapter.

Invert Selection  Selects all previously deselected rows, and deselects all currently selected rows.
**Clear Row States**  Clears all active row states in the data table. All rows become included, visible, unlabeled, and show in plots as black dots. It does not affect row states saved in row state columns. See “Delete Row Characteristics” on page 242 in the “Enter and Edit Your Data” chapter.

**Add Rows**  Adds the specified number of rows to the data table. See “Add Rows to Data Tables” on page 193 in the “Enter and Edit Your Data” chapter.

**Delete Rows**  Removes all selected rows from the data table. Use the **Undo** command on the **Edit** menu to undo an accidental deletion. See “Delete Rows in Data Tables” on page 211 in the “Enter and Edit Your Data” chapter.

**Cursor Forms**

The cursor takes different forms, depending on its location in the data grid.

**Arrow Cursor**  The standard arrow cursor appears in the following locations:

– In the panels area to the left of the data table

– In the triangular rows and columns area, located in the upper left corner of the data grid

You can perform the following actions with the arrow cursor:

– To select a column using the arrow cursor, click its name in the Columns panel.

– Double-click a column name in the Columns panel to edit it.

– Click the triangular areas in the upper left corner of the data grid to deselect rows and columns.

**Selection (Large Plus) Cursor**  When the cursor is at the top of a column heading, or in a row number area, it becomes a large plus, indicating that you can select rows or columns. When you click, that row or column is selected and highlighted. Click and drag to select multiple rows or columns, and press Ctrl and click to select discontiguous rows or columns.

– Double-click a column heading area to see the Column Info window for that column.

– Select a column to change the column name. The column highlights. Begin typing (if it is not in a locked column or locked data table).

– Double-click the row number area to edit the rows using the Row Editor.

**I-beam Cursor**  When you select editable text, the cursor becomes a standard I-beam. To edit text, position the I-beam within highlighted text. Click to mark an insertion point, or drag to select text for replacement.

**Double Arrow Cursor**  The cursor changes to a double arrow when it is on a column or a panel boundary. Drag this cursor left or right to change the width of a column or panel.
Changing the width of a column does not affect the column field width specified in the Column Info window (accessed by double-clicking a column name).

**Tip:** You can adjust widths of all selected columns at once by pressing Alt as you drag the double arrow cursor on any of the selected column boundaries.

**List Check Cursor** ▼ The cursor changes form when you move the mouse over values in columns that have data validation in effect. It becomes a small, downward-pointing arrow on a column with list checking. When you click, the value is highlighted and the cursor becomes the I-beam. Enter or edit data as usual with any values defined as valid text or valid numbers. See “List Check” on page 305 in the “Set JMP Column Properties” chapter.

**Pointer Cursor**  The cursor changes to a pointer over these objects:
- Red triangle menus for options
- Triangular disclosure icons that open or close panels
- Modeling type icons for changing

**Options to Open Data File**

**Note:** For more information about opening files, see the “Import Your Data” chapter on page 67.

To open a data set, select **File > Open** and select the file type. Some file types have additional features and options that appear in the Open Data File window (Table 2.1).

**Tips:**
- Windows only: To open the same file type every time, select the **Select this filter the next time this window is invoked** check box.
- Open a file by dragging it onto the JMP Home Window.
- To change which directory the **File > Open** command looks in, see “Preferences for File Locations” on page 707 in the “JMP Preferences” chapter.

Platforms and Reports

JMP consists of platforms that are organized by the type of statistical analysis. For example, the Distribution platform produces a univariate analysis (the distribution of a single variable) using histograms, additional graphs, and reports. You might analyze data in the Distribution platform and then choose another platform to examine the data more thoroughly.

Platforms and reports work together in these ways:

1. The data table is the input for a platform. See “Data Table Features” on page 36.
2. The platform analysis starts in a launch window. See “Launch Windows in Platforms” on page 52.
3. The platform results appear in a report window. See “Analysis Results in Reports” on page 55.

Figure 2.2 “Anatomy of a Typical JMP Session on Windows” on page 35 shows how a platform interacts with the data table and then displays the results in a report window. Information about using platforms is available in the JMP documentation library.

Launch Windows in Platforms

The launch window is your point of entry into a platform, where you specify the columns to analyze. Figure 2.11 shows the Distribution launch window.
Figure 2.11 Launch Window Features

All launch windows have in common provide the following options:

Select Columns  Lists all of the variables in your current data table. Note the following:
   - Right-click the modeling type icon next to a column name to change the modeling type.
   - Right-click the column name to create a transform column. See “Transform Columns in a JMP Platform” on page 254 in the “Enter and Edit Your Data” chapter.
   - Filter and sort the columns using the options in the red triangle menu. See “Column Filter Menu” on page 54.

Cast Selected Columns into Roles  Moves selected columns into roles (such as Y, X, and so on.) You cast a column into the role of a variable (like an actor is cast into a role). See “Cast Selected Columns into Roles Buttons” on page 54.

In the Graph Builder window, click the Dialog button on the left or select Redo > Relaunch Analysis to show this panel.

Action  The following options are available:

OK  Performs the analysis.

Cancel  Stops the analysis and quits the launch window.

Remove  Deletes any selected variables from a role.

Recall  Populates the launch window with the last analysis that you performed.

Help  Takes you to the Help for the launch window.
Tip: To reopen the platform launch window that was last opened, select View > Recall Last Platform (Windows) or Window > Recall Last Platform (macOS).

Cast Selected Columns into Roles Buttons

The following buttons frequently appear throughout launch windows. Buttons that are specific to certain platforms are described in the chapter for the specific platform.

Y Identifies a column as a response or dependent variable whose distribution is to be studied.

X Identifies a column as an independent, classification, or explanatory variable that predicts the distribution of the Y variable.

Weight Identifies the data table column whose variables assign weight (such as importance or influence) to the data.

Freq Identifies the data table column whose values assign a frequency to each row. This option is useful when a frequency is assigned to each row in summarized data. If the value is 0 or a positive integer, then the value represents the frequencies or counts of observations for each row when there are multiple units recorded.

Validation Identifies the data table column whose values assign rows to training, validation, and test sets for cross validation in fitting models.

Notes:

– For some platforms, KFold validation is available if you specify more than three levels in the Validation column.

– If you click the Validation button with no columns selected in the Select Columns list, you have the option to create a Validation column. For more information about the Make Validation Column utility, see Predictive and Specialized Modeling.

By Identifies a column that creates a report consisting of separate analyses for each level of the variable.

Column Filter Menu

A Column Filter menu appears in most of the launch windows. The Column Filter menu is found by clicking the red triangle in the Select Columns panel. Use these options to sort columns, show or hide columns, or search columns.
Figure 2.12  The Column Filter Menu

Reset  Resets the columns to its original list.

Show Filter  Opens a box in which you type the column name that you want to find. Click the arrow next to the box and select options to customize the filter.

Sort by Name  Sorts the columns in alphabetical order by name in ascending, descending, or original order.

Modeling Type  Provides options for showing or hiding columns with specific modeling types.

Numeric  Shows or hides columns whose data type is Numeric.

Character  Shows or hides columns whose data type is Character.

Expression  Shows or hides columns whose data type is Expression.

Exclude Formats  Excludes columns with specific formats from the column selection list.

Column Groups  Shows or hides groups of columns. See “Group Columns in Data Tables” on page 213 in the “Enter and Edit Your Data” chapter.

Ungrouped Columns  Shows or hides columns that have not been grouped.

Analysis Results in Reports

After you launch your analysis, the JMP report window appears. The report window shows the output of your analysis using interactive graphs and text reports. See the “JMP Reports” chapter on page 443.
Manage Files and Open Windows

The JMP Home Window provides instant access to open window and files. Opening recently opened files, closing windows, and pinning frequently used files are a few of the options.

**JMP Home Window on Windows**

On Windows, the JMP Home Window appears when you open JMP.

- Open recent files in the Recent Files list or pin a frequently used file.
- Right-click files in the Recent Files list to perform common tasks.
- Open or close active JMP windows in the Window List.
- Set an open data table as the current data table by selecting it from the data table list at the top.
**Figure 2.14** JMP Home Window Actions

- Right-click a window to access options such as closing and hiding the window.
- Hover over a window to see a thumbnail.

**JMP Home Window Buttons**

On Windows, the JMP Home Window panels can contain the following buttons:

- ![Open Selected](image)
  The Open Selected button opens the selected files in the Recent Files list.

- ![Sort By Name](image)
  The Sort By Name button sorts recent files alphabetically.

- ![Filter](image)
  The Filter button filters the types of files that appear in the Recent Files and Window List panels.

- ![Font Size](image)
  Enlarges the font size and icon size of items in the Recent Files list.

- ![Close](image)
  The Close button closes the panel.

**Recent Files**

On Windows, the Recent Files list provides quick access to files that you recently opened.
Keep your favorite files at the top of the list for quick access. Hover over the filename and click the pin icon . To unpin a file, click the pin icon .

You can drag files from the Recent Files list into these locations:

- the JMP Window List to open the file
- a Windows folder or on to your desktop to create a copy of the file
- applications such as Microsoft Notepad or Microsoft Word to edit the file

Right-click files to access the following options:

- Open a file
- Copy the location path to a file
- Open a file within the folder that contains it
- Sort files alphabetically by name or by most recent
- Remove a selected file or files from the list
- Remove a file or files that are no longer in the same location (Alternatively, you can select the files and press Delete.)
- (JSL scripts) Edit, run, or debug a script
- (Text files) Change the import method or open as plain text
- (SQL queries) Run an SQL query that you saved in Query Builder. You can also create a new query using an existing query as a template.
- Run or edit a JMP application

When you open a non JMP file from the Recent Files list, JMP applies your import preferences to arrange the data. You can right-click a text file to change the import method or to open the file in a text editing window. Your import preference is bolded in the pop-up menu.

**Tip:** To prevent files that were opened by a script from appearing in the Recent Files window, select **File > Preferences > General** and de-select **Add files opened by scripts to the Recent Files list.**

**Search the Recent Files List for JMP Files**

To find a recently opened file in a long list of files, enter part of the file name in the Recent Files Filter box.

The following options are provided:

- Enter part of the file name in the Filter box above the list of files.
- Hover over the Filter box to view search tips.
• As the files are filtered, the Up and Down arrow keys change the selected file. Press Enter to open the selected file, or select the file with your cursor.
• If a file is selected in the Recent Files list, press Ctrl+F to activate the Filter box.
• Press Esc or click the X button to exit the filtering mode after you typed a search term.

Window List

On Windows, the Window List shows open JMP windows, such as data tables, reports, and scripts. You can open, close, rearrange, and hide JMP windows.

• If you hover over a file in the Window List, a thumbnail appears.
• To open the Window List in its own window, select View > Window List.
• To display windows side-by-side, right-click the selected windows and select Arrange.
• To always automatically display the Window List inside maximized windows, select File > Preferences > Windows Specific and select Dock the Window List in maximized windows.

Right-click files to access the following options:

• View a window
• Close a window (Alternatively, you can select files and press Delete.)
• Close all windows except the currently selected window (if the selected window is a report window, the dependent data table also remains open)
• Move a window to the back
• Hide a window from the Windows taskbar or unhide a window
• Select all windows, or clear all selections

Note: The active file is formatted with bold text.

Rearrange Panels in the Home Window

To rearrange the panels in the Home Window on Windows, click and drag the title bar of the panel. Drop the title bar onto a top, bottom, left, or right arrow to position the panel. A blue box indicates where the panel will be placed. To turn the panels into tabs, drag and drop any panel into the middle of the Home Window.

Tips:

• To put the Home Window back into its original order, select View > Home Window Panes > Revert to Factory Layout.
• If you close a panel and want to reopen it, select View > Home Window Panes and select the panel that you want to open.
• Open the JMP Home Window by selecting View > Home Window or clicking the JMP Home Window button in the lower right corner of most JMP windows. If you cannot see the JMP Home Window button, select View > Status Bars.

• If you prefer to see the JMP Starter or the Window List upon start-up, you can specify that in the Preferences (Windows only). Select File > Preferences > General and select an option from the Initial JMP Window list.

JMP Home Window on macOS

Use the JMP Home window on the macOS to quickly access JMP files and open windows.

• Open recent files in the Recent Files list.
• Press Control and select a file in the Recent Files list to perform common tasks, such as adding or removing a favorite.
• Open or close active JMP windows in the Windows list.
• Set an open data table as the current data table by selecting it from the Active Table list. Press Option while selecting the data table from the list to activate the data table without bringing it to the front.
• Open the log.
• Find a file in the Recent Files list or an open window in the Windows list by entering a search term in the Search box.
• Click Toggle Layout to display the Recent Files and Windows lists horizontally instead of vertically.

Open the JMP Home window on macOS by selecting Window > JMP Home (Figure 2.15). To view the window each time you open JMP, select JMP > Preferences > General > Home Window.
Figure 2.15 Example of the JMP Home Window (macOS)

Tips:

- The Status bar area shows the path for the currently selected file. You can click a folder to open the folder to view its contents.
- To be able to quickly view the JMP Home window from any JMP window, press Ctrl and click the window, select Customize Toolbar, and drag the JMP Home icon to the toolbar.
- To copy a file from Recent Files to another document or into the Finder, select the file and then select Edit > Copy.

Recent Files

On macOS, the Recent Files list provides quick access to files that you recently opened. You can also click the star that appears when you hover over the file name to add it to your favorites.

Press Ctrl and select a file to access other options. For example, you can run or debug a JSL script by pressing Ctrl and selecting Run Script or Debug Script.

Tip: To prevent files that were opened by scripts from appearing in the Recent Files window, select JMP > Preferences > General and de-select Add files opened by scripts to the Recent Files list.
Windows List

On macOS, the Windows list shows open JMP windows, such as data tables, reports, and scripts.

To close a window, click the x button that appears when you hover over the window in the Windows list.

If the window that you are closing is a parent to one or more children, you are prompted to Hide Data Table, Cancel, or Close All windows. Select Close All to close the parent and all its children windows.

Search for Recently Opened Files on Windows

On Windows, recently opened files appear in the Home Window. You can also search for recently opened files from any JMP window.

Select File > Quick Open or press Alt+Shift+O to open the Filter box and enter your search term. This option also lets you view the path of the file. Press Esc or click the X button to close the window after you type a search term.

Close Multiple Files

On Windows, close several files at once from the JMP Home Window. Select the files in the Window List, right-click, and select Close. To leave a single file opened and close the rest, select the single file and then select Close All But This.

On macOS, select File > Close Multiple and then select the files that you want to close.

Display and Arrange Open Windows

In JMP, typically you have several windows open at once (for example, data tables, reports, and the JMP Home Window). JMP provides several ways to arrange and display these open windows.

On Windows:

- Press Ctrl+Tab to switch between windows.
- Use the Reveal feature (F9 or Window > Reveal). See “Using the Windows Reveal Feature” on page 65.
- Use the options in the Window menu. Note that Arrange options are also available using the Arrange Menu option in the bottom right corner of most windows. If you cannot see Arrange Menu, JMP Home Window, and View Associated Data buttons, select View > Status Bars.
Tip: From the Arrange Menu option on Windows, you can merge open windows by selecting Combine Windows. See “Example of Combining Windows to Create a Dashboard” on page 631 in the “Combine and Present Reports Using Dashboards” chapter.

- To display the JMP Home Window, click the JMP Home Window button in the lower right corner of most windows, or press Ctrl+1.
- To show the data table for a report, click View Associated Data button in the bottom right corner of the report.
- To open an associated report when you are viewing a data table, double-click the thumbnail preview of the report in the bottom pane. To enlarge the preview, hover over the thumbnail (Figure 2.16).
- Middle-click the thumbnail preview to close the associated report.

Figure 2.16 Thumbnail Previews of Open Reports

On the macOS:
- Use the options in the Window menu.
- Use the Expose feature (F9 or F3).
Preview JMP Files

For some JMP file types, you can use Windows Explorer or macOS Finder to view a portion of the selected file. Windows supports a preview of JMP data tables, journals, and scripts. macOS supports a preview of data tables and scripts.

To preview a JMP file

1. In Windows Explorer or the macOS Finder, select the file that you want to preview.
2. In Windows Explorer, select the Show the preview pane button in the upper right corner. Support in e-mail programs varies.

   In the macOS Finder, select the file and press the spacebar, or select the Quick Look option on the pop-up menu or File menu. In Mail, select the Quick Look Attachment option on the pop-up menu or File menu.

   The preview pane shows a portion of the selected file.

Figure 2.17  Data Table Preview Pane (Windows)
Using the Windows Reveal Feature

The Reveal feature shows a top-level window with thumbnails of all open JMP windows. On Windows, press F9 to use the Reveal feature.

- Click a window to activate it.
- Press the spacebar to turn on Preview mode, where a full-sized view of the thumbnail under the cursor appears in the center of the screen.
- By default, the windows are ordered to match the original ordering on the screen in a top-down, left-to-right order. Press S to sort the thumbnails by name.

To exit the Reveal feature, press F9, Esc, or Alt+Tab and then select another application.

JMP Starter Window

The JMP Starter window is a good place to begin if you are not familiar with JMP or data analysis. Options are categorized and described, and you launch them by clicking a button. The JMP Starter window covers many of the options found in the Analyze, Graph, Tables, and File menus.

- To open the JMP Starter window, select View (Window on macOS) > JMP Starter.
- To display the JMP Starter automatically when you open JMP on Windows, select File > Preferences > General, and then select JMP Starter from the Initial JMP Window list. On the macOS, select this option on the JMP > Preferences > General page.

Figure 2.18 shows the JMP Starter window for Windows. The macOS JMP Starter window is identical.
Figure 2.18 The JMP Starter Window (Windows)
Chapter 3
Import Your Data
Create Data Tables

This chapter covers the following topics:

- How to import data, such as text files, PDF files, SPSS files, and SAS data
- How to transfer Excel data
- How to read in real-time data
- How to create a new data table

About Importing Data

You can import many file formats into JMP and save them as data tables. JMP opens many files by default. The file formats which JMP does not support by default require specific Open Database Connectivity (ODBC) drivers.

The Following File Formats Are Supported by Default:

- Comma-separated (.csv)
- .dat files that consist of text
- ESRI shapefiles (.shp)
- Flow Cytometry versions 2.0 and 3.0 (.fcs)
- Hierarchical Data Format, Version 5 (.h5)
- HTML (.htm, .html)
- JSON (.json)
- MATLAB (.m, .M)
- Microsoft Excel 1997 through 2019 on macOS (.xls, .xlsx)
- Microsoft Excel 2010 through 2019 on Windows (*.xlsx, *.xlsm)
- Minitab Portable Worksheet (.mtp)
- Plain text (.txt)
- R (.r)
- SAS transport (.xpt, .stx)
- SAS versions 7 through 9 on macOS (.sas7bdat)
- SAS versions 7 through 9 on Windows (.sas7bdat, .sas7bxat)
- SPSS (.sav)
- SQLite 3.0 or higher (.sqlite, .db, .sqlite3, .db3)
- Tab-separated (.tsv)
- Teradata database (.trd)
- Triple-S (.sss, .xml)
- xBase data files (.dbf)
- XML data files (.xml)

Notes on SAS Support:

On both Windows and macOS, you can open SAS data sets directly through the File > Open command. See “Import SAS Data Sets” on page 139.
Another option is connecting to a SAS server by selecting **File > SAS > Browse Data**. See “Open SAS Data Sets through a SAS Server” on page 149.

**The Following Files Require ODBC Drivers:**

- Database (dBASE) (.ndx, .mdx) is supported with a V3+ compliant ODBC driver. .dbf files do not require an ODBC driver.
- Microsoft Access Database (.mdb) is supported with a V3+ compliant ODBC driver.

See “Import Data from a Database” on page 165 for more information for working with databases.

Your computer’s available memory affects data import. Very large files might load slowly or not at all. Consider splitting up large files before importing them. You can then join or concatenate the tables. See “Concatenate Data Tables” on page 356 in the “Reshape Your Data” chapter and “Join Data Tables” on page 359 in the “Reshape Your Data” chapter.

**Note:** You can open R code (.R) and SAS program files (.sas) in JMP, but the text opens in a Script window, not in a data table.

## Import Microsoft Excel Files

Microsoft Excel files open in the Excel Import Wizard by default. The wizard shows a preview of the data. You can then modify the settings before importing the data. For example, you might indicate which row the data begin on and whether the worksheet contains column headers or hidden rows or columns. Microsoft Excel .xls, .xltm, and .xlsx file formats are supported.

For information about opening a Microsoft Excel file outside the wizard, see “Import a Microsoft Excel File Directly” on page 83.

**Notes:**

- Between Windows and macOS, the number of digits after a decimal point and the date format of imported data might differ. For example, “10/25/2012” might be formatted as “25Oct2012” on macOS. Columns might be imported as character columns on macOS but not on Windows.
- Consider setting the *Autosave timeout* value in the General preferences to automatically save open data tables. This autosave value also applies to other JMP document types.
Preview and Import Microsoft Excel Data

Before you import a worksheet, open the spreadsheet in Excel and decide how you want the data to be structured in the final data table. For example, you need to know whether the worksheet includes hidden or merged cells. In the wizard, you can then exclude hidden columns or rows.

To import a Microsoft Excel file that contains several worksheets, follow these steps:

1. Open the worksheet in Microsoft Excel.
   For the figures in this example, we used the Team Results.xlsx file located in the JMP Samples/Import Data folder. The file has the following characteristics:
   - the data begin on row 4, column 2 and end on row 9, column 5
   - two worksheets
   - the second worksheet has two sets of merged cells
   - no hidden rows or columns

   **Figure 3.2 Team Results.xlsx Worksheet**

</tbody>
</table>

2. To open an Excel file, select **File > Open**.
   The Open Data File window appears.
3. Select **Excel Files** next to File name.
4. Select the Excel file and click **Open**.
   The worksheet opens in the Excel Import Wizard, where a preview of the data appears along with import options.
Figure 3.3  Example Initial Data Preview

Note the following characteristics in the Data Preview:

– Both worksheets are selected for import in the upper right corner.
– The first column has been automatically been removed.
– Text from the first row of the worksheet appears as the column headings. However, you want the text in row 3 of the worksheet to be used as the column headings.
– The first data row is empty.

Note: JMP remembers your previous changes each time you import a worksheet, even after closing and reopening JMP. This feature is helpful when you want to reimport the same worksheet several times and experiment with options. To clear those changes when you import a different worksheet, click Restore Default Settings.

5. Type 3 for Column headers start on row
6. Data starts on row changes to 4.
7. Select Ungrouped Team Results in the Worksheets pane.
   Only this worksheet will be imported.
8. Deselect Use for all worksheets.
These settings apply only to Ungrouped Team Results.

**Figure 3.4** Selecting the Column Header Row

**Tip:** Right-click a numeric column header in the Data Preview pane to change the format.

See “Individual Worksheet Settings” on page 75 for more information about all options.

9. Click **Next** to configure other import settings.

   The window displays additional import settings.

10. For **Data ends with row**, type 9.

11. For **Data ends with column**, type 5.
Figure 3.5  Specifying the Last Column

See “Additional Individual Worksheet Settings” on page 76 for more information about all options.

12. Click Import to convert the worksheet as you specified.

Figure 3.6  Final Data Table

The following sections describe options in the Excel Import Wizard.

Individual Worksheet Settings

**Worksheet contains column headers**  Select if the worksheet contains rows with column headers.
Column headers start on row  Indicates which row the column headers begin on in the worksheet. Click the up arrow until the headers begin on the correct row, or enter the row number and press Enter.

Number of rows with column headers  Indicates whether the worksheet has multiple rows as column headers. Click the up arrow until the header rows appear correctly, or enter the number of rows and press Enter.

Data starts on row  Indicates which row the data start on in the worksheet.

Data starts on column  Indicates which column the data start on in the worksheet.

Concatenate worksheets and try to match columns  Merges all worksheets into one data table. JMP matches columns that have the same header.

Create column with worksheet name when concatenating  Adds a new Source Table column that lists the worksheet name for each imported table. This option is available after you select the preceding concatenate option.

Use for all worksheets  Applies the current import settings to all worksheets that are selected in the upper right corner.

Additional Individual Worksheet Settings

Treat multiple column header lines as hierarchies  Indicates that the worksheet contains multiple rows as column headers and you want these headers to be hierarchies. This option is only for stackable data.

Replicate data in spanned rows  Indicates cells are merged in the worksheet across rows. JMP unspan the cells and copy the cell contents into all of the resulting cells. The option is selected by default.

If you deselect Replicate data in spanned rows, JMP unspans the cells and copies the cell contents into the topmost cell. The remaining unspanned cells are left empty.

Suppress hidden rows  Prevents hidden rows from appearing in the data table.

Suppress hidden columns  Prevents hidden columns from appearing in the data table.

Suppress empty columns  Indicates whether an empty column that has a column header is imported. Deselect the option to import the column.

Data ends with row  Indicates the last row in the worksheet that contains data.

Data ends with column  Indicates the last column in the worksheet that contains data.
Advanced Options

Column Name Separator String  Indicates the separator between each word in a column heading if the headings were originally in different rows. Specify the number of rows with column headers on the first Excel Import Wizard window. Then enter a character or space in the Column Name Separator String box. The default string, a hyphen, results in a column heading such as “First-Second-Third”.

Multiple Series Stack  Divides subcategories into separate columns in a worksheet with hierarchical headings. You must also select Treat multiple column header lines as hierarchies. The main category is imported as the Label column.

Replicate headers in spanned rows  Repeats the header text in each cell for rows that are spanned in the worksheet. For example, the State column heading shown in Figure 3.7 was in a merged cell in the worksheet. On the left, the heading is replicated. Deselect the option to avoid repeating the heading as shown on the right.

Figure 3.7 Replicated Headers in a Microsoft Excel File

Replicated headers

<table>
<thead>
<tr>
<th>State-</th>
<th>State</th>
</tr>
</thead>

<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TX</td>
</tr>
<tr>
<td>2 TX</td>
</tr>
<tr>
<td>3 TX</td>
</tr>
<tr>
<td>4 TX</td>
</tr>
</tbody>
</table>

Import cell colors  Applies the cell coloring from the worksheet to the data table. On macOS, only primary and secondary colors can be reliably imported.

Limit column type detection  Scans a maximum of 100 rows to determine the column type. Select this option to speed up the import of large worksheets.

Tips:

- JMP remembers your previous changes each time you import a worksheet, even after closing and reopening JMP. This feature is very helpful when you want to reimport the same worksheet several times and experiment with options. To clear those changes when you import a different worksheet, click Restore Default Settings.
- Your import settings are saved in a data table script named Source. To reimport the worksheet using the same settings, run the script. The script includes the path to the worksheet, so make sure that other users have access to that location.
- To speed up the data preview in large worksheets, deselect Update settings on any change on the first wizard window. Modify the settings and then click Update now to refresh the data preview.
• To view all rows in the Data Preview pane, select **Show all rows**. The preview might be slightly delayed depending on the size of the spreadsheet.
• You can combine two worksheets from the same workbook into one data table. The column names are matched on import, so the order of the columns is irrelevant.

**Import a Microsoft Excel File with Hierarchical Headings**

In an Excel worksheet, multiple header rows can have an implied hierarchy; the second header row contains data that are categories of the first header row. Figure 3.8 shows an example. In the worksheet at the top, the seasons “Winter” and “Spring” are in spanned cells above the months within those seasons. In the JMP data table, you want the seasons in one column and their corresponding months in another column.
To import the worksheets and maintain multiple column hierarchies, follow these steps.

1. In JMP, select **File > Open**.
2. In the Open Data File window, select **Texas Precipitation.xlsx**, located in the JMP Samples/Import Data folder, and then click **Open**.
The worksheet opens in the Excel Import Wizard, where a preview of the data appears along with import options.

Figure 3.9 Excel Import Wizard Preview

Figure 3.9 shows the default settings for this worksheet:

1. All worksheets are selected for import. Press Ctrl and click a worksheet to exclude it from the import.

2. Each season is split over several columns.

3. Data from the second heading row of the worksheet appear in the first row.

4. The empty rows at the top have been removed.

3. Under Preview Pane Refresh, make sure that **Update settings on any change** is selected.
This means that the Data Preview automatically refreshes when you make changes.

4. Next to **Number of rows with column headers**, click the up arrow once.
   Notice that **Data starts on row** automatically updates to 3.

**Figure 3.10** Updated Settings on Page One

5. Click **Next**.

6. Next to **Data ends with row**, type 6 and press Enter.
   After the first three empty rows are removed from the worksheet, the data end with row 6.
   
   **Tip:** Instead of you typing the end row number, JMP can calculate the row for you. In the Data Preview pane, select row 4. Click the plus sign **+** next to **Data ends with row**.
**Figure 3.11 Updated Settings on Page Two**

Notice that **Replicate data in spanned rows** is selected by default. JMP unmerges data that were merged in the worksheet and copies the cell contents as separate categories. “TX” was originally in a merged cell. In JMP, it will be copied into separate cells.

7. Select **Treat multiple column header lines as hierarchies**.

   Each season and month in the header rows of the worksheet will become categories in the data table.

8. Click **Import**.

   The four worksheets open as separate data tables. The data tables contain a Source script, which you can run to import the data into new data tables using the same import settings (Figure 3.12). Your import settings are also saved the next time you open the worksheet in the Excel Wizard in any JMP session.
Import Your Data

Using JMP Import Microsoft Excel Files

Figure 3.12 The Final Data

Import a Microsoft Excel File Directly

Microsoft Excel files open in the Excel Import Wizard by default. This option is helpful when the structure of data in the worksheet is irregular. For example, you might want to exclude hidden columns or convert text in the third row to column headings.

Instead of opening spreadsheets in the Excel Import Wizard, you can select File > Open to open the file. By default, JMP detects whether the first row contains labels and converts them to column headings. You can change this setting in the General preferences. The Excel Open Method preferences are in File > Preferences > General (Windows) and JMP > Preferences > General (macOS). From the Use Excel Labels for Headings list, select Always or Never.

To set the Excel Open Method preference

To always open Microsoft Excel files outside the wizard, change the Excel Open Method preference. Choose to open all worksheets at once or select them from a list.

To open a Microsoft Excel file (Windows)

1. After you set the Excel Open Method as described above, select File > Open.
2. To convert text in the first row to column headings, select *Always* next to *Always enforce Excel Row 1 as labels*.
3. Select the *Excel Files* file type, select the file, or enter the URL.
4. To import all worksheets, click *Open*.
   or
   To select the worksheets that you want to open, click the *Open* button arrow, and then select *Open Selected Worksheets*. Select one or more worksheets and click *OK*.

*To open a Microsoft Excel file (macOS)*
1. Select *File > Open* and select the file.
2. (.xls only) To convert text in the first row to column headings, select *Use Excel Labels as Headings*.
3. (.xls only) To open specific worksheets, select *Select Individual Excel Worksheets*.
4. Click *Open*.
   If you chose to open specific worksheets, select those worksheets from the list, and then click *OK*. You can also click *Select All* if you change your mind and want to import all worksheets.

If you selected an .xlsx file, a preview of the data appears in the Excel Wizard. See “Preview and Import Microsoft Excel Data” on page 72.

---

**Import Text Files**

You can open text files with the extensions .txt, .csv, and .tsv, and the text is converted to a data table. Files with the .dat extension that consist of text are also supported. Text files can be delimitied using almost any character, or they can be fixed-width files.

Trailing whitespace is removed when you import text files into JMP.

When JMP finds an integer in the text file that is greater than 9,007,199,254,740,991, the column is considered character data. You can set the column to numeric using the Text Import Wizard window or an import script.

*Tip:* You can import more than one text file at a time using the Multiple File Import option. See “Import Multiple Files” on page 94.

*To adjust import settings, choose from one of the following options*

- Select *File > Preferences > Text Data Files* to change the import settings so that JMP determines the best way to structure and format the data table.
• Manually select the import settings as you open the file (described in this section).
• Open the file in the Script Editor, edit the content, and then import the content. This option is helpful when you need to add text delimiters or modify the text.

To import a text file

1. Select File > Open.
2. On Windows, you can set the file type to Text Files.
3. Select the text file that you want to open.

   For information about the options, see Table 3.1 and Table 3.2.

### Table 3.1 Opening Text Files on Windows

<table>
<thead>
<tr>
<th>Automatically Determining Data Arrangement</th>
<th>Manually Specifying Data Arrangement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Select File &gt; Open.</td>
<td>1. Select File &gt; Open.</td>
</tr>
<tr>
<td>2. From the list next to File name, select Text Files.</td>
<td>2. From the list next to File name, select Text Files.</td>
</tr>
<tr>
<td>3. To use the import rules from the preferences, select Data, (Using Preferences). (See “Preferences for Importing and Exporting Text Files” on page 691 in the “JMP Preferences” chapter.) To have text import use its best guess to arrange the data, select the Data (Best Guess) option.</td>
<td>3. Select Data (Using Preview) next to Open as at the bottom of the window.</td>
</tr>
<tr>
<td></td>
<td>4. Select the file that you want to open.</td>
</tr>
<tr>
<td></td>
<td>5. Click Open.</td>
</tr>
<tr>
<td></td>
<td>6. Complete the Text Import window. See “Options in the JMP Text Import Wizard” on page 87.</td>
</tr>
<tr>
<td></td>
<td>7. Click Import.</td>
</tr>
</tbody>
</table>

**Tip:** The JMP Home window provides a shortcut to the above steps if you recently opened the file. Right-click the file in the Recent Files list and select Import (Preferences) or Import (Best Guess). (Your import preference is bolded in the right-click menu.)
Table 3.2  Opening Text Files on macOS

<td>3. Click <strong>Open</strong>.</td>
</tr>
<tr>
<td></td>
<td>5. Click <strong>Import</strong>.</td>
</tr>
</tbody>
</table>

Notes:
- On Windows, JMP can open text files in your computer’s default text editor. Select **File > Open**, and then select **All Files (*.*)** from the **File name** list. Select the text file, and then select **Use default program to open. Uncheck to open as text**.
- If you cancel the import while JMP is scanning the data, data is imported based on what JMP detected. The data might not appear as you expect. For example, you might see missing values in a column that was incorrectly detected as numeric. If you cancel the import after the data is scanned, only the data read up to that point is imported.

For more information about importing text from a Script window, see “Import Text from the Script Editor” on page 93.

---

**Find Missing Characters in Imported Data**

JMP attempts to detect the character encoding in your document. Sometimes the document might use an encoding that JMP does not recognize, or JMP might have chosen the wrong encoding.

Text that JMP does not recognize is replaced with a Unicode character 🔄. Find the text by searching for \x{fffd}.

1. In the data table, select **Edit > Search > Find**.
2. Type \x{fffd} next to **Find what**.
3. Make sure that **Use regular expressions** is selected.
4. Make sure that **Search data** is selected.
5. Click **Find** to find the first instance.
Chapter 3
Using JMP

6. Replace all instances with another string.

Figure 3.13 Searching for the Unicode Character

Options in the JMP Text Import Wizard

When you open a text file that JMP supports, JMP can show a preview of the text before opening the file as a data table. This option lets you manually arrange and format the data. For example, you can specify the end-of-line character or strip quotation marks.

JMP detects the file’s structure and shows options for importing text with either delimiters or fixed width fields. If JMP chooses the wrong file structure, click the Delimited fields or Fixed width fields radio button to import the data as the correct format. (For example, the fixed width window might appear when your file is actually delimited.)

The text import wizard options are shown in Figure 3.14 and Figure 3.15.
Figure 3.14 Text Import Wizard for Fixed Width Files

Fixed data format: click to create additional column dividers. Drag the dividers to the proper position. Drag a divider on top of another divider to delete it. The numbers at the top are the column positions and the column widths. The next step sets the column names and types.
Figure 3.15  Text Import Wizard for Delimited Files

Charset
Select the character set used in the imported file, or let JMP detect the character set. If incorrect characters are displayed in the imported file, open the file again and select another character set.

End of Field
(Available only in the Delimited Import window.) Select the check boxes beside the character that marks the end of a field. Alternatively, select the check box beside Other and enter a character if the appropriate character is not listed.

End of Line
(Available only in the Delimited Import window.) Select the check boxes beside the character that marks the end of a line (row). Alternatively, select the check box beside Other and enter a character if the appropriate character is not listed. Note that when JMP finds double quotation marks, the delimiter rules change to look for an end double quotation mark. Other text delimiters, including spaces embedded within the quotes, are ignored and treated as part of the text string.

File contains column names on line
Tell JMP where to find data to use as column names. For example, if the column names in your text file are on line (row) 3, select this option and type 3 in the check box. Otherwise, JMP uses the data in the first line of the imported file as the column name in the JMP data table or takes the first line as data.

Data starts on line
Specify the number of the first line that contains data.
Number of Lines Specify the number of lines (rows) that you want to import.

Strip enclosing quotation marks (Available only on fixed-width imports.) Select this check box when you want JMP to remove quotation marks that enclose data in the text file.

Two-digit year rule Specify how to display dates that have two-digit years. Select the 100-year range in which your dates fall. For example, if the earliest date is 2/2/79, and the year is 1979, select 1970-2069. If the earliest date is 2/2/12, and the year is 2012, select 2000-2099. If dates span centuries, you must recode the dates with four-digit years before importing the data.

Recognize apostrophe as quotation mark (not recommended) (Available only in the Delimited Import window). Use this option only if your data comes from a nonstandard source that places apostrophes around data fields rather than quotation marks.

Use Regional Settings Specifies whether the operating system’s regional settings are used when importing a text file. If the option is deselected (the default setting), files that use a period for a decimal point and a comma for the value separator import correctly. You must specify the value separator in the Text Data Files import preferences.

If the file uses a comma for a decimal point, you must also set the following options: the OS regional settings must use a comma for a decimal point (Windows and macOS), or the Windows Specific Display Language preference must be set to a language that uses commas for decimal points.

When you are finished selecting the settings, click Next. The next window shows each column’s modeling type. To change the default modeling types, do one of the following:

- Click the data type icon to change the data type from numeric (_numeric) to character ( _char_ ). Clicking the icon cycles between the modeling type and exclude ( _excl_ ). Exclude means that the column is not imported.
- To change a numeric column’s data format, select the format from the red triangle menu.
- Click the column heading to modify the text.

The top of the text import window shows a preview of the text file as it appears when imported into a JMP data file. Click the Import button to import the data.
Chapter 3
Using JMP
Import Your Data

Using JMP Import Text Files

<td>BARBARA</td>
<td>13 F</td>
<td>60</td>
<td>112</td>
</tr>
</tbody>
</table>

Click a column name to change it. Click the icon to specify the numeric or character data type, or click the icon to exclude the column. Click the red triangle to select the data type for a numeric column. When you are finished, click the Import button to complete the import.

**Note:** To specify the format of dates, select the red triangle next to the column name, select **Date**, and then select the date format. To specify how the dates appear after you’ve imported the data, right-click the date column in the data table, select **Column Info**, and change the date next to Format.

7. When you are finished setting up the data, click **Import** to complete the text import.

**Note:** Both the Text Import Wizard and Multiple File Import import columns of numbers as numbers by default. If you have something like part numbers with leading zeros that you want to keep, or part numbers with more than 15 digits, you can force the column to be character. In the Text Import Wizard, you can do this column-by-column (on the second wizard pane, top of the column). In Multiple File Import, you can select the check box that causes **all** columns to be imported as character. (Otherwise leading zeros are not preserved, and digits beyond 15 are lost.) See “Import Multiple Files” on page 94 for more information about Multiple File Import.

**Edit Text Before Importing into JMP**

You can open a text file in a Script window, where you edit the text. Then you can import the text as a data table. This feature is helpful when you want to reformat the text before importing it as a data table. For example, you might need to insert the correct delimiters or modify the text.

Another option is opening a JMP add-in definition (.def) file as text and then editing it in a Script window.
**To open a text file in a text editing window (Windows)**

Files that you recently opened are listed in the JMP Home window. For most files, right-click the text file and select **Open as Plain Text** to open the file in a text editing window. JMP add-in definition files cannot be opened as plain text from the JMP Home window.

When you are opening the file for the first time, follow these steps:

1. Select **File > Open**.
2. Select **Text Files** from the list next to **File name**.

![Figure 3.17 Select Text Files](image)

3. (Optional) To set the default option file type to **Text Files**, select the check box beside **Select this filter the next time this window is invoked**.
4. Select the file.
5. Select **Plain text into Script window** next to **Open as**.
6. Click **Open**.

   The text appears in a Script window.

**To open a text file in a text editing window (macOS)**

1. Select **File > Open**.
2. Select the file.
3. Click **Options**.
4. Select **Text in the Script Editor** from the **Open As** list.
5. Click **Open**.

The text appears in a Script window.

For more information about converting the text to a data table, follow step 3 in “Import Text from the Script Editor” on page 93.

**Import Text from the Script Editor**

You can import text from the Script Editor as a data table. The text can be in a table format (for example, from a Microsoft Word document or Web page) or in plain text format. This feature is helpful when you want to reformat the text before importing it as a data table. For example, you might need to insert the correct delimiters or modify the text.
JMP uses the import settings in the preferences to determine how to structure and format the text. Some options include removing quotation marks around text and specifying the rows that contain column headings and data. See “Preferences for Importing and Exporting Text Files” on page 691 in the “JMP Preferences” chapter.

**Note:** You can also import an entire web page as a data table. See “Import Data from the Internet or a Remote Computer” on page 184.

This section describes how to import text that you paste into the Script Editor. For more information about opening a text file in the Script Editor, see “Edit Text Before Importing into JMP” on page 91.

**To import text from the Script window**

1. Open a new Script window by selecting File > New > Script (Windows) or File > New > New Script (macOS).
2. Copy and paste the text into the Script Editor.
3. Do one of the following:
   - To import all text from the Script Editor, select Edit > Import as Data.
   - To import specific text, select the text, and then select Edit > Import as Data.

   The text is imported into a JMP data table.

**Note:** To preview text that you import from the Script Editor, press Shift before you select File > Import as Data.

---

**Import Multiple Files**

Multiple File Import (MFI) imports CSV data and unstructured text files from one directory and stack them in a data table (or to import them in separate data tables). You can save the import settings as a script and then run the script when the data is updated in the future.

Multiple File Import supports the following file types:

- XLSX
- CSV
- TSV
- DAT
- TXT
- SAS7BDAT
Chapter 3
Using JMP

Import Your Data

Using JMP Import Multiple Files

- XML
- JMP
- JSON
- PNG
- JPG
- GIF

Multiple File Import can also import only one file. Table 3.3 can help you decide whether to use the standard Text Import, Multiple File Import, or JSL.

Table 3.3 Choosing Between the Text Import Wizard and MFI

<table>
<thead>
<tr>
<th>Import Characteristics</th>
<th>One File</th>
<th>Multiple Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV, TSV, DAT</td>
<td>Text Import has a preview wizard to help name the columns, pick date formats, and subset the data.</td>
<td>MFI can stack similar files automatically. You can change formatting later.</td>
</tr>
<tr>
<td>Unstructured text</td>
<td>MFI, possibly in JSL with Load Text File().</td>
<td>MFI</td>
</tr>
<tr>
<td>Large files over 100MB</td>
<td>You can use the Source script from a previous Text Import to speed up the next import.</td>
<td>MFI imports in parallel and might be much faster than Text Import.</td>
</tr>
<tr>
<td>Unsere about format</td>
<td>Text Import might be able to guess. The preview wizard lets you see the results before the text is imported.</td>
<td>MFI does not guess. You specify the tab delimiters. There is no preview, but select Keep dialog open, and it is easy to try different import settings.</td>
</tr>
<tr>
<td>Pictures</td>
<td>Try the JSL Open() function.</td>
<td>MFI understands PNG, JPG, and GIF files. You’ll get a table with a picture column.</td>
</tr>
</tbody>
</table>
Table 3.3 Choosing Between the Text Import Wizard and MFI (Continued)

<table>
<thead>
<tr>
<th>Import Characteristics</th>
<th>One File</th>
<th>Multiple Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>JMP, XLSX, and JSON</td>
<td>Try the JSL <code>Open()</code> function.</td>
<td>MFI opens JMP, XLSX, and JSON files using JSL <code>Open()</code> and will stack them if requested. MFI does not keep the table and column scripts when it opens JMP tables, so you might need to use <code>Files In Directory()</code> and <code>Open()</code> if you need all of those scripts.</td>
</tr>
</tbody>
</table>

To import multiple files, follow these steps:

1. Place the files that you want to import in the same directory.
   This example uses import data found in the JMP Samples/Import Data folder.
2. Select **File > Import Multiple Files** (Windows) or **File > Open Multiple** (macOS).
3. Browse to select the JMP Samples/Import Data folder.
4. In the **Select Files by name or extension** box, type `UN*.csv` and press Enter.
   In this example, the files have the UN prefix and are CSV files.
   The Files list updates to show which files have been selected.
   Specify multiple file names and extensions by separating them with semicolons, or click **Add Extension** and select an extension.
Figure 3.19 Selected CSV Files

Notice that the Refresh button flashes if the files have changed in the directory since the last refresh.

5. Specify the columns that you want added to the data table.

By default, no extra columns are added. You might like a File Name column to show the names of the imported files. Select **Add file name column**.

**Note:** The Text Data Files preferences do not determine which options are selected in the CSV settings, although the settings are similar.

6. Keep **Stack Similar Files** selected because these CSV files have the same columns.

7. Click **Import**.

JMP applies the file name, file size, and file date and time filters to stack the files. Data with columns that contain the same column headings are imported in the same data table.
If the columns do not match, the mismatched columns are imported into a separate data table.

</tbody>
</table>

**Notes:**
- To import hidden files, select **Include hidden files**.
- To import files that are in subdirectories, select **Include subfolders**.
- To import files in a certain size range, in the **Select files by size** box, type the lower and upper file size limits.
  Consider specifying the limits if you don’t want to import large files over a certain limit. Specify file sizes in KB (kilobytes). One KB equals 1,000 bytes.
- To import files that were modified during a certain date and time range, in the **Select files by date and time** box, click the calendar button to specify the range.
- (Unstructured text files) Select **Text, Whole File on One Row** or **Text, One Line Per Row** based on how the file is structured.

**Notes:**
- These two options are not supported for XLSX, JSON, and JMP files.
- When you select Text, Whole File on One Row, the import includes the whole file and does not skip lines before the first data line.
- **JMP creates a data table that lists the files that could not be imported** (for example, SAS datasets).

**Import Structured Data with Different Quoting**

Sometimes export filters place something other than quotation marks around fields. You specify the delimiter in the CSV settings.
Text in a CSV file might contain escape sequences such as a backslash instead of doubling the quotation mark. You also specify the delimiter in the CSV settings.

**Tips:**

- **Keep dialog open** is off by default, but you might turn it on while testing. This enables you to import files to see what the data looks like, edit the source files if necessary, and reimport them with the same settings.
- When you import files that are not supported, a data table called “@ Unused Files” is created. The file names are listed in the Files table script. Right-click the script and select Edit. To output the file names of unsupported files in this data table, select **Add file name column** on the Multiple File Import window.
- Right-click the Files list and select Sort by Column to change the way the Files list is sorted.
- The Import button is unavailable if no files match the filters that you selected.
- JMP automatically changes the CSV settings when you select either of the two options for Text Explorer-style data (the bottom center radio buttons). A delimiter is not specified, which loads all data in one column. JMP also changes the CSV settings to not use an end-of-line character, which loads the entire file in one row. You can also change the CSV settings. If you try the manual approach, be sure to set No Headers and First Data Line to 1.

---

**Import PDF Files**

The PDF Import Wizard enables you to preview a PDF file, adjust the import settings, and view the results in the data table preview before you import the data. JMP attempts to auto-detect the data structure in the PDF file, or you can customize the structure.

**Note:** A PDF file consists of tables that contain data. In the PDF preview, the tables are outlined and selected on each page.

- “Concatenate Tables into One Data Table”
- “Concatenate Tables by Column Headers”
- “Import Tables that JMP Does Not Auto-Detect”
- “PDF Preview Red Triangle Options”
- “Data Table Preview Options”
- “PDF Preview Right-Click Options”
Chapter 3
Import PDF Files Using JMP

Concatenate Tables into One Data Table

1. Select File > Open and select PDF Files from the list next to File name.
2. Navigate to the JMP Samples/Import Data folder and double-click Food Distribution.pdf.
3. In the Import PDF Wizard, a preview of the PDF file is shown on the left. A preview of the data in a data table is shown on the right.
   The PDF file consists of one table on each page.

Figure 3.21 Initial PDF File and Data Table Preview

Note the following:
- There are seven rows at the top of the PDF that you don’t want to import.
- You also don’t want the footnotes in the last row of the PDF file.
4. In the corner of the table, click the red triangle and select Number of rows to use as header > Specify rows.
5. Type 7 and click OK.
   In the PDF file preview, the first seven rows are selected.
   In the data table preview, the data begin on row 1.
6. In the PDF file preview, scroll down to page 2.

7. Drag the bottom of the PDF table upward until the footnotes are no longer selected (Figure 3.22).

**Note:** You can also simply delete the row from the final data table.

![Figure 3.22 Dragging the Table to Remove Data](image)

8. In the Table report on the right, select **Concatenate all tables into one**.

   When you concatenate data tables, you combine rows from two or more data tables into one data table.

9. At the bottom, click **OK**.

   The data is imported into a data table.

**Figure 3.23** Final Data Table (Partial View)
**Concatenate Tables by Column Headers**

When a PDF file contains tabular data with the same column headers on each page, you can concatenate the tables based on the column headers.

1. Select **File > Open** and select **PDF Files** from the list next to File name.

2. Navigate to the JMP Samples/Import Data folder and double-click Iris.pdf.

3. Scroll through the PDF preview and notice that the column headers are the same on each page.

4. In the Table report on the right, make sure that **Concatenate tables with matching column names** is selected.

5. At the bottom, click **OK**.

**Figure 3.24** Final Data Table (Partial View)

**Import Tables that JMP Does Not Auto-Detect**

Sometimes tables in PDF files cannot be auto-detected. In these cases, you can drag boxes around the columns to group and divide tables.
Chapter 3
Import Your Data
103
Using JMP Import PDF Files

Figure 3.25  Partial PDF File Preview

Notice that rows in the first column were auto-detected as three tables.
Drag the top edge of the third table up until it surrounds the two columns.

Figure 3.26  Creating One Table

In the first table shown in Figure 3.27, drag the far right border to the left until only columns one and two are in the same table, and columns 3 and 4 are outside the table (Figure 3.27).
Drag a box around the remaining two columns to put them in a table (Figure 3.28).

**Figure 3.28** Final Tables on Page One
Chapter 3
Import Your Data

Using JMP Import PDF Files

Note: Groundhog Day Predictions.pdf in the Samples/Import Data folder shows a cleaned-up version of the data that is auto-detected in the PDF Import Wizard.

PDF Preview Red Triangle Options

The section describes the red triangle options on the PDF preview pane.

Global Red Triangle

The red triangle in the upper left corner of the PDF preview window contains two options:

Auto-detect tables on this page If you previously divided or combined tables, this option reverts the changes you made so that the tables are auto-detected again.

Ignore tables on this page Removes the tables from the page. That data is not imported.

Red Triangle on Each Table

Ignore this table Removes the table. The data is not imported.

Number of rows to use as header Specifies the number of header rows in the PDF file that will not be imported as data.

Auto-detect tables on this page If you previously divided or combined tables, this option reverts the changes you made so that the tables are auto-detected again.

Ignore tables on this page Removes the tables from the page. That data is not imported.

Data Table Preview Options

This section describes options that are on the data table preview pane.

Auto-detect tables If you previously divided or combined tables, this option reverts the changes you made so that the tables are auto-detected again.

Ignore all tables Removes the tables from the PDF file. The data is not imported.

Minimum column count Avoids importing tables that have fewer columns than specified.

Minimum row count Avoids importing tables that have fewer rows than specified.

Concatenate all tables into one Combines rows from two or more data tables into one data table.

Individual tables Imports the data into multiple tables.
**Concatenate tables with matching column names**  Combines rows from two or more data tables that have matching column names into one data table.

**PDF Preview Right-Click Options**

See “Red Triangle on Each Table” on page 105 for descriptions of most PDF preview right-click options. The following options are also available:

- **Add column divider**  Creates a column divider at the selected point. Choose this option to create a new column in the data table (for example, if the columns weren’t auto-detected).

- **Remove column divider**  Deletes the column border at the selected point.

- **Add row divider**  Creates a row border at the selected point. Choose this option to create a new row in the data table.

- **Remove row divider**  Deletes the column border at the selected point (for example, if the rows weren’t auto-detected).

**Import XML and JSON Files**

**Preview and Import XML and JSON Data**

The XML Import Wizard imports two types of nested text data: XML and JSON files. Both kinds of files contain structured text that can be nested to represent hierarchical relationships. This wizard helps you pick out the elements of the hierarchy that hold values and elements that determine rows to build a data table.

A useful way to imagine a nested text file: the document is a book of short stories. Some of the short stories might have chapters, others only have paragraphs. Chapters have paragraphs. Paragraphs have sentences. Here’s an example of the full tree for such a book.

```xml
<book>
  <story name="car poll">
    <wheels>4</wheels>
    <para><name>chev</name></para>
    <para><name>ford</name></para>
    <para><name>volk</name></para>
  </story>
  <story name="big class">
    <para><name>ralph</name><height>6</height></para>
    <para><name>billy</name><height>5</height></para>
  </story>
  <story name="cheese" location="NC">
```
To import an XML or JSON file in the XML Import Wizard

1. Select File > Open.
2. Browse to JMP’s Samples/Import Data folder.
3. On Windows, set the file type to XML Data Files.
4. Select Book.xml and click Open.
   The file opens in the XML Import Wizard.
**Note:** “Data (Using Preview)” is selected on the Open Data File window so that the XML file opens in the wizard automatically. You can also import XML and JSON files directly. See “Import XML Files Directly” on page 114.

**Determine How the Data is Imported**

1. In the Row column, select the element that should create a new row in the data table. In this example, the row is created when `<para>` is processed, and the columns are written for that row with their current values.

**Figure 3.29 Row Element Selected in the Row Column**

2. In the Col column, select the data type for that column next to the Col circle.
   - location: **Character**
   - name: **Character** (both instances)
   - price: **Numeric**
   - quantity: **Numeric**

**Tip:** The values in the Sampler column give an idea of what the data type should be.
3. In the Fill column, specify which values fill the cells.

   For location and the both instances of name, click the Fill circle and select +book/story. This setting fills cells with the values until the node <book/>/<story> begins again.
When adding each row to the data table, JMP decides what to do on the next row if no new value is found for a column. For example, the chapter name is not specified for each type of cheese, Missing values follow “american” and “swiss”.

- The Use Once option means use the value once and forget it; the second, third, and fifth rows would be missing if the data is not given again.
- The Fill Forever option means never forget the value but replace it with new values when found.
- You select the +book/story option in this example. This option indicates that, when the opening <book/>/<story> elements are found, JMP fills in the cells until the <book/>/<story> node begins again. The –<element> option refers to the closing tag of the element, which will be the point at which the node ends.

4. In the Format column, click Best next to price, select Fixed Dec, type “2” for the decimal place, then click OK.
5. In the Column Name column, rename columns as shown in Figure 3.33.
6. At the bottom of the window, click **OK**.

   The data is imported in a data table as you specified.

**Figure 3.34** Final Data Table

View the Statistics in the XML Import Wizard

Click **Stat Cols** at the top of the XML Import Wizard to show statistics for the elements.
**Occurs**  The number of times the element occurs. The root element occurs once and is usually not the element to make rows from. You’ll get as many rows from the element as occur.

If you pick multiple rows, then the actual number might be less than the total of the “occurs”; elements that end right after another element ends don’t generate an extra row. For example, if you select both `<para>` and `<chapter>` as row makers, then you don’t get an extra row when the chapter ends right after the last paragraph. But you could get an extra row if there were a `<footnote>` for `<chapter>` after the last paragraph and before the end of the chapter. You’d have to select the footnote column to make that happen.

**Writes**  The number of times the source has a value that could be written. If it is zero, you probably don’t want to make a column from this element, because the values would be all missing.

**Unique**  The number of unique values (less than or equal to the Writes value).

**Repeats**  The maximum number of times this element repeats within its parent element. Bigger repeat values are likely candidates to make rows. If this element repeats and is used as a column, a character column will make a list; an expression column might be even better because it uses {lists} (within curly brackets) to indicate where the values stop and start. A numeric column will get only one of the repeating values.

**Sampler**  The values for the element.

**XML Import Wizard Options**

**Guess**  JMP selects the settings based on the size of data table that you select. **Tall guess** selects an element that will make as many rows as possible (the default setting). **Wide guess** selects an element to make rows that will make as many columns as possible. **Huge guess** selects as many elements to make rows as it needs to get all of the data into the table; it might be bigger than you expect.

**Undo**  Reverses the last change made to the window.

**Redo**  Recalls the last change made to the window.

**Name Col**  Shows or hides the Column Name column.

**Stat Cols**  Shows or hides statistics for the elements in the tree.

**Stack**  Applies to nodes that repeat within a parent node that is creating rows. By default, extra values are stored in a single table cell separated by commas. If this option is selected, repeating values are stacked in extra rows.

**Import Preview**  Shows a preview of the imported data according to the options that you select.
Import Your Data

Chapter 3

Import XML and JSON Files Using JMP

Source View  Shows the source XML document.

Script View  Shows a JSL script of the settings that you select.

Import XML Files Directly

JMP can detect the structure of an XML or JSON file and import it directly into a data table. If you don’t want to see a preview of the data in the XML Import Wizard, use this method.

1. On Windows:
   – Select File > Open.
   – Set the file type to Data Files.
   – Select the file.
   – Next to Open as, select Data (Best Guess).

2. On macOS:
   – Select File > Open and select the file.
   – Click Options on the lower left corner of the window.
   – Select Data (Best Guess).

3. Click Open.

The file opens as a data table.

If you are not satisfied with the results, consider using the XML Import Wizard to customize the import. See “Preview and Import XML and JSON Data” on page 106.

Note: You can import XML or JSON text from a script editor window by selecting Edit > Import as Data. If nothing is selected in the file, then the import is based on the file extension. If text is selected, then JMP attempts to parse the text as JSON or XML. Otherwise, the text is imported into a CSV file.

Import JSON Files Directly

A JSON file consists of name and value pairs that are imported as column headings and data. You can import a JSON files with the XML Import Wizard (“Preview and Import XML and JSON Data” on page 106) or directly.

To open a JSON file directly, follow these steps:

1. On Windows:
   – Select File > Open.
   – Set the file type to JSON Data Files.
Chapter 3 Import Your Data

Using JMP Build SQL Queries in Query Builder

1. Select the file.
2. On macOS:
   - Select **File > Open** and select the file.
   - Click **Options** on the lower left corner of the window.
   - Select **Data (Best Guess)**.
3. Click **Open**.

The file opens as a data table.

Notes:
- The imported JSON file does not contain date, time, currency, geographic, percent, and scientific information to determine the column format. If you want to use any of these formats, right-click the numeric column, select **Column Info**, and change the format in the Data Type list.
- Member names in name-value pairs are case insensitive.
- The JSON import code does not use the JSON file’s numeric, Boolean, or string distinction. Instead, it determines the entire column can be numeric or not. You can explicitly specify the column as character if the guess is not what you want.
- For nested items, JMP repeats the outer item for each row.
- The file cannot have an empty array element. The name must be quoted before the colon in the name-value pair.
- The JSON standard accepts decimal numbers with decimal points.

Build SQL Queries in Query Builder

Query Builder is the preferred method for selecting and importing data from a SQL database without writing SQL statements. You can preview the data before importing it into a data table. Share your queries so that other users can customize and run the queries.

Query Builder provides an alternative to writing your own queries using the File > Database > Open Table feature. However, you can also start building a query in Query Builder and then add your own SQL statements.

SAS Query Builder is also available for querying SAS data sets on SAS servers. See “Open SAS Data Sets with SAS Query Builder” on page 148.

Notes:
- Database table names that contain the characters $# -/+/%&| ;? are not supported.
• The Value Order column property is not supported. Consider writing a script in the Post-Query Script window to sort the rows.

**Connect to a SQL Database**

Set up the ODBC connection through the Windows Control Panel or inside JMP.

1. Select **File > Database > Query Builder** to display the Select Database Connection window. The Connections box lists data sources that you connected to in the current JMP session.
2. If the desired data source is *not* listed in the Connections box, click **New Connection** to choose a data source. The method of choosing a data source depends on your operating system and the ODBC driver. See “Connect to a Database” on page 165.
3. Select a table or schema from the Schemas - Tables box and click **Next**. Query Builder examples are based on a table named SQBTest, which contains movie rental data.

**Figure 3.35  Select the Database Schema**

![Select Database Schema](image)

**Tip:** To find the table in a long list, enter the name in the search box above the schemas. You can also search for tables above the list of tables. The red triangle menu provides options for matching case and searching with regular expressions.

**Select Tables from a SQL Database**

After connecting to the SQL database, select the tables that you want to query. Either select a primary table or join several tables to query them all.
By default, JMP attempts to join tables based on key relationships that are assigned in the tables.

- A primary key identifies a column that uniquely describes the data (for example, a customer ID number). All rows from the primary table are included in your query.
- A foreign key in a secondary table matches the primary key in one of the joined tables. Only matching rows from the secondary table are included in your query.

If there are no keys, data are matched by column name, which joins the two tables. By default, only matching rows from the secondary tables are included in the query.

This example shows how to join multiple tables. However, you can also build a query using a single table. In this case, joining is not necessary.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165.
2. Select the schema from the Schemas - Tables list.
   - If you also select a table, that table will be the primary table after you click Next.
3. In the Select Tables for Query window, select **g6_Customers** from the Available Tables list, and then click **Primary**.
   - The Columns tab shows that CustID is the primary key. The data is indexed, which speeds up the query.
4. Select **g6_Movies** and **g6_Rentals** from the Available Tables list, and then click **Secondary**.
   - The Left Join icon indicates that the tables were automatically joined (Figure 3.36). CustID is the primary key in g6_Customers and matches a foreign key in one of the other tables.

**Tip:** After you add a primary or secondary table, click **Add Related Tables** to add tables that have matching columns. The button is unavailable when no related tables are found or when a primary or secondary table is not selected.
Figure 3.36 shows the completed window.

**Figure 3.36** Selecting Primary and Secondary Tables

Tip: To find the schema in a long list, enter the name in the search box above the schemas. You can also search for tables above the list of tables. The red triangle menu provides options for matching case and searching with regular expressions.

5. Click the **Table Snapshot** tab for each table to preview the data.
6. Below the primary and secondary tables, click **Preview Join** to see a preview of the table that was created from the specified joins.

**Tips:**

- The icon next to a secondary table indicates that the table is not joined in the query. Click the **Edit Join** button to specify the columns to join. If you cannot find columns to join, click the **Remove** button to remove the table. See *Edit the Conditions for Joining Tables*.

- On the Columns tab, the Key column might show multiple keys; some columns can be both primary and foreign keys. A unique key icon does not appear next to primary keys, because all primary keys are unique.

- On the Columns tab, the Reference is specified for foreign keys that match primary keys in another schema. The reference is the name of the schema and column.

- Click **Change Data Source** to query a different schema or database.

- To join data from different sources (for example, a database and Microsoft Excel), use Query Builder to import the database data into a data table; import the Excel data into a data table; use JMP Query Builder in the Tables menu to query and join the tables.

- When you import a table that contains a primary key, the Link ID column property is added to the column in the data table. The column property enables you to virtually join data tables. See “**Virtually Join Data Tables**” on page 374 in the “Reshape Your Data” chapter.
Edit the Conditions for Joining Tables

In the Select Tables for Query red triangle menu, Auto join Database Tables is initially selected. JMP automatically joins database tables based on key relationships or matching column names.

If there are no keys, or when column names do not match, click **Edit Join** to specify the columns to join.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

**To edit the conditions for joining tables**

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165.
2. In the Select Tables for Query window, select **g1_books** as the Primary table and **g1_charges** as the Secondary table.
   
   The **x** icon next to the secondary table indicates that the table is not joined in the query.
3. Select **g1_charges** in the Secondary table pane and click **Edit Join**.
   
   The Add Condition window appears.
4. In the Left Column list, select **g1_books**.
5. Select **Book ID** from the Left Column box.
6. Select **ID** from the Right Column box.
7. Make sure that the equal sign is selected between the two boxes.

**Figure 3.38** The Add Condition Window

8. Click **Next**.

   The Edit Join window shows that non-matching rows from g1_books will be included in the data table. Rows that are only in g1_charges will be omitted.

   To do a full join and import all rows, you would select **Include non-matching rows from g1_charges**. If only one of the non-matching options is available, the database does not support full joins.
9. Click **OK**.

**Note:** The **OK** button is unavailable until all of the secondary tables are joined.
To prevent tables from joining automatically

- Deselect **Auto join Database Tables** from the Select Tables for Query red triangle menu above the primary table.
- If you frequently query large databases, deselect **Automatically join tables added to a query** in Preferences > Query Builder to prevent memory issues.

**Build an SQL Query**

After selecting database tables, you either import the data or build a query. Query Builder enables you to interactively create the database query rather than write SQL expressions.

After selecting database tables (and joining them if necessary), click **Build Query** to open the Query Builder window. You can continue to refine the query by selecting which columns to include and specifying criteria for sampling and filtering. You can also save the query to edit and run again later.

The columns from all database tables appear in the Available Columns list. Prefixes such as t1 and t2 (also called **aliases**) associate each column with the corresponding database table.

To skip the Query Builder step and import all data, click **Import Now** instead.

**Note:** The JMP Query Builder in the Tables menu provides many of the same options but lets you query and join JMP data tables. See “Query and Join Data Tables with JMP Query Builder” on page 371 in the “Reshape Your Data” chapter.

**Select Columns from the Database Table**

Suppose that you want to view movie rentals by movie genre, rating, and demographic data such as marital status and age.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165.
2. In the Select Tables for Query window, select **g6_Customers** and click **Primary**.
3. Select **g6_Movies** and **g6_Rentals** and click **Secondary**.
4. Click **Build Query** to show the Query Builder window.
6. Click **Add** on the Included Columns tab.
Figure 3.39 Selected Columns

Notes:

– When a query contains eight tables or more, a search box appears above the table names near the upper left corner. To find a column in a long list, enter the name in the search box below Available Columns. The red triangle menu provides options for matching case and searching with regular expressions. To hide the search box, deselect Show Search Box from the Available Columns red triangle menu.

– Reference columns no longer appear in the Available Columns list because they are not supported in queries.

– You can change the width of the column by selecting an option from the Format list in the Included Columns list.

7. Select the SQL tab below the columns to view the SQL statements for your query. This code is saved as a data table property after you run the query.

8. Click Save in the lower right corner.

   Your work is saved as g6_Customers.jmpquery, which you can open later to return to this point or to run the query.

9. Click Run Query to import the data.

   The data table includes the following scripts:

   – Run the Source script to reconnect to the database and import the data.
– Run the Modify Query script to open the query in Query Builder.
– Run the Update From Database script to re-import and refresh the data.

**Tips:**

- To rename a column, double-click the JMP Name in the Included Columns tab and enter a new name.
- To rename an alias, right-click the table in the Select Tables for Query window and select **Change Alias**. Aliases are not case sensitive.
- The query runs in the background unless you deselect **Run queries in the background when possible** from the Query Builder ODBC preferences. You can also check the progress of all ODBC queries by selecting **View > Running Queries**.

**Note:** For SAS Query Builder, all queries run in the foreground.

- Deselect **Update preview automatically** if the preview loads too slowly. Click **Update** below the Query Preview tab to update the data view. Consider changing the Preview options in the JMP Query Builder preferences if you frequently work with large databases. Consider limiting the maximum number of rows that can be previewed. In the JMP Query Builder preferences, change the value of **Maximum number of rows for previews**.
- To omit duplicate rows from the database, select **Distinct rows only** on the Included Columns tab.

**Maintain Compatibility with JMP 12**

If you add a JMP 16 feature to a query, that query will no longer load in JMP 12. If you are using JMP 13, but you need to create queries that will still run in JMP 12, select **Keep this query compatible with JMP 12** in the Query Builder Preferences. After you select the option, features that create compatibility problems are hidden in Query Builder.

When you are ready to move JMP 12 queries to a later version, deselect this preference.

**Create a Computed Column**

You can create a new column from existing columns. You might calculate the mean for two columns and store the mean in a new column. Date-time values might be in the wrong format. Click the Available Columns red triangle, select **Add Computed Column**, and create the new column in the formula editor.

Suppose that you want to calculate the maximum number of times you can watch a movie during the rental period. You are querying a database that contains the length of each movie and number of days the movie was checked out. This example shows how to create a new computed column from these data.
Note: The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165.

2. In the Select Tables for Query window, select **g6_Rentals** as the Primary table and **g6_Movies** as the Secondary table.

3. Click **Build Query** to show the Query Builder window.

4. Click the Available Columns red triangle and select **Add Computed Column**.
   
The Computed Column window appears. The window contains the JMP Formula Editor.

**Figure 3.40** Computed Column Window with Formula Editor

---

**Notes:**

- Operators and functions are provided in the list on the left side of the Formula Editor (Figure 3.40). In some instances, you might need to change the server type based on your database.

- The Operators list does not provide a Concatenate (||) operator. You must type the formula in the Formula Editor box.

5. From the g6_Rentals list on the left, select **Days Out** and click the multiplication (×) button.
Figure 3.41  Computed Column

6. Select the blank box, type (24 * 60, and press Enter.

   This formula multiplies the number of minutes in an hour by the number of minutes in
day. Notice that when you type the first parenthesis, then second one is automatically
inserted.

Figure 3.42  First Portion of the Formula

7. Click the outer box to select the entire equation and click the division button.
8. Select g6_Movies from the list on the left and then select LengthMins.

Figure 3.43  Second Portion of the Formula

9. Click OK.

   A new column named Calc1 is created.

10. Right-click the column and select Rename Column.
11. Type MaximumTimesWatched and click OK.
12. In the Available Columns list, select MaximumTimesWatched and click Add.
13. Select t2.Name and click Add.

   On the Query Preview tab, notice that Nanny McPhee can be watched 160 times while the
movie is rented.

Group the Common Values

You can combine (or group) common values in a column before importing the data into JMP.
To group common values, select an Aggregation function to determine how the common
values are calculated.

Note: Aggregation support is based on your database. See the database documentation.

Suppose that you are interested in the number of times a specific movie was rented. In this
example, the count for each item number is calculated, and common movie values are
grouped into single rows.
1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “**Connect to a Database**” on page 165 for.

2. In the Select Tables for Query window, select **g6_Movies** as the Primary table and **g6_Rentals** as the Secondary table.

3. Click **Build Query** to show the Query Builder window.

4. In the Available Columns box, select **t1.Name** and **t2.ItemNo** and click **Add**.

5. Select **t2.ItemNo** and select **Count** from the Aggregation list.

   The Group By check box is selected for **t1.Name**. All instances of a specific movie name will be grouped into one row.

   **Figure 3.44** Grouped Columns

6. Click **Run Query** to import the data.

7. In the data table, right-click the **Count-ItemNo** column and select **Sort > Descending**.

   Scarface was rented most frequently.
Figure 3.45  Partial View of the Sorted Count-ItemNo Column

<table>
<thead>
<tr>
<th>Name</th>
<th>Count-ItemNo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scarface</td>
<td>15991</td>
</tr>
<tr>
<td>Rambo</td>
<td>15643</td>
</tr>
<tr>
<td>Nanny McPhee</td>
<td>15289</td>
</tr>
<tr>
<td>Marmaduke</td>
<td>15255</td>
</tr>
<tr>
<td>A Bug’s Life</td>
<td>15128</td>
</tr>
<tr>
<td>Diary of a Wimpy</td>
<td>14989</td>
</tr>
<tr>
<td>Cars</td>
<td>14905</td>
</tr>
</tbody>
</table>

Tips:

• To clear the grouped rows, select **None** from the column’s Aggregation list.

• The DISTINCT Aggregation functions show only rows that contain distinct values. Rows with duplicate values are omitted. These functions are useful when a database contains many duplicate values.

Import a Sample of the Data

With large databases, consider sampling the data. Sampling returns a subset of rows and decreases the query time. The database query runs, and a smaller portion of data are imported based on options that you select on the Sample tab.

Sampling methods differ based on the database vendor.

• SQL Server supports block sampling by default. A block sample takes an entire page of rows (such as all rows on pages 1 and 5). If you select 1,000 rows, approximately 1,000 rows are imported.

• Oracle and other databases support row sampling. If you select 5,000 rows, between 4,800 and 5,200 rows per sample are typically imported, based on how Oracle cycles through the data.

For major database vendors, JMP detects the capabilities and provides vendor-specific options when possible. Features that are unsupported by the vendor are unavailable on the Sample tab.

Suppose that you want to import a sample of the data. In this example, you select 5,000 random rows.

Note: The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165 for.
2. In the Select Tables for Query window, select g6_Rentals as the Primary table and g6_Movies as the Secondary table.

3. Click Build Query to show the Query Builder window.

4. Click the Add All button on the Included Columns tab.

5. Click the Sample tab and select Sample this result set.

6. Select Random N Rows and type 5,000.

   In the Sample By area, Blocks or Pages is the only option based on which type of sampling the database supports.

7. Click Run Query to import the data.

   The new data table consists of approximately 5,000 rows. With block or page sampling, you might get a sample of 4,900 rows one time and 5,600 rows the next time.

Tips:

- To re-create the same sample set each time you run a query, set the Seed value to any positive integer up to 64,000. Suppose that you want to query movie rentals by gender. Type 1 as the Seed value and run the query. The distribution of male customers in the results is low. Type 2 as the Seed value and run the query again. Repeat this process to find the Seed value that results in a similar distribution of males and females.

- To add individual columns to the Included Columns tab, right-click the column and select Include Column or click the Add button.

Select Filters to Import a Subset of the Data

Add filters to import a subset of values from the selected filters into the data table. Some filters are not available if the query is compatible with JMP 12. See “Maintain Compatibility with JMP 12” on page 123.

Filters for Both Continuous and Categorical Columns

Simple Comparison Matches values using the specified operator.

   Age > 14 matches ages that are greater than 14.

Range Matches a range of values using the specified operator.

   12 ≤ Age ≤ 17 matches ages that are between 12 and 17.

Is NULL or Is Not NULL Matches missing values.

   Either NULL or not NULL matches missing values and non-missing values.

Custom Expression Enables you to write your own SQL expression.
( ( t2.Gender IN ( 'F' ) ) AND ( t2.Age >= 20 ) AND ( t2.Age <= 50 ) )

matches the F Gender. It also matches Age between 20 and 50.

Filters that are Only for Categorical Columns

**List Box**  Displays a list box from which you select one or more values. List Box is the default filter for categorical columns based on the Query Builder preferences.

**Manual List**  Enables you to enter the column values.

**Check Box List**  Displays a check box list.

**Note:** List Box, Manual List, and Check Box List include a **Not in list** option that enables you to retrieve rows that do not match the selected values.

**Contains**  Matches a string that contains or does not contain the specified value. **Contains Comedy OR Romance** matches Comedy and Romance.

For most categorical columns, the filter is a List Box by default. For columns that contain over 1,000 levels, the Contains filter is automatically selected. You can change the number of levels in the Query Builder preferences.

**Like or Not Like**  Matches a string that is similar to or not similar to the specified value. Supports the `%` wildcard (zero or more characters) and `_` wildcard (exactly one character).

**Genre Like %com** matches any number of characters before “com”, as in “RomCom”. To also match “Comedy”, use `%com%` or **Contains com**.

**Match Column Values**  Matches the specified column value. Select the table and then select the columns. The **Select non-matching** option enables you to filter all rows except for the selected rows. See “Import Matching Data from an Existing Data Table” on page 131 for an example.

This example shows how to import data for age 30 and over customers, and movies in the RomCom and Comedy genres.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165.
2. In the Select Tables for Query window, select **g6_Rentals** from the Available Tables list, and then click **Primary**.
3. Select **g6_Customers** and **g6_Movies** and then click **Secondary**.
4. Click **Build Query** to show the Query Builder window.
5. In the Available Columns box, select \texttt{t2.Gender}, \texttt{t2.Age}, and \texttt{t3.Genre}, and then click \texttt{Add} on the Included Columns tab.

6. Select all columns on the Included Columns tab and click \texttt{Add Selected Items to Filters}.
Filters for the columns appear in the Filters outline.

7. Set the \texttt{t2.Age} filter to $\geq 30$.

8. Click the \texttt{t3.Genre} red triangle and select \texttt{Like}, type \%com\%, and press \texttt{Enter}.

The \% wildcards match any number of characters before and after “com”. On the Query Preview tab, notice that movies in both the RomCom and Comedy genres are shown.

Figure 3.46 Selecting Filters

9. Click the Filters red triangle and select \texttt{All Prompt on Run}.

Users who run the query can customize the filters.

10. Click \texttt{Run Query}.

11. In the Query Prompts window, click \texttt{OK} to apply the preselected filters and import the data.

Notes:

- For most categorical columns, the filter is a list box by default. For columns that contain over 1,000 levels, the Contains filter is automatically selected. You can change the number of levels in the Query Builder preferences.

- The Conditional option in a filter’s red triangle menu enables you to filter data within hierarchical categories. For example, suppose that you have a State filter and a City filter.
To select a state and then display only cities that are in that state, click the City red triangle and select Conditional.

- The Inverse option at the top of the Filters list enables you to select all but the specified rows for all filters. The option is unavailable for filters that select all rows.
- “<Blank>” in the filter list indicates that the database contains a missing value for that column.
- To create a filter for large columns of categorical data, JMP attempts to determine the number of rows in the table.
  - The Query Builder preference called Retrieve category levels for tables whose size cannot be determined is selected by default so that JMP automatically retrieves the levels. If you deselect the preference, the Contains fallback filter type in the Query Builder preferences is selected.
  - If the categorical column has more than 1 million rows, JMP does not automatically retrieve the unique category levels for the filtered column. The Query Builder preference called Maximum rows in table for which category levels will be automatically retrieved supports a minimum of -1 (no limit) and a maximum value of 1 billion rows.
- The default filter for categorical columns is a list box unless the Keep this query compatible with JMP 12 Query Builder preference is selected.

Import Matching Data from an Existing Data Table

You can also select rows from an open data table that match a column in your query. Consider a database of airline data. The database includes data such as flight duration and tail number. You also have a data table that includes tail number data. Use the Match Column Values filter to import only data for matching tail numbers.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

1. Select Help > Sample Data Library and open Air Traffic.jmp.
2. Select File > New > Database Query, connect to the database, and select the SQBTest schema. See “Connect to a Database” on page 165.
3. In the Select Tables for Query window, select g5_AIRLINE_ONTIMEPERF from the Available Tables list, and then click Primary.
4. Click Build Query to show the Query Builder window.
5. Click Add All on the Included Columns tab.
6. Select t1.TailNum on the Included Columns tab and click Add Selected Items to Filters.
7. Click the t1.TailNum red triangle in the Filters column, select Filter Type, and then select Match Column Values.
8. Select Air Traffic below Match values from table.
9. Select the Tail Number column and then select All rows (38,118) from the list.
   The data view on the Query Preview tab updates to show the filtered values.
10. Click Run Query to import the data.
    The data table includes only data for rows that are in the Tail Number column.

Write a Custom Expression to Import a Subset of the Data

In addition to selecting filters to subset the data, you can write custom SQL expressions if you do not want to use the filters that are provided.

Note: The Query Builder examples are based on a database that is not installed with JMP.

1. Select the columns that you want to filter (described in “Select Filters to Import a Subset of the Data” on page 128).
2. Click the Filters red triangle and select Add Custom Expression.
3. Type the following text in the Custom Expression box:
   \(( (t2.Gender IN ( 'F' ) ) AND (t2.Age >= 20) AND (t2.Age <= 50) ) )\)
4. Click outside the Custom Expression box to update the Query Preview tab.
   This expression matches the F Gender. It also matches Age between 20 and 50.

Figure 3.47 Writing a Custom Filter Expression
Sort the Selected Data

You can sort the rows in specific columns by values to control how the data appear in the data table. In this example, you sort the Married column in descending order and sort the data by age and then height.

**Note:** The Query Builder examples are based on a database that is not installed with JMP.

1. Select **File > New > Database Query**, connect to the database, and select the **SQBTest** schema. See “Connect to a Database” on page 165 for.
2. In the Select Tables for Query window, select **g4_bigclass** as the Primary table.
3. Click **Build Query** to show the Query Builder window.
4. On the Included Columns tab, click **Add All**.
5. Select t1.age and t1.height and click **Order by the Selected Items**.

The columns appear in the Order By outline in the right column.

The columns are sorted by age first (youngest to oldest) and then height (shortest to tallest).
6. In the Order By outline, select t1.height and then click \textit{Sort the values in descending order} below the columns. The height column is sorted from tallest to shortest.

7. Select t1.height and click \textit{Move the Selected Items Up in the List}. The height column is sorted first. Values in the age column are sorted within each level of height. For a height of 68, age is sorted from 14 to 17.
Figure 3.49 Result of Reordering Columns

View the Query Status

On the Query Status tab, view the status of a query as it runs in the background. The query name, SQL statements, and number of processed records appear. You can stop a query at any time and view only the processed records. To view background queries from other JMP windows, select View > Running Queries. The status details are unavailable if you deselect Run queries in the background when possible from the Query Builder preferences.

Note: For SAS connections in Query Builder, all queries and query previews run in the foreground.

Write a Post-Query Script

On the Post-Query Script tab, write a JSL script that runs after you run the query. For example, you might want to import the data and then create a distribution.

Distribution( Column( :age, :gender ) );

This script is part of the Source script in the final data table.

Save and Run a JMP Query

Save your query as a .jmpquery file to modify or run the query later. You are prompted to enter the password if the server connection string does not specify it. The .jmpquery file can also be opened and run by a JSL script.
After you build a query, click **Save** in the lower right corner to save the settings as a .jmpquery file. Clicking **Save** again overwrites the file with your latest changes. Clicking **Save As** saves the query in a new .jmpquery file.

**Run a JMP Query**

A query file opens in Query Builder by default, where you modify the query and then run it as needed to import the data. After you are satisfied with the query, you can configure it to run when opened instead of opening in Query Builder.

When you are building the query, select **Run on Open** from the red triangle menu next to the Query Name box in the upper left corner.

To override the Run on Open setting, press Ctrl (Windows) or Command (macOS) before opening the file from the file system. On Windows, you can also right-click the query in the JMP Home Window and select **Edit Query**.

**Use a Saved Query as a Template**

You can also use the .jmpquery file as a starting point for a new query. This option prevents you from overwriting your original query if you accidentally click **Save**. It works the same as clicking **Save As** after you modify the query.

1. Right-click the .jmpquery file in the JMP Home Window’s Recent Files list.
2. Select **Open as Template**.
3. Modify the query and click **Save** to create a new .jmpquery file.

**Note:** The .jmpquery file contains database login information. You must have set up the database connection before running the query. See “Connect to a Database” on page 165.

**Open the Selected Data**

After you specify the columns and data to import from the SQL database, click **Run Query** to open the data in a data table. The SQL statements are saved as a table variable. The following scripts are available:

**Source**  Runs the query.

**Modify Query**  Opens the query in Query Builder, where you can change which columns and data are imported and further customize the query.
**Update From Database**  Connects to the database to refresh the data and then run the query. If the data table and database table contain the same number of columns, values in the existing data table are updated when the database is refreshed.

The existing data table is also updated when only formula columns follow the last column that is refreshed.

Otherwise, the updated data appears in a new data table.

**Query Builder Red Triangle Options**

The Query Builder red triangle menu provides scripting and custom SQL options. The modify and run scripts are always automatically saved in the final data table.

- **Copy Modify Script**  Copies a script to the computer’s clipboard that lets you modify the query.

- **Copy Run Script**  Copies a script to the computer’s clipboard that lets you refresh the data and run the query.

- **Save Modify Script to Script Window**  Saves the Modify Query script to the script window.

- **Save Run Script to Script Window**  Saves the Update From Database script to the script window.

- **Run on Open**  Runs the query when you open the query file.

- **Convert to Custom SQL**  Shows the query statements in a new script editor window. You must remove prompting filters before selecting this option.

  When you save the query from the Custom SQL window, the custom SQL is saved. Interactive components that were present before you customized the query are not saved. Revert to Interactive is also unavailable on the red triangle menu.

- **Keep this query compatible with JMP 12**  Makes subsequent changes to the query compatible with JMP 12. Features that cause compatibility issues with JMP 12 are hidden while you edit the query. After you deselect this option and make a change that is supported only in JMP 13 and later, this option is no longer available.

  The JMP Query Builder preferences include the same option, which is deselected by default. When you open a query in JMP 16 that is marked as JMP 12 compatible, features that create compatibility problems are hidden regardless of how the preference is set.

- **Revert to Interactive**  Displays the interactive query in the Query Builder window. Changes that you made on the Custom SQL tab are not saved when you revert.
Write SQL Statements in Query Builder

Query Builder enables you to interactively create SQL queries without writing SQL statements. You can also build a query in Query Builder and then add custom statements to the query.

Note: The Query Builder examples are based on a database that is not installed with JMP.

1. Select File > New > Database Query, connect to the database, and select the SQBTest schema. See “Connect to a Database” on page 165.
2. In the Select Tables for Query window, select g6_Rentals as the Primary table.
3. Select g6_Movies and g6_Customers as the Secondary tables.
4. Click Build Query to show the Query Builder window.
5. Click the Add All button on the Included Columns tab.
6. Click the Query Builder red triangle and select Convert to Custom SQL and click OK.
   The SQL that Query Builder generated appears on the Custom SQL tab.
7. Click before the semicolon and type the following SQL statement:
   
   WHERE ( ( ( t2.Gender IN ( 'F' ) ) AND ( (t2.Age >= 20) AND (t2.Age <= 50) ) ) )
   
8. Click Run Query to import the data into JMP.
   The data table scripts include the custom query.

Note: If you select Revert to Interactive from the red triangle menu, the changes that you made on the Custom SQL tab are not saved. If you save the custom query and reopen it, Revert to Interactive is not available.

See “Structured Query Language (SQL): A Reference” on page 170 for a brief primer of SQL statements.

Import Data from SAS

You can connect to a SAS server and work directly with SAS data sets.

Java Runtime Environment (JRE) Requirements

- On Windows, Java Runtime Environment (JRE) 7 or later must be installed on your computer to access SAS. However, JRE 7 does not need to be specified as the current version.
• On macOS, JRE 7 or later must be installed for SAS integration.

**Note:** On Windows, the bitness of the JRE must match that of JMP. For example, 64-bit JMP communicates with both 32-bit and 64-bit SAS if the 64-bit JRE is installed.

### SAS Menu Options

The following options are in the File > SAS menu.

**Browse Data**   
Browse and import data residing on a SAS Server.

**SAS Query Builder**   
Select and import data on a SAS server without writing SQL statements. See “Build SQL Queries in Query Builder” on page 115.

**Export Data to SAS**   
Export JMP data tables to a SAS Server.

**Browse SAS Folders**   
Browse and run SAS stored processes or open Metadata-defined data tables.

**New SAS Program**   
Opens a script window for writing and submitting SAS code.

**Submit to SAS**   
Sends SAS code directly from JMP to the currently active SAS server.

**Open SAS Log Window**   
Opens a SAS log window for the active SAS server.

**Open SAS Output Window**   
Opens a SAS output window for the active SAS server. This window shows recent SAS output.

**Server Connections**   
Administer connections to SAS servers.

You can also find shortcuts for SAS options on the SAS page of the JMP Starter, and there is a SAS toolbar. You can save certain settings pertaining to SAS Integration on the SAS Integration page of the Preferences window (**File > Preferences**). For more information about setting your SAS Integration preferences, see “Preferences for SAS Integration” on page 712 in the “JMP Preferences” chapter.

### Import SAS Data Sets

SAS data sets are saved in one of many SAS formats:

• Windows supported formats are .sas7bdat and .sas7bxat.
• macOS supports reading and writing .sas7bdat files.
• Windows and macOS support reading and writing .xpt files.
When you open a data set in JMP, the file opens as a data table. JMP uses SAS variable names as column names by default. To use variable labels in a specific file on Windows, select the option when you open the file (see step 5 below).

The following ISO date formats are supported for .sas7bdat files: B8601DA, B8601DN, B8601DT, B8601DZ, B8601LZ, B8601TM, B8601TZ, E8601DA, E8601DN, E8601DT, E8601DZ, E8601LZ, E8601TM, E8601TZ, and IS8601DA. If the date format is not supported, the data is imported with the Scientific Notation format.

The following date formats are supported for .xpt files: BEST, DATE, DATETIME, DAY, MMDDYY, DOWNAME, HHMM, HOUR, TIME, YYMMDD, DDMMYY, MMSS, DTDAT, IS8601DA, E8601DA, PERCENT, and DOLLAR.

To open a SAS data set from JMP:

1. Select File > Open.

2. (Windows only) Select SAS Data Sets from the list next to File name as shown in Figure 3.50.

   **Note:** SAS variable names and formats are preserved and can be saved after changes are made to the SAS data set. See “Save JMP Data as a SAS Data Set” on page 573 in the “Save and Share Your Data” chapter.

3. Select the file.
Chapter 3 Import Your Data

Using JMP Import Data from SAS

Figure 3.50 Open SAS Data Set

Note: To select the columns to import, click the arrow on the Open button and select Select columns.

4. (Optional) Select any of the following options:

   SAS variable labels   Uses the SAS variable labels (instead of variable names) as the column names in the JMP data table.

   SAS variable names   Uses the SAS variable names (instead of the labels) as the column names in the JMP data table.

5. (Optional on Windows) Select any of the following options:

   Apply table and column properties from SAS 9.4 extended attributes   If the SAS server supports extended attributes (SAS 9.4), includes the extended attributes when storing JMP metadata. This setting overrides the SAS 9.4 Extended Attributes preference on the SAS Integration page.
Select this filter the next time this window is invoked  Sets the default file type choice to the option that you select next to the File name list. If selected, the default file type will be SAS Data Sets the next time you reach this window.

6. (Optional) Select any of the following for a SAS Transport (.xpt) file:

Select member  Lets you enter the name of a specific member, or table, for JMP to open. On macOS, select Member Tables > Specified and then enter the name.

Open all members  Opens all members, or tables, in the transport file. On macOS, select Member Tables > All.

Save all members  Saves the file as a JMP file as soon as you open it. The file is saved to the same directory where the SAS transport file was opened. On macOS, the option is Save all.

Select columns  Tells JMP to open only certain columns from the transport file. Select the columns that you want to import from the list that appears. On macOS, the option is Select columns before opening.

7. Click Open.

Note: If you are importing date variables from a SAS file, JMP looks for a SAS date format and translates it to a JMP date column.

Create SAS Transport Files in SAS from JMP

JMP can open SAS transport files that were saved using the SAS XPORT engine. For example, below is sample SAS code that creates a transport file called test.

Note: misc and work are SAS libref names.

data test;
input name $ age weight;
cards;
Susan 12 72
Melanie 10 68
Jonathan 11 77
Sheila 13 67;
libname misc xport 'C:/test.xpt';
proc copy in=work out=misc;
run;
Connect to SAS from JMP

You can either connect to a SAS Metadata Server or directly to a SAS Workspace Server. Once connected to a SAS Metadata Server, you can browse through SAS servers, libraries, and data sets.

**Note:** SAS Server version 9.4 is the default setting in the JMP SAS Integration preferences though you can change the version to 9.3 if necessary.

To begin, select **File > SAS > Server Connections**. The SAS Server Connections window shown in Figure 3.51 appears. All connections are made in this window.

**Figure 3.51 SAS Server Connections**

The following sections describe how to connect to a SAS server.

- “Connect to a SAS Metadata Server from JMP” on page 144
- “Connect to a Remote SAS Workspace Server from JMP” on page 146
- “Connect to a SAS Environment from JMP (Windows Only)” on page 147
- “Connect to SAS on Your Local Machine from JMP (Windows Only)” on page 148
Connect to a SAS Metadata Server from JMP

**Note:** You can be connected to only one Metadata Server at a time. If you make a second connection, your first one is disconnected.

**To connect to a Metadata Server**

1. Select **File > SAS > Server Connections**. The SAS Server Connections window shown in Figure 3.51 on page 143 appears.
2. Select the version for the SAS Server. Your SAS Metadata Server administrator should have this information.
   SAS Server version 9.4 is selected by default based on the JMP SAS Integration preferences.
3. Select the profile that you want to use.
   If you do not have a profile set up, see “To create or modify a SAS Metadata Server profile” on page 145.
4. Click **Connect**.
   If JMP is unable to establish a connection, an error message appears. Common reasons are invalid user names or passwords. If you need to update the information for the profile, see “To create or modify a SAS Metadata Server profile” on page 145.
5. Click **Close**.

Once you are connected to a SAS Metadata Server, you can connect to any SAS Workspace Servers that the Metadata Server offers.

**To connect to a SAS Workspace Server (Windows only)**

1. Select **File > SAS > Server Connections**. The SAS Server Connections window shown in Figure 3.51 on page 143 appears.
2. Select the Workspace Server to connect to.

**Figure 3.52** Open a Connection to a Workspace Server
3. Click Connect.

Under Open Workspace Server Connections, the Workspace Server is shown as the current active connection.

Figure 3.53  Current Active Connection

4. Click Close.

To change the active connection

Note: The active connection is what is used to submit SAS code or handle SAS script commands.

To change the active connection, you first need to be connected to more than one server. Follow the instructions in “To connect to a SAS Workspace Server (Windows only)” on page 144 to add two or more server connections.

1. In the Open Workspace Server Connections section, click the drop-down menu and select the desired server.
2. Click Set as Active.
3. Click Close.

Tip: You can change the active server at any time.

To disconnect from a SAS Workspace Server

1. In the SAS Server Connections window, select the Workspace Server to disconnect under Open Workspace Server Connections.
2. Click Disconnect.

To disconnect from a SAS Metadata Server

1. In the SAS Server Connections window, select the Metadata Server to disconnect.
2. Click Disconnect.

To create or modify a SAS Metadata Server profile

1. In the SAS Server Connections window, select the SAS Server Version.
2. Click **Manage Profiles**.
3. Click **Add** to add a new profile, or click **Modify** to change a profile’s settings.

   The Create Profile or Modify Profile window appears. If you are adding a new profile, all fields are empty except the Authentication domain field, which contains DefaultAuth, and the Port field. If you are modifying a profile, the fields contain the current information.

   ![Create or Modify a Metadata Server Profile](image)

4. Fill in the information needed to connect to a SAS Metadata Server. Your SAS Metadata Server administrator should have this information.

   - **Profile name**  Select a name for this profile. This name is shown in the list of profiles.
   - **Description**  (Optional) You can enter a short description of this profile.
   - **Machine**  The name of the machine that hosts the Metadata Server. (Example: myserver.mycompany.com)
   - **Port**  The port through which you should connect to the machine. (Example: 8561)
   - **Use Integrated Windows Authentication**  Select this option to use your Windows log in ID and password to access the server. When enabled, the User name and password fields are disabled. This option is disabled by default.
   - **User name**  Your user name for the Metadata Server.
   - **Password**  Your password. This is always displayed as asterisks.
   - **Authentication domain**  The domain you, as a user, belong to.

5. Click **Save**.

**Connect to a Remote SAS Workspace Server from JMP**

You can also connect directly to a SAS Workspace Server, instead of going through a Metadata Server.
To connect to a Remote SAS Workspace Server

1. Select File > SAS > Server Connections. The SAS Server Connections window shown in Figure 3.51 on page 143 appears.
2. Under Establish New Workspace Server Connection, select Connect to remote SAS server on.

![Figure 3.55 Open a Connection to a Remote SAS Server](image)

3. Enter the machine name and the port number. Your SAS server administrator has this information.
4. Click Connect.
5. Enter your user name and password in the window that appears.
6. Click OK.
7. Click Close in the SAS Server Connections window.

To disconnect from a Remote SAS Workspace Server

1. In the SAS Server Connections window, select the server to disconnect under Open Workspace Server Connections.
2. Click Disconnect.

Connect to a SAS Environment from JMP (Windows Only)

On Windows, you can connect to a SAS mid-tier (or SAS environment) if SAS Server version 9.3 or 9.4 is selected in JMP’s preferences and your computer or JMP has been configured correctly. (SAS Server version 9.4 is the default setting in the JMP SAS Integration preferences.)

The SAS installer should have set up your computer to find the SAS environment definition file. If not, you can enter the path to the file in the JMP preferences.

To configure your JMP preferences

1. Select File > Preferences > SAS Integration.
2. Select **I want to connect to a SAS Environment** and then click **Configure**.

3. To connect to an environment that JMP has already detected, click **Automatic discovery**, and then select the URL from the list if necessary.

4. To enter the path to the SAS environment definition file, click **Manual configuration** and enter the URL.

5. Click **OK**.

**To connect to a SAS Environment**

1. Select **File > SAS > Server Connections** to open the SAS Server Connections window.

2. In the Metadata Server Connection area, select **Connect to a SAS Environment**.

   If this option is not available, either your computer or JMP is not configured to find the environment. See “**To configure your JMP preferences**” on page 147.

3. Select the name of the environment from the Environment list if necessary.

4. Click **Connect**.

5. Enter your user name and password if prompted.

**Connect to SAS on Your Local Machine from JMP (Windows Only)**

You can also connect directly to SAS on your local machine.

**To connect to SAS on your computer**

1. Select **File > SAS > Server Connections** to open the SAS Server Connections window.

2. Under Establish New Connection, select **Connect to SAS on this machine**.

   This option is disabled if SAS is not installed on the computer.

3. Click **Connect**.

4. Click **Close** in the SAS Server Connections window.

**To disconnect from SAS on your computer**

1. In the SAS Server Connections window, select **Local** under Open Connections.

2. Click **Disconnect**.

**Open SAS Data Sets with SAS Query Builder**

SAS Query Builder is the preferred method for selecting and importing data from a SAS server. You can preview the data before importing it into a data table. You can also save the queries to modify and run later or to reference in a JSL script.
SAS Query Builder provides an alternative to opening SAS data sets with the File > SAS > Browse Data feature.

To open a SAS data set with SAS Query Builder, follow these steps:

1. Select **File > SAS > SAS Query Builder**.

2. In the Connect to SAS Server window, select a Metadata server or a remote server.
   - To connect to a Metadata server that you have already set up in JMP, select the server from the **Connect to metadata-defined SAS server** list.
     
     **Connect to all available libraries** is selected by default based on the SAS Integration preferences. This option connects metadata-defined SAS libraries automatically across all JMP sessions. When the Workspace Server contains a large number of metadata-defined SAS libraries, consider deselecting this option to speed up your connection to the server.
   
   - To add or configure a Metadata server, click **Manage Profiles** and follow steps in “To create or modify a SAS Metadata Server profile” on page 145.
   
   - To connect to a remote server, enter the machine name and the port number. Your SAS Metadata Server administrator should have this information.

3. Click **OK**.

   The SAS Query Builder window appears.

For more information about using Query Builder, see “Build SQL Queries in Query Builder” on page 115.

**Notes:**

- All Query Builder queries run in the foreground.
- Extended attributes are not imported by default. To import them, modify the JMP SAS Integration preferences. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS). Select **SAS Integration** and then select **On import, apply table and column properties from extended attributes**.
- SAS Query Builder does not support local server connections.

**Open SAS Data Sets through a SAS Server**

Once you connect to a SAS Workspace Server, you can browse through the SAS libraries on that server and import data into JMP.

To browse the data sets on the SAS server, select **File > SAS > Browse Data**. The Browse SAS Data window appears.
The window is initially populated with a list of servers the SAS Metadata Server provides (if connected). Any physical and local connections are also shown (as listed in Figure 3.55 on page 147).

- Select a server to see a list of libraries that server contains.
- Select a library to see a list of data sets within that library.
- Select a data set to see a list of columns within that data set.

When you close and reopen the Browse SAS Data window, the previously viewed library and data set appear in the window. However, at any time, you can select a different server from the SAS Server list and then select a library and data set.

**Tip:** If a server is unavailable, or if the connections failed, the server’s name is shown in light, italic text. Click it to try to re-establish the connection.

### Browse SAS Data Information

You can select a SAS data set and see information about its contents before opening it using the Get Details, Column Details, and Data Preview options.

### Data Preview

When you select a data set, the Data Preview outline shows you the first ten rows and columns in the data set.
Figure 3.57  Data Preview

Data Set Details
Click Get Details in the Browse SAS Data window to see the size and last modification date for each data set in the library. This option helps you estimate whether your computer can process the entire data set.

Column Details
To see information about a particular column in the data set, select it. The Column Details outline shows you some basic information about the data column.
Import Your Data
Chapter 3
Import Data from SAS

Figure 3.58  Column Details

<table>
<thead>
<tr>
<th>Name</th>
<th>Column name from the SAS data set.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Descriptive column label. The label can be longer than the name, and is often helpful to determine what the column name means.</td>
</tr>
<tr>
<td>Type</td>
<td>Specifies whether the column has a character or numeric data type.</td>
</tr>
<tr>
<td>Length</td>
<td>The length in bytes of data in the column.</td>
</tr>
<tr>
<td>Sort Order</td>
<td>How the column is sorted in SAS.</td>
</tr>
<tr>
<td>Format</td>
<td>The format for the SAS column, such as DOLLAR. This format field also contains information about the width of formatted values and the number of decimal places.</td>
</tr>
</tbody>
</table>

Open a SAS Data Set

You can import SAS data sets directly into JMP.

1. From the Browse SAS Data window, select a data set.
   By default, JMP specifies All rows for import.

2. Click Import.

The entire SAS data set is imported into a JMP data table. When SAS data is imported, JMP attempts to make the best match to the SAS format.
Import a Sample of a SAS Data Set

You can import a sample of a SAS data set directly into JMP.

1. From the Browse SAS Data window, select a data set.
2. Open the Import Options outline.

Figure 3.59 Import Options

3. If you want to import only a portion of a data set, you can do any of the following:
   - Select the first $x$ number of rows only. See “To import the first $x$ number of rows only” on page 154.
   - Select to auto-sample a specified file size. See “To import an auto-sample file of a specified size” on page 154.
   - Select a subset of the columns. See “To select a subset of columns” on page 154.
   - Construct a WHERE clause to filter the data. See “To import using a WHERE clause” on page 154.
   - Take a custom sample of the data. See “Importing a Random Sample of the Data” on page 155.

The following options are also available:

**Use labels for imported column names**  Converts SAS labels to column names.

**Add SQL table variable to imported table**  Saves the SQL table variable as a data table variable.

**Restore JMP metadata from SAS extended attributes**  Includes JMP metadata (table and column properties) that were saved in the SAS data set as extended attributes.
To import the first \( x \) number of rows only
1. In the Import Options section, select **First \( x \) rows only** and specify the number of rows to import.
2. In the Browse SAS Data window, click **Import**.
   JMP imports the specified number of rows.

To import an auto-sample file of a specified size
1. In the Import Options section, select **Auto-sample** and specify the number of MB to import.
2. In the Browse SAS Data window, click **Import**.
   JMP imports the specified number of MB.

To select a subset of columns
1. In the Import Options section, click **Select Columns**.
   The Select Columns window appears.
2. Select the columns that you want to import.
   To select more than one column at a time, press Ctrl and click each column.
3. Click **Add**.
4. When you have added all the columns that you want, click **OK**.
5. In the Browse SAS Data window, click **Import**.
Only the columns that you selected from the SAS data set are imported into a JMP data table.

To import using a WHERE clause
1. Click **Where**.
2. Use the WHERE clause editor to construct your WHERE clause.
3. Click **OK** to return to the Browse SAS Data window.
4. Click **Import**.
Only the data that matches your WHERE clause are imported into a JMP data table.

For information about constructing WHERE clauses and using the WHERE clause editor, see “Use the WHERE Clause Editor” on page 174.

**Note:** If you import data using both a WHERE clause and sampling, the WHERE clause is applied first, and then a sample of the filtered data is taken.

You can also write your own SQL statements.

*To import using a custom SQL statement*

You can also open a SAS data set using a custom SQL statement.

1. Open the Custom SQL outline under the Import Options outline.

**Figure 3.61** Custom SQL

2. Enter your SQL statement in the window.

3. Click **Execute Custom SQL**.

**Note:** Your SQL is run on the selected server but is not restricted to any selected library or data set.

**Importing a Random Sample of the Data**

You can also import a random sample of the rows of the SAS data set.

**Note:** The sampling feature requires that the SAS server has the SAS/STAT product licensed and installed. If SAS/STAT is not present, sampling is disabled.

In the Sample Imported Data area of the Import Options outline, select the **Custom random sample** check box. By default, 5% of the rows are imported. To change the random sample import settings, click the **Settings** button.
Figure 3.62 Sampling Settings

In this window, you specify any of the following:

**Sample Size**  You can set the sample size be percentage or by number of rows. To ensure that each row is sampled only once, de-select the *With replacement* option. To ensure that any row can be sampled and appear more than once in the imported data, select the option.

**Selecting by Column**  You can select strata by moving columns into the Strata list.

**Handling Multiple Row Sampling**  If *With replacement* is selected, you can specify to either add each duplicated row as a separate row or combine all duplicated rows into one row. If the second option is selected, a column is added to the table that contains a count of how many times each row was sampled.

**Setting minimum and maximum numbers of items selected**  Select the option and enter a number.

**Setting the random number seed**  Select the option and enter a seed. Specifying the seed lets you reproduce the exact same sample multiple times.

**Note:** If you import data using both a WHERE clause and sampling, the WHERE clause is applied first, and then a sample of the filtered data is taken.

**Import Options**

There are additional options that you can use to specify how SAS data is imported into JMP.

**Use labels for imported column names**  When selected, this option switches the column name, which has a limited length and might be difficult to decipher, with the column label. This option is turned off by default. To use the SAS data column names as column names in JMP, deselect this box.
Add SQL table variable to imported table  When selected, this option adds SQL queries to the data table panel as a variable. This option is turned on by default. If you turn off this option, only two variables are added when you import the data table: the SAS server and the data set.

Restore JMP metadata from SAS extended attributes

**Tip:** If your data is password-protected, you might want to turn this option off, because your password might be shown in the SQL.

Table Variables

After you import the JMP data table, table variables appear in the upper left panel of the data table. These variables show the SAS server, data set, and the SQL query and sampling settings if applicable. There is also a source script added that lets you re-do the import at any time.

Open Password-Protected Data Sets

JMP can open SAS version 7 or higher data sets that are password protected. The passwords are not case sensitive.

**To open password-protected data sets**

1. Select **File > Open**.
2. Select **SAS Data Sets** from the **Files of type** list.
3. Select the file.
4. Click **Open**.
5. Enter the password and then click **OK**.

When the password is incorrect, you are prompted to enter it again until you get it right.

Using SAS Extended Attributes to Import Metadata

SAS extended attributes are metadata that you define in SAS code to import information such as table scripts, labels, length, and type. You associate the extended attributes with a data set or variable and define them in name-value pairs, such as `_JMP_TABLESCRIPTNAME_2="OnOpen"`. See the SAS documentation on extended attributes at [https://sas.com](https://sas.com).

On export from JMP to SAS, items such as column properties and table scripts are preserved automatically. You map SAS extended attributes to JMP attributes only when importing SAS code into JMP.
Here is an example of defining extended attributes in SAS code. The attributes define a table script name and the table script itself.

```sas
/* specify two table scripts. */
%LET _DS_ATTRIBUTES=_JMP_TABLESCRIPTCOUNT=2
/* define the table script names */
_JMP_TABLESCRIPTNAME_1="Favorite Movie By State"
_JMP_TABLESCRIPTNAME_2="OnOpen"
_JMP_TABLESCRIPTVALUE_2="CurrentDataTable() << RunScript(""Favorite Movie By State"");"
/* define the OnOpen table script */
_JMP_TABLESCRIPTVALUE_1=
/* a portion of the OnOpen table script */
"
   Current Data Table();
   New Column("max_name", Character, Width(128));
);
```

The following example shows how to combine PROC DATASETS with extended attributes:

```sas
%LET _DS_ATTRIBUTES = attr-name=attr-value...attr-name=attr-value;
%LET _VAR_ATTRIBUTES= var-name (attr-name=attr-value...)...var-name
(at attr-name=attr-value...);

PROC DATASETS NOLIST LIB=WORK;
   MODIFY AttributeReferenceTable;
   XATTR OPTIONS MAXCHUNK=100;
   XATTR SET DS &_DS_ATTRIBUTES;
   XATTR SET VAR &_VAR_ATTRIBUTES;
RUN;
QUIT;
```

See “Conventions for Mapping JMP Attributes to SAS Extended Attributes” on page 788 for more information about SAS extended attributes and their corresponding JMP attributes.

Two SAS Integration preferences determine whether extended attributes are imported or exported. Select **On export, store table and column properties in extended attributes to export extended attributes**. Select **On import, apply table and column properties from extended attributes**. The options are deselected by default.

To see an example of exporting extended attributes, run the following script:

```sas
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
sd = dt << Make SAS Data Step Window( SaveJMPMetadata( 1 ) );
```
Run Stored Processes

Stored processes are SAS DATA step code saved on the SAS server that you are connected to. You can run them from JMP and see the results of the script.

**Note:** Depending on the preferences that you have set for SAS, error messages are sent either to the JMP log or to a separate SAS log window.

You must be connected to a Metadata Server to view and run stored processes. If you select **File > SAS > Browse SAS Folders** without such a connection, you are prompted to either make a connection or cancel your action.

To select and run a stored process

1. Select **File > SAS > Browse SAS Folders**.
   - The Browse SAS Folders window appears.
2. Browse through the stored processes to find the one that you want to run.
3. Select it and click **Run**.
   - The data opens as a JMP data table.

On Windows, you can also right-click a stored process and select **Copy Metadata Path**. This option copies the path to the clipboard. You can then paste it into a script window to include it as a parameter for the JSL operator **Meta Get Stored Process()**. See the **JSL Syntax Reference**.

**Note:** Static graphs might not appear in the results returned from a SAS stored process when streaming output is selected.

Stored processes send reports to HTML by default, but you can select RTF or PDF instead on the SAS Integration page of the JMP preferences. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS) to view the JMP preferences.

Submit SAS Code

You can submit SAS code directly from JMP to the currently active SAS server. If the submitted SAS code generates SAS Listing output, that output is automatically retrieved from the SAS server and displayed in JMP. Also, the generated SAS Log is retrieved, and, if there are any errors in the submitted code, the SAS Log is automatically displayed in the SAS Log window.
All analyses in JMP are run natively within JMP without any dependency on the SAS System. The SAS code that JMP generates is intended to enable you to perform a separate but similar analysis in the SAS System after the initial JMP analysis, or to score new observations in the SAS System using a model that was fit within JMP.

**Figure 3.63** SAS Code Submission Example

<table>
<thead>
<tr>
<th>SAS Code</th>
<th>JMP Code to Submit SAS Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>data a;</td>
<td>SAS Connect(&quot;sasmain&quot;);</td>
</tr>
<tr>
<td>x=1;</td>
<td>SAS Submit(&quot;data a; x=1; proc print; run;&quot;);</td>
</tr>
<tr>
<td>proc print;</td>
<td></td>
</tr>
<tr>
<td>run;</td>
<td></td>
</tr>
</tbody>
</table>

The following JMP platforms generate SAS code:

- Standard Least Squares - PROC GLM
- REML - PROC MIXED
- Stepwise - PROC GLM
- Nominal and Ordinal Logistic - PROC LOGISTIC
- GLM - PROC GENMOD
- Time Series (ARIMA and TFM) - PROC ARIMA
- Neural - SAS Data Step scoring code
- Partition (Decision Tree, Bootstrap Forest, Boosted Tree) - SAS Data Step scoring code

**Note:** Use the JSL function `As SAS Expr('formula');` to turn any prediction formula into an expression that can be used in a SAS Data Step. See the *JSL Syntax Reference*.

**To run SAS code directly from JMP**

1. Either open an existing SAS program using **File > Open**, or create a new SAS program. (Create a new SAS program by selecting **File > SAS > New SAS Program** and typing in the SAS code.)

2. Click the **Submit to SAS** icon.

   You can also right-click in the Program Editor window and select **Submit to SAS**. The menu item also includes the name of the active SAS server that the SAS code will be submitted to.

   You can also press F8 (press Command+Shift+R on macOS).
To run SAS code using a JSL script

Write and run a JSL script that uses either the SAS Submit or SAS Submit File JSL functions. For more information about writing JSL scripts that submit SAS code, see the Scripting Guide.

To view the SAS Listing output

If the submitted SAS code generates SAS Listing (textual) output, that output is automatically be displayed in a SAS Output window when the job is completed. If you need to view the SAS Listing output again later in the JMP session, select File > SAS > Open SAS Output Window. The SAS Output Window retains the listing output from the previous 25 submits to the active SAS server.

To view the SAS log

If the submitted SAS code contained errors, the SAS Log window for the active SAS server is automatically opened, displaying the SAS Log for the job. However, you can view the SAS Log for the most recent 25 submits to the active server at any time by selecting File > SAS > Open SAS Log Window.

If you prefer that SAS Log information is appended to the JMP log after a submit completes:
1. Select File > Preferences (Windows) or JMP > Preferences (macOS).
2. Open the SAS Integration category.
3. In the Show SAS Log section, select JMP Log rather than Separate Window.

Also, in the Show SAS Log section, you can set whether the SAS Log should be displayed Always, Never, or On Error (the default).

Generate ODS Results

The SAS Output Delivery System (ODS) is a powerful mechanism for generating reports in HTML, RTF, PDF, and other formats. ODS output is generally much more attractive and customizable than plain-text SAS Listing output. You can set your submitted SAS code generate ODS results rather than SAS Listing output using Preferences.

To generate ODS results from your submitted SAS code
1. Select File > Preferences (Windows) or JMP > Preferences (macOS).
2. Open the SAS Integration category and find the large SAS Submit Options group.
3. Select the **Automatically generate ODS results** option.

4. From the **ODS Result Format** list, select the format in which to generate the ODS results: HTML, PDF, RTF, or a JMP report.

5. (Optional) You can use other options to specify a style or style sheet to format the results or set the format for generated graphics. See “Preferences for SAS Integration” on page 712 in the “JMP Preferences” chapter.

Performing the previous steps causes JMP to generate additional SAS code, including an ODS statement, that is wrapped around the SAS code that you submit. The SAS code that you submit then automatically generates ODS results in the specified format. Those results are downloaded to your computer and displayed either within JMP, when possible, or in an appropriate external application.

**Import Generated SAS Data Sets**

SAS code that you submit might generate SAS data sets. You can have them automatically imported into JMP for further analysis.

1. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS).

2. Open the SAS Integration category.

3. Select the **Import generated SAS data sets into JMP** option.

**Export JMP Data Tables to SAS**

You can export JMP data tables to a SAS Workspace Server.

1. Connect to the SAS Workspace Server.

2. Open the file that you want to export.

3. Select **File > SAS > Export Data to SAS**.
If necessary, you are connected automatically using your profile’s user name and password.

4. Select the data table that you want to export to SAS from the list of open data tables under Select Data to Export.

**Figure 3.65 Export Data to SAS**

5. (Optional) To export only some of the columns in the data table, click **Select Columns**. See “To select columns to export” on page 163.

6. Select the Destination Server.

7. Select the Library.

**Tip:** If your libraries do not appear, see “Show Libraries in the Export Data to SAS Window” on page 164.

A list of the data sets in the library appears.

8. Enter the name as you want it to appear in the SAS library.

9. (Optional) Set the export options that you want to use. See “Export Options” on page 164.

10. Click **Export**.

**To select columns to export**

1. To export only some of the columns in the data table, click **Select Columns**.

2. In the window that appears, select the columns to export and click **Add**.
3. When all the columns have been added to the Selected Columns list, click **OK**.

**Export Options**

**Ignore ‘excluded’ row state (export all rows)** Select this option to export all rows in the data table. Deselect this option to export only those rows that are not excluded. This option is on by default.

**Preserve SAS variable names** This option is useful for data tables that were imported originally from SAS. When importing a SAS data set, the original SAS variable name is saved in a column property for each column. Select this option to use the SAS variable name for each column when exporting to SAS. Deselect this option to export the JMP variable names. This option is off by default.

**Preserve SAS formats** This option is useful for data tables that were imported originally from SAS. When importing a SAS data set, the original SAS format and informat is saved in a column property for each column. Select this option to use the SAS format and informat for each column when exporting to SAS. Deselect this option to export the JMP formats instead. This option is on by default.

**Show Libraries in the Export Data to SAS Window**

If your libraries do not appear in the Export Data to SAS window, define the library in one of the following ways:

- Using JSL, submit code to the SAS server. The code defines a library using a `libname` command.
- Define an `autoexec.sas` file that runs a snippet of SAS code every time SAS is invoked. This creates the same `librefs` every time you connect to SAS. For more information about `autoexec.sas` files, see the SAS documentation.

Libraries that are defined in metadata (such as libraries defined in the SAS Management Console under the Data Library Manager) cannot be accessed from the Export Data to SAS window.
Import Data from a Database

You can import data from a database if you have an ODBC (Open Database Connectivity) driver for the database and then save the data back to the database.

You can use Structured Query Language (SQL) statements to control what you import from an external database. When you open a database file in JMP, you are actually sending a SQL statement to the database. By default, this statement gets all columns and records in the database table. See “Build SQL Queries in Query Builder” on page 115 for more information about interactively building queries. See “Write SQL Statements to Query a Database” on page 168 for more information about writing queries yourself.

This section describes how to connect to a database and import the data.

Notes:

• Database table names that contain the characters $# -+/%()&|;? are not supported.
• Multiple connections to a datasource are not permitted.
• Use a 64-bit version of the ODBC driver to match the bitness of JMP.

Connect to a Database

JMP can communicate with databases using ODBC data sources using an ODBC manager. The ODBC manager and associated drivers depend on your operating system. After you create the data source in the operating system software, follow these steps to connect to the database in JMP.

1. Select File > Database > Open Table. The Connections box lists data sources that you have connected to in the current JMP session.
2. Click New Connection.
3. (Windows) In the Select Data Source window (Figure 3.66), click the Machine Data Source tab, select the data source, click OK, enter the user name and password, and then click OK.
   (macOS) In the Choose DSN window, select the data source, enter the user name and password, and then click Choose DSN.
Open Data from a Database

After you connect to the ODBC database and select a table to import, the data is opened in a data table. Several table scripts are included in the data table.

- Run the Source script to reconnect to the database.
- Run the Update from DB script to re-import and refresh the data. If the database table has the same number of columns as the original JMP table, the values in that existing JMP table are updated in place. However, if the number of columns is not the same, then a new data table opens where the updated data is stored.
- Run the Save to DB script to save the data table to the database. The existing data in the database is replaced. This script might contain the user name and password. The preference called ODBC Hide Connection String can be set to prevent including this possibly sensitive information. Select File > Preferences > Tables (Windows) to find the preference (or JMP > Preferences > Tables on macOS).

To import data from a database

1. Select File > Database > Open Table.

   The Database Open Table window appears (Figure 3.67).

2. If you are already connected to the database, select it in the Connections box. Follow the steps in “Connect to a Database” on page 165.

   The Connections box lists data sources to which JMP is connected. The Schemas - Tables box lists schemas for those databases that support them.
Figure 3.67  Database Open Table Window

When one or more database connections are made, the list of connections shows in the Connections list.

If your database supports schemas (for example, Oracle), this field shows the schema list. It disappears if you select a database that does not support schemas.

If there are tables in the selected database file or directory, they appear in the Tables list.

Note: The Fetch Procedures check box is disabled if the ODBC driver does not support fetching procedures.

3. If the desired data source is not listed in the Connections box, click New Connection to choose a data source. The method of choosing a data source depends on your operating system.

4. Select the desired data source in the Connections box. The tables list in the Tables box updates accordingly. The update might take several seconds, depending on the number of tables and the speed of the connection to the database. If your database supports schemas, tables are loaded for the first schema in the list, and on other schemas as you click them.

5. Control which tables are listed by choosing the options in the Include in Table List group of check boxes.

Note: Different drivers interpret these labels differently.
User Tables When clicked, displays all available user tables in the Tables list. User tables are specific to which user is logged on to the computer.

Views When clicked, displays “views” in the Tables list along with all other file types that can be opened. “Views” are virtual tables that are query result sets updated each time you open them. They are used to extract and combine information from one or more tables.

System Tables When clicked, displays all available system tables in the Tables list. System tables are tables that can be used by all users or by a system-wide service.

Synonyms When clicked, displays all available ORACLE synonyms in the Tables list.

Sampling Enter the percentage of rows that you want to appear in the list of tables. Selecting this option speeds up queries in large databases. JMP uses the sampling method supported by the database. The check box is unavailable when the database does not support sampling.

6. Select the desired table from the Tables list.

Note: If you are connected to a dBase database, select the database folder to which you would like to connect. Individual files are grayed out and cannot be selected.

7. Click Open Table to import all the data in the selected table, or click Advanced to specify a subset of the table to be imported. Some databases require that you enter the user ID and password to access the data.

You might see a short delay when opening large tables. To see the status of all active ODBC queries, select View > Running Queries.

Note: If the data were previously exported to a database in JMP and contained an Expression column, the column will be imported as a Character column. Select Cols > Column Info and change the Data Type to Expression.

Write SQL Statements to Query a Database

You can use Structured Query Language (SQL) statements to control what you import from a database. When you open a database file in JMP, you are actually sending a SQL statement to the database. By default, this statement gets all columns and records in the database table. In some cases, this is too much data. When you are interested only in a subset of the table’s data, you can customize the SQL request to only request the data that you want. After you execute a SQL query, the code for the query is stored in the data table in the SQL table variable.

This section describes how to write SQL statements to retrieve data. To interactively query data without writing SQL statements, use Query Builder. You can also start creating a query in Query Builder and then add your own SQL. See “Write SQL Statements in Query Builder” on page 138.
1. Select **File > Database > Open Table**.

   The Database Open Table window appears (Figure 3.67).

2. Connect to the database if necessary or select an existing database connection. Follow the steps in “Connect to a Database” on page 165.

   The Connections box lists data sources to which JMP is connected. The Schemas - Tables box lists schemas for those databases that support them.

   **Note:** The SQL Query that you run in this window operates only on the tables and procedures that are displayed in the left panes of the window. Running unrelated SQL here has no results.

3. From the Database Open Table window, click the **Advanced** button to open specific subsets of a table.

4. Either type in a valid SQL statement, or modify the default statement. Figure 3.68 shows a default SQL **Select** statement appropriate for the selected file. See “Structured Query Language (SQL): A Reference” on page 170, for a description of SQL statements that you can use.

   Instead, you can add expressions by clicking the **Where** button and using the WHERE Clause editor to create expressions. See “Use the WHERE Clause Editor” on page 174.

---

**Figure 3.68**  Reading All Variables from the Solubility Table Stored in an Excel File

- List of tables that are accessible in the current database
- List of columns that appear in the table.
- Highlight another table name in the list on left to view its columns

- Type the SQL statement in this box.
5. Click Execute SQL. A JMP data table appears with the columns that you selected. See “Use Data Table Variables” on page 283 in the “Enter and Edit Your Data” chapter.

6. To see the status of all running queries, select View > Running Queries.

Note that you can enter any valid SQL statement and click Execute SQL to execute the command. Valid SQL varies with the data source and ODBC driver.

Structured Query Language (SQL): A Reference

The following sections are a brief introduction to SQL. They give you insight to the power of queries, and they are not meant to be a comprehensive reference.

Use the SELECT Statement

The fundamental SQL statement in JMP is the SELECT statement. It tells the database which rows to fetch from the data source. When you completed the process in “Write SQL Statements to Query a Database” on page 168 with the Solubility.jmp sample data table, you were actually sending the following SQL statement to your data source:

```
SELECT * FROM "Solubility"
```

The * operator is an abbreviation for “all columns.” So, this statement sends a request to the database to return all columns from the specified data table.

Rather than returning all rows, you can replace the * with specific column names from the data table. In the case of the Solubility data table example, you could select the ETHER, OCTANOL, and CHLOROFORM columns only by submitting this statement:

```
SELECT ETHER, OCTANOL, CHLOROFORM FROM "Solubility"
```

Note: JMP does not require you to end SQL statements with a semicolon.

JMP provides a graphical way of constructing simple SELECT statements without typing actual SQL. To select certain columns from a data source, highlight them in the list of columns.

To highlight several rows

- Press Shift and then click to select a range of column names
- Press Ctrl and then click (Windows) or press Command and then click (macOS) to select individual column names.

Note that the SQL statement changes appropriately with your selections.

Sometimes, you are interested in fetching only unique records from the data source. That is, you want to eliminate duplicate records. To enable this, use the DISTINCT keyword.

```
SELECT DISTINCT ETHER, OCTANOL, CHLOROFORM FROM "Solubility"
```
Sort Results

You can have the results sorted by one or more fields of the database. Specify the variables to sort by using the ORDER BY command.

```
SELECT * FROM "Solubility" ORDER BY LABELS
```

selects all fields, with the resulting data table sorted by the LABELS variable. If you want to specify further variables to sort by, add them in a comma-separated list.

```
SELECT * FROM "Solubility" ORDER BY LABELS, ETHER, OCTANOL
```

Use the WHERE Statement

With the WHERE statement, you can fetch certain rows of a data table based on conditions. For example, you might want to select all rows where the column ETHER has values greater than 1.

```
SELECT * FROM "Solubility" WHERE ETHER > 1
```

The WHERE statement is placed after the FROM statement and can use any of the following logical operators.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal to</td>
</tr>
<tr>
<td>!= or &lt;&gt;</td>
<td>Not equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less Than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>NOT</td>
<td>Logical NOT</td>
</tr>
<tr>
<td>AND</td>
<td>Logical AND</td>
</tr>
<tr>
<td>OR</td>
<td>Logical OR</td>
</tr>
</tbody>
</table>

Table 3.4 WHERE Operators

When evaluating conditions, NOT statements are processed for the entire statement first, followed by AND statements, and then OR statements. Therefore

```
SELECT * FROM "Solubility" WHERE ETHER > -2 OR OCTANOL < 1 AND CHLOROFORM > 0
```
is equivalent to

    SELECT * FROM "Solubility" WHERE ETHER > -2 OR (OCTANOL < 1 AND CHLOROFORM > 0)

Use the IN and BETWEEN Statements

To specify a range of values to fetch, use the IN and BETWEEN statements in conjunction with WHERE. IN statements specify a list of values and BETWEEN lets you specify a range of values. For example,

    SELECT * FROM "Solubility" WHERE LABELS IN ('Methanol', 'Ethanol', 'Propanol')

fetches all rows that have values of the LABELS column Methanol, Ethanol, or Propanol.

    SELECT * FROM "Solubility" WHERE ETHER BETWEEN 0 AND 2

fetches all rows that have ETHER values between 0 and 2.

Use the LIKE Statement

With the LIKE statement, you can select values similar to a given string. Use % to represent a string of characters that can take on any value. For example, you might want to select chemicals out of the Solubility data that are alcohols, that is, have the OL ending. The following SQL statement accomplishes this task.

    SELECT * FROM "Solubility" WHERE LABELS LIKE '%OL'

The % operator can be placed anywhere in the LIKE statement. The following example extracts all rows that have labels starting with M and ending in OL:

    SELECT * FROM "Solubility" WHERE LABELS LIKE 'M%OL'

Use Aggregate Functions

Aggregate functions are used to fetch summaries of data rather than the data itself. Use any of the following aggregate functions in a SELECT statement.

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUM( )</td>
<td>Sum of the column</td>
</tr>
<tr>
<td>AVG( )</td>
<td>Average of the column</td>
</tr>
<tr>
<td>MAX( )</td>
<td>Maximum of the column</td>
</tr>
<tr>
<td>MIN( )</td>
<td>Minimum of the column</td>
</tr>
</tbody>
</table>

Table 3.5 SELECT Statement Functions
Chapter 3
Using JMP

Import Your Data

Using JMP Import Data from a Database

Some examples include:

- The following statement requests the sum of the ETHER and OCTANOL columns:
  ```sql
  SELECT SUM(ETHER), SUM(OCTANOL) FROM "Solubility"
  ```
  
- This statement returns the number of rows that have ETHER values greater than one:
  ```sql
  SELECT COUNT(*) FROM "Solubility" WHERE ETHER > 1
  ```
  
- The following statement lets you know the average OCTANOL value for the data that are alcohols:
  ```sql
  SELECT AVG(OCTANOL) FROM "Solubility" WHERE LABELS LIKE '%OL'
  ```

**Note:** When using aggregate functions, the column names in the resulting JMP data table are Expr1000, Expr1001, and so on. You probably want to rename them after the fetch is completed.

### The GROUP BY and HAVING Commands

The **GROUP BY** and **HAVING** commands are especially useful with the aggregate functions. They enable you to execute the aggregate function multiple times based on the value of a field in the data set.

For example, you might want to count the number of records in the data table that have ETHER == 0, ETHER == 1, and so on, for each value of ETHER.

- **SELECT COUNT(ETHER) FROM "Solubility" GROUP BY (ETHER)** returns a single column of data, with each entry corresponding to one level of ETHER.
- **SELECT COUNT(ETHER) FROM "Solubility" WHERE OCTANOL > 0 GROUP BY (ETHER)** does the same thing as the above statement, but only for rows where OCTANOL > 0.

When using GROUP BY with an aggregate function of a column, include the column itself in the SELECT statement. For example,

```sql
SELECT ETHER, COUNT(ETHER) FROM "Solubility" GROUP BY (ETHER)
```

returns a column containing the levels of ETHER in addition to the counts.

### Table 3.5 SELECT Statement Functions (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| COUNT( ) | Number of rows in the column

**Table 3.5 SELECT Statement Functions (Continued)**
Use Subqueries

Aggregate functions are also useful for computing values to use in a WHERE statement. For example, you might want to fetch all values that have greater-than-average values of ETHER. In other words, you want to find the average value of ETHER, and then select only those records that have values greater than this average. Remember that SELECT AVG(ETHER) FROM "Solubility" fetches the average that you are interested in. So, the appropriate SQL command uses this statement in the WHERE conditional:

```
SELECT * FROM "Solubility" WHERE ETHER > (SELECT AVG(ETHER) FROM "Solubility")
```

Save and Load SQL Queries

After constructing a query, you might want to repeat the query at a later time. You do not have to hand-type the query each time you want to use it. Instead, you can export the query to an external file. To do this, click the Export SQL button in the window shown in Figure 3.68. This brings up a window that lets you save your SQL query as a text file.

To load a saved query, click the Import SQL button in the window shown in Figure 3.68. This brings up a window that lets you navigate to your saved query. When you open the query, it is loaded into the window.

Use the WHERE Clause Editor

JMP provides help building WHERE clauses for SQL queries during ODBC import. It provides a WHERE clause editor that helps you build basic expressions using common SQL features, allowing vendor-specific functions. For example, you do not need to know whether SQL uses ‘=’ or ‘==’ for comparison, or avg() or average() for averaging.

In addition, string literals should be enclosed by single quotes (‘string’) rather than double quotes ("string").

To open the WHERE clause editor

1. Connect to a database by following the steps in “Connect to a Database” on page 165.
2. From the Database Open Table window, click the Advanced button.
3. Click the Where button.

USE the WHERE Clause Editor to add any of the following from the work panel: expressions, functions, and terms. They are applied to the highlighted blue box.

1. Click the Table Name Browser to select a table. The columns in that table appear in the list.
2. Click the SQL Vendor Name Browser to select the type of SQL that you want to use: GenericSQL, Access, DB2, MySQL, Oracle, SQL Server, or all of the above. Perform an
action by clicking a function or operator in the list and selecting an operator from the list that appears.

**Note:** The following SQL Server data types are not supported: Binary, Geography, and Geometry.

3. Select an empty formula element in the formula editing area by clicking it. It is selected when there is a red outline around it. All terms within the smallest nesting box relative to the place that you clicked become selected. The subsequent actions apply to those combined elements.

4. Add operators to an expression by clicking buttons on the keypad.

5. (Optional) To customize your WHERE clause, select one of the options from the red triangle menu in the formula editor:

   **Show Boxing** Show or hide boxes around the WHERE clause terms.

   **Larger Font** Increase the font size of the formula.

   **Smaller Font** Decrease the font size of the formula.

   **Simplify** Simply the WHERE clause statement as much as possible.

   **Reset panel layout** Display the panels as shown in Figure 3.69.

The WHERE clause editor works similarly to the Formula Editor, which is described in the “Create Formulas in JMP” chapter on page 393.
Import Data from Google Sheets

A Google Sheet is a spreadsheet (which consists of sheets, like tabs) that is saved in your Google account. This enables you to continue to edit the spreadsheet and to share it with others.

Import data from a Google spreadsheet by logging into your Google account, copying the URL for the spreadsheet, and specifying how the data is structured. For example, you must know which row the data begin on if there are column headers.

To import data from a Google spreadsheet, follow these steps:

1. Log in to https://sheets.google.com and open the spreadsheet.
2. Copy the URL in the browser’s address bar.
3. In JMP, select File > Internet Open > Google Sheets.
4. Type your Google account name. (@gmail.com is unnecessary.)
5. Paste the URL in the spreadsheet URL or ID field.
6. Click Import.
The data are imported into a JMP data table.
If you are importing data using the specified Google account for the first time, you are prompted to give JMP access to your Google account.
a. Click **Allow**.
   The data are imported into a JMP data table.

**About Importing Google Sheets**

- Information that Google uses to authenticate your account is stored in \( C:/Users/<\text{user name}>/AppData/Roaming/SAS/JMP/OAuthTokens.jmp \). (Your Google password is encrypted.) This enables you to import and export data using the same Google account without providing the authentication information again. Note that a user with access to your computer’s user account has access to all of your Google spreadsheets. If they contain confidential information, reconsider sharing your user account.

- \(<\text{user name}>\)\@gmail.com is not required for your account name. However, if you do use it, \(<\text{user name}>\)\@gmail.com and \(<\text{user name}>\) are treated as separate accounts. You must enter the authentication code for both accounts when importing or exporting.

- If other users have access to your computer’s user account, they can copy OAuthTokens.jmp to their computer and import your spreadsheets.

- If **Display intranet sites in Compatibility View** in Internet Explorer on Windows is selected, the Google Sheet cannot be imported. To avoid this issue, follow these steps:
  1. In Internet Explorer, select the Tools button and then select **Compatibility View settings**.
  2. Deselect **Display intranet sites in Compatibility View**.

**Note:** In Google Sheets, you can select **File > Publish to the web** to publish the sheet for an audience to view. In this case, the link to the published sheet includes the pubhtml suffix. Use **File > Internet Open** to open these sheets. See “Import Data from the Internet or a Remote Computer” on page 184.

**Google Sheet Settings**

Change the following settings, if necessary, and then click **Import** to import the sheet data.

**Sheet contains column headers**  Select if the worksheet contains rows with column headers.

**Column headers start on row**  Indicates which row the column headers begin on in the worksheet. Click the up arrow until the headers begin on the correct row, or enter the row number and press Enter.
Import Your Data

Chapter 3

Import SPSS Files

Data starts on row Indicates which row the data start on in the worksheet.

Select Sheets to Open Deselect any sheets you don’t want to import by pressing Ctrl and clicking a sheet.

Advanced Options

Cell Range Imports cells within the specified range (for example, G5:G17).

Import cell colors Applies the cell coloring from the worksheet to the data table.

Suppress empty columns Prevents empty columns from appearing in the data table.

Import SPSS Files

JMP opens SPSS files as data tables and maintains several SPSS features:

- General numeric and character data with minimal formatting are supported.
- SPSS date, datetime, and time formats are supported.
- By default, labels are converted to column headings. When you select this option, and the data contains no labels, the columns are named Column 1, Column 2, and so on.

You also have the option of selecting the conversion method for column headings when opening an SPSS file. The method that you select then overrides the preferences.

To change the default conversion method, select File > Preferences (or JMP > Preferences on macOS). On the General page, deselect Use SPSS labels for column names during import. Variable names are then imported automatically as column headings.

- The value labels that you defined in the SPSS file are saved as Value Labels column properties. The value label then appears in each data table cell instead of the original value. For more information about Value Label properties, see “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.

- SPSS can assign certain values in a variable to be treated as missing for analyses. For example, the value 64 could be regarded as missing for a Height variable. Then, the calculation of the distribution of height would ignore values of 64. When you import SPSS, these values are included in the Missing Value Codes column property for the appropriate variable.

Missing value ranges of up to 20 numbers are supported. If the range begins with a negative number, the numbers count down to the maximum value (for example, -10 through -5). If the range begins with a positive number, the numbers count up from the minimum value (for example, 1 through 12).
Custom currency formats selected in an SPSS file are not maintained on import. In addition, JMP does not read SPSS data that contains double-byte characters, such as non-Unicode Japanese characters.

**To open an SPSS file (Windows)**

1. Select **File > Open**.
2. From the list next to **File name**, select **SPSS Data Files (*.sav)**.
3. Select the SPSS file.
4. (Optional) To specify the column headings, select one of the following **Set JMP column names from** options:
   - **SPSS Labels** creates column headings from SPSS labels.
   - **SPSS Variable Names** creates column headings from variable names.
5. Click **Open**.
   
JMP opens the file as a data table.

**To open an SPSS file (macOS)**

1. Select **File > Open**.
2. Select the SPSS file.
3. (Optional) To specify the column headings, do one of the following:
   - Deselect **Use SPSS Labels as Headings** to convert variable names to column headings.
   - Select **Use SPSS Labels as Headings** to convert labels to column headings.
4. Click **Open**.
   
JMP opens the file as a data table.

**Notes:**

- As with importing other files, you might experience a delay when opening and saving large SPSS files.
- A pipe (|) now separates words within a multiple response in the .sav file’s SPSS label (as in “detergent|liquid”). To change the delimiter, run the following JSL script: `Preference(SPSSMultiResponseDelimiter(":"))`, where the colon is the new delimiter.
Import Triple-S Survey Data

Triple-S (SSS) is a specification for survey data. The survey data is stored in a pair of files: .xml or .sss, and a .csv, .dat, or .asc file. The .xml or .sss file defines the variables and describes the survey. The accompanying .csv, .dat, or .asc file contains the data gathered from each respondent.

Variable labels are converted to column headings by default. To convert variable names to column headings, deselect Use Triple-S Labels as Headings in the JMP General preferences.

To import a Triple-S file, follow these steps:

1. Place the pair of Triple-S files in the same folder and use the same root name for both files.
2. Select File > Open.
3. On Windows, select Triple-S Survey Files from the File name list.
4. Select the SPSS file.
5. (Optional on Windows) To override the Triple-S column heading preference, select Variable Labels or Variable Names next to Set JMP column names from:
6. Click Open.

JMP opens the file as a data table.

**Note:** The default encoding is UTF-8. Triple-S files that are encoded as Windows-1252 will be imported as ISO-8859-1.

Import HDF5 Data

Hierarchical Data Format, Version 5 (HDF5) is a portable file format for storing data. An HDF5 file consists of groups and datasets. When you import the file, JMP opens a group to present the names of the inner datasets. For example, if the file contains data for a group of musical recordings with songs and artists tables, JMP prompts you to open either “songs” or “artists”. If the file does not contain a group, JMP prompts you to open a single table.

JMP handles only tables with numeric (integer, float, double) and string types, and compound files with three or fewer dimensions that contain only simple types. If a data set does not appear in the import window, the file is most likely unsupported.

You can import up to 1,000,000 columns and an unbounded number of rows.

**Note:** Only ASCII characters are supported in HDF5 files. Non-ASCII characters such as French and Chinese characters are not supported.
To import an HDF5 file, follow these steps:

1. Select **File > Open**.
2. On Windows, make sure that **All JMP Files** or **HDF5 Data File** is selected from the File name list.
3. Select the HDF5 file.
   A list of groups or datasets in the file appears.
4. Select the data set that you want to import and click **Import**.
   The data are opened as data tables.

### Import Data from MATLAB

JMP provides a scripting interface to MATLAB. See the *Scripting Guide* and the *JSL Syntax Reference*.

### Import Data from R

JMP provides a scripting interface to R. See the *Scripting Guide* and the *JSL Syntax Reference*.

### Import Data Using the Excel Add-In

The add-in for Excel provides new capabilities to JMP and Excel users on Windows:

- Transfer selected cells in Excel to JMP data tables. See “Transfer Excel Data to a Data Table” on page 182.
- Use the JMP Profiler with calculation models in Excel workbooks. The profiler tool is designed to bring the power of the JMP profiler to models residing in Excel worksheets. You do not have to recreate your Excel models in JMP, verify that they are correct, and maintain the model in both JMP and Excel. See *Profilers*.

**Note:** During the JMP installation, select the Excel Add-In. This installs the add-in for your version of Microsoft Excel.

- Microsoft Excel 2010, Microsoft Excel 2013, Microsoft Excel 2016, Microsoft Excel 2019, and Office 365 Desktop Excel are supported.
Transfer Excel Data to a Data Table

You can use the JMP Add In for Excel to transfer a worksheet from Excel to the following JMP destinations:

- a data table
- Graph Builder
- Distribution platform
- Fit Y by X platform
- Fit Model platform
- Time Series platform
- Control Chart platform

You can also create models for profiling in JMP. See Profilers.

To transfer data from Excel to a JMP data table and platform

1. In your Excel worksheet, show the JMP add-in on the ribbon.
2. Click the Preferences button.
3. Accept the default Data Table Name (File name_Worksheet name) or type a name.
4. Select Use the first rows as column names if the first row in the worksheet contains column headers.
5. If you selected to use the first rows as column headers, type the number of rows used.
6. Select Transfer Hidden Rows if the worksheet contains hidden rows to be included in the JMP data table.
7. Select Transfer Hidden Columns if the worksheet contains hidden columns to be included in the JMP data table.
8. Click OK to save your preferences.
9. Select the cells to transfer into JMP, including any cells that you want to use as column names.
   
   If you are using cells as column names, they need to be the first rows in your selection.
   
   If only one cell (or no cell) is selected, the entire Excel worksheet is transferred to JMP.
10. Select the JMP destination from the toolbar:
    
    - Data Table
    - Graph Builder
    - Distribution platform
    - Fit Y by X platform
– Fit Model platform
– Time Series platform
– Control Chart platform

JMP opens, and the selected data is placed in a new JMP data table and the selected launch window appears.

Notes:

• Empty cells are imported as missing data, and dates, numbers, and strings are recognized correctly.
• Your JMP windows might be hidden behind your Excel window, especially if you maximize Excel.

For more information about using the various JMP platforms, refer to the proper JMP documentation.

About the JMP Add-In for Excel

The JMP add-in commands are in two groups:

Transfer to JMP

Preferences  Set preferences for transferring data from Excel to JMP.
Data Table  Transfer the selected data in your Excel file to a JMP data table.
Graph Builder  Transfer the selected data in your Excel file to a JMP data table and launch the Graph Builder platform.
Distribution  Transfer the selected data in your Excel file to a JMP data table and launch the Distribution platform.
Fit Y By X  Transfer the selected data in your Excel file to a JMP data table and launch the Fit Y by X platform.
Fit Model  Transfer the selected data in your Excel file to a JMP data table and launch the Fit Model platform.
Time Series  Transfer the selected data in your Excel file to a JMP data table and launch the Time Series platform.
Control Chart  Transfer the selected data in your Excel file to a JMP data table and launch the Control Chart platform.
Uninstall the JMP Excel Add-In

To uninstall the Excel Add-in, double-click the JMP installer, click Modify, and deselect Excel Add-In.

Import Data from the Internet or a Remote Computer

Import data from the Internet, FTP sites, or other computers by selecting File > Internet Open. A file path can start with http, ftp, or file; a drive letter; or, the path to a network drive (relative or absolute).

Using Internet Open, you can import data and images from the Internet or a remote computer and save it as a data table, web page, or text. You can also open a SAS stored process report using this option. See “Import Data from Google Sheets” on page 176 for more information about using Internet Open to import a Google spreadsheet.

Suppose that you want to import data (with images) from a table on a web page and save it as a data table. The specific web page lists countries by population.

1. Select File > Internet Open > Web Page.
2. Enter the following URL:
3. Keep Open As set to Data, and click OK.
   JMP finds several tables on the specified page.
4. Click Rank country (or dependent territory)... and click OK.
   JMP opens a data table that contains the information from the web page table.
5. (Optional) To add the images to the data table, run the Load pictures script.

Notes:
- You can open a remote file as one of the following formats:
  - Data Opens the file as a data table.
Web page  Opens the web page in the JMP browser (Windows) or the default browser (macOS).

From the File menu on Windows, you can then choose to save the file or import the data as a data table. Select this option to import data that is generated by web page scripts and server-side requests.

Text  Opens the file in the script editor. If you imported an HTML file, the HTML tags of a web page are displayed.

• When you open a file from an FTP server, an FTP login window appears. For an anonymous account, click OK. For an authenticated login, enter your user ID and password. The file then opens as you specified.

Note: Some anonymous FTP servers require a user ID. If the data table does not open, try typing either “ftp” or “anonymous” in the User ID text box. Leave the Password text box empty and click OK.

• JMP waits 60 seconds before stopping the import due to an error. You can change the Internet Time Out setting on the General preferences page.

• If the table that you are importing contains images, the images are first imported as text. To display the images in your data table, run the automatically generated table script named Load pictures. A new expression column that contains the images is added to the data table.

• Running the Source script in a data table enables you to re-import and refresh the data.

To open a SAS stored process report as a data table (Windows only)

1. Select File > Internet Open and select the file.
   The file opens in the JMP browser.
2. In the JMP browser, select File > Import Table as Data Table.
   A window appears that lists the tables found in the web page.
3. Select the table or tables that you want to import.
4. Click OK.
   Each table is opened as a new data table.

See “Run Stored Processes” on page 159 for more information about stored process reports.
Create New Data Tables

To create a new data table by entering data manually, follow these steps:

1. Select **File > New > Data Table**. This shows an empty data table with no rows and one numeric column, labeled Column 1.
2. Move the cursor onto a cell.
3. Click in the cell. The cursor appears as a line in the cell.

**Figure 3.70** A New Data Table

4. Enter a value.

There are several ways to fill a table with values:

- Create new rows and columns and type or paste data into the data grid. (See “Enter Data in Data Tables” on page 192 in the “Enter and Edit Your Data” chapter.)
- Construct a formula to calculate column values. (See “Build Formulas” on page 395 in the “Create Formulas in JMP” chapter.)
- Import data from another application. (See “About Importing Data” on page 70.)
- Copy values from another application and paste them into the table.
- Use a measuring instrument to read external measures. See in the Scripting Guide for more information about data feeds.
• Drag columns from one table to another.

See the “Enter and Edit Your Data” chapter on page 189 for more information about how to format, edit, and work with data tables.
Import Your Data
Create New Data Tables
After you import data into JMP or create a new data table, you can format your data to prepare it for analysis.

This chapter contains the following information:

- Change formatting for numeric values
- Add, delete, and select rows and columns
- Use the Row Editor to navigate within rows and edit rows
- Create scripts that are saved to the data table

**Figure 4.1 The Rows and Cols Menus**

Enter and edit data using the options in the Rows and Cols menus.

Enter Data in Data Tables

This section describes how to add rows and columns, fill columns with sequential data, and enter cell formulas.

- “Copy and Paste Data into Data Tables”
- “Add Rows to Data Tables”
- “Add Columns to Data Tables”
- “Fill Data Table Columns with Sequential Data”
- “Replace Missing Values with Previous Values in Data Table Columns”
- “Enter Cell Formulas into Data Table Columns”

**Tip:** Consider setting the Autosave Timeout value in the General preferences to automatically save open data tables at the specified number of minutes. This autosave value also applies to journals, scripts, projects, and reports.

Copy and Paste Data into Data Tables

When you paste data from another document into a data table, JMP adds rows and columns as needed. Click a cell and paste the data.

**Multiple Lines of Data**

When you copy one data table cell and paste several lines of data, each line is pasted into its own cell.

To paste all lines into one cell, do one of the following:

- Double-click an existing cell first and then paste.
- Right-click an existing cell and select Paste into Cell. The Paste into Cell option is available only on character and expression columns.

**Note:** If you try to paste into a cell that does not exist, the text will paste into separate cells.

The data type of the copied content needs to match the data type of the cells that you’re pasting into. You can add new columns and paste the data, paste the data into cells of the correct data type, or change the data type of the cells if necessary.

**Note:** To copy the entire numeric value, select Edit > Copy With Full Precision. The option applies only to the fixed decimal format.
Add Rows to Data Tables

To add any number of rows to the data table

1. Select **Rows > Add Rows**.
2. Enter the number of rows to add.
3. Specify where to add the new rows (at the start or end of the data table, or after a specific row).
4. Click **OK**.

To add a single row to the end of the data table

- Below the last row, click anywhere in a cell and begin typing.
- Below the last row, double-click in the empty row number area.

Add Columns to Data Tables

There are several ways to add new columns to a data table:

- Double-click the empty space to the right of the last data table column to add one column. See “About the Column Info Window” on page 291 for more information about changing attributes after you add the column.
- Select **Cols > New Columns**. Use this option to add one or more columns and change their attributes.
- Double-click the upper triangle in the data grid above the row numbers. The Add Multiple Columns window appears.

Notes:

- When you initially create a column, you can choose to fill it with initial data values. See “Initialize Data in a Column” on page 302 in the “Set JMP Column Properties” chapter. However, after you modify the cells, this option no longer appears.
- If any rows are selected in the data table, double-clicking to create a new column deselects the rows. Using Cols > New Columns to create a new column will not change the row selection.
- You cannot edit the data in the columns of a By group or a linked subset.

To add one or more columns using New Columns

1. (Optional) Select the column before or after which the new column or columns are added.
2. Select **Cols > New Columns**.
3. Change the column name.
By default, the new column names are Column 1, Column 2, and so on.

4. Select the data type, modeling type, and format for all of the columns. See “About the Column Info Window” on page 291.

5. (Optional) Select initial data values for all of the columns. See “Initialize Data in a Column” on page 302 in the “Set JMP Column Properties” chapter.

6. Specify where you want to put the new columns. If you do not select an option, the column is added after the last column.

7. (Optional) For multiple columns, specify whether the columns should be grouped. See “Group Columns in Data Tables” on page 213.

8. To add more columns, follow these steps:
   a. Click Apply to add the new column.
   b. Click Next, change the column properties, and then click Apply.
   c. Click Next to add another column.

9. Click OK to save your changes.

**Figure 4.2** The New Column Window

**Tip:** To change the modeling type after the columns are created, click the modeling type icon in the Columns panel and select a different type.

To add one or more columns using Add Multiple Columns

1. Double-click the upper triangular area in the data grid. The Add Multiple Columns window appears.
2. Change the prefix for each column.
   By default, the new column names are Column 1, Column 2, and so on.
3. Enter the number of columns to add.
4. Specify whether the columns should be grouped. See “Group Columns in Data Tables” on page 213.
5. Select the data type for all of the columns. See “About the Column Info Window” on page 291.
6. Specify where you want to put the new columns.
7. (Optional) Select initial data values for all of the columns. See “Initialize Data in a Column” on page 302 in the “Set JMP Column Properties” chapter.
8. Click OK to save your changes.

**Fill Data Table Columns with Sequential Data**

To fill columns with a repeating sequence of data or with a continuation of values, follow these steps:
1. Create a sequence of data in a column.
Figure 4.4  Example of a Sequence of Data

2. Highlight the cells containing the sequenced data. The cells can be in different columns.
3. Right-click the selected cells and select an option under Fill.

Fill Options

Repeat sequence to end of table  Specifies that the cells below the selection are filled with repeats of the selected cells.

Continue sequence to end of table  Specifies that the cells below the selection are filled with a continuation of the pattern found in the selected cells. For example, if the selected cells contain the numbers 1 and 2, then the remaining cells are filled with 3, 4, 5, 6, and so on. If the selected cells contain the numbers 2 and 4, then the remaining cells are filled with 6, 8, 10, 12, and so on.

Repeat sequence to  JMP repeats the pattern found in the selected cells to the row number that you specify.

Continue sequence to  JMP continues the pattern found in the selected cells to the row number that you specify.

Replace Missing Values with Previous Values in Data Table Columns

When a column contains missing values, you can replace those values with the value in the preceding cell. For example, if “4, ., ., 6, ., 7, .” is selected, the values are changed to “4, 4, 4, 4, 6, 6, 6, 7, 7”.

1. Select the cells that contain the missing and replacement values.
   The first cell that you select must immediately precede a missing value. After that, you can select non-adjacent cells.
Enter and Edit Your Data

Using JMP Enter Data in Data Tables

Figure 4.5  Missing Values

2. Right-click and select Fill > Replace Missing with Previous Value.

Figure 4.6  Replaced Values

Enter Cell Formulas into Data Table Columns

In numeric data table columns, you can enter cell expressions preceded by an equal sign (=). JMP evaluates the expression and stores the new number as the cell’s value. Unlike column formulas, a cell expression is not stored. Cell expressions can contain operators, constants, and global and column variables.

To enter an expression

1. Click the cell where you want to enter the expression.
2. Type an equal sign (=), and then type the expression (Table 4.1).
3. Press Enter.
Table 4.1  Examples of Expressions in Table Cells

<table>
<thead>
<tr>
<th>Example expression</th>
<th>Cell value</th>
</tr>
</thead>
<tbody>
<tr>
<td>=sqrt(2)</td>
<td>1.41</td>
</tr>
<tr>
<td>=456+890</td>
<td>1346</td>
</tr>
<tr>
<td>=height+weight</td>
<td>Sums the values of cells in columns height and weight located in the same row as the cell that you entered the expression.</td>
</tr>
<tr>
<td>=height[1]</td>
<td>Displays the value found in row 1 of the height column</td>
</tr>
</tbody>
</table>

Select Rows in Data Tables

To select one entire row

- Click in the empty space that contains the row number.

To select a specific row number

- Select Rows > Row Selection > Go to Row and type in the desired row number.

To select multiple rows

- For continuous selection:
  - Click and drag the cursor over the row numbers.
  - Press Shift and click the first and last rows of the desired range.
  - Press Shift and press the up or down arrow key.
- For discontiguous selection:
  - Press Ctrl and click each row.

To select or deselect all rows

- To select all rows, select Rows > Row Selection > Select All Rows.
  or
- Press Shift and click the lower triangular area in the upper left corner of the data grid to select. Click again in the same area to deselect all rows (Figure 4.7).
- To clear all highlighted areas in the data table, press Esc.
Figure 4.7 Lower Triangular Area

To select random rows
1. Select **Rows > Row Selection > Select Randomly**.
2. You can randomly select either a specific number of rows, or a proportion of the total number of rows:
   - Enter a whole number to select that number of rows.
   - Enter a value between 0 and 1 to select that proportion of rows.
   For example, enter 10 to select 10 rows. Enter 0.1 to select 10% of the rows.

To invert the row selection
- Select **Rows > Row Selection > Invert Row Selection**.

To select dominant rows
1. Select **Rows > Row Selection > Select Dominant**.
2. Choose the column(s) whose values you want to use to determine dominance.
3. Select the high or low values to dominate by for each column.
4. Click **OK**.

Note the following about dominant values and rows:
- A value is dominant over another value if it is higher or lower (based on your specification).
- The Select Dominant option selects each row that is not dominated by any other row. A row dominates another row only if all of its values are dominating the other row’s values.
- The resultant set of rows is called the Pareto Frontier.

To save the current row selection in a new column
1. Select **Rows > Row Selection > Name Selection in Column**.
2. Type a column name.
3. Label the selected and deselected rows.
4. Click **OK**.

**Tip:** If you repeat this process after creating the new column and indicate the same column name, the original column is overwritten. Changes that you made in the data table to Selected or Unselected values are lost. Avoid overwriting those values by clearing the corresponding box in the Name Selection in Column window. For example, to avoid overwriting the Unselected values, make sure that the Unselected box is cleared.

**To select excluded, hidden, or labeled rows**

1. Select **Rows > Row Selection**.
2. Select from the following options:
   - Select Excluded
   - Select Hidden
   - Select Labeled

**Note:** For more information about excluded, hidden, or labeled rows, see “Assign Characteristics to Rows and Columns” on page 232.

**To select rows that contain duplicate values**

1. Select **Rows > Row Selection > Select Duplicate Rows**.
   - All duplicate rows except for the first are selected. If no columns are selected, duplicate rows are selected using all the columns.
   - If columns are selected, duplicate values are found in the rows of those columns.
   - The match is case sensitive.

**Find Matching Cells in Rows**

Find cells that have matching values using the Select Matching Cells option.

- Select **Rows > Row Selection > Select Matching Cells**
  or
- Right-click one of the highlighted row numbers and select **Select Matching Cells**.
Select Rows That Contain Specific Values

JMP can search for a specific value (or text string) and highlight all of the cells in the data table that contain the specific value.

1. Select **Rows > Row Selection > Select Where**.

**Figure 4.8** Specify Criteria for Selecting Rows

2. From the column list, highlight the name of the column whose rows you want to select.

3. Use the drop-down menu to select a condition from the list (equals, does not equal, and so on). See Figure 4.8.

4. Type the search value.

5. Click **OK**.

You can also specify the following optional features:

- To compare the values of two columns, click the **Compare column** check box. Select from the list of columns for comparison.
- To make the search case-sensitive, click the box beside **Match Case**.
- You can save a Where clause from the Select Rows window to the clipboard, data table, or script window. Select **Keep dialog open**, select rows and other options, and select one of the Save Script options from the Row Selections red triangle menu. Add JSL to the script that reruns the query:

```
dt = Open("$SAMPLE_DATA/Big Class.jmp");
Current Data Table() << Row Selection(
    Select where( :age == 15 ),
    Dialog( Edit( Source Column( :age ) == "" ), Keep dialog open )
```
If rows are currently selected in the data table, you can specify the following features:

- Click an option under **Current Selection** to tell JMP how to handle that current selection:
  - **Clear** removes the highlight from currently selected rows and selects all rows that contain the specified value.
  - **Extend** keeps the currently selected rows selected and also selects the rows in which the specified value has been found.
  - **Restrict** selects the rows in the currently selected array that contain the specified values.

- Click **Add Condition** to add a condition to the list.

- To add more conditions to the search, repeat the previous steps. Click the appropriate item in the **Select Rows** area to specify if you would like JMP to select rows conditionally: if *all* conditions are met, or if *any* of the conditions are met.

### Locate the Next Selected Row

You can locate the next selected row after the current row and cause it to flash by selecting **Rows > Next Selected**.

Each time you select **Rows > Next Selected**, the next selected row is found and flashes. A beep signals when the last selected row is located.

You might want to use this feature when you have selected rows intermittently in a large data set and want to look through the selected rows in the data table.

#### Example of Locating Next Selected Rows

1. Select **Help > Sample Data Library** and open **Diamonds Data.jmp**.
2. Select **Analyze > Fit Y by X**.
3. Select Carat Weight and click **Y, Response**.
4. Select Price and click **X, Factor**.
5. Click **OK**.
6. Select **Tools > Lasso**.
   
   If you cannot see the menu bar, hover over the blue bar below the title bar to reveal it.

7. Lasso some of the points near the 10,000 dollar price at the bottom of the plot (Figure 4.9).
8. In the data table, select **Rows > Next Selected** (or you can press F7).

You can easily navigate through the selected rows to see the data for each.
Select Columns in Data Tables

There are several ways to select columns:

- Select columns in the data table itself. See “How to Select Columns” on page 203.
- In a data table that has many columns, select columns by attributes, properties, and statistics in the Columns Viewer. See “Select Columns in the JMP Columns Viewer” on page 204.
- Find the next or previously selected column. See “Locate Next and Previously Selected Columns in Data Tables” on page 210.

How to Select Columns

Choose one of several methods for selecting columns in a data table.

To select one entire column

- In the data grid, click in the empty space around the column name.
  
  or
  
- In the Columns panel, click the column name.

To select a specific column number

1. Select Cols > Column Selection > Go to.
2. Enter the column number or name and click OK.
To select multiple columns

- For continuous selection:
  - Click and drag the cursor over the column name.
  - Press Shift and click the first and last columns of the desired range.
  - Press Shift and press the left or right arrow key.
- For columns that are not next to each other:
  - Press Ctrl and click each column.

To select or deselect all columns

- Press Shift and click the upper triangular area in the upper left corner of the data grid to select. Click again in the same area to deselect all columns.

Figure 4.10 Upper Triangular Area

Tip: To clear all highlighted areas in the data table, press Esc.

To invert the column selection

Select Cols > Column Selection > Invert Column Selection. Selects any column that is currently deselected and deselects any column that is currently selected.

Select Columns in the JMP Columns Viewer

The Columns Viewer option in the Cols menu helps you quickly select columns by attributes, properties, and statistics, particularly in a data table that has many columns. You can view summary statistics and properties for those columns, view quartiles in the summary statistics, subset the data, and more. And columns in the Columns Viewer window are also linked to the data table columns.
The Columns Viewer gives you a quick view of data table characteristics. For example, the Summary Statistics report shows which columns contain missing values. You can select those columns in the report and then exclude them in the data table.
The Summary Statistics report shows the following information:

- the total number of rows (N)
- the number of rows with missing values (N Missing)
- the number of categories (N Categories)
- for continuous data, the Min, Max, Mean, and Std Dev

Other options include the following:

**Clear Select**  Deselects columns in the data table and in the Columns Viewer. This option ensures that no columns are selected before you begin selecting columns.

**Subset**  Creates a linked subset data table from the selected columns.

**Show Summary**  Creates a linked Summary Statistics report for the selected columns.

Right-click to select options such as sorting by column or creating a data table. Select **Show Quartiles** to include lower quartiles, upper quartiles, and interquartile ranges. To create a linked data table from all columns in the report, click the Summary Statistics red triangle and select Data Table View.

**Find Columns with Properties**  Shows a list of column properties in the Columns with Properties report. Select the properties that you want to find and then click **OK** to create a linked report from all columns. Or you can select columns first in the Select Columns list and then show the list of properties just for those columns.
Notes:

- Each time you click the **Show Summary** or **Find Columns with Properties** buttons, a new report is added to the window. To delete a report, select **Remove** from the report’s red triangle menu.

- Deleting rows from a data table view created from Columns Viewer is not undo-able.

Example of Finding Columns with a Specific Property

This example shows how to find columns that have a Formula property and then view all formulas at once.

1. Select **Help > Sample Data Library** and open **Consumer Preferences.jmp**.
2. Select **Cols > Columns Viewer** to open the Data Table Columns Viewer window.
3. Select **Find Columns with Properties**, select **Formula**, and click **OK**.

   The Columns with Properties report appears. Several columns include the Formula property. Because the list is so long, you want to view all formula columns together.

4. Right-click the report, select **Sort by Column, Formula**, and then click **OK**.

   Columns that have a Formula property appear at the top of the report.
5. Select the Employee Tenure, Position Tenure, and Salary Group columns and select **Column Info**.

   Formulas for the selected columns appear in the data table’s Column Settings window.

### Example of Showing Summary Statistics

This example shows how to find columns with a low standard deviation. This can be helpful if you want to delete or exclude that data from an analysis.

1. Select **Help > Sample Data Library** and open Semiconductor Capability.jmp.
2. Select **Cols > Columns Viewer** to open the Data Table Columns Viewer window.
3. Type PNP in the box and press Enter.

   The grouped processes are shown.
4. Expand the processes group to show the PNP columns.
5. Click **Show Summary** to add the Summary Statistics report.

The rows show the minimum, maximum, mean, and standard deviation for each column.

6. Right-click in the report and select **Sort by Column**.
7. Select **Std Dev** and **Ascending**, and then click **OK**.

Notice that PNP6 has no standard deviation, because the minimum, maximum, and mean values are 0.
Enter and Edit Your Data

Resize Rows and Columns

8. In the Summary Statistics report, select the row for PNP6 and then display the data table.

9. View the data table and press Delete to remove the selected column.
   
   The column is instantly removed from the data table.

10. To close the Columns Viewer, click the X button in the upper right corner (Windows) or upper left corner (macOS) of the window.

**Locate Next and Previously Selected Columns in Data Tables**

You can find the next selected column after the current column by selecting *Cols > Column Selection > Next Selected Column*. Similarly, you can find the previously selected column before the current column by selecting *Cols > Column Selection > Previous Selected Column*.

Each time you select one of these options, the next or previously selected column appears and flashes. The options are available only when columns are selected.

You might want to use this feature to look at intermittently selected columns in a large data table.

**Resize Rows and Columns**

To resize rows

Resize rows by dragging one of the row borders. All rows are resized to the same height. Graphics that appear inside each cell shrink based on the row height.

To resize columns

To resize a column, drag the column border to the right or left.

To resize several columns to the same width, follow these steps:
1. Select the columns that you want to resize.
2. Press Alt (Windows) or Option (macOS) and drag one of the column borders. All columns are resized to the same width.

Organize Data in Data Tables

Choose one of many methods to rearrange data in a data table.

- “Delete Rows in Data Tables”
- “Delete Columns in Data Tables”
- “Rearrange Columns in Data Tables”
- “Group Columns in Data Tables”
- “Move Values in Data Tables”
- “Color Cells in Data Tables”
- “Edit or Delete Cells in Data Tables”
- “Edit Column Names in Data Tables”
- “Hide and Exclude Rows in Data Tables”
- “Exclude Rows in Data Tables”
- “Hide Rows in Data Tables”
- “Exclude Columns in Data Tables”
- “Hide Columns in Data Tables”
- “View Patterns of Missing Data in Data Tables”
- “Find and Replace Cell Values in Data Tables”
- “Edit Cells in Data Tables”
- “Right-Click Menus for Rows and Columns”
- “Compare Data Tables”

Delete Rows in Data Tables

To delete rows in a JMP data table, follow these steps:

1. Highlight the rows that you want to delete.
2. Press Delete, or right-click the row numbers and select Delete Rows.
Caution: When you try to delete thousands of rows, an alert might appear if your computer has insufficient memory to save data for undo. Either select fewer rows to delete or select **Disable Undo** from the Table panel red triangle menu. This option removes all actions from the undo history and does not record future actions. When the **Disable Undo** option is selected, it is in effect only while the data table is open; the setting is not saved with the data table.

Delete Columns in Data Tables

To delete columns in a JMP data table, follow these steps:

1. Highlight the columns to delete.
2. Press Delete, or right-click and select **Delete Columns**.

Rearrange Columns in Data Tables

You can rearrange or sort data table columns by their name, data type, or modeling type, or reverse the current order. To reorder columns, select **Cols > Reorder Columns** and select from one of the following options:

**Move Selected Columns**  Moves the selected columns to a particular place in the data table. Specify where to place the selected columns in the Move Selected Columns window:

- **To first**  Moves the selected columns so that they are in the left-most position in the data table.

- **To last**  Moves the selected columns so that they are in the right-most position in the data table.

- **After**  Moves the selected columns so that they are after a column that you identify.

**Original Order**  Returns the columns to the order they were in when data table was last saved.

**Reorder by Name**  Arranges the columns from left to right in alphabetical order by column name.

**Reorder By Data Type**  Arranges the columns from left to right in alphabetic order by data type (expression, row state, character, numeric).

**Reorder By Modeling Type**  Arranges the columns from left to right in alphabetic order by modeling type (none, continuous, ordinal, nominal, multiple response, unstructured text, vector). Row state columns have no modeling type, and are shown last.

**Reverse Order**  Reverses the order of the data table columns.
Group Columns in Data Tables

Group columns within a single heading to manage large numbers of columns and facilitate analysis role assignment. Grouped columns appear in an outline format within the Columns panel.

To group or ungroup columns

1. Within the data grid, select the columns that you want to group.
2. From the main menu, select Cols > Group Columns or Cols > Ungroup Columns.

or

1. From the Columns panel, select the columns that you want to group.
2. Right-click the selected columns and select Group Columns or Ungroup Columns.

Note: Grouped columns are automatically retained for data tables generated from the following commands: Subset, Sort, Summary, Join, Stack, and Split. For the Stack command, if all the columns in the stack group belong to the same columns group, then the group’s name is used for the column name.

Move Values in Data Tables

To move values in a data table, select the values, click and pause, and then drag and drop the values into the new location.

Tip: Clicking and dragging on a selection without pausing extends the selection.

When dragging and dropping values, note the following:

• Cells retain all of their characteristics and column properties.
• After you move cells, missing values appear in the cells that you initially selected.
• The selected cells and the destination cells must have the same data type.
• If you drag a set of cells to an empty area of the table, new columns are automatically created.
• New columns have the original columns’ display format and modeling types.

To specify where to move rows

1. Highlight the rows that you want to move.
2. Select Rows > Move Rows.
3. Specify where you would like to move the rows in the Move Rows window:
Enter and Edit Your Data

Chapter 4

Organize Data in Data Tables

– To the beginning of the table (At start)
– To the end of the table (At end)
– After a specific row number (After row:

Move Content into Another JMP Window

On Windows, you can drag selected content over a minimized window. The minimized
window moves to the front and you can paste your content into it. You can do the same thing
in JMP. For example, you can drag selected content over the Home Window button
(located in the bottom right corner of most windows). Then in the Window List, drag the
content over the window that you want to move the content into. That window moves to the
front and you can drop in the content.

Tip: If you cannot see the JMP Home Window button, select View > Status Bars.

For example, you can drag a selected column, row, or cell from one data table into another;
drag selected text from one script window into another; or drag selected content from a report
into a journal.

Color Cells in Data Tables

You can select one or more data table cells and change the color to highlight a specific value.
Right-click the cell or cells, select Color Cells, and select a color. To remove color from cells,
select the cells, right-click, and select Cols > Clear Color.

Edit or Delete Cells in Data Tables

To edit or delete the contents of a cell, follow these steps:
1. Click the cell containing the value that you want to edit or delete.
2. Press Delete.
3. To edit the value, click the cell a second time, and then edit the cell’s value.

Edit Column Names in Data Tables

To edit a single column name, select the column and begin typing. You can also edit the
column name in the Column Info window, or select the header and press Enter.

To edit all of the column names at once, click Cols > Column Names and select one of the
following options:

Move up  Moves the first row of data up to replace the column names.
Move up and append  Moves the first row of data up and appends the entries to the existing column names.

Move down  Moves the columns names down to become a row of data. The columns are then named Column 1, Column 2, and so on.

Recode Column Names  Opens the Recode window to recode the column names. See “Recode Data in a Column” on page 264.

Hide and Exclude Rows in Data Tables

Apply Hidden and Excluded row states to rows that you do not want to include in analysis or plot calculations and that you do not want to display in plots. These rows are not included in subsequent analyses.

Notes:

- Plots found under the Graph menu, with the exception of Profilers, are immediately recalculated to reflect hidden and excluded rows.
- For many platforms, reports and plots are not updated immediately to reflect excluded and hidden observations. You need to rerun the analysis to recalculate analysis results and the related plots. For exceptions, see “Platforms that Update Immediately for Hide and Exclude” on page 216.
- When you Exclude and Hide rows, they are excluded and hidden in all open reports and plots that update automatically.
- When you Exclude and Hide rows, a circle with a strikethrough ( , for Exclude) and a mask icon ( , for Hide) appear beside the row number.
- Rows remain hidden and excluded until you highlight the rows and select Hide and Exclude again

To hide and exclude one or more rows

1. Select the rows that you want to hide and exclude.
2. Do one of the following:
   - Right-click the highlighted area next to the row numbers and select Hide and Exclude.
   - From the Rows menu, select Hide and Exclude.
Platforms that Update Immediately for Hide and Exclude

When you apply Hide and Exclude to rows, for most platforms under the Analyze menu, points or plot elements that correspond directly to rows are usually hidden immediately in plots. However, calculations shown in accompanying reports usually are not updated. For the following platforms, applying Hide and Exclude results in immediate updates to plots and calculations:

- Tabulate
- Control Chart Builder

Exclude Rows in Data Tables

Apply the Excluded row state to rows that you do not want to include in subsequent calculations. Statistics are recalculated without the excluded rows.

To exclude one or more rows, follow these steps:

1. Select rows that you want to exclude.
2. Do one of the following:
   - Right-click the highlighted area next to the row numbers and select Exclude/Unexclude.
   - From the Rows menu, select Exclude/Unexclude.

Notes:

- In most cases, when a row is represented by a point or an individual plot element, excluding the row does not hide it in plots.
- In Graph Builder, when a plot element is represented by a group of rows, the plot is reconstructed using only the unexcluded rows. The plot also does not display plot elements corresponding to the excluded rows. Excluded rows are treated as if they are both hidden and excluded.
- Plots found under the Graph menu (with the exception of Profilers, Parallel Plot, and Scatterplot Matrix) are immediately recalculated to reflect excluded rows.
- For many platforms, reports and plots are not updated immediately to reflect excluded observations. You need to rerun the analysis to recalculate plots and analysis results.
- When you Exclude rows, they are excluded in all open plots and reports that are updated immediately.
- A circle with a strikethrough ( ) appears beside the row number of an excluded row.
- Rows remain excluded until you highlight the rows and select Exclude/Unexclude again.
Hide Rows in Data Tables

Apply the Hidden row state to rows that you do not want to include in plots.

**Note:** Not all plots hide the elements that correspond to hidden rows. This is often the case when the calculations used to construct the plot elements use the data from the hidden rows. As a general rule, if there is a one-to-one correspondence between rows and plot elements, the points or elements corresponding to the hidden rows are hidden.

To hide one or more rows, follow these steps:

1. Select rows that you want to hide.
2. Do one of the following:
   - Right-click the selected area next to the row numbers and select **Hide/Unhide**.
   - From the **Rows** menu, select **Hide/Unhide**.

**Notes:**

- When you Hide rows, they are hidden in all open plots that are updated immediately.
- Hiding rows does not exclude them from calculations and analyses.
- When each hidden row corresponds to a point or an individual plot element, plots are updated immediately when you apply the Hidden row state to rows.
- Depending on the platform, plot elements are calculated using multiple observations, but they do not correspond directly to a row. In these cases, the plot elements generally are not updated to reflect hidden observations unless those rows are also excluded.
- For some plots where plot elements correspond to groups of rows, when you Hide rows, the plot is updated to hide plot elements corresponding to hidden rows. See “JMP Plots Where Grouping Elements are Updated for Hide” on page 217.
- A mask icon ( 🔒) appears beside the row number of a hidden row.
- Rows remain hidden until you select the rows and select **Hide/Unhide** again.

**JMP Plots Where Grouping Elements are Updated for Hide**

When you apply Hide to rows, in plots with a one-to-one correspondence between rows and plot elements, the points or plot elements are usually hidden immediately. However, for the following platforms and options, applying Hide results in immediate updates to plot elements that correspond to groups of rows:

- Control Chart Builder. See *Quality and Process Methods*.
- Graph Builder. The bar chart, heat map, and pie chart are updated to reflect hidden rows. See *Essential Graphing*.
- Bubble Plot. See *Essential Graphing*.
Exclude Columns in Data Tables

When your data table contains columns that you do not want to consider for analysis, you can exclude those columns so that they do not appear in selection lists in launch windows. Note the following:

- Excluded columns remain visible in the data grid.
- A circle with a strikethrough ( ) appears to the right of the column name in the Columns panel.

To exclude columns from launch windows

1. Select one or more columns that you want to exclude.
2. Do one of the following:
   - Right-click the highlighted column name in the Columns panel and select Exclude/Unexclude.
   - From the Cols menu, select Exclude/Unexclude.

To unexclude columns

1. Select the columns in the Columns panel.
2. Do one of the following:
   - Right-click the highlighted column name in the Columns panel and select Exclude/Unexclude.
   - From the Cols menu, select Exclude/Unexclude.

Hide Columns in Data Tables

When your data table contains columns that you do not want to see in the data grid, you can hide those columns. Note the following:

- Hidden columns appear in launch windows and are available for analyses.
- A mask icon ( ) appears to the right of the column name in the Columns panel.

To hide columns

1. Select one or more columns that you want to hide.
2. Do one of the following:
   - Right-click the highlighted column name in the Columns panel and select Hide/Unhide.
   - From the Cols menu, select Hide/Unhide.
To unhide columns

1. Select the columns in the Columns panel.
2. Do one of the following:
   - Right-click the highlighted column name in the Columns panel and select **Hide/Unhide**.
   - From the **Cols** menu, select **Hide/Unhide**.

View Patterns of Missing Data in Data Tables

If your data table contains missing data, you might want to determine whether there is a pattern to the missing data. The pattern might help you make discoveries about your data.

To view patterns of missing data, follow these steps:

1. With your data table open, select **Tables > Missing Data Pattern**.
2. Select the columns for which you would like to find patterns of missing data.
3. Click **Add Columns**.
4. Select **Count Missing Value Codes** to count missing value codes as missing values.
5. Select **Add Value Colors Property** to consistently color columns that contain 0 or 1 (missing value indicators).
   
   For example, nonmissing is always colored blue, missing is always colored red. This is especially helpful for data tables that might have similar values across columns.
6. Click **OK**.

Example of Viewing Patterns of Missing Data

1. Select **Help > Sample Data Library** and open Missing Data Pattern.jmp.
2. Select **Tables > Missing Data Pattern**.
3. Highlight all of the columns.

**Note:** For more information about the options in the red triangle menu, see “Column Filter Menu” on page 54 in the “Get Started with JMP” chapter.

4. Click **Add Columns**.
5. Click **OK**.

**Figure 4.19** A Missing Data Pattern Table

**Tip:** To quickly create a Treemap or Cell Plot of the data, click the green triangle next to the Treemap or Cell Plot script in the table panel.
Figure 4.19 shows the following patterns:

- Row 1 shows that there are two instances where all rows in Trial 1, Trial 2, Trial 3, and Trial 4 have no missing values.
- Row 2 shows that there are two rows in the source table whose one missing value is in the Trial 4 column.
- Row 3 shows that there are two rows in the source table whose missing values are in the Trial 3 and Trial 4 columns.
- Row 4 shows that there is one row in the source table whose three missing values are in the Trial 2, Trial 3, and Trial 4 columns.

The Count column is assigned the frequency role. If you now use the Missing Data Pattern data table to run an analysis, JMP automatically uses Count as a frequency. See “Assign a Preselected Analysis Role to a Column” on page 334 in the “Set JMP Column Properties” chapter.

Find and Replace Cell Values in Data Tables

You can find and replace cell values by selecting the Edit > Search > Find options.

Figure 4.20 The Find Window

The following rules apply to searching for values:

- To find values in hidden columns, unhide the column.
- Values found in locked columns cannot be modified.
- The Undo command works only with Replace. You cannot undo Replace All.
- If your data table contains value labels, using the Search commands searches for actual values, but does not search for labels. See “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.
- If your data table contains formatted values (such as dates, times, or durations) using the Search command searches for the formatted values, not the actual values.
Find Window Options

Refine your search with the following options:

**Match Case**  Performs a case-sensitive search, which can be useful for locating proper nouns or other capitalized words.

**Match entire cell value**  Detects empty spaces, which lets you search for a series of words in a character column, or locate strings with unwanted leading or trailing empty spaces.

*Tip:* To find missing character values, leave the **Find what** box empty and check **Match entire cell value**. To find missing numeric values, insert a period into the **Find** box and check **Match entire cell value**.

**Use regular expressions**  Assumes the find string to be a regular expression instead of the literal string that you enter in the **Find what** box. The regular expressions follow standard semantics.

**Restrict to selected rows**  Restricts the search to selected rows.

**Restrict to selected columns**  Restricts the search to selected columns.

**Search data**  Searches only data cells (omitting column names).

**Search column names**  Searches only column names (omitting data cells).

**By column**  Searches the table column by column, from top to bottom, until it reaches the last cell in the rightmost column, or until you stop the search.

**By row**  Searches the data table row by row from left to right, to the rightmost cell in the last row or until you stop the search.

**Multiple lines**  Increases the Find and Replace boxes to 3 lines long instead of 1. The Enter key inserts a return into the field.

*Tip:* You can alternatively click and drag on the Find and Replace boxes to make them larger. If you copy and paste, the boxes resize to 1 line long, but all of your text is still there.

**Keep dialog open**  Keeps the Find window open during your search.

Search Actions

This section describes some common searches that you might perform.

Begin by searching for a value in the data table. The search begins with the first cell in the first column and searches every cell until it locates the value or reaches the end of the table.
To replace the currently highlighted cell value

Enter a value in the Replace with box and click Replace. Or, if the Search window is closed, select Edit > Search > Replace. If the replace value is a missing value, the currently highlighted cell content becomes a missing value.

To replace all occurrences of the specified value

Enter a value in the Replace with box and click Replace All. Or, if the Search window is closed, select Edit > Search > Replace All.

To replace the value and search for the next value

Enter a value in the Replace with box and click Replace. Or, if the Search window is closed, select Edit > Search > Replace and Find Next. Or, press Ctrl+L.

To use a selected value as the Find what value

In the data table, select a value. Select Edit > Search > Use Selection for Find. Next, select Edit > Search > Find. The value that you selected in the data table is already entered in the Find what field.

To use a selected value as the Replace with value

In the data table, select a value. Select Edit > Search > Use Selection for Replace to populate the Replace with field.

To find the next value when the Search window is closed

Select Edit > Search > Find Next. Or, press Ctrl+G, or F3, on Windows.

To find a missing value:

- To find missing character values, leave the Find what field empty and select Match entire cell value.
- To find missing numeric values, type a period into the Find what text box.

Edit Cells in Data Tables

Use the Row Editor to browse or edit cells one row at a time. Open the Row Editor in one of the following ways:

- Select Rows > Row Editor.
- In a data table, double-click in the row number area. The row that you use is the row that first appears in the Row Editor.
- In a report window, right-click in a plot or graph and select Row Editor.
Figure 4.21  Row Editor

Note the following:

- If you have a report window open, and you want edited data to be automatically reflected there, make sure that Automatic Recalc is turned on. See “Automatic Recalc” on page 455 in the “JMP Reports” chapter.

- If your data table contains value labels, the Row Editor displays the label, and when the cell is highlighted for editing, it shows the actual value. See “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.

Row Editor Buttons

Click the arrow buttons to browse through selected rows or the entire data set if no rows are selected.

- Shows the previous row.
- Shows the previously selected row.
- Makes the row blink in graphs.
- Shows the next selected row.
- Shows the next row.
- Creates a new row at the end of the data table.

Note: Changes made to a row using the Row Editor are written to the data table when you change fields in the Row Editor. You still need to save the changes to the data table.

Row Editor Options

The red triangle menu in the Row Editor contains the following options:

**Next Selected**  Displays information for the selected row that is located after the current one.

**Prev Selected**  Displays information for the selected row that is located before the current one.
Next  Displays information for the row that is located after the current one, regardless of whether the row is selected.

Prev  Displays information for the row that is located before the current one, regardless of whether the row is selected.

Save  Saves the data table and any changes that you have made to it via the Row Editor.

New Row  Creates a new row in the data table.

Find  Displays the same window as if you had selected Rows > Row Selection > Select Where. Select one of the options from the Current Selection menu, and then highlight the column whose rows you want to select. Type in the value for which you want JMP to search. See “Resize Rows and Columns” on page 210.

Blink  Causes the current row’s highlight to flash at a rapid rate.

Note: Text in a locked column or a locked data table cannot be edited. See “Lock” on page 291 in the “Set JMP Column Properties” chapter and “Lock Data Tables” on page 281.

Right-Click Menus for Rows and Columns

When you right-click in the row number area, or at the top of a column in the column name area, pop-up menus appear. These menus provide quick access to selected commands in the Rows and Columns menus. For more information about these options, see “Right-Click Options for Columns” on page 47 in the “Get Started with JMP” chapter and “Right-Click Options for Rows” on page 48 in the “Get Started with JMP” chapter.

Compare Data Tables

JMP can compare two open data tables and report the differences between data, scripts, table variables, column names, column properties, and column attributes. The numbers of columns and rows in each data table are shown at the top of the Compare Data Tables window. In this example, the sample data tables Popcorn Trials.jmp and Popcorn.jmp are compared.

Figure 4.22  Basic Information about Data Tables
Specify Matching Columns

Columns with the same name are automatically matched. Lines are drawn between each matched column. You can also manually link two columns.

1. Select Help > Sample Data Library and open Popcorn.jmp and Popcorn Trials.jmp.
2. Show Popcorn Trials.jmp and select Tables > Compare Data Tables.
3. From the With list, select Popcorn.jmp.
   Popcorn Trials.jmp should automatically be selected from the Compare list.
4. In the Match Columns pane, select yield and yield1 and then click Link.

**Figure 4.23 Manually Linked Columns**

Columns that have the same name are automatically linked.

**Note:** If you click the Compare Data icon, the linked columns will not be compared. The values for that pair of columns will show up in the results, but they won’t be compared.

5. Click Compare.
   The results are shown in the Data report.
The first eight rows are the same so they are not shown. The remaining rows (colored blue) are only in the second table, Popcorn.jmp.

6. In the Data report, deselect Hide rows with no differences.
The first eight rows are shown because they are the same in both data tables.

7. Deselect **Hide columns with no differences**.
Columns that are in both data tables and that match are shown. You might select this option to give more context to the matched data.

**Note:** If the data in a cell isn’t ‘completely shown, select the text and then view the data in the Cell Data box.

### Data Table Compare Options

**Align Data Options**

**Flexible by Row**  Searches for common rows to align. Consider this option for smaller data tables if you think that the data tables are nearly the same.

**By Row**  Compares rows one by one. Consider this option if you already know that the rows should line up row by row. The comparison will run much faster. However, if the default Flexible by Row was selected, and the comparison is taking too long, you might want to select this option.

**Use ID Columns**  Uses the selected ID column to compare rows. The rows of the data table are uniquely identified by the values of the ID column. Consider this option if the data tables are large, sorted differently, or have missing rows. You can select more than one column.
Fuzzy Compare Options

**Ignore missing**  Ignores missing data.

**Allow Relative Error**  Enables you to specify the relative error rate for numeric data. The numeric values are considered equal if they are within the relative error rate that you specify. The smaller the relative error rate, the more precise the comparison.

**Ignore case**  Disregards case when comparing text.

**Ignore whitespace**  Disregards whitespace when comparing text.

Data Options

**Show fuzzy differences**  Shows differences in numeric and string data that are approximately the same. Works with the value in the Relative Error field to remove insignificant differences.

**Hide columns with no differences**  Shows or hides all matched columns.

**Hide rows with no differences**  Shows or hides rows that contain matching data.

Compare Table Properties

Click the red triangle and select **Compare Table Properties** to see differences in table scripts and variables. Figure 4.27 shows that the table variables and scripts are different. To see the full variable or script, select the line and view the selected metadata.

In this example, both notes differ, and the reference variable and scripts are only in Popcorn.jmp. The Notes variable is selected so that you can see its contents in both data tables in the Selected Metadata box. The red shading indicates that the text is only in Popcorn.jmp. The blue shading indicates that the text is only in Popcorn Trials.jmp.

**Figure 4.27  Different Table Variables**
Deselect **Show Diff** to see the name of each data table and the complete contents of each Notes variable instead of only showing the differences.

*Shortest run* is the smallest number of consecutive characters that are required to be the same (between the two files) before you can declare the characters as a *common subsegment*. A common subsegment has no background color because it is present in both files. The shortest run is set to 3 to prevent subsegments that are too short from showing up as common, which is typically unhelpful. For example, a shortest run of 1 means that any single character that is in both files could match. This leads to many very short segments of common text and differences, which is usually not a good reading experience.

**Compare Column Attributes and Properties**

Click the red triangle and select **Compare Column Attributes and Properties** to see differences in column notes, value colors, and the like.

Figure 4.28 shows that column notes are different in Popcorn.jmp and Popcorn Trials.jmp. The popcorn column is selected so that you can see the complete note and differences between the two notes in the Selected Metadata box.

**Figure 4.28** Comparing Column Attributes and Properties

---

Notes:

```
Stack Yield1 and Yield2 with Stack command in ounces. This is the response for the Settings of Tables menu to get the POPCORN data table. three factors:  
apcorn, oil amt, and batch.
```
Assign Characteristics to Rows and Columns

This section describes how to exclude, hide, label, color, or mark rows and columns in order to customize the appearance of points in scatterplots and graphs.

- “How to Find Options for Rows and Columns”
- “Label Rows and Columns”
- “Assign Colors or Markers to Rows”
- “Create Color Themes in Graphs”
- “Delete Custom Color Themes in Graphs”
- “Select Matching Row State Cells”
- “Delete Row Characteristics”
- “Lock Columns”

How to Find Options for Rows and Columns

The menu for row actions can be accessed from the following places:

- the Rows menu in the main menu
- right-click a row
- the red triangle in the Rows panel
- the left red triangle in the upper left corner of the data grid

Similarly, the menu for columns actions can be accessed from the following places:

- the Cols menu in the main menu
- right-click a column
- the red triangle in the Columns panel
- the right red triangle in the upper left corner of the data grid

Label Rows and Columns

When you position the arrow cursor over a point in a plot, the point’s label appears. By default, row numbers are used as labels. You can customize the labels:

- You can change the label to display column values instead of the row number.
- You can enable the label to always appear, not only when you position the cursor over points.
• A label or yellow tag icon ( ) appears beside the column name in the Columns panel, indicating that points on plots are identified by the column value. If there are multiple columns that are labeled, their values appear on plots separated by a comma.

• Data remain labeled until you select Label/Unlabel again.

To change the label to display column values
1. Highlight one or more columns whose values you want to appear as the label in plots.
2. Select Cols > Label/Unlabel from the menu or right-click and select Label/Unlabel.

To enable the label to always appear (not just when you position the cursor over points)
1. Highlight one or more rows whose label you want to always appear in plots.
2. Select Rows > Label/Unlabel from the menu.

To turn off labeling for rows or columns
1. Highlight the labeled rows or columns that you no longer want labeled.
2. Select Label/Unlabel from the Rows menu or Cols menu. You can also right-click columns or rows and select Label/Unlabel.

Tip: A photo can be displayed in the label when you hover over data. For example, the SAS Offices.jmp sample data table contains an Expression column that is labeled. A photo of each office is stored in the column. When you hover over a data point on the map, the photo for that row appears. See “Expression Role” on page 326 in the “Set JMP Column Properties” chapter.

Assign Colors or Markers to Rows

Assign colors or markers to rows to differentiate rows in a data table.

• If you assign a color to a row, the points representing the values in that row are colored in the plot.
• If you assign a marker to a row, the point is replaced with the marker in the plot.
• You can also assign colors or markers based on column values.

Assign a Color to Rows

Assigning a color to selected rows means that the points in plots appear in the color that you select. In the data grid, the active color assigned to a row appears next to the row number.
To assign rows a color

1. Highlight one or more rows that you want to assign a color to.
2. Right-click the highlighted rows and select **Rows > Colors**.
3. Select one of the available colors.

**Tip:** To clear an assigned color from the selected rows, assign the color black.

Add Markers to Rows

To replace the standard points in plots with a marker, use the JMP markers palette. In the data table, these markers also appear next to row numbers.

1. Highlight one or more rows that you want to apply the marker to.
2. Right-click the selected rows and select **Markers**, and then select the marker shape.
   - Select **Other** to create custom markers. You can type alphabetic characters, numerals, and other keyboard symbols.

**Tip:** To return to the default marker, select the initial dot marker.

Assign Colors or Markers to Rows Based on Column Values

You can assign colors or markers to your data table rows based on the values found in a particular column. For example, in a column called **Sex**, you could assign all rows whose value is F a red circle marker. All rows whose value is M could have a green plus marker. These colors and markers replace the default black dot in plots and appear next to its row number in the data table.

To assign colors or markers to rows based on column values

1. Select **Rows > Color or Mark by Column**.
2. Select the column to color and or mark.
3. Select the **Colors** and **Markers** schemes to apply.
   A preview of your selection appears under Row States.

4. (Optional) Select any additional options. See “**Color or Mark by Column Options**” on page 235.

5. Click **OK**.

6. (Optional) To shade all rows according to their row state, right-click in the row numbers area within the data grid and select **Color Rows by Row State**.
   From then on, the rows are shaded with the color that you assign to the rows.

**Color or Mark by Column Options**

**Colors**  
Select a color theme to assign different colors to the rows in your data table. Color assignment is based on the values of the selected column.

**Continuous Scale**  
Assigns colors in a chromatic sequence based on the values in the highlighted column.

**Reverse Scale**  
Assigns colors in a reversed chromatic sequence based on the values in the highlighted column.

**Markers**  
Assigns a different marker to each row in your data table based on the values found in the column that you highlighted.

**Make Window with Legend**  
Includes a legend with your new characteristics so that you can easily identify which colors and markers correspond with which row.

**Save To Column Property**  
Saves the color and marker information as a column property. The rows in the selected column of the data table are colored, based on the color theme.

**Save To Table Property**  
Saves the color and marker information as a table property.

**Excluded Rows**  
Assigns colors or markers to rows that are excluded.
Create Color Themes in Graphs

JMP includes several color themes that can distinguish a range of values in a graph. You can also create your own color themes based on an existing color theme or create custom themes.

**Note:** When you select a default color theme, the colors are not applied to reports that are open. You need to rerun the existing reports to format them with the default color theme.

See “Delete Custom Color Themes in Graphs” on page 241 for more information about deleting custom color themes.

**To create a color theme**

1. Select **File > Preferences > Graphs**.
2. To either create a new Continuous Color Theme or Categorical Color Theme, click the appropriate color theme.
   
   If you are creating a new continuous color theme, the Continuous Color Themes window appears.

**Figure 4.30** Continuous Color Themes Window

The sequential color “Cividis” is a form of Viridis that is designed for viewing with color limitations.

If you selected to create a new categorical color theme, the Categorical Color Themes window appears.
3. (Optional) To base the theme on an existing theme, select a color themes from the available themes.

4. Click the Custom Color Theme disclosure icon to show the Custom Color Theme panel. Figure 4.32 shows the color theme panels for both continuous and categorical themes (respectively).

5. Click **New** to create a new theme.

   A new color theme is created based on the selected color theme. A temporary name is assigned to the theme.

6. Type a new name in place of the temporary label. On Windows, do not press Enter. The window closes if you do so.

7. To modify the color theme, do any of the following:
– To modify the missing color, click the missing color to open a color palette. Select the desired missing value color and click **OK**.

– To modify the gradient of continuous color, move the sliders left or right.

– To add more colors to the gradient, click the color bar to choose a color. A new slider is displayed under the color bar.

– To change the color of a slider, click the slider to display the Color window and choose another color.

– To reverse the order of the colors on the gradient, click **Reverse**.

– To distribute the colors evenly on the gradient, click **Space Evenly**.

– To list the custom theme in the Sequential pane, select **Sequential** from the list.

– To list the custom theme in the Diverging pane, select **Diverging** from the list.

– To list the custom theme in the Chromatic pane, select **Chromatic** from the list.

– To prevent a theme from appearing in lists of color themes, select **Hidden**.

– To remove a color from the color theme, click the color’s slider and drag the slider above or below the color bar.

– To discard your changes, click **Cancel**.

8. Click **Save** to save the custom color theme.

   The new custom color theme is appended to the contents of the selected pane.

9. Click **OK** to close the color theme window.

**Continuous and Categorical Color Themes**

The following figure shows examples of the two types of color themes in JMP, continuous and categorical. When a color theme is selected for continuous data, the colors are graduated (as shown on the left). When the same color theme is selected for categorical data, the color consists of distinct blocks of color. (as shown on the right).
Custom Color Themes

Custom color themes can be applied in the same way as built-in color themes:

- You can select custom color themes as defaults from the **Continuous Color Theme** and **Categorical Color Theme** drop-down menus in the Graphs preferences. Only continuous color themes are available for continuous data. All color themes are available for categorical data.
- You can apply the custom color themes to components such as markers and data table rows. See “Assign Colors or Markers to Rows Based on Column Values” on page 234.
- In certain reports, such as treemaps and surface plots, you can select specific custom color themes. See Essential Graphing.

Use Custom Color Themes on Multiple Computers

In Windows, the color themes that you create are defined in the JMP preferences file called JMP.PFS. If you use JMP on more than one computer (for example, at home and at work), you can copy the color theme definitions from one JMP preferences file to another. Custom colors are then available on both computers.

In the preferences file, the code for a custom color theme looks like this:

```plaintext
Add Color Theme(
    "Pink to Blue", 2051, {{255, 168, 255}, {255, 0, 255}, {0, 128, 255}}
),
```
In this example, the name of the color theme is “Pink to Blue.” The Red/Green/Blue (RGB) values for each color slider are located in brackets. The first slider defines the RGB values 255, 168, and 255. The second and third groups of brackets define colors for the second and third sliders.

**Note:** The second value (2051) is the category of the color theme, such as Categorical or Continuous. You can omit the category, but JMP always includes the information in the preferences file or when `Show Preferences()` is run.

In a text editor (such as Microsoft Notepad) add this color theme to the preferences file on your other computer. The preferences file is located in your `Users` folder within the `JMP` or `JMPPro` folder.

C:/Users/<user_name>/AppData/Roaming/SAS/JMP/16
C:/Users/<user_name>/AppData/Roaming/SAS/JMPPro/16

**Note:** To see the preceding folders, you must configure Windows Explorer to show hidden files and folders. For more information, refer to the Windows help.

To transfer color themes to another Windows computer

1. On the computer that contains the customized JMP preferences, select **File > New > Script**. The Script window appears.
2. Type the following JSL function:
   ```jsl
   Show Preferences()
   ```
3. Click **Run Script**.
   
   Your customized preferences are written to the log.
4. Select **View > Log** (or display the open log).
   
   The custom color theme that you created appears, for example:
   ```jsl
   Add Color Theme(
   "Pink to Blue", 2051, {[255, 168, 255], {255, 0, 255}, {0, 128, 255}}
   ),
   ```
   
   This definition might be in the middle of other customized preferences that appear in the log.
5. Save the log as Log.jsl and open the file on the computer whose preferences you are updating.
6. On the computer whose preferences you are updating, close JMP.
7. Make a backup of JMP.PFS, and then open the original JMP.PFS in a text editor.
8. Copy and paste the custom color definition from Log.jsl to JMP.PFS. The definition goes after `Preferences()` as shown in the following example:
Preferences(
Add Color Theme(
"Pink to Blue", 2051, {{255, 168, 255}, {255, 0, 255}, {0, 128, 255}}
),
);

**Note:** Be sure to include the closing parenthesis and comma. The code does not need to be indented. You can put the code in any valid location. Pasting it after `Preferences()` helps ensure that you do not delete any necessary parentheses or commas.

9. Save the file.

If you open JMP and the new color definition is not displayed in the preferences, delete the updated preferences file and add the definition to the original preferences file. Make sure that you copy and paste the definition in the correct location.

### Delete Custom Color Themes in Graphs

1. Select **File > Preferences > Graphs.**
2. To either delete a color theme, select either the Continuous or Categorical Color Theme. The relevant Color Themes window appears.
3. Click the Custom Color Theme disclosure icon to show the Custom Color Theme panel.
4. From the appropriate pane, select the custom color to delete.

**Note:** You can delete only custom color themes.

5. Click **Delete.**
6. Click **OK** to save your changes and close the Color Themes window.

### Select Matching Row State Cells

You can select a cell in a row state column and then select all cells that contain the selected cell’s attributes. This option enables you to select cells with any combination of row state attributes, such as Exclude, Hide, color, or marker. For example, if a cell has a red marker and is excluded, and you select matching cells, all cells in excluded rows with red markers are selected.

1. Right-click the cell whose row state you want to select.
2. Select **Select Matching Cells.**

The cells with matching row states are selected.
Delete Row Characteristics

To clear all row states in the data table, select **Rows > Clear Row States**. To clear row states only in selected rows, select **Rows > Clear Selected Row States**.

All rows become included, visible, unlabeled, and show in plots as black dots. The **Clear Row States** command does not affect row states saved in row state columns.

Lock Columns

You can lock a column in place so that when you scroll horizontally, the column remains visible. Highlight the columns and select **Cols > Scroll Lock/Unlock**. Note the following:

- Hidden columns cannot be scroll locked.
- The name of a locked column appears in italics in the Columns panel.
- Scroll locked columns are moved to the left in the data grid. Once you unlock them, they are not moved back to their original locations in the data table, but remain on the left.
- Columns remain scroll locked until you highlight the columns and select **Scroll Lock/Unlock** again.

Restructure Data

JMP provides several ways to restructure data in a data table, such as creating a column from multiple columns, creating indicator columns, and recoding data.

- “Split a Data Table Column into Multiple Columns”
- “Create a New Column by Text Matching”
- “Make Indicator Columns”
- “Combine Columns in Data Tables”
- “Compress Selected Columns in Data Tables”
- “Make a Binning Formula in a Data Table Column”
- “Convert Labels to Codes and Codes to Labels”
- “Make a New Formula Column”
- “Transform Columns in a JMP Platform”
- “Recode Data in a Column”
Split a Data Table Column into Multiple Columns

Use the Text to Columns option to make a character column with delimited fields into multiple columns. Highlight a column from a data table and select Cols > Utilities > Text to Columns. The maximum number of delimited fields across all rows determines the number of new columns created.

Note: Text to Columns is case-sensitive.

The Text to Columns window has the following options:

Delimiter Specify text, such as a comma, to indicate how the data in the source column is organized into new columns. For example, if the original cell reads “NY, NJ, PA,” and the delimiter is a comma, three new columns contain “NY”, “NJ”, and “PA”.

TAB Specifies tabs as delimiters.

NEWLINE Specifies newline characters (\r, \n, and \r\n) as delimiters.

Make Indicator Columns Makes new columns that are named after the distinct fields in the source column with cell values of either 0 or 1.

Include Missing Allows any empty rows to be counted as a category. An additional column named Missing is added to the data table. A value of 1 indicates an empty row.

Create a New Column by Text Matching

The New Column by Text Matching option enables you to use regular expressions (which identify patterns in text) to match unstructured text in a column and then create a new column from the matched text. This feature is an alternative to using the Text Explorer platform to write regular expressions and then save the results to a column.

2. Select the Survey Response column.
3. Select Cols > Utilities > New Column By Text Matching.
4. Below the Leftover box, click the Add button .
5. Select Blank from the list and click OK.
6. Next to Title, enter Cat.
7. Next to Regex, enter (cat(?:s?))(\[\s\.\]).
   This expression finds “cat”, optionally followed by “s”, with either a space or period afterward.

   **Note:** If the regular expression has an error, an X icon appears to the left of Cat.

8. Click the Add button again.
9. Select Blank from the list and click OK.
10. Next to Title, enter Dog.
11. Next to Regex, enter (dog(?:s?))(\[\s\.\]).
12. (Optional) To save the script so that you do not have to repopulate the Regular Expressions Editor after closing and reopening it, select one of the Save Script options from the red triangle menu.
13. Click OK.
The Use Result Specification option in the Regular Expressions Editor gives you control over which matched text appears in the new column:

- If you don’t select Use Result Specification (the default setting), the result in the new column is whatever is produced by the regular expression in the right side of the editor.
- If you select Use Result Specification, then the result in the new column is whatever is produced by the Result expression in the right side of the editor. If your regular expression is `Air(port)`, then the new column contains the word `port` when found in the original column.

For more information about the Regular Expression Editor, see Basic Analysis.

To learn more about regular expressions, visit Regular-Expressions.info.

### Make Indicator Columns

Convert a categorical column into multiple indicator columns based on each distinct category. The columns are named after each level in the column. For example, when you make an indicator column from `sex` in Big Class.jmp, the indicator columns are named `F` and `M`.

Highlight a column in a data table and select **Cols > Utilities > Make Indicator Columns**. You can then indicate whether you want to prepend the original column name to the indicator column names (as in `sex_F` and `sex_M`) and include missing values.

Multiple columns with values of either 0 or 1 are created. A value of 1 indicates that the original column contains that specific category.

If the given column has the Multiple Response modeling type or Multiple Response column property, the categories are determined from the set of responses.
Combine Columns in Data Tables

The Combine Columns option is the opposite of Text to Columns. Instead of making multiple columns, you can combine a set of columns into one character column with delimited fields.

To combine indicator columns, follow these steps:

1. Select Help > Sample Data Library and open Consumer Preferences.jmp.
2. Select the columns, Floss After Waking Up, Floss After Meal, and Floss Before Sleep.
4. Type “Combined Floss” for the column name, and keep the default delimiter as a comma.
5. Select Selected Columns are Indicator Columns and click OK.

Figure 4.36 Combined Floss Column

The selected columns are represented in the Combined Floss column with each field separated by a comma. Only the columns that have a value of 1 are represented in the combined column for each given row.

Note: Value labels show a label in the data table instead of a value. A label appears for each instance of the value in the combined column. You can show the original values by double-clicking a label within a cell. To avoid using value labels, select No Value Labels when you combine the columns.
Compress Selected Columns in Data Tables

JMP lets you compress columns in a data table to minimize the size of the file and reduce the amount of memory required to analyze data. This feature is helpful when numeric columns contain many small integers or when any column contains fewer than 255 unique values. For example, compressing columns in a data table with 389 columns and 85,000 rows might decrease the file size from 250MB to 33MB, depending on the type of data.

When you compress columns, JMP verifies whether the data can be stored in a more compact form based on the data type:

- In character columns with fewer than 255 unique values, the List Check property is added to the column where appropriate (Figure 4.37). When the preference Allow 16 Bit List Check Compression is selected, the List Check property is also added to character columns that have more than 255 unique values.

  The List Check property restricts the values in the selected column to valid values. The List Check property is not applied when the number of values in the selected column is too great. For example, if the number of values is almost the same as the number of rows, the data table does not add the List Check property to the column.

- For numeric columns, only those with the Best, Fixed Dec, or Data format are compressed. Data is compressed to 1-byte, 2-byte, or 4-byte integers when possible (Figure 4.38). For more information about short integers, see “The Short-Integer Format” on page 294 in the “Set JMP Column Properties” chapter.

  A numeric column with non-integer values can also be compressed if there are fewer than 255 unique values. In this case, the List Check property is added to the column.

Notes:

- To automatically compress a column that has less than or equal to 65,535 unique values, select the Allow 16 Bit List Check Compression preference in the General group. The List Check property is also added to the column.

- In a column with the List Check property, you can enter only a value that is in the list. Otherwise, JMP warns that the cell contains invalid data when you try to enter the new value. See “List Check” on page 305.
Restructure Data Using JMP

Figure 4.37  List Check Property Added to a Compressed Character Column

Figure 4.38  Column Info Window Showing Numeric Column before and after Compression

To compress columns, select one or more columns and select Cols > Utilities > Compress Selected Columns. (Select all columns if you do not know which columns can be compressed.)

The column or columns are compressed if possible. The log shows which columns were compressed and how they were compressed. (Select View > Log to show the log.)

Note: To compress a numeric column manually, set your Tables preferences to allow short numeric data and then change the column’s data type to 1-byte integer, 2-byte integer, or 4-byte integer. For more information about this preference, see “Preferences for Data Tables” on page 682 in the “JMP Preferences” chapter.

Make a Binning Formula in a Data Table Column

You can distribute your data into bins using the Make Binning Formula option. Select the column or columns that you want to divide into bins, and select Cols > Utilities > Make Binning Formula. A histogram of the bins and a Value Label legend are shown, along with a red triangle menu that contains options for defining the cutpoints. There are several ways to add cutpoints, remove cutpoints, and adjust the bin sizes.

• Right-click in the histogram to add or remove cutpoints.
• Click and drag the vertical lines in the histogram to adjust the bin sizes.
• Edit the boxes next to the cutpoint value labels to edit the cutpoint values and adjust the bin sizes.
• Use the add and remove buttons above the Value Label legend to add and remove rows, which is equivalent to adding and removing cutpoints.
• Use the undo and redo buttons to undo or redo actions done on the bin settings.

There is an option to add formula columns for the cutpoints to the data table.

**Right-Click Options for Make Binning Formula**

Right-click the histogram in the Make Binning Formula window to select the following options:

**Add Cutpoint**  Adds a cutpoint line to the histogram in the location that was clicked.

**Remove Cutpoint**  Removes a cutpoint line. This option is available only if you right-click on an existing cutpoint.

**Show Counts**  Shows or hides the counts above the bars.

**Show Percents**  Shows or hides the percentages above the bars.

**Subset**  Creates a subset data table based on the current selection.

**Fill Pattern**  Specifies the fill pattern for the bars in the histogram.

**Red Triangle Options for Cutpoints**

The Cutpoints red triangle contains the following options:

**Fill using Equal Width Bins**  Specifies a start (offset) and a bin width. JMP fills in the table until it goes past the largest possible values. For example, if you enter offset=50 and width=10 and your largest data value is 95, you will get the following bins: 50, 60, 70, 80, 90, 100.

**Fill using Bin Count**  Specifies a start, end, and a bin count. JMP divides the space between the start and end equally by the bin count. If you change the bin count, the reported bin width is automatically updated in the window.

**Fill using Percentiles**  Specifies a percentage between 1 and 50. JMP divides the range of the data by that quantile. For example, if you specify a percentile of 20, you get five equal weight bins.

**Fill using Mean/StdDev**  Specifies the bin cutpoints to be set at the mean of the data plus the first, second, or third standard deviation from the mean based on your selection in the window.
Fill using Jenks Natural Breaks  Specifies a bin count and creates bin cutpoints so that the variance within each bin is minimized and the variance between the bins is maximized.

Bin Label  Specifies whether value labels are shown instead of the data values.

- **Use Value Labels**  Shows a label instead of the value shown in the new formula column defining the bins.

- **Use Range Labels**  Includes the lower and upper values for each range in the label.

- **No Labels**  Uses the lower edge value as the label.

- **Character**  Applies the Character data type. The formula produces the labels.

See “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.

| Tip: Value Labels are recommended in most platforms, many of which do not support range labels. In the Categorical platform, you must use value labels. On some axes, you might find that range labels more clearly identify the values, or you can try adjusting the offset and width for the axis. |

Bin Label Style  Specifies a preset that defines what the Value Labels or Character output look like in the table.

- **Low–High**  Defines the Value Labels by the lowest and highest points of each bin. The format is Low–High.

- **Low to High**  Defines the Value Labels by the lowest and highest points of each bin. The format is Low to High.

- **Low, High**  Defines the Value Labels by the lowest and highest points of each bin. The format is Low, High.

- **Low–High–1 (integers)**  Defines the Value Labels by the lowest point and one less than the highest point of each bin. The format is Low–High–1.

- **Low to High–1 (integers)**  Defines the Value Labels by the lowest point and one less than the highest point of each bin. The format is Low to High–1.

- **[Low, High) (mathematical)**  Specifies that the lower value is included in the range and the upper value is not. For example, if your range is [50,60), then a value of 50 would be in the bin, but a value of 60 would not be.

- **Low**  Defines the Value Labels by the lowest point of each bin.

- **Midpoint**  Defines the Value Labels by the midpoint of each bin.

- **Integer Sequence**  Defines the Value Labels by a sequence of consecutive integers. Define the starting integer in the Integer Sequence Labels window.
**Uppercase Alphabetical**  Defines the Value Labels as uppercase letters in alphabetical order.

**Lowercase Alphabetical**  Defines the Value Labels as lowercase letters in alphabetical order.

**Custom**  Enables you to enter custom Value Labels.

**Column Format**  Specifies how the Value Labels are formatted. By default, the format of the column is applied. However, you might want to override the setting (for example, changing the format to Dollar). This setting is most useful if the column format is something like Best, but you really want your bins to have no decimals. Instead of cleaning up all of the value labels, you specify the format.

**Histogram**  Specifies whether counts or percentages appear above the bars.

**Show Points**  Shows or hides the observed data points below the bars.

**Rescale Axis**  Resets the axis to the original scale.

**Recall**  Populates the Make Binning Formula window with the last binning actions that you performed.

**Make All Like X**  (Appears only if multiple columns are selected.) Applies the choices made for the first column (X) to the remaining columns in the dialog.

**Make Formula Columns**  Creates the formula columns and closes the window.

**Tip:** Once you create a formula column, you can edit the formula by right-clicking on the column header and selecting **Edit Binning Formula**. This reopens the Make Binning Formula window. To update the binning formula column, edit the cutpoints and click **Update Column**.

---

**Example of Making a Binning Formula**

1. Select **Help > Sample Data Library** and open **Big Class.jmp**.
2. Select the **height** column.
3. Select **Cols > Utilities > Make Binning Formula**.
   
   You want the range of values to appear as X-X, so in the Bin Label Style, keep the range set to **Low - High**.
4. Click the Cutpoints red triangle and select **Fill using Equal Width Bins**.
5. In the window that appears, change the **offset** to -0.5.
Tip: For integer data, setting the offset to -0.5 helps disambiguate values on the edge. In this example, one of the bins covers 59.5 to 64.5, so it is clear that 59 and 65 are not included in this bin.

6. Keep the width set to 5.

7. Click OK.

8. Keep the Bin Label setting of Use Value Labels so that you can see the range of values for the bin.

Figure 4.39 Completed Binning Window

9. Click Make Formula Column.

A column called height Binned is added to the Big Class.jmp data table.

10. To see how the formula is calculated, right-click the height Binned column and select Formula.

Figure 4.40 Formula
Convert Labels to Codes and Codes to Labels

Suppose that you have a column of strings such as “dissatisfied”, “somewhat dissatisfied”, and “somewhat satisfied”, and “satisfied”. You can recode the values to “1”, “2”, “3”, and “4”. The original strings are placed in the Value Labels column property for that column. If the column has a List Check property, the property is removed. The column data type is changed to 1-byte Integer. Converting a column of strings to short numeric codes saves memory and can speed up processing.

You can also convert a numeric column of codes to labels. The column must have value labels. The column data type is changed to Character, and the Value Label column property is removed. This is, in effect, the opposite of converting labels to codes.

Convert Labels to Codes

1. Select the character column and select **Cols > Utilities > Labels to Codes**.

**Figure 4.41** Converting Labels to Codes

![Labels to Codes dialog box](image)

Default codes are assigned to the values.

2. Change the codes if desired and click **OK**.

   The column is recoded, and value labels are added to the column.

Convert Codes to Labels

1. Select the numeric column that contains value labels and select **Cols > Utilities > Codes to Labels**.

2. Change the labels if desired and click **OK**.

   The column is recoded with the original value labels.
Make a New Formula Column

To perform further analyses on your data, use the New Formula Column menu options from your existing data table. Formula columns use formulas or calculations to define column values.

Right-click a column heading in your data table and select **New Formula Column**. Choose from Transform, Character, Combine, Pairwise, Aggregate, Distributional, Date Time, Random, Row, or Vector to calculate column values. A new formula column is added to the data table. See “Transform Columns in a JMP Platform” on page 254 for a description of these options.

**Note:** The same options exist in both the New Formula Column menu, and the right-click column menu in the launch window. However, performing these tasks in a launch window results in a temporary column, and New Formula Column adds a new column to the original data table.

Right-click options depend on the selected column’s data type and the number of columns selected. If the selected column is a Character column, Character and Row options appear. See “Character Menu” on page 262 and “Row Menu” on page 262.

Transform Columns in a JMP Platform

Each launch window in JMP enables you to create one or more temporary transform columns for use in performing analyses. These transform columns are not part of the source data table and only can be used within the context of the current launch window. Transform columns use formulas or calculations to define the column values. Closing the launch window deletes any transform columns.

Each column listed in the Select Columns pane of the launch window includes an icon representing the column’s modeling type (continuous, ordinal, or nominal) and the column name. Right-click a column name to create a transform column using Transform, Character, Combine, Pairwise, Aggregate, Distributional, Date Time, Random, Row, Vector, or Formula to calculate the column’s values.

Right-click options depend on the selected column’s data type and number of columns selected.
Group By  For ordinal and nominal data, specifies the column to use for grouping data. A separate analysis is computed for each level of the specified column.

Notes:

- The transform column is available only in the current launch window. To make the transform column available outside of the current launch window, right-click the transform column and select Add to Data Table. The transform column is added to the source data table.

- You can paste a transform column into a Roles box on the launch window. For example, you might copy a transform column from a script. Right-click in the appropriate launch window Cast Selected Columns into Roles box and select Paste. This is an alternative to right-clicking the column in the Select Columns list, selecting the transform, and adding the transform column to a role.

- If the transform function is invertible, the following platforms use the original scale for the prediction profiler and to save the predicted values and formulas.
Restructure Data Using JMP

- Fit Y by X
- Standard Least Squares
- Partition
- Boosted Tree
- Bootstrap Forest

- Define your own transform by writing a JSL script. See the Scripting Guide.

Transform Menu

Select a function from the Transform menu to create a transform column containing the calculations based on the selected function. See the Scripting Index in the Help menu or Fitting Linear Models.

**Note:** You can apply unary functions to multiple columns resulting in multiple transform columns.

### Table 4.2 Descriptions of the Transform Menu Options

<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Round</strong></td>
<td>Rounds date values. For example, in a chart of weeks, Round converts the date values into the first date of each week that they occur on.</td>
</tr>
<tr>
<td><strong>Scale Offset</strong></td>
<td>Enables you to specify a general linear transform. For example, you might multiply the value by 1.8 and apply an offset of 32 to convert Celsius temperatures to Fahrenheit.</td>
</tr>
<tr>
<td><strong>Custom Binning</strong></td>
<td>Opens the binning window which enables you to distribute the data into bins.</td>
</tr>
<tr>
<td><strong>Square Root</strong></td>
<td>Takes the square root of the values of the selected column.</td>
</tr>
<tr>
<td><strong>Square</strong></td>
<td>Calculates the square for the selected column values.</td>
</tr>
<tr>
<td><strong>Log</strong></td>
<td>Applies the natural logarithm transformation to the selected column.</td>
</tr>
<tr>
<td><strong>Log x+1</strong></td>
<td>Calculates Log(col+1).</td>
</tr>
<tr>
<td><strong>Exp</strong></td>
<td>Applies the exponential transformation to the selected column.</td>
</tr>
<tr>
<td><strong>Log10</strong></td>
<td>Applies the base-10 logarithm transformation to the selected column.</td>
</tr>
<tr>
<td><strong>Pow10</strong></td>
<td>Calculates 10 raised to the power of the selected column values.</td>
</tr>
</tbody>
</table>
### Table 4.2 Descriptions of the Transform Menu Options (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cube Root</td>
<td>Calculates the cube root for the selected column values.</td>
</tr>
<tr>
<td>Cube</td>
<td>Calculates the cube for the selected column values.</td>
</tr>
<tr>
<td>Reciprocal</td>
<td>Calculates the reciprocal (1/column) for the selected column values.</td>
</tr>
<tr>
<td>Absolute Value</td>
<td>Calculates the absolute value for the selected column values.</td>
</tr>
<tr>
<td>Negation</td>
<td>Calculates the negative for the selected column values.</td>
</tr>
</tbody>
</table>
| Arrhenius      | Applies the Arrhenius transformation to the variable \( T \) (temperature in degrees Centigrade):  
|                | \[ X = \frac{11604.5181215503}{T + 273.15} \]  
|                | This is the component of the Arrhenius relationship that is multiplied by the activation energy. |
| Arrhenius Inverse | Applies the inverse of the Arrhenius transformation to the variable \( X \):  
|                | \[ T = \frac{11604.5181215503}{X} - 273.15 \]                                |
| Logit          | Calculates the inverse of the logistic function for the selected column (where \( p \) is in the range of 0 to 1):  
|                | \[ \text{Logit}(p) = \log\left(\frac{p}{1-p}\right) \]                     |
| Logistic       | Calculates the logistic (also known as Squish and Logist) function for the selected column (where the result is in the range of 0 to 1):  
|                | \[ \text{Logistic}(x) = \frac{1}{1 + e^{-x}} \]                            |
| Logit Percent  | Calculates the logit as a percent for the selected column (where \( pct \) is a percent in the range of 0 to 100):  
|                | \[ \text{LogitPct}(pct) = \log\left(\frac{\frac{pct}{100}}{1 - \frac{pct}{100}}\right) \]  

Table 4.2 Descriptions of the Transform Menu Options  (Continued)

| Logistic Percent | Calculates the logistic (or logist) as a percent for the selected column (where the result is in the range of 0 to 100):
| LogisticPct(x) = \frac{100}{1 + e^{-x}} |

Combine Menu

Select multiple columns to access the Combine menu. The Combine menu creates a transform column containing the calculations based on the selected function.

The following functions are included in the menu:

- **Sum**  Calculates the sum of the first and second columns (A + B).
- **Difference**  Calculates the difference between the first and second columns (A - B).
- **Difference (reverse order)**  Calculates the difference between the second and first columns (B - A).
- **Product**  Calculates the product of the first and second columns (A X B).
- **Ratio**  Calculates the ratio of the first column to the second column (A / B).
- **Ratio (reverse order)**  Calculates the ratio of the second column to the first column (B / A).
- **Minimum**  Returns the minimum value of the selected columns.
- **Maximum**  Returns the maximum value of the selected columns.
- **Average**  Returns the average value of the selected columns.
- **Standard Deviation**  Calculates the standard deviation of the values in the selected column.
- **Median**  Calculates the median value for the selected column.
- **Quantile**  Calculates the quantile of the specified percentage for the selected column.
- **Geometric Mean**  Returns the $n$th root of the product of the data.

Pairwise Menu

Select a function from the Pairwise menu to create pairwise results for two or more columns. This menu appears only when the number of selected columns is even and greater than or equal to four.

- **Sum**  Calculates the sum of the first and second columns (A + B).
**Difference**  Calculates the difference between the first and second columns (A - B).

**Difference (reverse order)**  Calculates the difference between the second and first columns (B - A).

**Product**  Calculates the product of the first and second columns (A X B).

**Ratio**  Calculates the ratio of the first column to the second column (A / B).

**Ratio (reverse order)**  Calculates the ratio of the second column to the first column (B / A).

**Minimum**  Returns the minimum value of the selected columns.

**Maximum**  Returns the maximum value of the selected columns.

**Average**  Returns the average value of the selected columns.

**Geometric Mean**  Returns the nth root of the product of the data.

### Aggregate Menu

Select a function from the Aggregate menu to create a transform column containing the statistics calculated from the selected column (or part of a column if you specified a Group By column).

**Note:** The **Group By** option is useful for these functions.

The following functions are included in the menu:

**Mean**  Returns the average value of the selected column.

**Sum**  Calculates the sum of the values in the selected column.

**Count**  Calculates the number of values in the selected column.

**Median**  Calculates the median value for the selected column.

**Quantile**  Calculates the quantile of the specified percentage for the selected column.

**Minimum**  Returns the minimum value of the selected column.

**Maximum**  Returns the maximum value of the selected column.

**Standard Deviation**  Calculates the standard deviation of the values in the selected column.

### Distributional Menu

Select a function from the Distributional menu to create a transform column containing the statistics calculated from the selected column. See the Scripting Index in the Help menu.
The following functions are included in the menu:

**Center**  Subtracts the column mean from each value across all rows of the selected column.

**Standardize**  Calculates the column value minus the mean divided by the standard deviation across all rows of the selected column.

**Range 0 to 1**  Scales the data up or down so that the minimum value is greater or equal to 0, and the maximum value is less than or equal to 1.

**Box Cox**  Transforms the data using the Box-Cox equation. See *Fitting Linear Models*.

**Johnson Normalizing**  Transforms the data using one of the Johnson equations. The new column name indicates either Johnson Su, Johnson Sb, or None, depending on which equation was used to calculate the new data.

**Informative Missing**  Creates two columns. The Informative column replaces missing values with the column mean. The Is Missing column indicates 1 for missing values, and 0 otherwise.

**Rank**  Returns the rank, ranging from 1 as the lowest, with row-order tie-breaking.

**Rank (reverse order)**  Returns the rank, ranging from 1 as the highest, with row-order tie-breaking.

**Cumulative Probability**  Calculates the cumulative probability: Col Rank(col) / (Col Number(col) + 1).

**Normal Quantile**  Calculates the quantile from a Normal distribution.

**SHASH**  Calculates the cumulative distribution function (cdf) evaluated at $x$ of the sinh-arcsinh (SHASH) distribution.

### Random Menu

For numeric columns, select a function from the Random menu to create columns with random values.

The following functions are included in the menu:

**Random Uniform**  Generates random numbers uniformly between 0 and 1.

**Random Normal**  Generates random numbers that approximate a normal distribution with a mean of 0 and standard deviation of 1 if no arguments are used, or with the mean and standard deviation entered as arguments.

**Sample without Replacement**  Shuffles the values randomly each time it’s evaluated. The result for the first value affects the result for the second value.
Sample with Replacement  Shuffles the values randomly each time it’s evaluated. The result for the first value does not affect the result for the second value.

Date Time Menu

For column values containing date or time values, select a function from the Date Time menu to create a transform column containing values calculated from the selected column.

The following functions are included in the menu:

**Day**  Returns the day of the month for the date in the selected column.

**Month**  Returns the month number for the date in the selected column.

**Month Abbr.**  Returns the abbreviated month for the date in the selected column.

**Year**  Returns the year for the date in the selected column.

**Month Year**  Returns the month number and year for the date in the selected column.

**Quarter**  Returns the year’s quarter (1, 2, 3, or 4) for the date in the selected column.

**Week**  Returns the number of the week in the year for the date in the selected column.

**Year Quarter**  Returns the year and the year’s quarter (1, 2, 3, or 4) for the date in the selected column.

**Year Week**  Returns a string representing the ISO-8601 week of year format (for example, June 12, 2013 results in “2013W24”).

**Day of Year**  Returns the day of the year for the date in the selected column.

**Day of Week**  Returns the day of the week for the date in the selected column.

**Day of Week Abbr.**  Returns the abbreviated day of the week for the date in the selected column.

**Day of Week Name**  Returns the full day of the week for the date in the selected column.

**Date**  Returns the month, day, and year for the date in the selected column.

**Time of Day**  Returns the time for the date in the selected column.

**Hour**  Returns the hour part of the date in the selected column.

**Minute**  Returns the minute part of the date in the selected column.

**Second**  Returns the seconds part of the date in the selected column.
Character Menu

Select a function from the Character menu to create a transform column containing strings formed by the selected Character function.

The following functions are included in the menu:

- **Length**  Calculates the number of characters in each string in the selected column or columns.
- **Concatenate**  Concatenates the strings in the selected column or columns into a new string.
- **Concatenate with Space**  Concatenates the strings in the selected column or columns into a new string with each sub-string separated by a whitespace character.
- **Concatenate with Comma**  Concatenates the strings in the selected column or columns into a new string with each sub-string separated by a comma character.
- **Titlecase**  Converts the strings to title-case (for example, “Sheila Smith”).
- **Uppercase**  Converts the strings to uppercase (for example, “SHEILA SMITH”).
- **Lowercase**  Converts the strings to lowercase (for example, “sheila smith”).
- **First Word**  Extracts the first word from a character string in the selected column or columns.
- **Last Word**  Extracts the last word from a character string in the selected column or columns.
- **Rank**  Returns the rank, ranging from 1 as the lowest, with row-order tie breaking.
- **Rank (reverse order)**  Returns the rank, ranging from 1 as the highest, with row-order tie-breaking.

Row Menu

Select a function from the Row menu to create a transform column containing calculations determined by the selected Row function.

In addition to the functions described in the appendix, the following functions are included in the menu:

- **Row**  Returns the current row number.
- **Selected**  Returns the selected index.
- **Difference**  Calculates the difference of each value in the selected column using the formula:
Note: The Difference function also supports the Group By option.

**Lag** Returns the value in the previous row for the selected column.

**Lag Multiple** Returns the values from multiple previous rows for the selected column.

**Cumulative Sum** Calculates the cumulative sum for each value in the selected column using the formula:

\[
\text{Cumulative Sum} = \begin{cases} 
\text{Row}() = 1 & \Rightarrow 0 \\
\text{else} & \Rightarrow \text{kHours} + \text{Lag}()
\end{cases}
\]

Note: The Cumulative Sum function also supports the Group By option.

**Moving Average** Calculates the exponentially weighted moving average, EWMA (using a smoothing parameter between 0 to 1.0) for each value in the selected column. The following example uses a smoothing parameter of 0.25:

\[
\text{Moving Average} = \begin{cases} 
\text{Row}() = 1 & \Rightarrow \text{kHours} \\
\text{else} & \Rightarrow \text{kHours} \times 0.25 + \text{Lag()} + 0.75
\end{cases}
\]

**Weighting** Determines how the values are weighted. Incremental weighting is a ramp or triangle. The exponential moving average is EWMA or EMA.

**Items Before** Controls the size of the range (or window) by including the specified number of items before the current item in the average (in addition to the current item). -1 means all prior items.

**Items After** Controls the size of the range (or window) by including the specified number of items after the current item in the average (in addition to the current item). -1 means all following items.

**Report missing values for partial window** Controls how missing values are treated. By default, missing values are ignored.

Note: JMP evaluates the formula entered on-demand; complex formulas might require a lot of processing time.

**Vector Menu**

Select a transform from the Vector menu to create transform columns from vector data.

**To Columns** Expands the vector into individual number columns.
Sum  Returns the sum of the arguments or of the values within the vector.

Min  Returns the minimum value among the values within the vector.

Max  Returns the maximum value among the values within the vector.

Loc Min  Returns the first position of the minimum value.

Loc Max  Returns the first position of the maximum value.

Transform Column Options

After creating a transform column, you can perform the following actions:

Rename  Renames the transform column.

Add to Data Table  Adds the transform column to the data table as a formula column.

Recode Data in a Column

Use the recoding tool to change all of the values in a column at once. For example, suppose you are interested in comparing the sales of computer and pharmaceutical companies. Your current company labels are Computer and Pharmaceutical. You want to change them to Technical and Drug. Going through all 32 rows of data and changing all the values would be tedious, inefficient, and error-prone, especially if you had many more rows of data. Recode is a better option.

Notes:

- To recode similar values within multiple columns, use the Recode option in Cols > Standardize Attributes. See “Standardize Column Attributes” on page 332 in the “Set JMP Column Properties” chapter.

- To recode only column headings, select Cols > Column Names > Recode Column Names.

To recode data, follow these steps:

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select the Type column by clicking once on the column heading.

   Notice that New Column is selected by default to place the recoded values in a new column. The new column is named Type 2.

4. In the Recode window, enter the desired values in the New Value boxes. For this example, enter Technical in the Computer row, and Drug in the Pharmaceutical row.

   Notice that the recoded values appear in the Changes box.
Figure 4.43  Recode Window

The asterisk indicates which values have changed.

5. Click Recode.

The new values appear in the data table under a new column called Type 2.

Notes:

- By default, the recoded data appears in a new column. To always recode the column that you selected, select File > Preferences (Windows) or JMP > Preferences (macOS), select Recode, and then select In Place from the Commit Style list.

- By default, the data in the Recode window is sorted by new value in ascending order. This applies to both Recode and Recode Column Names. To change how data is sorted, select File > Preferences (Windows) or JMP > Preferences (macOS), select Recode and change the Sort Style preference. Select Old Value to sort column names by the natural order they appear in the data table and data by the order in the value order column property, if specified. Select Count to sort by count in descending order.

- If the data table contains value labels, the labels appear in a column in the Recode window called New Labels. Editing the labels also modifies the Value Labels column property. You
can also select **Replace values with value labels** to modify the data in the New Values column.

- The following column properties are updated when you recode a column: Value Labels, Value Scores, Value Order, Value Colors, Supercategories, Coding, and Missing Value Codes.

- If you enter a non-numeric value in a column with a Numeric data type, you are prompted to convert the data type to Character. Click **Yes** to convert the column and display the new value. Click **No** to keep the column Numeric and display a missing value.

- Selecting rows on the Recode window also selects them in the data table for quick editing.

### Recode Options

The following options are available in the list next to the Recode red triangle:

**New Column**  Creates a new column for the changed data and retains the original column.

**Formula Column**  Creates a new column with the changes as a formula instead of values. Changing a value in the original column in the data table causes the formula column to update that value automatically.

**In Place**  Applies any change to the original data column.

The remaining options are available on the Recode window:

**Filter**  Searches for specific values. Click the down arrow to select search options. For more information about each option, see “**Search Filter Options in Recode**” on page 271. Note that you can type a regular expression to customize the filter.

**View Groups**  Deselect to view ungrouped values. Selected by default.

**Show Only Grouped**  Shows recoded values that have been grouped.

**Show Only Ungrouped**  Shows values that have not been grouped.

**Group**  Becomes active when multiple values are selected. Click **Group** to make highlighted values part of the same group. If you previously edited a value before grouping, the edited value becomes the group representative in the New Value column. Otherwise, the group representative is the value that occurs most often.

**All**  Shows all data values.

**Only Modified**  Shows only modified recoded values.

**Only Unmodified**  Shows only unmodified recoded values.

**Changes**  Shows a list of changes made in the Recode window.

Reverses the last change made to the window.
Recalls the last change made to the window.

Scripting

To save a script to re-create the recoded data table, select Script from the red triangle menu and then select an option.

The Recode window includes the following script options:

**Script sequence of actions**  Attempts to save your actions to a script and omit the data. If you convert all strings to uppercase using the red triangle option, the generated script contains code that converts input strings to uppercase without including the data.

**Compress sequence**  Compresses the script of sequenced actions by removing unnecessary operations. Consider this option to speed up recoding that contains multiple edits.

Multiple Response

**Remove empty items**  In a Multiple Response column, excludes empty items in the column when recoding the column in the data table.

**Remove duplicate items**  In a Multiple Response column, excludes duplicate items. For example, if the original data were a, b, b, c, and no changes to those particular items were made, the recoded column in the data table would contain a, b, c.

**Sort items**  In a Multiple Response column, sorts items alphabetically. For example, if the original data were b, a, c, and no changes to those particular items were made, the recoded column in the data table would contain a, b, c.

Red Triangle Options for Recode

The red triangle menu contains options for the Recode window.

**Convert to Titlecase**  Converts the first letter of each word to uppercase, and the remaining letters to lowercase.

**Convert to Uppercase**  Converts all values to uppercase.

**Convert to Lowercase**  Converts all values to lowercase.

**Trim Whitespace**  Removes leading and trailing whitespace characters. For example, if an extra space was imported before and after the name John, this command would delete the spaces.

**Remove Whitespace**  Removes trailing, leading, and interior whitespace characters.
**Collapse Whitespace**  Removes leading and trailing whitespace characters and removes duplicate interior whitespace characters. That is, if more than one whitespace character is present, the *Collapse Whitespace* command replaces the two spaces with one space.

**Remove Punctuation**  Removes special characters (such as quotation marks and ampersands) from the beginning, middle, and end of words.

**Replace String**  Replaces all occurrences of specified characters with a new string or with nothing. Note that you can type a regular expression to customize the replacement.

**First Word**  Groups values based on the first word of the string. For example, if “John Smith” and “John Adams” were values, this command would group them under “John.”

**Last Word**  Groups values based on the last word of the string.

**Group Similar Values**  Enables you to customize how data is grouped. Choose from the grouping options list. See “Group Similar Values Options for Recode” on page 270.

**Advanced**

**All but First Word**  Splits values based on the remaining value after the first word is excluded.

**All but Last Word**  Splits values based on the remaining value after the last word is excluded.

**Apply Mapping from Table**  Enables you to use columns in a mapping data table to modify values in the target table. See “Example of Applying Values from Mapping Columns” on page 276.

**Extract Segment**  Enables you to extract specific strings. See “Example of Splitting on a Comma” on page 273.

**Choose Closest**  Enables you to map values in the column of a mapping data table to the column that you are recoding.

**Parse as Numbers**  Converts the data to numbers.

**Labels to Codes**  Converts labeled values to codes.

**Convert to Character**  In a numeric column, converts the column to a character column.

**Add Value Labels**  Enables you to assign value labels to each value.

**Replace Values with Value Labels**  Replaces the values specified in the Value Label column property with the value labels that you specify. This option is available only when the column has a Value Label property.

**Recall**  Recalls previous changes made in the Recode window.
**Start Over**  Returns the window to the default condition.

**Script**  View options to import, merge, or save Recode scripts.

- **Import from File** imports a JSL script to recode previously recoded data. Run the same script on different data to recode data the same way.
- **Import from Data Table** imports a JSL script saved to a data table.
- **Import from Recode Result Column** imports data from the column that you select, usually the column in which you saved previous recode results.
- **Save to File** saves Recode changes to a JSL script. After selecting Save, you are prompted to name and save the file.
- **Save to Data Table** saves a Recode script to current data table. To modify the recoding in a saved script, right-click the script in the data table and select **Edit with Recode**. After making changes, select **Script > Save to Data Table** from the red triangle menu again to save your changes in a new script.
- **Merge with Data Table Script** merges changes made in the Recode window to the current Recode script saved to the data table. If there are multiple scripts, you are prompted to choose which script to merge your recoded data with.
- **Save to Script Window** appends the Recode script to the script window.

**Publish to Formula Depot**  Publishes the recode script to the Formula Depot, which enables you to reuse the code in other scripts.

**Right-Click Options for Recode**

The first six options are available for grouped values:

**Group to New Value**  (Available only when you select multiple values) Enables you to specify a new value for the two or more selected values.

**Group to**  (Available only when you select multiple values) Right-click selected values to select a different grouping value, or group representative. The list shows the first eight possible group representatives.

**Swap New Values**  When two values are highlighted, select **Swap New Values** to make the new value of the first value adopt the new value of the second value, and vice versa.

**Make Representative**  Right-click a single value from a group and select **Make Representative** to make the selected value the new value.

**Remove From Group**  After values are grouped, right-click one or more values to remove them from that group.

**Group Similar Values**  Right-click a single string to find values that are similar. The Grouping Options window appears. See **Group Similar Values Options for Recode**.
**Open All Groups**  Opens the groups so that you can see all of the values in each group.

**Close All Groups**  Collapses the values within each group.

The following options are available for all data:

**Select Rows**  Selects the selected rows in the data table. When you select a row in the Recode window, the corresponding rows are automatically selected in the data table. However, if you select rows in the data table, the rows are not selected in Recode. If you want to select only the rows shown in the Recode window, right-click the row, and select this option.

**Make into Data Table**  Creates a data table of the results shown in the Recode window.

**Copy Selected Column Rows**  Copies the data only from the column that you right-clicked. You can then paste the data into a data table.

**Copy Selected Table Rows**  Copies the data for all columns. You can then paste the data into a data table.

**Group Similar Values Options for Recode**

Select the following Group Similar Values commands to increase the accuracy of grouping:

**Ignore Case**  Item case is ignored.

**Ignore Non-Printable Characters**  Non-printable characters are ignored. Some data can include non-printable characters (such as file separators) that only the computer can read.

**Ignore Whitespace**  White space is ignored.

**Ignore Punctuation**  Punctuation is ignored.

**Allow Character Edits**  Enables characters to be replaced by the new value when similar values are grouped.

**Max Difference Ratio**  Groups values according to the maximum proportional difference. For example, type “.25” to group values that are at most 25% different.

**Max Character Difference**  Groups values according to a maximum number of nonadjacent character differences. For example, type “5” to group values that differ by five characters or less.

**Min Source String Length**  Prevents strings from being matched if they are too short. Experiment with this option and the Difference Ratio and Max Character Difference options to specify a value that works for your data.
Search Filter Options in Recode

Click the down arrow button next to the search box to refine your search.

Contains Terms  Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.

Contains Phrase  Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).

Starts With Phrase  Returns items that start with the search criteria.

Ends With Phrase  Returns items that end with the search criteria.

Whole Phrase  Returns items that consist of the entire string. A search for “text box” returns entries that contain only “text box”.

Regular Expression  Enables you to use the wildcard (*) and period (.) in the search box. Searching for “get.*name” looks for items that contain “get” followed by one or more words. It returns “Get Color Theme Names”, “Get Name Info”, and “Get Effect Names”, and so on.

Invert Result  Returns items that do not match the search criteria.

Match All Terms  Returns items that contain both strings. A search for “t test” returns elements that contain either or both of the search strings: “Pat Test”, “Shortest Edit Script” and “Paired t test”.

Ignore Case  Ignores the case in the search criteria.

Match Whole Words  Returns items that contain each word in the string based on the Match All Terms setting. If you search for “data filter”, and Match All Terms is selected, entries that contain both “data” and “filter” are returned.

Example of Grouping by Similar Values

You can group similar values according to the number of characters that differ between them.

1. Select Help > Sample Data Library and open Candy Bars.jmp.
2. Select the Name column.
4. Click the red triangle and select Group Similar Values.
5. Make sure that Allow Character Edits is selected.
6. Next to Max Different Ratio, type “.5”.

Example of Grouping by Similar Values

You can group similar values according to the number of characters that differ between them.

1. Select Help > Sample Data Library and open Candy Bars.jmp.
2. Select the Name column.
4. Click the red triangle and select Group Similar Values.
5. Make sure that Allow Character Edits is selected.
6. Next to Max Different Ratio, type “.5”.

Example of Grouping by Similar Values

You can group similar values according to the number of characters that differ between them.

1. Select Help > Sample Data Library and open Candy Bars.jmp.
2. Select the Name column.
4. Click the red triangle and select Group Similar Values.
5. Make sure that Allow Character Edits is selected.
6. Next to Max Different Ratio, type “.5”.
This allows JMP to group values that differ by 50% or less. In other words, values that share at least 50%, or half, of the same characters. The Difference Ratio is determined by comparing the total number of characters of each value and the total amount of unique characters between two given values.

7. Next to Max Character Difference, type "6".

Values that have no more than six characters are grouped.

8. Click OK.

**Figure 4.44** Grouping Similar Values

The values shown in the New Value column represents the grouped values in the recoded data table.

9. (Optional) To change the new value to represent a different old value in a group, right-click Almond Roca and select Make Representative.
10. (Optional) To replace the original data in the data table with the recoded data, select **In Place** from the red triangle menu, and then click **Recode**.

**Example of Splitting on a Comma**

The Aircraft Incidents.jmp sample data table contains a column of city and state names separated by a comma. You can split the values in that column on the comma and recode the column with only state names.

1. Select **Help > Sample Data Library** and open Aircraft Incidents.jmp.
2. Select the **Location** column and select **Cols > Recode**.

**Figure 4.46  Original Data**

3. Click the red triangle and select **Advanced > Extract Segment**.
In the Preview pane, notice that the data contain cities followed by a comma and abbreviated state names. You will extract the last two characters of each string.

4. Deselect **Include Whitespace** and **Include Punctuation** at the top of the window. Whitespace and punctuation will not be considered in the extraction.

5. Type a comma in the Characters box.

**Figure 4.47** Specifying a Delimiter

![Delimiter Window]

The comma is used to extract the last two characters.

6. In the Extract Segment window, type “2” above Start Anchor and End Anchor. The segment extraction begins and ends with the second word.

7. Make sure that From Start is selected for the Start Anchor and End Anchor options.
**Tip:** In the Text to Capture section, click the left or right arrow to scroll through the values. This enables you to preview your settings.

8. In the Preview pane shown in Figure 4.48, notice that the replacement values contain only the state abbreviations.

9. Scroll down in the Preview pane. Notice that the current value and replacement value for Atlantic Ocean are the same. The data couldn’t be split on a comma.

**Figure 4.49** Data with No State

10. Click **OK**.

Entries with a matching state name are grouped.
Example of Applying Values from Mapping Columns

A column in a mapping data table contain values that you can use to recode a column in another data table. In this example, U.S. states in State Capitals.jmp are replaced with the state abbreviations defined in State Abbreviations.jmp (the mapping data table).

1. Select **Help > Sample Data Library** and open State Abbreviations.jmp and State Capitals.jmp.
2. In State Capitals.jmp, select the U.S. States column.
3. Select **Cols > Recode**.
4. Click the red triangle and select **Advanced > Apply Mapping from Table**.
5. Click **Choose Table**, select State Abbreviations.jmp, and click **OK**.
6. In the Match Column box, select **U.S. States**.
7. In the Replace With Column box, select **Abbreviations**.

   The Match and Replace With columns show the result of the mapping.

8. Select the **Replace unmatched items with** box and type “no match”.

   The Preview section shows how the values are mapped. Scroll down and notice that the “no match” states are misspelled, so they don’t map to any state in the Abbreviations column.
9. Click **OK** and then click **Recode**.

A new column of abbreviated state names appears in State Capitals.jmp in a new column called U.S. States 2.

To fix the entries that weren’t matched, see “Example of Fixing Misspelled Words” on page 278.
**Example of Fixing Misspelled Words**

You can use a data table as a dictionary to fix misspelled words. State Abbreviations.jmp contains columns of U.S. state names and abbreviations. State Capitals.jmp contains a few misspelled state names to mimic real data. This example shows how to fix the misspelled state names.

1. Select **Help > Sample Data Library** and open State Abbreviations.jmp and State Capitals.jmp.
2. In State Capitals.jmp, select the U.S. States column.
3. Select **Cols > Recode**.
4. Click the red triangle and select **Advanced > Choose Closest**.
5. Click **Choose Table**, select State Abbreviations, and click **OK**.
6. In the Match Column box, select **U.S. States**.
7. In the Preview pane, scroll down and notice that “Massachusets” will be replaced with “Massachusetts”, “Missisippi” will be replaced with “Mississippi”.

![Figure 4.54 Misspelled State Replacement](image)

8. Click **OK** and then click **Recode**.

A new column that contains the updated state names is added to the data table.

**Example of Parsing as Numbers**

The Parse as Numbers option turns character data into numeric data. This option is comparable to the JSL `Num()` character function.

Many formats are supported, such as date and times, currency, and scientific notations. If a format is unsupported, a missing value is displayed.

1. Open your data table and select a column that contains both numeric and character values.
Figure 4.55  Column of Numeric and Character Data

2. Select Col > Recode.

3. Select Parse as Numbers from the red triangle menu.

   The old and new values are shown.

Figure 4.56  Preview of New Values

4. Click Recode.

   A new column with recoded values is added to the data table. The data type of the column is Numeric.

   “a” couldn’t be parsed as a number, so a missing value is displayed in the new column for that value.

Figure 4.57  Parsed Numbers

Example of Applying Recoded Values to a Different Column

When you recode a column, you can save the recoded values in a script. When you import or run the script, the column that you originally recoded is recoded again.
Suppose that you want to recode a different column with the same values. Save the recoded values in a formula column and then edit the formula.

1. Enter the recoded values in the New Values column of the Recode window.
2. Select **Formula Column** from the list next to the red triangle menu.
3. Click **Recode**.
4. Right-click the formula column and select **Formula**.
5. In the formula, select the column that was recoded.
   In this example, the *sex* column was recoded.

**Figure 4.58** Recoded Column

6. In the Columns list, select the column that will replace *sex*.
   In this example, you want to replace the *sex* column with *gender*, so select *gender*.

**Figure 4.59** Selecting the gender Column
Edit Data Tables

JMP provides many ways to change the basic properties of a data table.

- **Rename Data Tables**
- **Lock Data Tables**
- **Compress Data Tables**
- **Copy Table Scripts**
- **Use Data Table Variables**
- **Create and Save Scripts in Data Tables**

## Rename Data Tables

A data table’s name appears at the top of its window, in the table panel, and on all related analysis reports. You can change a data table’s name in any of the following ways:

- Select **File > Save As** and save as the new name.
- In the table panel, click table name, type the new name, and then press Enter.
- On Windows, select **Window > Set Title**.

## Lock Data Tables

Locking a data table prevents data and column properties from being added or edited. You can still assign row states, run analyses, and so on. To lock a data table, click the red triangle next to the table name in the table panel and select **Lock Data Table**.

A lock icon 🏁 appears next to the data table name. To unlock the file, select **Lock Data Table** again.

If you make a data table read-only outside of JMP (for example, by changing its properties on Windows), the data table contains a note informing you that it is locked (Figure 4.60). This type of lock allows users to edit the data table, but not save the changes.
Compress Data Tables

Compressing a data table reduces the size of the stored file. You can still run analyses, assign characteristics, and so on. To compress a data table, click the red triangle next to the table name in the table panel and select **Compress File When Saved** and save the data table.

After saving the data table, a compressed icon appears next to the data table name. To decompress the file, select **Compress File When Saved** again.

In addition, you can configure JMP to always use GZ compression when saving by selecting **Preferences > General > Save Data Table Columns GZ Compressed**.

**Note:** The **Compress File When Saved** option only decreases the file size. This command does not affect the memory required to analyze the data. To reduce both the file size and memory required for analyzing, use **Cols > Utilities > Compress Selected Columns**. See “Compress Selected Columns in Data Tables” on page 247.

Copy Table Scripts

Copying a table script enables you to paste the script into another script to recreate the table
Use Data Table Variables

A data table variable can contain textual information (for example, source information for the data), or a value that can be used by column formulas or JSL scripts. Data table variable names appear in the table panel at the left of the data grid.

Figure 4.61 Table Variables in the Table Panel

![Table Variables in the Table Panel](image)

Uses for Table Variables

Use table variables in the following situations:

- To document tables
- In formulas
- In JSL scripts

Use Table Variables to Document Tables

Table variables are used primarily to document tables. Many sample data tables installed with JMP contain a table variable named Notes. This variable provides details about the data (for example, the source of the data). The example in Figure 4.61 shows a data table that contains Notes as one of its table variables. JMP also automatically creates table variables when you create a design table using the Design of Experiments commands in JMP. The design table has a table variable named Design with the name of the design type as its value.

Reference Table Variables in Formulas

Table variables can also be incorporated in formulas that you build using the Formula Editor. These formulas calculate values for a column by referring to a table variable. For more information about constructing a formula that uses table variables, see “Refer to Data Table Values in Formulas” on page 397 in the “Create Formulas in JMP” chapter.
Use Data Table Variables in JSL Scripts
You can also incorporate table variables into JSL scripts. See the *Scripting Guide*.

Data Table Variable Actions

*To add new data table variables*
1. In the Table panel, click the red triangle to the left of the data table name.
2. Select **New Table Variable**.
3. Give the variable a name and value in the boxes labeled **Name** and **Value**.
4. Click **OK**.
   The table variable appears in the Table panel.

*To view or edit table variables*
1. Double-click the content of an existing table variable.
2. Edit the content.

*To edit a table variable name*
1. Double-click the table variable name.
2. Edit the name.

*To delete table variables*
Select one or more table variables and press Delete, or right-click the selected variables and select Delete.

Concatenating Data Tables with Table Variables
See the “Example of Concatenating Data Tables and Table Variables” on page 358 in the “Reshape Your Data” chapter.

Create and Save Scripts in Data Tables
To automatically complete various analyses and tasks, you can create a JSL script and save it to the data table (Figure 4.62). For more information about writing data table scripts, see the *Scripting Guide*. 
Save a Report Script to a Data Table

Once you have run an analysis and you are in the report window, you can add a script to the data table. This script generates the JSL that reproduces your analysis.

To save a script to the data table

From the report window, click the red triangle for the platform and select Save Script > To Data Table.

Example of Saving a Report Script to a Data Table

First, you create your analysis, then you save the script.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select height and click X, Factor.
5. Click OK.
6. Click the red triangle next to Bivariate Fit of weight By height and select Fit Line.
7. Click the red triangle next to Bivariate Fit of weight By height and select **Save Script > To Data Table**.

8. In the Save Script As window, enter the name of the script.

9. To replace an existing script with the same name, select it from the Name list and select **Replace existing script**.

10. To save a script that has the same name as an existing script and use the same name, select **Append unique suffix**.

   A number is added to the end of the script name.

11. Click **OK**.

The script is added to the bottom of the Table panel.

**Tip:** If you want a particular script to run automatically every time the data table is opened, name the script **OnOpen**. Only one script saved in the data table can be set to run automatically. If you name the script **Model** (or **model** in a Fit Model script, the launch window is automatically filled in based on the script when you select **Analyze > Fit Model**.

---

**Write a JSL Script for the Data Table**

To add a script to a data table using JSL

1. Click the red triangle to the left of the data table name in the Table panel.
2. Select **New Script**.

3. Give the script a name by typing it into the box beside **Name**.

4. Add the script by entering JSL code into the box beside **Script**.

5. Perform one of the following actions:
   - If you want to run the JSL Debugger on the script to check it for errors, click **Debug Script**.
   - If you are finished editing the script, click **OK**. The script appears in the Table panel and the window closes.
   - If you are not finished editing the script and want to save it, click **Save**. The script appears in the Table panel and the window remains open for further editing.
   - If you want to run the script, click **Run**.

**Run, Edit, Delete, or Copy Scripts**

*To run, edit, delete, or copy a script that is saved to the data table*

1. In the Table panel, right-click the green triangle beside the script’s name or right-click the script name.
2. Select one of the following commands:
   – Run Script
   – Edit
   – Delete
   – Copy

Once you copy a script, you can then paste it into a script window or into the Table panel of another data table.
Use the Column Info window to set specific properties on a column in a data table. Here are some examples of the actions that you can perform on a column:

- Change data and modeling types
- Change numeric formats
- Add formulas
- Specify restrictions on values or missing values
- Order categorical values or row data
- Save specification, control, or response limits
- Enter a known value for sigma

You can also standardize attributes and properties across multiple columns, assign a preselected analysis role to columns, and compress columns in a data table.

Figure 5.1 The Column Info Window
About the Column Info Window

Use the Column Info window to specify all of the attributes and properties of a column. You can access the Column Info window in any one of the following ways:

- Select Cols > New Columns.
- Click an existing column heading and select Cols > Column Info.
- Right-click an existing column heading and select Column Info.
- Double-click directly above a column name.
- In the Columns panel, right-click a column and select Column Info.

Figure 5.2 The Column Info Window

The Column Info window contains the following information:

**Column Name**  Type or edit the name of the column.

**Lock**  Lock the column so that none of its values can be edited. After you lock a column, the lock icon (🔒) appears next to the column name in the data table’s Columns panel. If you add a formula to a column, the column automatically locks.

**Data Type**  Select or change the data type of a column, which determines the following:
- How the column’s values are formatted in the data grid
- How the column’s values are saved internally
- Whether the column’s values can be used in calculations

See “About Modeling Types” on page 294.
Choose from the following data types:

**Numeric**  The columns contain only numbers (with or without a decimal point).

**Character**  The columns contain any characters, including numbers. In character columns, numbers are seen as characters and are treated as discrete values instead of continuous values. The maximum field width for character values is 32,766 bytes.

**Row State**  The columns contain row state information, which indicates whether the rows are excluded, hidden, labeled, colored, or marked. See “Store Information in Row State Columns” on page 300.

**Expression**  The columns contain JSL expressions that can range from simple entries to complicated statement sequences. In particular, an expression can correspond to a picture, a matrix, or an expression. You can drag-and-drop expressions, such as an image, from your desktop to cells in an expression column. See “Expression Role” on page 326.

**Notes:**

– If you change a column’s Data Type from Character to Numeric, any character values become missing data values and are not recoverable.

– If you enter non-numeric data in a column with a Numeric data type, a warning window is displayed, prompting you to change the data type to Character. Click **Try Again** to return to the data table to re-enter the value. Click **Change** to change the data type. Click **Revert** to cancel your edit and return the cell’s value.

– Short-integer formats might also be available. See “The Short-Integer Format” on page 294.

**Modeling Type**  (Numeric or Character data types only) Select or change the modeling type of a column, which tells JMP how to treat the column’s values during analyses. You can change the modeling type to look at a variable in different ways. See “About Modeling Types” on page 294.

Choose from the following modeling types:

**Continuous**  Only numeric data types. Continuous values are treated as continuous measurement values. JMP platforms use the numeric values directly in computations.

**Ordinal**  Either numeric or character data types. JMP platforms treat ordinal values as discrete categorical values that have an order. In Graph Builder, if there are more than 50 discrete values, JMP treats the column as continuous.

– If the column has a numeric data type, the values are ordered according to their numeric magnitude.

– If the column has a character data type and a Value Order column property is saved to the column, values are ordered according to the Value Order property. Otherwise,
values are ordered according to their alphanumeric data value ordering. However, in special cases where the values have an obvious order, values are automatically ordered appropriately. See “Value Order” on page 308.

**Nominal**   Either numeric or character data types. JMP platforms treat all values as discrete values with no implicit order.

**Multiple Response**   Only character data types. Distinct entries in a single cell must be separated by commas. JMP platforms that support multiple response columns treat each entry in the comma-separated list as a separate data value. If your entries are separated by a character other than a comma, use the Multiple Response column property instead. See “Multiple Response” on page 319.

**Unstructured Text**   Only character data types. These values are generally unique and are therefore not appropriate for categorical analysis. The Text Explorer platform is ideal for analyzing unstructured text values.

**Vector**   Only expression data types. The entries in the cells are column or row vectors. JMP platforms that support the Vector modeling type recognize the vectors and treat them appropriately in calculations.

**None**   Any data type. Use None as a modeling type when a column is not well represented by the other modeling types. For example, a column of pictures or ID values might be assigned the None modeling type. JMP launch windows do not allow you to assign roles to columns with the None modeling type.

**Tip:** You must use the Column Info window to change a column’s modeling type to Multiple Response, Unstructured Text, or Vector.

**Format**  (Numeric data types only) Select or change the display format of a numeric column. See “Numeric Formats” on page 295.

**Initialize Data**  (Appears only during new column creation) Specify the type of initial data values that you want to appear in the column. See “Initialize Data in a Column” on page 302.

**Column Properties**  (Contains a list of different properties) Assign properties to columns. See “Column Properties in JMP” on page 303.

**Tip:** Click the Next button to continue adding columns.
About Modeling Types

A column in a JMP data table can contain different types of information. However, all information in a single column must have the same data and modeling types.

- When you import data, JMP guesses which data and modeling types to use. Therefore, you should verify that JMP has guessed correctly.
- When you manually insert data, you should assign a data type and a modeling type at that time.

Figure 5.3 illustrates the icons that identify the different modeling types.

**Figure 5.3  Modeling Type Icons in the Columns Panel**

Click an icon to change the modeling type to **Continuous, Nominal, Ordinal, or None**.

See “Modeling Type” on page 292.

**Tip:** You can select Continuous only if your data type is numeric. If the Continuous option is dimmed on the menu and you want to make the column continuous, you must first change the column’s data type in the Column Info window.

The Short-Integer Format

When you use the correct short-integer format for your data, you do not see any difference in how the numbers appear. However, the numbers occupy less disk space and use less memory. Short-integer formats must be activated in preferences to appear in the Column Info window.

To make short-integer formats available in the Column Info window

1. Select **File > Preferences** and click **Tables**.
2. Select the **Allow short numeric data format** option.
3. Click **OK** to return to the data table.

To store numeric data in short-integer format:

1. Double-click above the column name whose values you want to be short-integer.
   The Column Info window appears.
2. From the Data Type menu, select **1-byte integer**, **2-byte integer**, or **4-byte integer**.

JMP stores values as integers in the range that you selected. The following numbers are examples:

- For 1-byte integer, the range of numbers that you can enter is from -126 to 127.
- For 2-byte integer, the range of numbers that you can enter is from -32,766 to 32,767.
- For 4-byte integer, the range of numbers that you can enter is from -2,147,483,646 to 2,147,483,647.

**Numeric Formats**

For numeric columns, the Format menu appears in the Column Info window. Specify the format to tell JMP how to display numbers in the column. For all format options, you can specify the number of total characters that you want the cells in the column to accommodate. See “Specify Width” on page 295.

For descriptions of the format options, see “Numeric Format Options” on page 295.

**Tip:** To add commas to values that equal a thousand or more, select the **Use thousands separator** option. You must account a space for each comma in the Width box, or else they might not appear. This option is available for the Best, Fixed Dec, Percent, and Currency formats.

**Specify Width**

When you specify a number in the Width field, be sure to include the total number of possible characters. Characters include: numbers, decimal points, commas, and currency symbols.

**Numeric Format Options**

Choose from the following numeric format options:

- **Best**  Allows JMP to consider the precision of each cell value and select the best way to show it. By default, the physical width of the column is 12 characters.
Fixed Dec  Shows all values in the column rounded to the number of decimal places that you specify.

- To see only whole numbers, set the number of decimal places to zero.
- If the number of integers following the decimal point is smaller than the number of decimal places that you specify, zeros are added to reach the number of decimal places. For example, if the value is 1.23 and you type 5 in the Dec box, JMP shows the number with five decimal places: 1.23000.

Percent  Multiplies numeric values by 100 and shows the number followed by a percent sign.

PValue  Shows probability values. The default value of the width is 12. If a number is less than 0.0001, the number is displayed as <.0001. The format is mostly used in JSL scripts and rarely needed for a data table column.

Scientific  Shows a number in standard scientific notation. If you enter the number 123456, it appears as 1.23456e+5. Select Dec to show the decimal points and enter the number of points.

Engineering  Similar to Scientific, but the exponent is always a multiple of 3 and the Dec field represents significant digits.

Engineering SI  Same as Engineering, but the exponent is replaced with an SI symbol.

Precision  Rounds the number to a given number of significant digits. Specify the number of significant digits in the Dec field.

Currency  Formats values with two decimal positions, thousands separators, and the currency sign that is specified in your computer’s locale settings. The default width of the Currency format is 15. If you have a number that requires a wider field width, the format defaults to the Best format. Once assigned, the currency symbol appears in the column and in graphs that contain the column.

Date  Shows all values in the column as a date. See “Date Formats” on page 297.

Time  Shows all values in the column as a specific instance in time, such as 12/2/03 at 2:23 PM. See “Time Formats” on page 298.

Duration  Shows all values in the column as a duration of time, such as hours, minutes, and seconds.

:day:hr:mm, :day:hr:mm:ss  Shows a duration of time, such as 52:03:01:30, or fifty-two days, three hours, one minute, and thirty seconds.

hr:mm, hr:mm:ss, min:ss  Shows a duration of time, such as 17:37, or seventeen hours and thirty-seven minutes.
Geographic  Shows latitude and longitude number formatting for geographic maps.
Latitude and longitude options include the following:

- **DDD**  Degrees
- **DMM**  Degrees and minutes
- **DMS**  Degrees, minutes, and seconds

In each format, the last field can have a fraction part. You can specify the direction with either a signed degree field or a direction suffix. To show a signed degree field, such as -59°00’00”, deselect Direction Indicator. To show the direction suffix, such as 59°00’00” S, select Direction Indicator.

To use spaces as field separators, deselect Field Punctuation. To use degrees, minutes, and seconds symbols, select Field Punctuation.

Custom  Enables you to define a custom format for a numeric column, including customization of column width and number of decimal places. Select Custom, click Set Custom Format, and define the format in the Formula Editor window. For example, if you don’t want to display the percentage sign next to a number, select this option and multiply the number by 100. This is an alternative to selecting the Percent format. Or if your data is in meters and you want to show it in kilometers with the unit, add the formula Char(:value / 1000) || " km". You might also want to apply a date/time format that isn’t available in the Format Date or Time lists, such as D/M/Y.

Format Pattern  Enables you to customize the date-time formatting of numeric values. See “Customize Date-Time Formats with Format Patterns” on page 299 for details.

Date Formats
When you choose a Date format, you can also specify an Input Format. The Date format indicates how the date appears in the data table cells, and the Input Format indicates how you enter the date.

If you assign a date format to a numeric column that already contains data, then the numeric values are treated as the number of seconds since January 1, 1904. For example, if you have a numeric column with a cell value of 1,234,567,890 and you change the format to Date > m/d/y, the cell value appears as 02/13/1943.

The examples in Table 5.1 use the date of December 31, 2004.

<table>
<thead>
<tr>
<th>Format</th>
<th>Appears As</th>
</tr>
</thead>
<tbody>
<tr>
<td>m/d/y</td>
<td>12/31/2004</td>
</tr>
</tbody>
</table>
Table 5.1  Date Formats  (Continued)

<table>
<thead>
<tr>
<th>Format</th>
<th>Appears As</th>
</tr>
</thead>
<tbody>
<tr>
<td>mmdyyyy</td>
<td>12312004</td>
</tr>
<tr>
<td>m/y</td>
<td>12/2004</td>
</tr>
<tr>
<td>yyyyQq</td>
<td>2004Q4</td>
</tr>
<tr>
<td>d/m/y</td>
<td>31/12/2004</td>
</tr>
<tr>
<td>ddmmyyyy</td>
<td>31122004</td>
</tr>
<tr>
<td>ddMonyyyy</td>
<td>31Dec2004</td>
</tr>
<tr>
<td>Monddyyyy</td>
<td>Dec312004</td>
</tr>
<tr>
<td>y/m/d</td>
<td>2004/12/31</td>
</tr>
<tr>
<td>yyyyymmdd</td>
<td>20041231</td>
</tr>
<tr>
<td>yyyy-mm-dd</td>
<td>2004-12-31</td>
</tr>
<tr>
<td>Date Long</td>
<td>Friday, December 31, 2004</td>
</tr>
<tr>
<td>Date Abbrev</td>
<td>Dec 31, 2004</td>
</tr>
<tr>
<td>Locale Date</td>
<td>Varies based on local OS setting. Here is an example: in the United States, the local OS setting is mm/dd/yyyy (12/31/2004).</td>
</tr>
</tbody>
</table>

**Note:** To change how a date appears in a graph without changing how it appears in a data table, see “Change the Numeric Format of an Axis” on page 498 in the “JMP Reports” chapter.

**Time Formats**

When you choose a Time format, you can also specify an Input Format. The Time format indicates how the time appears in the data table cells, and the Input Format indicates how you enter the time.

- You can add the number of hours, minutes, and seconds after midnight of the prepended date for the following date formats:
  - m/d/y
  - d/m/y
  - y/m/d
  - ddMonyyyy
– Monddyyyy
– Locale Date

For example, December 31, 2004 has a numeric value of 3,187,296,600, which represents 12/31/2004 12:10 AM.

- **:day:hr:m** and **:day:hr:m:s** show the number of days, hours, minutes, and seconds since January 1, 1904. For example, the results for December 31, 2004 are :36890:00:10: and :36890:00:10:00.

- **h:m:s** and **h:m** show the hours, minutes, and seconds portion of the date in the date field. For example, the results for December 31, 2004 at 12:10 AM are 12:10:00 AM and 12:10 AM.

- **yyyy-mm-ddThh:mm** and **yyyy-mm-ddThh:mm:ss** show the year, month, day, and time. For example, 2004-12-31T12:10:00. T is a literal value, representing itself.

**Note:** To change how a time appears in a graph without changing how it appears in a data table, see “Change the Numeric Format of an Axis” on page 498 in the “JMP Reports” chapter.

**Customize Date-Time Formats with Format Patterns**

Format patterns are strings that define a date-time format, such as `<YYYY></YYYY</><MM</><DD</<hh><:/><mm><:/><ss><ampm>`. The parts of the pattern in angle brackets are called field descriptors. The field descriptors represent a value (such as `<YYYY>`, which is a four-digit year) or other date-time text (such as `</>`, which is a locale-specific date separator).

A format pattern enables you to build formats that aren’t provided in JMP. These formats can be used for both formatting and inputting data. You can type the pattern yourself, use a built-in format as a starting place, or select field descriptors from a list.

You can use format patterns anywhere built-in date-time formats can be selected.

**Build a Format Pattern**

1. Create a numeric column in a data table.
2. Right-click the column and select **Column Info**.
3. Select **Format Pattern** from the Format list.
4. Click **Set Format Pattern**.
5. To use a built-in format as a starting place, select **Builtins**, select a date-time format, and then edit the format.
6. To edit the format, type the field descriptors in the Format Pattern field, or select a format pattern from the Field Descriptors list.
7. Click **OK**.
Build an Input Format Pattern

1. In an existing numeric column, right-click and select **Column Info**.
2. Select **Format Pattern** from the Format list, and then deselect **Use Output Format**.
3. Click **Set Format Pattern**.
4. Build the pattern as described in the preceding task.

**Note:** Some formats cannot be used for input. For example, when a variable-length number field descriptor is followed immediately by another number, some dates are ambiguous. The format `<YYYY><M><D>` cannot process input because `<M>` is a single digit month; dates such as 2020111 would be ambiguous. It’s unclear whether the date is Jan 11 or Nov 1.

**International Formats**

If you are importing or entering data that contains formatting specific to country standards, you might need to make sure that your number formats are interpreted correctly. On Windows, access the Control Panel’s region and language option, and select the country for which the number should be formatted. On macOS, from the Apple menu, select **Language & Region > Formats**, and select the correct country. On later versions of macOS, this option may appear under System Preferences > Language and Region.

**Store Information in Row State Columns**

Similar to assigning row states to rows, you can create a column that contains only row state information. A row state column stores information about whether rows are excluded, hidden, labeled, colored, marked, or selected. To designate a column as a row state column, in the Column Info window next to Data Type, select **Row State**.

**Figure 5.4** Row States in Rows and a Row State Column

Since row state columns store the row states, you can apply them again later. Populate row state columns by copying them from the current row states or with column formulas.
To create a row state column

1. Select Cols > New Columns.
2. Next to Data Type, select Row State.
3. Click OK.

Populate the cells with new row state information or copy existing row state information from rows.

To populate cells with new row state information

1. To populate only certain rows in the row state column, highlight those rows. Or, to populate all rows in the column, highlight the row state column.
2. Right-click and select Row States Cells.
3. Select the row state that you want to apply.

To copy existing row state information

1. To populate only certain rows in the row state column, highlight those rows. Or, to populate all rows in the column, highlight the row state column.
2. Click the star icon (⭐) beside the column name in the Columns panel.
3. Select one of the following:
   - **Copy from Row States** Replaces the row states in the column with the row states from the rows.
   - **Add from Row States** Adds the row states from the rows to the row state column.
   - **Copy to Row States** Replaces the row states in the rows with the row states from the column.
   - **Add to Row States** Adds the row states from the row state column to the row states in the rows.

Permanently Select Cells

You can save a selection in a row state column just like you save other row state characteristics (hide, exclude, color, and so on). This places a “permanent” highlight on a cell.

To permanently select cells

1. Right-click a cell and select Row States Cells > Select/Deselect.
2. Repeat this for as many cells as you would like to select.
3. To remove the highlight, right-click the cell and select Row States Cells > Select/Deselect.
Initialize Data in a Column

When you first add a new column to a data table, the Initialize Data menu appears in the Column Info window. Specify the type of initial data values that you want to appear in the new column. Initializing data is not available for Row State data types.

Select one of the following options:

**Missing/Empty**  Places missing values in the column, represented by a black dot (•) for numeric data and a blank space for character data.

**Constant**  Places one number or character in all of the column’s rows. Enter the number or character into the box that appears. Enter any number of characters.

**Today**  Places today’s timestamp in the column for each row. This option is relevant only for the Date or Time formats.

**Sequence Data**  Inserts sequential data based on the parameters that you specify. See “Numeric or Character Sequence Data” on page 303.

**Random**  Inserts randomly generated data values into the column. Select a method for generating the random values:

- **Random Integer**  Enter minimum and maximum integer values. Integer values within this range are generated so that each occurs with approximately equal frequency.

- **Random Uniform**  Enter a range for continuous values. Random uniform values within this range are generated.

- **Random Normal**  Enter the mean and standard deviation for a normal distribution. Random normal values from this distribution are generated.

- **Random Indicator**  Enter up to three values and corresponding desired proportions. The proportions should sum to 1. Values are generated to have a distribution that corresponds as closely as possible to the specified proportions.

**Note:** This method generates values in the exact proportions that you specify unless the number of rows multiplied by one of the proportions results in a fractional value.

Suppose that there are \( n \) rows and that the three proportions are \( p_1, p_2, \) and \( p_3 \). Here is how the values are generated:

- Each row is assigned a random uniform value between 0 and 1.
- The rows are ordered according to their random uniform values.
- The rows corresponding to the smallest Round\( (np_1) \) random uniform values are assigned the first value, the rows corresponding to the next smallest Round\( (np_2) \)
random uniform values are assigned the second value, and the remaining rows are assigned the third value.

**Numeric or Character Sequence Data**

*To insert sequential data for numeric data*

1. Next to **Data Type**, make sure **Numeric** is selected.
2. Next to **Initialize Data**, select **Sequence Data**.
3. In the **From** and **To** boxes, assign a starting and ending point.
4. In the **Step** box, assign the sequence.
5. (Optional) In the **Repeat each value N times** box, enter the number of times that you want each numeric value repeated.
6. Click **OK**.

For example, if you want the column to contain even numbers from 2 to 60, type 2 in the **From** box, 60 in the **To** box, and 2 in the **Step** box.

*To insert sequential data for character data*

1. Next to **Data Type**, make sure **Character** is selected.
2. Next to **Initialize Data**, select **Sequence Data**.
3. In the box next to **Add**, enter the character data and click **Add**.
4. (Optional) In the **Repeat each value N times** box, enter the number of times that you want each character value repeated.
5. Click **OK**.

---

**Column Properties in JMP**

A column property is information that is attached to a column. Once that information is entered, it is saved as part of the data table. You can select column properties and apply them to columns. There are some column properties that JMP creates for your convenience. Often, you can modify these.

Column properties are listed in the Column Info window’s Column Properties menu. The area below the Column Properties menu shows column properties that have been saved to a column. To view or edit a property, select it from this list.
In the Columns panel of the data table, an icon appears next to the name of each column that contains a property, other than the Notes property. The Notes property is not denoted by an icon. Icons include the following:

- ✓ Indicates that the range or list check property is applied
- ✗ Indicates that the column contains a formula
- ⚫ Indicates that the column contains a property other than the Note, Range Check, or List Check column property

For information about more column property icons, see “Icons Representing Column Characteristics and Properties” on page 41 in the “Get Started with JMP” chapter.

To assign a column property to one or more columns

1. Select the column or columns to which you want to assign a property.
2. Do one of the following:
   - Right-click the header area, select **Column Properties**, and select the property.
   - Right-click the header area, select **Column Info**, and select the property from the Column Properties menu.
   - Select **Cols > Column Info** and select the property from the Column Properties menu.
3. In the column property panel that appears, specify values and select options as appropriate.
   - Click **Apply** to add the column property or click **OK** to add the column property and close the column properties window.

A column might already contain a property that you want to apply to other columns. Use the Standardize Attributes command to apply that property to other columns. See “Standardize Attributes and Properties Across Columns” on page 331.

The following sections describe the properties that you can add to columns.

**Basic Column Properties**

Basic column properties that apply generally include Formula and Notes.

**Formula**

Insert a formula into a column to compute the values for that column. After a formula is added, the column is locked so that its data values cannot be manually edited (preventing invalidation of the formula).

- Click **Edit Formula** to create a formula. For more information about creating a formula, see the “Create Formulas in JMP” chapter on page 393.
• If you do not want JMP to evaluate the formula, click **Suppress Eval**.
• If you do not want JMP to alert you about errors in your formula, click **Ignore Errors**.
• Once you have created a formula:
  – In the Column Info window, a visual of the formula appears at right. However, if your formula is long, only a portion of it might appear. Click and drag the borders of the formula box to resize it.
  – From the data table, edit the formula by clicking (idences) next to the column name in the Columns panel.

**Tip:** To bypass the Column Info window when creating a formula, right-click the column and select **Formula**.

**Notes**

Adds notes to the selected column.

**Properties That Validate Column Values**

The following properties help validate values in a column: Range Check, List Check, and Missing Value Codes.

**Range Check**

Range checking validates the data in a column. Set up the column to accept only numbers that fall within a specified range.

Select which formula to use to set up the range. \( x \) is the value entered into the column, \( a \) is the beginning of the range, and \( b \) is the end of the range.

• \( a = \) the lowest value that the column accepts
• \( b = \) the highest value that the column accepts
• For a single-sided range check, leave either \( a \) or \( b \) empty.
• From the data table, modify the range check by clicking (indicators) next to the column name in the Columns panel.

**List Check**

List checking validates the data in a column. Set up the column to accept only the individual values that you specify. List checking is useful when you want to specify how to order the data in your graphs or plots.

• You can use up to 127 values.
• Use the buttons to add new values, change, or reverse the order of values, and remove values.
• Once a list check is set on a column, the cursor changes to \( \) when positioned over the cells. If you try to enter a value not included on the validation list, a warning message appears.
• To see a menu of acceptable values, right-click a cell and select **List Check Values**. You can select the cell value from the menu instead of entering it into the cell.
• From the data table, modify the list check by clicking \( \) next to the column name in the Columns panel.

**Missing Value Codes**

Use missing value codes to specify column values that should be treated as missing. For example, sometimes the value 99 is used as a placeholder to represent missing values, or perhaps several values are used to represent different types of missing values.

**Note:** The Missing Value Codes column property is an extended attribute. If you plan to export to a SAS 9.4 server or Save As a SAS 9.4 file format, you should enable extended attributes in the SAS Integration Preference page. See “Preferences for SAS Integration” on page 712 in the “JMP Preferences” chapter. Alternatively, you should select **Store table and column properties in SAS 9.4 extended attributes** in the Save As window. If extended attributes are not selected, JMP exports or saves Missing Value Codes as missing values. Extended attributes are supported only by SAS 9.4. Earlier versions of SAS disregard any extended attributes.

**To remove missing value codes for a single column**

1. In the Columns panel of the data table, next to the column, click \( \) > **Missing Value Codes**.
2. Missing Value Codes is highlighted in the list. Click **Remove**.
3. Click **OK**.

**To remove missing value codes across multiple columns**

1. Select the columns containing the missing value codes that you want to delete.
2. Select **Cols > Standardize Attributes**.
3. Under Delete Properties, click **Column Properties > Missing Value Codes**.
4. Click **OK**.
Properties That Attach Information to Column Values

The following column properties attach information that is used in reports and plots to the values in a column:

- Value Labels
- Value Scores
- Value Order
- Row Order Levels
- Value Colors
- Color Gradient
- Short Name
- SPSS Name
- SPSS Label
- SAS Name
- SAS Label
- Long Name
- Question

Value Labels

Use value labels to show a label in the data table instead of a value. A label appears for each instance of the value. You can show the original values by double-clicking a label within a cell.

- Enter the value that you want to assign a label to in the Value box.
- Enter the label that you want to appear in the Label box.
- To use ranges, click Allow Ranges then specify the lower and upper values. If Allow Ranges is selected, Value Labels can be non-integers. Graph Builder can use the Value Labels for the x- and y-axes.

Tip: To assign a label to missing values, enter a period (.) for the lower bound and leave the upper bound empty. To assign a label to all other values, enter three periods (....) for the lower bound and leave the upper bound empty.

- Add, change, or remove labels.

Tips:

- To turn off value labels in the data table without deleting the value labels that you have set up, in the Column Properties window, deselect Use Value Labels. Or, to quickly show or
hide value labels in a data table, right-click a column and check or uncheck **Use Value Labels**.

- When your data table contains value labels, using the **Search** commands searches for actual values, but does not search for labels.
- When your data table contains value labels, the **Row Editor** displays the label, and when the cell is highlighted for editing, it shows the actual value.
- If you copy and paste a cell with a value label, the actual value is pasted.
- In a formula, when you reference a column using value labels, hover over the value label to see the actual data value.

**Value Scores**

Use value scores to indicate a value-score pair for categorical data columns. The value is a data value and the score is a number. This property associates a data value with a score (for example, the column’s data value could be “not satisfied”, “satisfied”, “very satisfied”). The user could assign a score of 0 to “not satisfied”, 50 to “satisfied”, and 100 to “very satisfied”. Those scores are then used for computation purposes like computing the mean. See *Consumer Research* for an example.

*To use value scores*

1. In the data table, right-click the column and select **Column Info**.
2. From the **Column Properties** list, select **Value Scores**.
3. Enter the value that you want to assign a label to in the Value box (for example, “satisfied”).
4. Enter the label that you want to appear in the Score box (for example, “50”).
5. Click **Add**, **Change**, or **Remove**.
6. Click **OK**.

**Value Order**

Value Order assigns an ordering to values in a column that is then used in reports and plots. The default ordering for reports and plots is alphanumeric data value ordering, except in the following cases, where values are automatically ordered appropriately:

- January, February, March, April, May, June, July, August, September, October, November, December
- Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec
- Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday
- Very Low, Low, Medium Low, Medium, Medium High, High, Very High
• Strongly Disagree, Disagree, Neutral, Indifferent, Agree, Strongly Agree
• Failing, Unacceptable, Very Poor, Poor, Bad, Acceptable, Average, Good, Better, Very Good, Excellent, Best

Tip: You can anonymize Value Order so that the Value Order properties are renumbered. To do this, highlight the column with the Value Order column property and select Tables > Anonymize.

When you construct a design using a DOE platform, the Value Order column property is automatically assigned to categorical factors. For examples of assigning and editing the Value Order column property, see the Design of Experiments Guide.

Note: When you’re comparing character data, select Use Locale Comparisons for Characters to consider locale information when determining the ordering.

Custom Order

By default, Custom Order is selected. This option allows you to order data values in a user-defined order. Initially, character data is ordered alphabetically and numeric data is sorted numerically. You can use the arrows to move the values and the plus sign to add values.

Sorted Order

Deselect Custom Order to move the values to the Sorted Order box. Then you indicate the rules for sorted items.

Items that are not custom ordered are affected by the sorted order. Drag items down to the Sorted Order area to remove them from the custom order and have the sorting rules applied to those items. Deselect Custom Order to apply sorting rules to all items.

The sort order rules are applied when you select or deselect the check boxes.

Row Order Levels Sorts the column values by their occurrence in the data table, rather than sorting by value. This option does not apply to sorting data table columns.

Note: If both Row Order Levels and Common Order are selected, the row order levels apply

Common Order If all values have a predefined sort order (for example, the days of the week), remaining items are sorted on that basis. Common order is the typical ASCII ordering. This option is available only for character data.

Numerical Order Sorts character column values by splitting the data into string and numeric segments.
Here are the numerical order rules:

- Strings are broken into segments of numeric (not including +/-, but including dots in the middle) and non-numeric characters.
- Segments are compared between two strings, comparing numbers by magnitude as long as the numbers don’t start with leading zeros. Numbers with leading zeroes are sorted before any numbers without leading zeros.
  
  If both numbers have leading zeroes, then the numbers are compared digit-by-digit. For example, “0CH2” is sorted before “0 CH2”.
- If two strings differ by segment type, a numeric segment sorts before a string segment.
- The locale compare affects symbols; characters such as hyphens and lowercase or uppercase are ignored in locale sorting. (Note that lowercase is sorted before uppercase in ASCII ordering. The rules are different for each language. The goal is to sort the same way that the operating system sorts file names.
  
  To use ASCII ordering, deselect Numerical Ordering in the Value Order column property.
- The string segments are compared using locale compare by default. This comparison is language-aware. The comparison is provided by the operating system, so there are subtle differences between behavior on Windows and macOS.

Value Colors

Use value colors to assign the values of a nominal or ordinal column a certain color or range of color themes. The column’s values appear with the assigned color in all applicable graphs, such as mosaic plots and plots with color-coded legends. You can also color the values in the data table column.

- To change the color of a specific value, right-click a color circle and select a color.
- To use a color theme, click Color Theme below the list of value colors and then select the color.
- To create a custom color theme, see “Create a Custom Color Theme” on page 310.
- To also color the cells in the data table, select Color Cell by Value.
- Select from the options in the Macros menu. See “Macros Options” on page 311.

Create a Custom Color Theme

To create a custom color theme

1. Click Color Theme below the list of value colors in the column properties.
2. Open the Custom Color Theme outline.
3. Click **New**.
4. Create the color using the sliders.
5. Name the color and click **Save**.
6. Click **OK**.

You can access the new custom color in the Color Theme menu the next time you use the Value Colors property. The color is also saved in your preferences. See “Create Color Themes in Graphs” on page 236 in the “Enter and Edit Your Data” chapter for more information about creating color themes.

**Macros Options**

The Macros menu contains the following options:

- **Gradient between ends** Sets the colors of the top and bottom values. JMP applies a color gradient across the entire range of values. Use this command to make all of the colors in between for the other levels.

- **Gradient between selected points** Sets the colors of the top and bottom values so that JMP can apply a color gradient to a range of values that you have highlighted in the Value Colors list.

- **Reverse colors** Reverses the color of the values from top to bottom or bottom to top.

- **Revert to old colors** Sets the colors back to their original color values.

**Color Gradient**

Select a color gradient to color a continuous column in a plot. Color gradients are supported in the Graph Builder, Bubble Plot, Treemap, and Cell Plot platforms.

- To also color the cells in the data table, select **Color Cell by Value** above the list of value colors.
- Select a color gradient from the menu.
- Enter the minimum, maximum, and center values:
  - Minimum values reflect the color at the left of the gradient.
  - Maximum values reflect the color at the right of the gradient.
  - Center values reflect the color in the middle of the gradient.

**Note:** To see color gradients in Graph Builder, you must assign the column to the Color zone. To see color gradients in Bubble Plot and Treemap, you must assign the column to the Coloring role.
Short Name, SPSS Name, and SAS Name

These column properties insert the specified short name in a Categorical structured report when the Show Columns Used in Report red triangle option is selected.

SAS Name is also a column property that is added when you import SAS data. It contains the name of the variable in the SAS data set. Modifying it will affect the SAS data set if the data are exported back to SAS.

SPSS Label, Long Name, SAS Label, and Question

These column properties insert the specified long name in a Categorical structured report when the Show Columns Used in Report red triangle option is selected.

SAS Label is also a column property for imported SAS data. It contains the description of the column in the SAS data set. Modifying it will affect the SAS data set if the data are exported back to SAS.

Properties That Control the Display of Columns

The Axis and Units column properties control how column values are displayed.

Axis

Use the Axis property to change the default axis settings for a column. JMP automatically uses your settings when the column appears in an analysis. See “Customize Axes and Axis Labels in Graphs” on page 496 in the “JMP Reports” chapter for more information about the properties.

When you add the Axis column property, you can save all column properties or only the properties that you changed. For example, you might want the axis to start at 0 and are not concerned about the upper bounds of the axis. Set the minimum axis value and select Changed Properties Only from the Save to column list.

To set default axis properties for a column from within a graph

1. Create the graph.
2. Change the axis to your preferred specifications.
3. Right-click the axis and select Save to Column Property.
Units

Use the Units property to specify the measurement units that were used to collect the data for the column. The units appear in parentheses after the column name in the data table and when the column appears in plots. For example, you might want a column to indicate that age values are measured in months, or that a monetary value is in thousands of dollars.

Properties Used in Modeling and DOE

When you construct a design using the DOE platforms, column properties are saved to the resulting design table. However, some of these column properties are useful in general modeling situations. To use the properties more generally, you can specify them yourself.

**Note:** the *Design of Experiments Guide* describes the properties associated with DOE in detail and presents examples. Only a brief description of these properties is provided here.

The following column properties are used in modeling and DOE:

- Response Limits
- Detection Limits
- Design Role
- Coding
- Mixture
- Factor Changes

**Response Limits**

The Response Limits column property defines a desirability function for the response. The Prediction and Contour Profilers use desirability functions to find optimal settings. See the *Design of Experiments Guide*.

**Detection Limits**

The Detection Limits column property defines bounds beyond which the response cannot be measured. You can use these limits to specify a censored response in the Generalized Regression platform. See *Fitting Linear Models*. 

Design Role

The Design Role column property indicates how a column is used in both a designed experiment and in the model used to fit the data. For example, a column could represent a continuous factor, a categorical factor, a blocking factor, and so on. See the Design of Experiments Guide.

Coding

The Coding column property applies a linear transformation to the data in a numeric column. The data are transformed to –1 and +1 based on bounds that you specify. JMP then uses the transformed data values whenever the column is entered as a model effect in the Fit Model platform. See the Design of Experiments Guide.

Mixture

The Mixture column property is useful when a column in a data table represents a component of a mixture. The components of a mixture are constrained to sum to a constant. The Mixture column property identifies a column as a mixture component and defines a coding for that column. See the Design of Experiments Guide.

Factor Changes

The Factor Changes column property indicates how difficult it is to change factor settings in a designed experiment. It is used to create and analyze split-plot, split-split-plot, and two-way split-plot designs. See the Design of Experiments Guide.

Properties Associated with Control Charts and Capability

The Specification Limits, Control Limits, Sigma, and Process Capability Distribution properties are associated with control charts and capability.

Spec Limits

Specification limits are used when you perform a capability analysis using the Distribution and Capability platforms. Note that in old data tables, the column property might be named Capability Analysis.

You can specify any combination of a Lower Spec Limit, an Upper Spec Limit, or a Target. The Show as Graph Reference Lines option displays the specification limits and target that you specify as reference lines on appropriate plots.

Tip: To add specification limits to several columns at once, see Quality and Process Methods.
Control Limits

The Control Limits column property enables you to specify control limits for a column, rather than having JMP calculate control limits from the values in the column. This is useful when you are comparing process data to historical control limits.

The Control Limits column property can be assigned only to a numeric column. To assign the Control Limits column property, select the control chart type and then enter the requested values. If any of these entries are missing, JMP replaces it with a calculated value in the control chart.

Sigma

Use the Sigma property to enter a known sigma value. This value is used by applications such as control charts or any application that requires a sigma value to complete computations. If no sigma value is supplied, sigma is calculated from the sample.

Process Capability Distribution

The Process Capability Distribution column property specifies a process distribution for the column. The Process Capability Distribution column property is used only in the Process Capability platform. See also “Distribution and Process Capability Distribution” on page 316.

QC Alarm Script

You can generate automatic alarms by writing a script and storing it as a column property or data table property named QC Alarm Script.

The following QC Alarm Script automatically writes a message to the log whenever a test fails:

```
Write(
    "Out of Control for test ",
    qc_test,
    " in column ",
    qc_col,
    " in sample ",
    qc_sample
)
```

Properties That Control How Columns Are Used in Platforms

The following properties control how columns are used in platforms:

- Distribution
For a column that contains continuous numeric data, use the Distribution property to select a distribution type to fit to the column. This distribution is used in the Distribution platform and is used in the Process Capability platform under certain conditions. See “Distribution and Process Capability Distribution” on page 316.

When you obtain a Distribution report (by selecting Analyze > Distribution) for the column, JMP automatically estimates a fit using the specified distribution. A curve representing the fitted distribution is superimposed on the histogram.

If you set both the Distribution property and the Spec Limits property, then the Distribution platform produces a Capability Analysis report that is based on the distribution specified in the Distribution column property.

**Note:** In older data tables, the Capability Analysis column property might have been assigned to a column to specify spec limits. We recommend that you use the Spec Limits property instead.

**Distribution and Process Capability Distribution**

If you are using the Process Capability platform to analyze a column that does not contain a Process Capability Distribution property, the distribution specified in the Distribution column property results in a nonnormal fit in the Process Capability platform. If this distribution is supported in the Process Capability platform, then it is used. However, if this distribution is not supported, the platform uses a Johnson fit.

If both the Distribution and Process Capability Distribution column properties are saved for a given column, then the distribution specified in the Distribution column property is used in the Distribution platform, and the distribution specified in the Process Capability Distribution column property is used in the Process Capability platform.
Time Frequency

When using the Time Series platform, you can assign the Time Frequency property to data. The Time Frequency property specifies the frequency with which the data is reported (such as annually, quarterly, monthly, and so on). Specifying a time frequency allows JMP to take things like leap years and leap days into account. If no frequency is specified, the data is treated as equally spaced numeric data.

Map Role

If you have created a data table that contains boundary data (such as countries, states, provinces, or counties), to see a corresponding map in Graph Builder, use the Map Role property.

Note the following:

- If the custom boundary files reside in the default custom maps directory, then you need to specify only the Map Role property in the -Name file.
- If the custom boundary files reside in an alternate location, then you must specify the Map Role property in the -Name file and in the data table that you are analyzing.
- The columns that contain the Map Role property must contain the same boundary names, but the column names can be different.

For an example using the Map Role property, see Essential Graphing.

To add the Map Role property into the -Name data table

1. Right-click the column containing the boundaries and select Column Properties > Map Role.
2. Select Shape Name Definition.
3. Click OK.
4. Save the data table.

To add the Map Role property into the data table that you are analyzing

Note: Perform these steps only if your custom boundary files do not reside in the default custom maps directory.

1. Right-click the column containing the boundaries and select Column Properties > Map Role.
2. Select Shape Name Use.
3. Next to Map name data table, click to browse to a -Name map data table. You can enter the relative or absolute path.
If the map data table is in the same folder, enter only the filename. Quotation marks are not required when the path contains spaces.

4. Next to **Shape definition column**, enter the name of the column in the map data table whose values match those in the selected column.

5. Click **OK**.

6. Save the data table.

When you generate a graph in Graph Builder and assign the modified column to the Shape zone, your boundaries appear on the graph.

### Supercategories

When a data set contains ratings (for example, on a five-point scale), you might want to know the percent of the responses in a subset of those ratings. Add a Supercategories column property to group specific categories into one category.

Supercategories are supported only in the Categorical platform.

**To add the Supercategory property to a data column**

1. Right-click the column that contains categories that you want to group.

2. Select **Column Properties > Supercategories**.

   The column properties window shows the Supercategories options (Figure 5.5).

3. Select the categories in the Column’s Categories list that you want to group.

4. Enter a descriptive name next to Supercategory Name.

   Leave the name blank, and JMP names the supercategory after the categories that you selected.

5. Click **Add** to create the supercategory.

6. Click the **Supercategories** red triangle and select from the following options:

   - **Options > Hide**  Hides data in the selected supercategory from reports and graphs.

   - **Add All**  Creates a supercategory from all of the categories in the column.

   - **Add Mean and Add Std Dev**  Calculate statistics for value scores. See *Consumer Research*.

7. Click **OK** to add the property to the column.
**Figure 5.5  Example of a Supercategories Configuration**

**Multiple Response**

The term *multiple response* refers to the situation where the cells in a column contain more than one response value. For example, many cells in the Brush Delimited column in the Consumer Preferences.jmp sample data table contain multiple values. For example, row 6 contains “Wake, After Meal, Before Sleep”.

Add the Multiple Response column property if you want to specify a delimiter other than the comma. Otherwise, change the column’s modeling type to Multiple Response in the Column Info window. See “About Modeling Types” on page 294 for more information about the Multiple Response modeling type.

JMP automatically assigns the Multiple Response modeling type to data tables saved in JMP 12 or lower. The column must contain the Multiple Response column property, and the delimiter must be a comma for the automatic assignment to take place. JMP does not remove the Multiple Response column property, though you might choose to do so.

**Figure 5.6  Multiple Response Configuration Window**

**Note:** You can use the Multiple Response property in the Categorical platform. See *Consumer Research*. You can also use this property in the Data Filter. See “The Data Filter” on page 458 in the “JMP Reports” chapter. If the delimiter is a comma, consider using the Multiple Response modeling type instead.
Target Level

Use the Target Level column property to specify the level of interest of a response column for logistic regression platforms. This level is used as the positive response level in logistic regression models, and it impacts the statistics, probability curves, and other measures of fit. This column property is designed for binary responses, but it can be used for any categorical column.

**Note:** The Target Level column property is used by the following platforms when a binary response column is specified: Fit Y by X (Logistic) and the Nominal Logistic personality of Fit Model.

Profit Matrix

Use the Profit Matrix column property to assign weights to the levels of a nominal or ordinal response variable for a predictive model. For a nominal response, you can specify the profit matrix entries using a probability threshold.

**Note:** The Profit Matrix column property is used by the following platforms: Model Comparison, Partition, PLS, and Fit Model. The personalities in Fit Model that use the Profit Matrix column property are Generalized Regression, Nominal Logistic, and Ordinal Logistic.

Profit Matrix

When you select **Column Properties > Profit Matrix**, a matrix template appears, with a row and column for each value in the selected column. The Actual levels are shown as rows and the predicted levels are shown as columns. Correct decisions are those on the diagonal, where the predicted level equals the actual level.

- For diagonal entries, enter values that reflect profits or weights for correct decisions.
- For non-diagonal entries, enter values that reflect profits (or losses) or weights for incorrect decisions.
- For situations where no prediction is made, use the Undecided column to indicate associated profits or losses.

Probability Threshold Specification for Profit Matrix

When the response is binary, additional options appear beneath the profit matrix template. These options enable you to specify a probability threshold instead of entering weights directly into the profit matrix.

Specify the Target Level and Probability Threshold. Then click Set to update the profit matrix.

**Target Level**  The level whose probability is modeled.
**Probability Threshold**  A threshold for the probability of the target level. If the probability that an observation falls into the target level exceeds the probability threshold, the observation is classified into that level.

**Set**  Enters values into the profit matrix template that reflect your specifications for Target and Probability Threshold. See “Probability Threshold Calculations” on page 321.

**Probability Threshold Calculations**

Denote the threshold probability by $t$. When you click Set, the entries in the profit matrix are assigned as follows:

- 0 for each diagonal entry, reflecting no loss from correct decisions
- -1 for a prediction of the target level when the actual value is the non-target level
- $-t/(1 - t)$ for a prediction of the non-target level when the actual value is the target level

This implies that the profits for classifying into the two levels are given as follows:

\[
\text{Profit for Target Level} = \left( \frac{-t}{1 - t} \right) \text{Prob}[\text{Non-Target Level}]
\]

\[
\text{Profit for Non-Target Level} = -\text{Prob}[\text{Target Level}]
\]

The Most Profitable Prediction is the level whose profit is the larger of these two values. It follows from the two Profit equations above that an observation is assigned to the target level whenever $\text{Prob}[\text{Target Level}]$ is at least $t$.

**Profit Matrix and Predictive Models**

For a nominal or ordinal column with the Profit Matrix column property, most modeling platforms enable you to save formula columns that reflect profit matrix entries. Fit your model and then select the Save Prediction Formula or Save Probability Formula option. In addition to saving the usual prediction formulas to the data table, JMP saves the following analogs of the usual formula columns:

- **Profit for <level>**: For each level of the response, a column gives the expected profit for classifying each observation into that level.
- **Most Profitable Prediction for <column name>**: For each observation, gives the level of the response with the highest expected profit.
- **Expected Profit for <column name>**: For each observation, gives the expected profit for the classification defined by the Most Profitable Prediction column.
- **Actual Profit for <column name>**: For each observation, gives the actual profit for classifying that observation into the level specified by the Most Profitable Prediction column.

See “Example of a Profit Matrix for More Than Two Levels” on page 322. For an example of using a profit matrix in modeling, see *Predictive and Specialized Modeling*. 
Example of a Profit Matrix for More Than Two Levels

The example below shows a profit matrix for the Airline column in the Travel Costs.jmp sample data table.

Figure 5.7 Example of Profit Matrix Window

To see how the values in this profit matrix were assigned, consider a travel agency that uses four airlines, Carrier 1 to Carrier 4, to service its customers. For each ticket sold, the agency realizes a profit that depends on the carrier selected by the customer. When the agency recommends, or predicts, a carrier, it reserves a ticket for a small fee. If the customer decides to use the predicted carrier, the agency profits by a certain amount less the reservation fee. However, if the customer decides to take a different carrier, the agency loses the reservation fee and must pay another reservation fee. The agency’s profit is lower due to the incorrect prediction.

Suppose that the reservation fees for Carriers 1 through Carrier 4 are $15, $20, $30, and $50, respectively, and that the profits from ticket sales are $40, $40, $100, and $110, respectively.

If the agency recommends Carrier 1 to a customer who then decides to purchase the ticket, the agency reserves a ticket for $15 and then receives $40 for a net profit of $25. If the agency predicts that a customer will choose Carrier 4 but the customer chooses Carrier 1, the agency loses $50 for the Carrier 4 reservation and must also pay $15 for the reservation on Carrier 1. This gives the agency a net loss of $40 - $50 - $15 = -$25.
Example of Using Probability Threshold to Define the Profit Matrix

The sample data table Liver Cancer.jmp gives disease Severity ratings for 136 patients. You are interested in modeling Severity using the predictors given in the columns from BMI to Jaundice. The usual prediction formulas for a model classify a patient into the Severity level that is most probable. However, classifying a patient as having Low severity when in actuality the patient’s severity is High is a more costly error than classifying a patient as having High severity when in actuality the patient’s severity is Low. As a result, you want to assign a higher cost to misclassifying a patient as Low, when the patient’s severity is actually high.

You can assign this higher cost by setting a probability threshold. With input from experts, you determine that the following is a good strategy: Classify into the High level of Severity any patient whose predicted probability of being in the High level exceeds 0.4.

1. Select Help > Sample Data Library and open Liver Cancer.jmp.
2. Select the Severity column and select Cols > Column Info.
3. Select the Profit Matrix column property.
4. Change the Target to High.
5. Enter 0.4 as the Probability Threshold.
6. Click Set.

The profit matrix updates to show the corresponding weights.

Figure 5.8 Profit Matrix Showing Weights Corresponding to Probability Threshold
The profit matrix shows that the loss for misclassifying a patient with High severity as having Low severity is -1, while the loss for misclassifying a patient with Low severity as having High severity is smaller, -0.6667.

**Informative Missing**

The Informative Missing column property directs most fitting platforms to use a coding system for columns that contain missing values. For continuous columns, the coding system consists of two columns. The first column is a column of the original values with missing values replaced by the mean of the nonmissing values; the second column is an indicator column to denote which rows are missing. For categorical columns, missing values are treated as a distinct level of the column.

**SAS Properties**

SAS Label, SAS Name, SAS Format, and SAS Informat are assigned to columns when you import a SAS data set. You can change the value in the column property to control the label, name, format, or informat of the column that gets created in the SAS data set if the data is exported back to SAS.

**Link Data Tables with Virtual Join Properties**

Virtual Join links a main data table to one or more auxiliary data tables. The feature enables the main data table to access data from the auxiliary data tables without physically joining the tables. See “Virtually Join Data Tables” on page 374 in the “Reshape Your Data” chapter.

The Link ID and Link Reference column properties make the linking possible.

**Notes:**

- The data types of the Link ID and Link Reference columns must match.
- Link ID and Link Reference do not work for Row State and Expression data types.
- Consider adding the Link ID column property before adding the Link Reference column property so that the referencing column in the main table has a column to link to.

**Link ID**

The Link ID column property marks a column in the auxiliary data table as the ID column. That is, the rows of the data table are uniquely identified by the values of the ID column. The data table that has a Link ID column property is referred to as the *referenced* data table.
To add the Link ID column property, select the column, select **Cols > Column Info** and then select **Link ID** from the Column Properties list. Make sure that the Link ID checkbox is selected and click **OK**. The selected checkbox indicates that the column is the ID column for the data table.

**Link Reference**

The Link Reference column property maps a column in the main data table to the ID column in the referenced data table. The column that has a link reference is referred to as the *referencing* column. The referencing column can look up the data of the auxiliary data tables through the ID column.

To add the Link Reference column property, select the column, select **Cols > Column Info**, and then select **Link Reference** from the Column Properties list. Enter the path to the main table and click **OK**. If you enter the path correctly, the referenced columns show up in the Columns panel of the main table after you click **OK**.

**Notes:**

- The path is case sensitive.
- Consider putting the data tables in the same folder. Then you can omit the directory name from the Link Reference property and include only the data table name. Otherwise, include the full path to the data table (such as `c:/users/marie/My Data.jmp`).
- You can also increase portability by using a JMP path variable in the Link Reference path. Figure 5.9 shows an example. Enter a forward slash in the path to share the data tables with both Windows and macOS users. See the *Scripting Guide* for more information about path variables.
- You can avoid entering the path by right-clicking a column to add the Link Reference property. See “Example of Virtually Joining Columns” on page 376 in the “Reshape Your Data” chapter.
- Select Row State Synchronization options to synchronize row states in data tables that contain virtually joined columns. See “Example of Virtually Joining Columns and Showing Row States” on page 379.
- Select Auto Open to open the linked table automatically when the main data table is opened. See “Update Data Tables” on page 387 in the “Reshape Your Data” chapter.
- You can specify that the linked column name be used in virtually joined columns. This option lets you specify a shorter column name (for example, *Cheese* instead of *Cheese[Choice]*). In the Link Reference column property, select **Use Linked Column Name**.
**Additional Column Properties**

There are three additional properties: Expression Role, Event Handler, and Other.

**Expression Role**

When you import a column of data that contains image data, the data type is set to Expression to show the data as pictures. Or you can assign the Expression data type in the Column Info window.

To customize how the image looks in the data table cell, or to display matrices and expressions as images, add the Expression Role column property. The default is set to Picture. If the Expression Role is set to Picture and the expression is a picture, then the expression evaluates to a picture and the picture appears in the data table. Otherwise, the expression shows as a JSL expression. Change this setting to alter how expressions are used.

**Note:** Expression columns that contain images greater than 32KB in size are truncated when saved to Microsoft Excel. Those expression columns are not restored when imported back into JMP.
Select from the following options:

**Picture**  If the expression contains picture data, the column evaluates and the picture is displayed.

**Matrix**  If the expression contains a matrix, the column evaluates and the matrix is displayed. Otherwise, the data is displayed as an expression.

**Expression**  If the expression is simply an expression, use this option to display it in the column.

Use Expression when you want to work with an expression that might contain picture data, but you want to prevent JMP from displaying the image.

**Picture expressions**  To customize how images appear in a data table cell, select one of the following options after selecting Picture from the list.

- **maximum width and height**  Specifies the maximum width and height of the image in the data table cell.

- **Stretch**  Enlarges a small image to fill the data table cell.

- **Preserve aspect ratio**  Maintains the image’s ratio of width to height in the data table cell. Selected by default.

- **Add a decorative frame to small images in a data table**  Displays a beveled edge around small images in the data table cell.

*To drag images into an expression column*

1. Create a new column in a data table.
2. Right-click the column, select **Column Info**, and then select the **Expression** data type.
3. Right-click the column, select **Column Properties**, and then select **Expression Role**.
4. Select options as described above.
5. Navigate to the website that contains the image that you want in your data table. You can also use an image that is on your computer.
6. Select the image, and drag it into an empty cell in the expression column. Resize the cell to make the image larger.

The SAS Offices.jmp and Big Class Families.jmp sample data tables show an example of an expression column.

**Tips:**

- You can also import data that contains a column of images to create an expression column.
• For more information about what you can do with images in an expression column, see “Use Images as Markers” on page 489 and “Add Images from Data Tables to Hover Labels” on page 558 in the “JMP Reports” chapter.

To add an expression column using Summary

1. Select Help > Sample Data Library and open CrimeData.jmp.
2. Select Tables > Summary.
3. Select State, and click Group.
4. Select Total Rate, and click Statistics > Histogram.
5. Click OK.

A new data table appears that contains a new expression column with images of histograms. Resize the row to make images larger.

For more information about Summary, see Chapter 8, “Summarize Your Data”.

6. Right-click the Histogram(Total Rate) column, and select Column Info.

Notice the column’s data type is set to Expression.

7. Select Expression Role from the Column Properties menu.

The Expression Role is automatically set to Picture. In the rare case that a picture needs to be displayed as an Expression, change the setting to Expression.

8. Click OK.

Expression Role is assigned to the Expression column.

Event Handler

Use the Event Handler column property to define hyperlinks in a text column. The hyperlinks can be used to open web pages and other documents.

Add the Event Handler to a column of URLs to open the URLs in a browser. You can also modify the placeholder scripts on the column property to open different kinds of resources. For example, in a data table of geographical data, you might edit the Click script to display a Google map when the user clicks the hyperlink in the data table. The SAS Offices.jmp sample data table provides examples.

See the Scripting Guide for more information about editing the scripts.

Other

Use the Other column property to create your own column property and assign it any name that you choose. This property is then available for JSL programming.

1. Right-click the column and select Column Properties > Other.
2. Enter a name for the new property.
3. Enter a value for the property.

Properties Assigned and Controlled by JMP

To control how information flows between platforms, JMP assigns some properties that you cannot control. These properties do not appear on the Column Properties menu.

Response Probability

In Profiler reports, the Response Probability property makes all levels of the categorical response variable appear in a single row. JMP automatically assigns the Response Probability property when certain probability formulas are saved to the data table.

Follow these steps to save the property:
1. Fit a logistic regression model using the Fit Model platform.
2. Click the report red triangle and select Save Probability Formula.
   - JMP automatically assigns the Response Probability property to the new probability columns.

For more information about the prediction profiler, see Profilers.

Expand Formula

In the Profiler and Nonlinear platforms, if an ingredient column to the model might have a formula, JMP substitutes the inner formula, as long as it refers to other columns. Add the Expand Formula property to prevent an ingredient column from expanding. Assign the value of 0.

See Profilers.

Predicting

JMP automatically assigns the Predicting column property when you fit a model to a continuous response and save the prediction formula or prediction values. The Predicting column property identifies the platform used to create the prediction formula. That platform is listed as the Creator in the Model Comparison platform.
Informative Missing Terms

Missing levels of a categorical variable are treated as informative missing in certain JMP platforms, either by default or if you request an informative missing fit. In these cases, JMP automatically assigns the Informative Missing Terms column property to a prediction formula column that includes the categorical variable. This column property ensures that the missing value category is treated as a distinct level of the categorical variable in plots and analyses that involve the prediction formula. In particular, profiler plots show the missing values as a level.

Column ID

JMP automatically assigns the Column ID column property to the column that is used to split the initial Bootstrap results data table. This column property assists the split operation and ensures that the column names in the split Bootstrap results table are meaningful.

ConstraintState

When you select Save Constraints, the coefficients of each linear constraint appear in a column in a data table. Each constraint column is assigned the ConstraintState column property. This property specifies the direction of the inequality that defines the constraint. When you select Load Constraints from a design platform, the ConstraintState column property tells JMP the direction of the inequality.

RunsPerBlock

The RunsPerBlock property indicates the maximum allowable number of runs in each block. This property is used by the Evaluate Design and Augment Design platforms to indicate the blocking structure for the factor.

DF

The DF column property is added by many modeling platforms to formula columns that calculate the standard error of the predicted values. The value of this column property is used by the Prediction Profiler to draw confidence intervals when both a prediction formula column and a standard error formula column are provided.

Caution: We do not recommend that you remove or change the value of this property. Doing so could adversely affect the confidence intervals in the Prediction Profiler.
Standardize Attributes and Properties Across Columns

A column might contain attributes (data types, modeling types, numeric formats, and so on) or properties (formulas, notes, list and range checks, and so on) that you want other columns to have. You can use the existing column to standardize the attributes and properties across columns. This includes both adding and deleting attributes and properties.

To apply an existing column’s attributes and properties to multiple columns

1. Select the column or columns containing the desired attributes or properties.
2. Select **Cols > Standardize Attributes**.

**Figure 5.10** Standardizing Attributes across Columns

Recode Column Values

Use the Recode option if you need to recode similar values within multiple columns in the same way. After you click **Recode**, the values that appear are generated from the union of all of the selected columns. For example, suppose that you have two columns with user responses. One column contains the values Agree and Disagree. The other column contains the values Agree, Disagree, Unsure, and Strongly Disagree. You want to simplify all of the values in both columns to be A, D, U, and SD.
Note: If you want to recode values only in a single column, you can also use the Cols > Recode option. See “Recode Data in a Column” on page 264 in the “Enter and Edit Your Data” chapter.

Standardize Column Attributes

By default, the items within the Standardize Attributes panel are dimmed. To access an item, click the Attributes button and select the items to be duplicated across columns.

Note: The Input Format item is applicable only for the Date, Time, and Duration formats.

To change the values of any of the attributes, use the menus in the Standardize Attributes panel.

Standardize Column Properties

To standardize properties across columns

1. Select the columns that you want to standardize. One of those columns must contain the property that you want to add to the other columns.
2. Select Cols > Standardize Attributes.
4. Select the property that you want to standardize. Modify the property settings if necessary.
5. Click Apply to standardize the property across selected columns. Changes are shown in the data table, open reports, and open graphs.
   Or click OK to standardize the property across selected columns and close the column properties window.

Delete Column Properties

To delete the same properties across multiple columns

1. Select the columns containing the attributes or properties that you want to delete.
2. Select Cols > Standardize Attributes.
3. Under Delete Properties, click Column Properties and select the properties that you want to delete.
4. Click OK.
Note: Make sure you click OK and not Remove. Clicking Remove simply removes the property from the list, but does not delete it.

Example of Standardizing a Formula

If you have applied a formula to a column, and you want to apply that same formula to additional columns in the data table, use the Substitute Column Reference option.

Note: This option is dependent upon the location of the column that is referenced in the original formula. For example, if your original formula is based on the previous column, then any other formulas applied to additional columns are based on their previous columns.

For example, the Blood Pressure.jmp sample data table contains blood pressure measurements taken on five subjects three times each day, over a period of three days. You want to find the log of each blood pressure (BP) column.

Create nine new columns, one for each existing BP column.

2. Select Cols > New Columns.

3. Add nine columns.

4. Click OK.

Apply your original formula:

5. Right-click Column 12 1 and select Formula.

6. Select BP 8M.

7. Select Transcendental > Log.

8. Click OK.

   Column 12 1 now contains the log of the BP 8M column. You want the rest of the empty columns to contain the log of the remainder of the BP columns.

9. In the data table, select all of the new columns that you created, including the one with the original formula (columns 12 1 through 12 9).

10. Select Cols > Standardize Attributes.

11. In the Standardize Properties panel, click Column Properties and select Formula.

12. Select the check box next to Substitute Column Reference.

13. Leave BP 8M selected.

   You want that column reference to be substituted in the subsequent column formulas.

14. Click OK.
Now all of the new columns are populated with the log of the BP columns, in the order in which they appear. Column 12 1 contains the log for BP 8M, Column 12 2 contains the log for BP 12M, and so on.

See “Copy and Replicate Formulas” on page 411 in the “Create Formulas in JMP” chapter.

Assign a Preselected Analysis Role to a Column

You can assign an analysis role, such as x, y, weight, or frequency, to a selected column and save the role with the data table. When you do this and then run an analysis, JMP uses the preselected role to automatically fill in the role boxes in windows. Then you do not have to specify these roles each time you run an analysis. For example, you might want a column named height to take the x role in every analysis of that data table. To enforce the x role, you assign the preselected role of x to the column.

When you select Freq, the values in that column are what JMP uses as the frequency of the observation. If \( n \) is the value of the Freq variable for a given row, then that row is used in computations \( n \) times. If it is less than 1 or is missing, then JMP does not use it to calculate any analyses.

When you select Weight, the values in that column provide weights for each observation in the data table. The variable does not have to be an integer, but it is included only in analyses when its value is greater than zero.

When you select Validation, that column is specified as a Validation column in platforms that support a Validation column role.

To assign a preselected role to a column

1. Highlight the column.
2. Select Cols > Preselect Role.
3. Select a role: No Role, X, Y, Weight, Freq, or Validation.

After you select the appropriate roles, icons in the Columns panel signify what roles have been assigned. Click the icon to access a list of roles and select a different one. See “Icons Representing Column Characteristics and Properties” on page 41 in the “Get Started with JMP” chapter.
This chapter covers the following tasks that you can perform on JMP data:

- create a new data table from a subset of rows and columns
- sort by any number of columns
- stack multiple columns into a single column
- split a column into two or more columns
- transpose rows and columns
- concatenate multiple tables end to end
- join two tables side by side
- virtually join tables without physically joining them
- update columns in a table with values from another table
- anonymize the data

Create a Subset Data Table

You can produce a new data table that is a subset of all rows and columns, only highlighted rows and columns, or randomly selected rows from the active data table.

*To create a subset*

1. Select **Tables > Subset**.

**Figure 6.2** The Subset Window

2. Specify the content that you want to subset. Select any combination of the following:
   - Subset by (the levels within selected columns)
   - Rows (all, selected, or random)
   - Columns (all or selected)

   In Figure 6.2, the `sex` column will be subset.

3. Customize your subset table further using the additional options.
4. Click **OK** to create the subset table.

**Subset Options**

**Subset by**  Subsets by the levels of a column. Select **Subset by** and then select the columns that you want to categorize for the subset.

Consider the fact that many new data tables might be created. A new data table appears for each level of the column that you specified in the Subset window.

**All Rows**  Creates a subset table that contains all rows from the active table.

**Selected Rows**  Creates a subset table that contains only the selected rows from the active table. Selected by default.

**Random - sampling rate**  Creates a subset table whose data is a random proportion of the active data table. Enter the proportion of the sample that you want in the text box. For example, if you want a random 50% of the data to be included in the new table, enter 0.5 in the text box.

**Random - sample size**  Creates a subset table whose data is a random sample of the active data table. Enter the size of the sample that you want in the text box. For example, if you want 16 random rows to be included in the new table, enter 16 into the text box.

If you select a random sample that is the entire source table, the result is a random shuffle of the rows of the data table. If you specify columns to stratify, the result is a random shuffle of each of the rows for each group. See “Stratified Subsets” on page 339.

**All columns**  Creates a subset table that contains all columns from the active table. Selected by default.

**Selected columns**  Creates a subset table that contains only the selected columns from the active table.

**Keep by columns**  Retains the column that you subsetted by in the output data tables.

**Output table name**  Specifies the name of the subset table.

**Link to original data table**  Links the subset table to the original table. When you change values in one table, the other table is updated.

**Copy formula**  Includes formulas from the original table in the output columns. Include all columns needed for the calculation of the formula. Selected by default.

**Suppress formula evaluation**  Prevents JMP from evaluating columns’ formulas when the new table is created. Selected by default.

**Save Default Options**  Saves your current settings.
Note: Save Default Options only saves the settings for Selected Rows, Selected Columns, Linked to original data table, Copy formula, and Suppress formula evaluation.

Keep dialog open   Keeps the Subset window open after you click OK.

Save Script to Source Table   Saves a script to the original data table that enables you to subset the data again using the same settings.

Stratified Subsets

If you specify a sample size and add stratification columns, the sample size represents the size per stratum, rather than the size of the whole subset.

Figure 6.3  Stratified Subsets

For stratified random samples with a specified sample size, two columns can be saved: Selection Probability and Sampling Weight. Check the corresponding check box to save these columns.

Create a Subset Data Table from a Report

Histograms and Pareto plots produce linked subsets of a data table.

Use a Histogram

Once you have produced output that contains a histogram (by selecting Analyze > Distribution), you can use the histogram to create a new data table. The new data table contains the data in the histogram’s highlighted bars.

To create a subset, double-click a highlighted bar. Or, right-click anywhere in the histogram and select Subset from the menu. The subset table appears.
**Reshape Your Data**

**Chapter 6**

Sort Data Tables

**Figure 6.4** Subset Created from a Histogram

![Histogram and data table](image)

**Note:** The subset data table contains a view of the data, not the actual data. You must explicitly save the table if you want a copy. Note that the saved copy of the data table is no longer linked to the source table.

**Using a Pareto Plot**

Once you have produced output that contains a Pareto plot (by selecting **Analyze > Quality and Process > Pareto Plot**), you can use the Pareto plot to create a new data table. The new data table contains the data in the Pareto plot’s highlighted bars. To create a subset, double-click a highlighted bar.

**Sort Data Tables**

You can sort a JMP data table by columns in either ascending or descending order. By default, columns sort in ascending order. You can either create a new table that contains the sorted values, or you can replace the original table with the sorted table.

If columns contain value labels, sorting is based on the actual data values, not the value labels. (See “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.) However, the value labels are displayed in the sorted data table.

If your sorted column uses either the Value Order property or the List Check property, the column is sorted according to that order.
Example of Sorting Data Tables

1. Select Help > Sample Data Library and open Popcorn.jmp.
2. Select Tables > Sort.

Figure 6.5 The Sort Window

3. Highlight the names of the columns that you want to sort by. For this example, select popcorn and yield.
4. Click By to add the columns to the sort list.
   The columns that you add to the list establish the order of precedence for sorting. The first column in the list is the major sort field. Each variable thereafter is sorted within the previous variable in the sort list. You can drag and drop within the By list to change the sort order.
5. Customize your sort further using the additional options. For this example, highlight yield and click the descending button.
6. Enter a name for the new sorted table in the box beside Output table name. For this example, enter sorted popcorn.
Sort Data Tables Using JMP

Figure 6.6 Completed Sort Window

7. Click OK.

Figure 6.7 Sorted in Ascending and Descending Order

Sort Options

**Select Columns Filter Menu**  Contains options to search and filter through columns. See “Column Filter Menu” on page 54 in the “Get Started with JMP” chapter.

**Replace Table**  Replaces the original data table with the sorted table instead of creating a new table with the sorted values. This option is not available if there are any open report windows generated from the original table.

**Output table name**  (Optional) Specifies the name of the sorted table.
Keep dialog open  Keeps the Sort window open after you click OK.

Save Script to Source Table  Saves a script to the original data table that enables you to sort the data again using the same settings.

By  Adds the columns that you want to sort by. The columns that you add to the list establish the order of precedence for sorting. The first column in the list is the major sort field. Each variable thereafter is sorted within the previous variable in the sort list.

Remove  Removes any highlighted columns.

Ascending and descending buttons (▲▼)  You can change the ascending or descending list order of the values for the grouping variables. In the By variable list, select a variable and click the appropriate ascending or descending button. The icon beside the variable changes to indicate the sorting order.

Save Default Options  Saves the current settings as the new default options.

Stack Columns

You can rearrange your data table by stacking two or more columns into a single new column, preserving the values from the other columns. Or, you can stack a set of columns into multiple groups. The various ways that you can stack columns are explained in “Stack Options” on page 344.

To stack columns, follow these steps:

1. Select Tables > Stack.
2. Highlight the names of the columns that you want to stack and click **Stack Columns**.
3. Customize your stacking further using the additional options.
4. Click **OK**.

**Stack Options**

**Select Columns Filter Menu** Contains options to search and filter through columns. See “Column Filter Menu” on page 54 in the “Get Started with JMP” chapter.

**Multiple series stack** Stacks selected columns into two or more columns. Specify the number of columns into which you want the selected columns to be stacked by entering the number into the Number of Series box. This box appears when you check the box beside **Multiple series stack**.

Select the **Contiguous** option if the series consists of adjacent columns.

See “Example of Stacking Columns into More Than One Column” on page 346.

**Note:** The order in which you add columns to the box on the right determines the group to which they belong.

**Stack by Row** Stacks columns by rows. Deselect the option to stack one column underneath another. Selected by default.

**Eliminate missing rows** Eliminates missing data from the new table. If Stack by Rows is checked also, only rows with *all* data missing are eliminated.
Non-stacked columns  Includes or drops non-stacked columns from the new data table. 
Select one of these options:

Keep All  Includes all of the non-stacked columns from the original table in the new table. 
Selected by default.

Drop All  Omits the non-stacked columns from the new table.

Select  Select the non-stacked columns that you want to include or drop in the new table.

Keep dialog open  Keeps the Stack window open after you click OK.

Save Script to Source Table  Saves a script to the original data table that enables you to stack 
the data again using the same settings.

Stack Columns  Adds the columns that you want to stack.

Remove  Removes any highlighted columns.

Output table name  (Optional) Specifies the name of the new table.

Stacked Data Column  Assigns a name to the column that will contain the data for the 
stacked columns. The default name is Data. Leave the box empty if you do not want this 
column to appear in the new table.

Source Label Column  Assigns a name to the column that will contain the original table’s 
column names. The default name is Label. Leave the box empty if you do not want this 
column to appear in the new table.

Copy formula  Includes formulas from the original table in the output columns. Selected by 
default.

Suppress formula evaluation  Prevents JMP from evaluating columns’ formulas when the 
new table is created. Selected by default.

Move Columns  Specifies where the stacked columns are moved to. To Last is the default 
value.

Example of Stacking Columns into a Single Column

A researcher has two columns in their data table representing yield, and they want to stack the 
two columns into a single column. (This new single column is called Data by default.)

1. Select Help > Sample Data Library and open Popcorn Trials.jmp.
2. Select Tables > Stack.
3. Select yield1 and yield2 and click Stack Columns.
4. Click OK.
The Label column represents the Source Label Column that identifies the source of the data. Its values are the column names in the original table from which the stacked values originated.

**Example of Stacking Columns into More Than One Column**

Suppose that a researcher has data on blood pressure readings. The readings were taken over three days: Monday, Wednesday, and Friday. Three readings were taken each day, at 8am, 12pm, and 6pm.

   
   Each BP (blood pressure) column is delineated according to the date and time. The BP 8M column corresponds to readings that were taken at 8am on Monday. The BP 12W column corresponds to readings that were taken on 12pm on Wednesday, and so on. The researcher wants to stack all of the blood pressure columns into three columns that correspond to each day: Monday, Wednesday, and Friday.

2. Select Tables > Stack.

3. Select all of the BP readings and click Stack Columns.
   
   The order of the columns reflects how the columns in the series should be grouped.

4. Select Multiple series stack.

5. Next to Number of Series, type 3.

6. Because you want to stack the columns vertically, select Contiguous.

7. Rename the Stacked Data Column from Data to BP (for blood pressure).
8. Rename the Source Label Column from Label to Day.

**Figure 6.10 Completed Stack Window**

9. Click **OK**.

**Figure 6.11 Stacked Data Table**

In the stacked data table, note the following:

- The first Day column represents Monday.
- The Day 2 column represents Wednesday.
Split Columns

You can create a new data table from the active table by splitting one column into several new columns. This column is split according to the values found in another column, referred to as the **Split By** column. You can also split columns according to the values of one or more grouping variables.

**Note:** If the split is on a categorical column that contains a missing value, the column name for the missing category is “.” for a numeric column.

To split columns, follow these steps:

1. Select **Tables > Split**.

**Figure 6.12** Split Window

2. Highlight the names of the column or columns that you want to split and click **Split Columns**.

3. Highlight a column whose values you want to use as the basis for splitting the column.

4. Click **Split**.

5. Customize your splitting further using the additional options.

- The Day 3 column represents Friday.
6. Click **Split**.

**Split Options**

**Select Columns Filter Menu**  
Contains options to search and filter through columns. See “Column Filter Menu” on page 54 in the “Get Started with JMP” chapter.

**Keep All**  
Includes all columns in the new table.

**Drop All**  
Includes only columns used in the split in the new table. Selected by default.

**Select**  
Selects which columns to keep in the new table.

**Keep dialog open**  
Keeps the Split window open after you click **OK**.

**Save Script to Source Table**  
Saves a script to the original data table that enables you to split the data again using the same settings.

**Split By**  
Adds the column whose values you want to use as the new column names, and as the basis for splitting the column.

**Split Columns**  
Adds the column or columns that you want to split.

**Group**  
Specifies a Group variable when you want your data to be split within each group of the selected variable. Each group results in a row in the output table. You must also specify the required variables, Split By, and Split Columns.

**Note:** If the variable that you want to group by contains unequal groups or is in a random order, specifying it as the Group variable ensures that your data is restructured properly, and any missing values are assigned in the appropriate places.

**Sort by Column Property**  
Sorts the order of the output columns by the Value Order column property. If the column does not have a Value Order property, and the data has an implied order (such as days or months), the implied order is applied.

**Output table name**  
(Optional) Specifies the name of the new table.

**Copy formula**  
(Appears if there is a formula in the data table.) Includes formulas from the original table in the output columns.

**Suppress formula evaluation**  
(Appears if there is a formula in the data table.) Prevents JMP from evaluating columns’ formulas when the new table is created.

**Examples of Splitting Columns**

This section contains two examples using the Split command:
• In the first example, one column is split by a second column. See “Split a Column: Basic Example” on page 350.
• The second example uses a Group variable. See “Split a Column: Grouping Rows Example” on page 351.

Split a Column: Basic Example

In the Popcorn.jmp data table, the data in the trial column shows that there are two trials, 1 and 2. In this example, split the yield column into two new columns: one for trial 1 and one for trial 2.

1. Select Help > Sample Data Library and open Popcorn.jmp.
2. Select Tables > Split.
3. Select the yield column and click Split Columns.
4. Select the trial column and click Split By.
5. Under Remaining columns, select Keep All.
   The default is Drop All, which omits any columns that are not in the Split By, Split Columns, or Group fields. Selecting Keep All includes these columns in the new table.
6. (Optional) Type Yield column split by Trial column in the Output table name field.
7. Click OK.

A new data table is created (Figure 6.13). Notice the following:
– The yield and trial columns are gone.
– The data table has two new columns, named after the unique values (1 and 2) from the original trial column.
– The values from the original yield column are now split into the new columns named 1 and 2.
– The columns other than trial and yield are exactly the same as they were in the original table.
8. (Optional) Rename the new columns to give them meaningful names. For example, rename 1 to yield (trial 1) and rename 2 to yield (trial 2).
Figure 6.13  New Table Created By Splitting yield Column by trial Column

Split a Column: Grouping Rows Example

The Drug Measurements.jmp sample data table contains measurements of three different drugs (a, b, and c) administered to 12 different subjects. You want to split the measurement into different columns, one for each drug type. You also want to group the measurements by subject.

1. Select Help > Sample Data Library and open Drug Measurements.jmp.
2. Select Tables > Split.
3. Select Drug Type and click Split By.
4. Select Measurement and click Split Columns.
   Notice that the Subject variable contains unequal groups. Most of the subjects were given all three drugs, but subject 2 was given only one drug, and subjects 7 and 12 were given only two drugs. In this situation, to ensure that the correct measurements are associated with the correct subject, specify Subject as the Group variable.
5. Select Subject and click Group.
6. Click OK.
You can see that the appropriate missing values appear for subjects 2, 7, and 12.

**Transpose Rows and Columns**

You can create a new JMP table that is a transposed version of the active data table. The columns of the active table are the rows of the new table, and its rows are the new table’s columns.

When you transpose columns, you do the following:

- Select the columns to be transposed.
- Specify a “label” column, from which the new columns get their names (optional).
- Specify “by” columns, which tells JMP to transpose data within groups (optional).

**Note:** Columns that you want to transpose must have the same data type. Also, if columns contain value labels, transposing uses the actual data values, not the value labels. (See “Value Labels” on page 307 in the “Set JMP Column Properties” chapter.)

To transpose rows and columns, follow these steps:

1. Open a data table that contains the rows and columns that you want to transpose.
2. Select **Tables > Transpose.**
3. Highlight the column name(s) you want to transpose in the Select Columns box on the left.
4. Click Transpose Columns.
5. (Optional) Customize your transposed table further using the additional options.
6. Click OK.

Transpose Options

Select Columns Filter Menu  Contains options to search and filter through columns. See “Column Filter Menu” on page 54 in the “Get Started with JMP” chapter.

Transpose selected rows only  Transposes only rows that are currently highlighted in the active table.

Output table name  (Optional) Specifies the name of the subset table.

Label column name  (Applicable only if you have specified a Label column.) Specifies an alternative name for the Label column. Otherwise, the default column name is Label.

Keep dialog open  Keeps the Transpose window open after you click OK.

Save Script to Source Table  Saves a script to the original data table that enables you to transpose the data again using the same settings.

Transpose Columns  Adds the columns that you want to transpose.

Label  Uses the data from a column in the original table as the column names in the new table. Follow these steps:
1. Highlight a column from the Select Columns box on the left.
2. Click **Label**. The column name appears in the Label box.

The default column name is **Label**. You can specify an alternative name for the column using the **Label column name** option. Only one column is created for each distinct value in the label column. Therefore, if there are duplicate values in the label column, JMP creates only one column for the duplicated value using the value from the last duplicated row.

**By** Organizes the transposed columns into groups based on the columns that you put into the By box. Follow these steps:

1. Highlight the column name(s) in the Select Columns box whose values you want to see as a group.
2. Click **By**.

Table 6.1 describes the rules that apply to transposing.

### Table 6.1 Rules for Transposing

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>The original table has columns but no rows</td>
<td>The new table contains one column that lists those column names.</td>
</tr>
<tr>
<td>The original table has one column and it is assigned to Label</td>
<td>Its values become the column names in the transposed table.</td>
</tr>
<tr>
<td>The original table has multiple columns and contains a label column</td>
<td>JMP automatically inserts the label column into the Label box when the window appears. You can remove this column if you do not want it to appear.</td>
</tr>
<tr>
<td>There is no label column in the original table</td>
<td>The column names in the transposed table are Row 1, Row 2, ..., Row n where n is the number of rows in the original table.</td>
</tr>
</tbody>
</table>

### Examples of Transposing Rows and Columns

This section contains three examples: a simple example of transposing, an example using the Label option, and an example using a By group.

#### Simple Example of Transposing

1. Select **Help > Sample Data Library** and open Materials1.jmp.
2. Select **Tables > Transpose**.
3. Select plastic, tin, and gold and click **Transpose Columns**.
4. Click **OK**.

**Figure 6.16** Simple Transposed Table

<table>
<thead>
<tr>
<th>Label</th>
<th>Row 1</th>
<th>Row 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>plastic</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>tin</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>gold</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

The original table in Figure 6.16 has two rows and three continuous columns called plastic, tin, and gold. The transposed table has a row for each of the three columns in the original table, and columns named Row 1 and Row 2 for the original table’s rows. The additional column called Label has the column names (plastic, tin, and gold) from the original table as values.

**Example Using the Label Option**

1. Select **Help > Sample Data Library** and open Materials2.jmp.
2. Select **Tables > Transpose**.
3. Select plastic, tin, and gold and click **Transpose Columns**.
4. Select item and click **Label**.
5. Click **OK**.

**Figure 6.17** Transpose with a Label

<table>
<thead>
<tr>
<th>Label</th>
<th>nails</th>
<th>hooks</th>
</tr>
</thead>
<tbody>
<tr>
<td>plastic</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>gold</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The values from the item column in the original table are used as column labels in the transposed table.

**Example Using a By Group**

1. Select **Help > Sample Data Library** and open Animals Subset.jmp.
2. Select **Tables > Transpose**.
3. Select subject and miles and click **Transpose Columns**.
4. Select season and click **Label**.
5. Select species and click **By**.
6. Click **OK**.
Concatenate Data Tables

When you concatenate data tables in JMP, you combine rows from two or more data tables. You can create a new data table or you can append rows to the first data table. A column name might be the same in the data tables that you want to concatenate. If so, then the column in the new data table lists the values from all of the data tables in the order of concatenation. If the two original data tables have columns with different names, those columns are included in the new data table showing missing values.

To concatenate two data tables with the same column names, follow these steps:

1. Select **Tables > Concatenate**.

2. Highlight the names of the data tables that you would like to combine, and click **Add**.

   You can concatenate as many data tables as you choose, and you can also add the same data tables multiple times. The number of rows in the new data tables is the sum of the number of rows in all the data tables.
3. (Optional) Click the **Save and evaluate formulas** choice to request that JMP include all formulas.

   If you do not select this option, no formulas are included in the new data table.

   **Note:** Columns with the same name can have different formulas. The formula from the first data table that contains a formula for that column is saved in the concatenated data table. This situation can occur when more than two tables are being concatenated and the second or third on has a formula for the column in question.

4. (Optional) Click the **Create source column** choice to add a column called **Source Table** to the new data table.

   This column identifies the name of the source data table in the corresponding rows.

5. (Optional) Select the **Append to first table** choice to append rows to the data table listed first in the **Data Tables to be Concatenated** field. This option is an alternative to creating a new data table.

6. (Optional) Enter a name for the new data table in the **Output table name** field.

   If you do not enter a name, JMP names the data table **Untitled** (for example, **Untitled1**). The **Output table name** field is not available if you selected the **Append to first table** choice.

7. Click **OK**.

### Example of Concatenating Data Tables

Suppose that you want to concatenate two data tables (Trial1 and Trial2) into a new data table.

1. Select **Help > Sample Data Library** and open Trial1.jmp and Trial2.jmp.
2. From the Trial1.jmp table, select **Tables > Concatenate**.
3. In the **Opened Data Table** list, select Trial2 and click **Add**.
4. Click **OK**.

The data tables combine into a new concatenated table with all of the rows from the first data table followed by all of the rows from the second data table.
Concatenated data tables always contain a column for every column name found in the original data tables. However, if the column names do not match exactly, they are not merged. For example, if the yield column was instead named yield1 and yield2, a separate column would be created for each in the concatenated data table.

When you concatenate two or more data tables containing table variables, separate columns are created for each table variable. This ensures that important distinctions are not lost when concatenating data tables.

**Note:** Columns are not created for table variables that begin with the name Notes.

### Example of Concatenating Data Tables and Table Variables

For example, suppose that two cancer trials were conducted at two different hospitals. One of the trials’ data is in the Cancer1.jmp data table, and the other trial’s data is in the Cancer2.jmp data table.

To consolidate the data and the variables into one table, follow these steps:

1. Select Help > Sample Data Library and open Cancer1.jmp and Cancer2.jmp.
   
   Notice that there are two distinct table variables: Dosage Amount and Location. In the concatenated table, columns are created for these two table variables.

2. From the Cancer1.jmp data table, select Tables > Concatenate.

3. Select Cancer2 and click Add.
Chapter 6  
Reshape Your Data

<td>Test</td>
<td>No</td>
<td>250</td>
<td>Asheville</td>
</tr>
</tbody>
</table>

The data and the variables are concatenated. The variables appear as columns in the concatenated table. The notes from each data table are added to the new data table as table variables.

**Join Data Tables**

You can combine two data tables into one new table by selecting **Tables > Join**. For an overall description of how to join two data tables, see “To join two data tables into a new data table, follow these steps:” on page 360. Tables can be joined in three different ways:

- By combining them according to row number. See “Example of Joining by Row Number” on page 362.
- In a Cartesian fashion, where you form a new table consisting of all possible combinations of the rows from two original tables. See “Examples of a Cartesian Join” on page 364.
- By matching the values in one or more columns that exist in both data tables, or in a single data table. See “Examples of Joining By Matching Columns” on page 366.

**Note:** The JMP Query Builder option in the Tables menu provides an option to query data before performing a simple join. See “Query and Join Data Tables with JMP Query Builder” on page 371 in the “Reshape Your Data” chapter.
To join two data tables into a new data table, follow these steps:

1. Open the two data tables that you want to join.
2. Select **Tables > Join**.

   In the window that appears, the names of all open tables appear below **Join...with**.

**Figure 6.22** The Join Window

3. In the **Join...with** box, select the table to join with the active table.
4. From the Matching Specification area, select the option that specifies how to join the tables.
5. Enter the name of the new table in the text box beside **Output table name**.
6. (Optional) Customize the join procedure further using the additional options.
7. Click **OK** to create the joined data table.

**Join Options**

**Keep dialog open**  Keeps the Join window open after you click **OK**.

**Save Script to Source Table**  Saves a script to the original data table that enables you to join the data again using the same settings.

**Preserve main table order**  Maintains the order of the original data table in the joined table, instead of sorting by the matching columns. Selected by default.
**Update main table with data from second table**  Data in the original table are updated with data in columns that have the same names. The results are displayed in a new data table.

Note the following:
- JMP does not replace data with missing values.
- The output table uses the same columns as the original table. Thus, when you use *Update main table with data from second table*, Select Columns for joined table is not applicable.
- The *Update main table with data from second table* option is available only when joining by row number or by matching columns.

**Merge same name columns**  Data from the second table replaces the data of the same name columns in the original table. Note that missing values in the first table are replaced by nonmissing values in the second.

If you are matching by column, Match Flag is selected when you select *Merge same name columns*. The new joined table contains a nominal column named *Match Flag*:
- If Main appears in this column, the data originated from the first (active) table.
- If With appears in this column, the data originated from the second table.
- If Both appears in this column, the data was found in both the first and second tables.

**Match flag**  Determines whether the *Match Flag* column is created when you are matching by column. Selected automatically when you select *Merge same name columns*.

**Copy formula (Main Table and Second Table)**  Includes formulas from the main table and/or the second table in the output columns. Selected by default.

**Suppress formula evaluation (Main Table and Second Table)**  Prevents JMP from evaluating columns’ formulas during the creation of the new table. Selected by default.

**By Matching Columns**  To join rows, select columns in both tables whose values and data types match. Follow these steps:

1. Highlight a column name from each list in the *Source Columns* area. The first highlighted column in the top list pairs with the first highlighted column in the bottom list, the second columns are paired, and so on. Rows join only if values and data types match for all the column pairs.

2. Click *Match*. The selected pair of columns appears in the *Match columns* box. Matching columns do not have to have the same names and do not have to be in the same relative column position in both tables.

3. (Optional) To include only the first match found, check the boxes associated with *Drop multiples* in both tables. Only the first match found is written to the new table. If you specify this option for one table, the first match value is joined with all matches in the
other table. If you do not check the boxes associated with **Drop multiples** in either table, a Cartesian join is performed within each group of matching column values.

4. (Optional) To include all rows from the data table, even when there is no matching value, check the boxes associated with **Include non-matches**. You can specify this option for either or both data tables being joined.

**By Row Number**  Joins the two tables side by side.

**Cartesian Join**  Joins two tables using a Cartesian fashion, where it forms a new table consisting of all possible combinations of the rows from two original tables. JMP crosses the data in the first table with the data in the second to display all combinations of the values in each set.

**Select Columns for joined table**  Selects a subset of columns from either table for inclusion in the output table. Follow these steps:

1. In the Source Columns area, highlight the columns from each table that you want to include in the new table.
2. Click **Select** in the Output Columns area.

**Output table name**  Specifies the name of the joined table.

### Examples of Joining Data Tables

The following sections provide examples using the Join command.

**Example of Joining by Row Number**

Joining tables by row number joins the two tables side by side. The new table has all of the columns from both tables, unless you specify to include only certain columns.

*To join tables with an unequal number of rows*

If the two tables that you want to join have an unequal number of rows, the new table contains values for the rows found in both tables.

1. Select **Help > Sample Data Library** and open Species1.jmp and Species2.jmp.
   Notice that the Species1.jmp table has two rows, and the Species2.jmp table has four rows.
2. From the Species1.jmp table, select **Tables > Join**.
3. In the **Join...with** box, select Species2.
4. From the Matching Specification area, select **By Row Number**.
5. Click **OK**.
If one table with two rows is joined with a table with four rows, then the new table contains four rows.

To join columns with the same name

If the two tables have column names that are the same, the names of these columns in the new table appear as “column name of table name.” For example, suppose that you want to combine the eight rows from the Trial1.jmp and Trial2.jmp data tables shown in Figure 6.24 into a single table. You want to combine them so that the new table contains all of the columns from both tables.

1. Select Help > Sample Data Library and open Trial1.jmp and Trial2.jmp.
2. From the Trial1.jmp data table, select Tables > Join.
3. In the Join...with box, select Trial2.
4. From the Matching Specification menu, select By Row Number.
5. Click OK.

A column name can be the same in the two original tables. The output column name is then qualified by the source table name. For example, the column names in the new table appear as <variable name> of table name.
To join only specified columns

Suppose that you do not want all of the columns from the original data tables to be in the joined table:

1. Select Help > Sample Data Library and open Trial1.jmp and Trial2.jmp.
2. From the Trial1.jmp data table, select Tables > Join.
3. In the Join...with box, select Trial2.
4. From the Matching Specification menu, select By Row Number.
5. Click Select columns for joined table to specify the subset of columns that you want to include.
6. In the Source Columns list, select popcorn and yield from the Trial1 list and select yield from the Trial2 list.
   Because identical data exists in the popcorn column of both tables, you need to select only one column.
7. Click Select.
8. Click OK.

Figure 6.25 Joining Only Specified Columns

Examples of a Cartesian Join

When doing a Cartesian join, JMP joins two tables in a Cartesian fashion: the new table consists of all possible combinations of the rows from two original tables. This creates cases in the output table where there are one case for each combination of column values.

Simple Example of a Cartesian Join

1. Select Help > Sample Data Library and open Species1.jmp and Species2.jmp.
2. From the Species1.jmp table, select Tables > Join.
3. In the Join...with box, select Species2.
4. From the Matching Specification menu, select Cartesian Join.
5. Click **OK**.

**Figure 6.26** Joining Tables Using Cartesian Join

<table>
<thead>
<tr>
<th>species</th>
<th>season</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOX</td>
<td>spring</td>
</tr>
<tr>
<td>FOX</td>
<td>summer</td>
</tr>
<tr>
<td>FOX</td>
<td>fall</td>
</tr>
<tr>
<td>FOX</td>
<td>winter</td>
</tr>
<tr>
<td>COYOTE</td>
<td>spring</td>
</tr>
<tr>
<td>COYOTE</td>
<td>summer</td>
</tr>
<tr>
<td>COYOTE</td>
<td>fall</td>
</tr>
<tr>
<td>COYOTE</td>
<td>winter</td>
</tr>
</tbody>
</table>

The data in Species1.jmp is crossed with the data in Species2.jmp to produce the joined table, which shows all combinations of the values in each set.

**Complex Example of a Cartesian Join**

In this example, use the **Tables > Join** command twice:

- The first join combines the Oil Amount.jmp table with the Batch.jmp table using the **Cartesian** option.
- The second join combines the resulting table (Cartesian oil amount + batch) with the Popcorn Type.jmp table and produces a final table with all tables joined.

1. Select **Help > Sample Data Library** and open Oil Amount.jmp, Batch.jmp, and Popcorn Type.jmp.
2. From the Oil Amount.jmp table, select **Tables > Join**.
3. In the **Join...with** box, select Batch.
4. From the Matching Specification menu, select **Cartesian Join**.
5. Under **Output table name**, type Oil Amount and Batch.
6. Click **OK**.

**Figure 6.27** Oil Amount and Batch Joined Table

<table>
<thead>
<tr>
<th>oil amount</th>
<th>batch</th>
</tr>
</thead>
<tbody>
<tr>
<td>little</td>
<td>small</td>
</tr>
<tr>
<td>little</td>
<td>large</td>
</tr>
<tr>
<td>lots</td>
<td>small</td>
</tr>
<tr>
<td>lots</td>
<td>large</td>
</tr>
</tbody>
</table>
The joined table contains all of the columns from the Oil Amount.jmp and Batch.jmp tables. Add the Popcorn Type.jmp columns:

7. From the Oil Amount and Batch table that you just created, select **Tables > Join**.
8. In the **Join...with** box, select **Popcorn Type**.
9. From the Matching Specification menu, select **Cartesian Join**.
10. Click **OK**.

**Figure 6.28** Oil Amount and Batch Joined with Popcorn Type

The final table contains all of the columns from all three original tables. Keep in mind that the number of rows produced by a Cartesian join is the product of the number of rows in the original tables.

**Examples of Joining By Matching Columns**

When you join data tables by matching columns, JMP aligns the rows in the two tables by matching column values.

**Caution:** If the matched columns do not result in unique rows, proceed carefully.

**Notes:**

- The columns used for matching must have the same data type (numeric, character, or row state).
- You can join a data table to itself, in order to remove duplicate values or rows from the data table.
- You can use a virtual join as an alternative to creating a new data table. See “Virtually Join Data Tables” on page 374.

**To join tables with a unique identifier**

You have two files of information about hot dogs. The second file contains one column, Size, that is missing from the first file. Use Join with a matching column to combine the data tables.
1. Select **Help > Sample Data Library** and open Hot Dogs.jmp and Hot Dogs2.jmp. The Product Name column is a unique identifier for the rows in your data tables. Each table has 54 unique product names.

2. From the Hot Dogs data table, select **Tables > Join**.

3. In the Join ‘Hot Dogs’ with list, select Hot Dogs2.

4. Select **By Matching Columns** in the Matching Specification area.

5. From the Hot Dogs and Hot Dogs2 lists, select Product Name.

6. Click **Match**.

7. In the Options, select **Merge same column names**. When the merge columns is used the Match Flag is automatically selected.

8. Select **Keep dialog open** in the lower left corner of the window so that you can easily return to the Join window in the case that the joined data table is not as you expected.

9. Click Apply.

**Figure 6.29** Joined Table by Matching Columns

The resulting table now includes the Size column that was in the Hot Dogs2 table. The Match Flag column indicates that the data originated from both tables for all rows.

To join tables with different numbers of rows and different column names

Suppose that Sarah and Joe are performing a popcorn experiment. They are popping different types of popcorn (gourmet and plain) in different amounts of oil. They are recording the amount (yield) of popcorn that is produced. Sarah gave you the first trial data in a file named Trial1.jmp. Joe gave you the second trial data in a file named Little.jmp. You want to combine the two tables into one table.

1. Select **Help > Sample Data Library** and open Trial1.jmp and Little.jmp.

2. From the Trial1.jmp table, select **Tables > Join**.

3. In the **Join...with** box, select Little.
You can see that three of the columns (popcorn, oil amt/oil, and batch) contain the same values in both tables. Identify these columns as matches. Also, because Sarah and Joe gave the oil and oil amt columns different names, you can tell JMP that oil amt and oil match.

4. Deselect **Preserve main table order**.

The joined table is sorted by matching columns, not by the order of data in Trial1.jmp,

5. Select **By Matching Columns** in the Matching Specification area.

6. From the Trial1 list, select popcorn, oil amt, and batch.

7. From the Little list, select popcorn, oil, and batch.

8. Click **Match**.

Looking at the two data tables, you can see that they have different numbers of rows. Trial1.jmp has values for eight experimental conditions, and Little.jmp has values for only four of those conditions. Sarah completed her experiment, but Joe only partially completed his experiment. You want the joined table to contain all of the rows in Trial1.jmp, even if that row in the Little.jmp table contains a missing value.

9. Select the **Include non-matches** boxes for both tables.

In the joined table, you want only one column for popcorn, one column for oil, and one column for batch. However, you want two columns for yield: one representing the yield from Trial1.jmp, and another representing the yield from Little.jmp.

10. Select the box beside **Select columns for joined table**.

11. From the Trial1 list, select all of the columns.

12. Click **Select**.

13. From the Little list, select yield.

14. Click **Select**.
Figure 6.30 Completed Join Window

15. Click **OK**.
Figure 6.31  Trial1.jmp and Little.jmp Joined

<table>
<thead>
<tr>
<th>popcorn</th>
<th>oil amt</th>
<th>batch</th>
<th>yield of Trial1</th>
<th>yield of Little</th>
</tr>
</thead>
<tbody>
<tr>
<td>gourmet</td>
<td>little</td>
<td>large</td>
<td>8.6</td>
<td>8.2</td>
</tr>
<tr>
<td>gourmet</td>
<td>little</td>
<td>small</td>
<td>12.1</td>
<td>15.9</td>
</tr>
<tr>
<td>gourmet</td>
<td>lots</td>
<td>large</td>
<td>9.2</td>
<td>*</td>
</tr>
<tr>
<td>gourmet</td>
<td>lots</td>
<td>small</td>
<td>18.0</td>
<td>*</td>
</tr>
<tr>
<td>plain</td>
<td>little</td>
<td>large</td>
<td>8.2</td>
<td>8.8</td>
</tr>
<tr>
<td>plain</td>
<td>little</td>
<td>small</td>
<td>9.9</td>
<td>10.1</td>
</tr>
<tr>
<td>plain</td>
<td>lots</td>
<td>large</td>
<td>10.4</td>
<td>*</td>
</tr>
<tr>
<td>plain</td>
<td>lots</td>
<td>small</td>
<td>10.6</td>
<td>*</td>
</tr>
</tbody>
</table>

The joined table is sorted by the matching columns. Note that the yield column from the Little.jmp table (Yield of Little) has missing values indicating no matching values with the Trial1.jmp table.

To join a table to itself (to remove duplicate entries)

1. Select Help > Sample Data Library and open Coffee Shop Purchases.jmp.
   You can see that some of the customers had the same drink on the same date. You want to consolidate these duplicate rows using Join.
2. Select Tables > Join.
3. In the Join...with box, select Coffee Shop Purchases.
5. From both Coffee Shop Purchases lists, select all three columns: Date, Customer, and Beverage.
6. Click Match.
7. Select the Drop multiples boxes for both tables (the Main Table and the With Table).
8. Type Coffee Shop Purchases Final for the Output table name.
9. Click OK.
Query and Join Data Tables with JMP Query Builder

The JMP Query Builder option in the Tables menu enables you to query data tables and save selected data into a new data table. This feature is similar to using the Join command but lets you perform queries before saving the data. For example, you can query SAT data and save only data for 2004 test scores in a data table. You can also include a prompt that lets the user run the query and choose a subset of the 2004 test scores.

1. Select Help > Sample Data Library and open SAT.jmp and SATByYear.jmp.
2. Display SATByYear.jmp.
3. Select Tables > JMP Query Builder.
   The current data table, SATByYear.jmp, is selected as the Primary table.
4. Select SAT.jmp in the Available Tables list and click Secondary.
5. Select SAT.jmp next to the Secondary button and view the Columns tab. The Join column shows that two columns have the same name and were joined.
6. Click **Build Query**.

**Add Columns**

2. Click **Add**.
   - The columns are added to the Included Columns tab.
3. Select **Distinct rows only** to avoid saving duplicate rows.
4. On the Query Preview tab, make sure that **Update preview automatically** is selected so that you can see the selected columns.

**Add Filters**

1. In the Included Columns list, select `t2.2004 Verbal` and `t2.2004 Math`, and then click **Add Selected Items to Filter**.
   - The columns are added to the Filters list.

**Figure 6.34 Selected Filters**
2. Click the red triangle next to each filter and select **Prompt on Run**. Accept the default prompt message.

**Run the Query**

1. Click **Run Query**.

   You are prompted to indicate which math and verbal scores to save in the data table. To save all data, do not change the values in the prompt window.

2. Click **OK** to create the data table.

![Figure 6.35 Queried Data](image)

See “Build SQL Queries in Query Builder” on page 115 in the “Import Your Data” chapter for more information about features that also appear in Query Builder for databases.

**Tips:**

- To join data from different sources (for example, a database and Microsoft Excel), use Query Builder to import the database data into a data table; import the Excel data into a data table; and use JMP Query Builder in the Tables menu to query and join the tables.

- When you open a query, data tables in the query open as hidden files that you can open from the JMP Home Window. You can also open the hidden files from the Table panel when you build the query.

- If you try to query a Microsoft Excel file that has more than 255 columns, only 255 columns are imported. Instead, select **File > Open** to open the Excel file in the Excel Import Wizard, and save the file as a data table.
About Links to Data Tables in Queries

When you query data tables, the resulting data table contains scripts for rerunning the query, updating the data, and editing the query. Data tables in these scripts have *absolute paths*. For example, the following portion of these scripts defines where two JMP sample data tables are stored.

```plaintext
JMP Tables(
    "SAT" => "C:\Program Files\SAS\JMPPRO\16\Samples\Data\SAT.jmp",
    "SATByYear" => "C:\Program
    Files\SAS\JMPPRO\16\Samples\Data\SATByYear.jmp"
),
```

However, when you save a query as a `.jmpquery` file, the file contains *relative paths* to the original data tables if it is possible to create them. The following example shows data tables that are stored in the `FuelData` subfolder that is relative to the `.jmpquery` file.

```plaintext
JMP Tables(
    "Cars" => "FuelData\Cars.jmp",
    "Trains" => "FuelData\Trains.jmp"
)
```

In the `.jmpquery` file, if a relative path cannot be created, an absolute path is used with path variable substitutions if possible. When you run the query, you are prompted to select the data table if the table cannot be found. JMP then detects whether other missing data tables in the query are in the selected folder.

You can also use path variables to locate the data tables. For example, you might write a script that selects a data table in the `$DOCUMENTS` folder. Or you can define a path variable in a JSL script and then run a query from the script. See the *Scripting Guide* for more information about path variables.

Virtually Join Data Tables

Virtual Join links a main data table to one or more auxiliary data tables. This feature enables the main data table to access data from the auxiliary data tables without physically joining the tables. Virtually joining tables saves memory, because the same data are not replicated in every table that references them. And updating linked data is simpler; linked data can be independently updated in the source table without being updated in the referencing table.

The Link ID and Link Reference column properties make the linking possible.

- The Link ID column property marks a column in the *auxiliary* data table as the ID column. That is, the rows of the data table are uniquely identified by the values of the ID column. The data table that has a Link ID column property is referred to as the *referenced* data table.
- The Link Reference column property links a column in the *main* data table to the Link ID column in the referenced data table. The column property specifies the path name of the
referenced data table. The column that has a link reference is referred to as the *referencing* column. The referencing column can look up the data of the auxiliary data tables through the Link ID column.

Figure 6.36 shows an example of virtually joined data tables. Pizza Profiles.jmp is the referenced data table because the ID column contains a Link ID column property. The ID column contains unique values that correspond to data in the referencing data table, Pizza Responses.jmp.

**Figure 6.36** Virtually Joined Data Tables

---

**Note:** A column can have a Link Reference column property, but it does not necessarily have to link columns from the referenced data table. The virtual join icon next to the column in the Columns list is gray 🅸. This can happen if the referenced data table is not opened or the referencing column is excluded. See “Virtual Join Icons” on page 43 in the “Get Started with JMP” chapter for more information about the other virtual join icons.

With the link column properties setup, all columns from the referenced data tables become part of your main data table. Therefore, if the main data table has a referencing column, the columns of the referenced table automatically appear in the Select Columns list of the launch window.
Example of Virtually Joining Columns

Suppose that respondents in a pizza experiment chose their favorite crust, topping, and cheese. To see which cheese the respondents preferred, follow these steps:

1. Select Help > Sample Data Library and open Pizza Profiles.jmp and Pizza Responses.jmp.
2. First, right-click the ID column in Pizza Profiles.jmp and select Link ID.
   This column contains unique values that correspond to values in Pizza Responses.jmp. For example, row one in Pizza Profiles.jmp indicates that pizza with thick crust, mozzarella cheese, and pepperoni toppings is nicknamed ThickOni. When all responses in Pizza Responses.jmp are “ThickOni”, the subject chose pizza with these attributes.
3. In Pizza Responses.jmp, select the three columns that begin with “Choice”.
4. Right-click and select Link Reference > Pizza Profiles.jmp.
   The selected columns are linked to the ID column in Pizza Profiles.jmp and appear in the main data table’s Columns list (Figure 6.36 on page 375).

   Note: Look at one of the column’s Link Reference properties again and notice that the Pizza Profiles.jmp data table is selected. See “Link Data Tables with Virtual Join Properties” on page 324 in the “Set JMP Column Properties” chapter for information about changing the link.

5. In Pizza Responses.jmp, select Analyze > Distribution.
6. Scroll down to select the three Cheese columns in the referenced column groups, click Y, Columns, and click OK.
More respondents chose Mozzarella in the Choice column. In Choice1 and Choice2, the proportion of Mozzarella to Jack is nearly even.

Figure 6.38  Distribution of Pizza Responses
Notes:

- See the Movie Rentals.jmp sample data table for another example of virtually joined columns. The data are already joined with Movie Customers.jmp and Movie Inventory.jmp, so you do not need to specify the Link Reference.
- A data table can have only one Link ID column property. The Link ID column cannot have duplicate values.
- A data table can have multiple referencing columns. The columns can reference different or the same data tables.
- A referenced data table can also have a referencing column (a column that references another data table).
- If the Link Reference column property is removed from the column, or the referenced data table is closed, the corresponding referenced columns are removed from the main data table.
- The data types of the linked columns must match.
- The Expression and Row State data types do not support the Link Reference or Link ID column properties.
- When the main data table is saved, the Link Reference column property is saved, but referenced columns are not saved. The data tables are relinked when you open them.
- When a referenced data table is renamed, the corresponding Link Reference column property is automatically updated.
- Referenced columns are not included when you select Copy Table Script from the Table panel red triangle menu.
- Select Row State Synchronization options to synchronize row states in data tables that contain virtually joined columns. See “Example of Virtually Joining Columns and Showing Row States” on page 379.
- A column can have both Link ID and Link Reference column properties.

Tips:

- In addition to right-clicking a column to add the Link ID and Link Reference column properties, you can add the properties through the Column Info window. See “Link Data Tables with Virtual Join Properties” on page 324 in the “Set JMP Column Properties” chapter.
- You can specify that the linked column name be used in virtually joined columns that are shown in the Columns list. This option lets you specify a shorter column name (for example, Cheese instead of Cheese[Choice]). In the Link Reference column property, select Use Linked Column Name. You can also manually rename the column as usual. The Table preference is called Virtual Join Use Linked Column Name. It is deselected by default.
• To share the data with another user, you might want to merge the data so that the data tables are permanently joined. This option is helpful because you provide one data table, not the main and auxiliary data tables. To merge the joined columns into the table that has a link reference, select **Merge Referenced Data** from the red triangle menu in the data table’s left pane. The data are replicated from the auxiliary data table to the main data table. When you save the main data table, the actual data are also saved. The Link Reference column property is removed from the referencing column in the main data table. See “Example of Merging Referenced Data in Virtually Joined Data Tables” on page 381.

### Example of Virtually Joining Columns and Showing Row States

When row states change in one data table that has a virtually joined column, those row states can automatically show up in virtually joined columns in other linked data tables. Suppose that the main and auxiliary data tables have a subject ID column. The row states are changed in the data table that contains a Link ID property on the subject ID column. Then the row states are updated in the data table that contains virtually joined Link Reference columns. You can specify whether the Link Reference columns send (*dispatch*) row states to the other data tables or receive (*accept*) row states.

1. Select **Help > Sample Data Library** and open Nic Demographics.jmp, Nic Labs.jmp, and Nic Adverse Events.jmp.

2. View Nic Labs.jmp.

   Notice that, in the Columns list, the blue Virtual Join icon 🗞️ appears next to **Unique Subject Identifier**. The blue color indicates that the column has a Link Reference column property and the referenced data table (Nic Demographics.jmp) is open. The Link Reference column property links the Unique Subject Identifier column in the current data table to the Unique Subject Identifier column in the referenced data table. If the icon is gray 🗞️, the referenced data table is not open, or the columns could be linked incorrectly.

Nic Adverse Events.jmp is set up the same way.
3. In Nic Labs.jmp, select the Unique Subject Identifier column and select **Cols > Column Info**.

4. Select the **Link Reference** column property.
   
   Notice that Accept is selected. This means that when rows in the referenced data table (Nic Demographics.jmp) contain a row state, the row state automatically appears in the current data table.

   Also notice that the Select, Exclude, and Hide row states are selected. When these row states are selected in Nic Demographics.jmp, the row states appear in Nic Lib.jmp and Nic Adverse Events.jmp.

5. In Nic Demographics.jmp, right-click the first row and select **Hide and Exclude**.
   
   The first row contains data for Unique Subject Identifier 101001.

6. View Nic Labs.jmp to see the hidden and excluded rows for Unique Subject Identifier 101001.

**Cautions:**

- Dispatching row states in multiple tables with multiple columns can be complex and should be done with caution.

- Dispatching row states is best used when no multiple row states are assigned to the same ID value. If a Link Reference column dispatches the color row state, ambiguity quickly develops when there are multiple rows with the same ID value but different color row...
states. For example, the data table has two rows with an ID value of 001. You color one row red and the other row green, There is no way for JMP to know how to set the row state in the linked data table.

**Notes:**

- Multiple columns in table A can link to table B. And Table B can itself have multiple columns that link to table C. The row states of all of the rows appear in the data tables that contain linked columns. For example, if row 1 is excluded in table A and row 1 is hidden in table B, the main data table shows that the row as excluded and hidden.
- If a data table is accepting a specific row state, avoid manually applying that row state in the data table. Let the dispatching column control that row state.

**Example of Merging Referenced Data in Virtually Joined Data Tables**

To share the data from virtually joined data tables with another user, you might want to merge the data so that the data tables are permanently joined. This option is helpful because you provide one data table, not the main and auxiliary data tables.

When you merge referenced data, the data are replicated from the auxiliary data table to the main data table. When you save the main data table, the actual data are also saved.

1. Select **Help > Sample Data Library** and open Pizza Profiles.jmp and Pizza Responses.jmp.
2. Right-click the **ID** column in Pizza Profiles.jmp and select **Link ID**.
3. Select the **Choice1, Choice2, and Choice** columns in Pizza Responses.jmp, right-click, and then select **Link Reference > Pizza Profiles.jmp**.

The selected columns are linked to the ID column in Pizza Profiles.jmp.
4. In Pizza Responses.jmp, select the Choice1 column if it is not already selected.

   **Note:** If you do not select the columns, then all columns will be in the merged data.

5. Click the red triangle next to the name of the data table and select **Merge Referenced Data**.
A message confirms that the selected column was merged. Notice that the blue virtual join icon for *Choice1* no longer appears in the Column list. The Link Reference column property was removed.

</table>
If you hover over one of the linked columns in the Columns panel, a tooltip indicates which data table it is linked to.

**Figure 6.43** Data Table that Contains the Linked Column

**Example of a Link ID and a Link Reference on a Single Column**

Suppose that employee data is available in multiple data tables and can be linked together by a single column that has both a Link ID and a Link Reference property. To see an example of how the data tables are set up, follow these steps:

1. Select **Help > Sample Data Library** and open **Employee Master.jmp**.

   **Note:** In the Employee Id column’s Link Reference column property, the Auto Open option is selected to automatically open two other tables, **Education History.jmp** and **Predicted Termination.jmp**. They appear in the Home Window’s Window List.

   - **Employee Master.jmp** has information about each employee.
   - **Education History.jmp** has the information about the education of each employee.
   - **Predicted Termination.jmp** has job performance information about each employee.

2. Open **Predicted Termination.jmp** from the Home Window’s Window List.

   Notice that the Employee Id column has a Link ID column property.

**Figure 6.44** Link ID Column Property
3. In Employee Master.jmp, select the Employee Id column and select **Columns > Column Info**.

**Figure 6.45** Link ID and Link Reference Column Properties in Employee Master.jmp

![Column Properties](image)

Notice that the column has a Link ID column property and a Link Reference to Education History.jmp.

In the data table’s Columns list, the Link Reference icon and Link ID icon appear next to the Employee Id column.

4. Open Education History.jmp from the Home Window’s Window List.

5. Select the Employee Id column and select **Columns > Column Info**.
As shown in Figure 6.46, Employee Id has a Link ID column property and a Link Reference to Predicted Termination.jmp.
The Employee Id column of Employee Master.jmp references Education History.jmp, which then references Predicted Termination.jmp. All data are available through virtual join from the main data table, Employee Master.jmp.

Notes:

- Auto Open in a column’s Link Reference property specifies whether the linked table is automatically opened when the main data table is opened.
- If referenced columns are unhidden when the data table is saved, those referenced columns are automatically linked and unhidden when the table is opened.
- When you close the data tables, it is a best practice to close the main table first (Employee Master.jmp), because there is a link between that table and all the others. Closing them in a different order might display a prompt indicating that the table that you are closing has other windows open. You might want to cancel and consider saving and closing your tables in a different order.

**Update Data Tables**

If you have two data tables and would like to update your original table with data from a new table, select **Tables > Update**. The Update command is a special case of Join in place. It is a Join with the Update option checked, and it does not result in a new table.
Before you update a table, make sure that the name of the column containing the values that you want to replace is the same as the name of the column containing the data that you want to replace it with.

To replace values in the active table with those found in another open table

1. Click the original table that you want to update (this is the table whose values you want to replace) to make it the active table.

2. Select Tables > Update.

Figure 6.48 Updating a Table

3. Highlight the new table containing the data that you want to transfer to the original table.

4. (Optional) If you do not want JMP to replace the values in the original table with any missing values found in the new table, select the box next to Ignore missing. The original table retains its original values if they correspond to missing values in the new table.

5. If the two tables have one or more columns whose values uniquely describe each row, JMP uses those columns as the match column values. That is, JMP updates the rows whose match column values coincide. JMP uses these columns to preserve the sorted order of the data. If your tables do not have matching column values, you can incorporate the updated values according to their row order by continuing here. To proceed with tables containing matching column values, see “To update a table using matching columns” on page 389.
6. From the Add Columns from Update Table area, select an option. Using these options, you can add columns (that do not exist) from the new table into the original table.
   
   – Choose **All** to add all columns from the new table into the original table.
   
   – Choose **Selected** to add only columns that you have selected from the new table into the original table.
   
   – Choose **None** if you do not want to add any non-existent columns from the new table into the original table.

7. (Optional) From the Replace Columns in Main Table area, select an option. Using these options, you can replace the values in columns that have the same names.
   
   – Choose **All** to add all columns with the same names from the new table into the original table.
   
   – Choose **Selected** to replace only columns with the same names that you have selected from the new table into the original table.
   
   – Choose **None** if you do not want to add any non-existent columns that have the same names from the new table into the original table.

8. Click **OK**.

*To update a table using matching columns*

1. Follow the first three steps outlined in the previous section, “To replace values in the active table with those found in another open table” on page 388.

2. Select **Match columns**.

**Figure 6.49** This Window Appears When You Click Match Columns
3. Highlight the two column names (in the respective tables) that you want to match.
4. Click **Match**.
5. (Optional) Repeat to match more columns.
6. Click **OK**.

**Note:** Columns that have different names from the columns in the table that you are updating (and that have not been assigned matches) are appended as separate columns. To avoid this problem, select the None option in the Add Columns from Update table area.

### Example of Updating a Data Table

Suppose a researcher has a data table containing height measurements for students. The researcher receives an updated table that contains more recent measurements of the students’ heights. The researcher wants to avoid scrolling through the data tables to find the students whose height has changed, and copying and pasting the new values. Using the **Update** command, the researcher can quickly update the original data table with the new height values.

1. Select **Help > Sample Data Library** and open Big Class.jmp and New Heights.jmp.
   
   The Big Class.jmp table contains the original data, and the New Heights.jmp table contains the updated data.
2. From the Big Class.jmp table, select **Tables > Update**.
3. In the **Update...with data from** box, select New Heights.
4. Select **Match columns**.
5. In the Big Class and New Heights lists, select name.
6. Click **Match**.
   
   This tells JMP to use name as the match column value, since it is the column whose values uniquely describe each row.
7. Click **OK**.
### Anonymize Data

The Anonymize Data feature enables you to create a new data table in which certain unique identifiers have been removed:

- Column headings, character data, and value labels are modified.
- Data in nominal columns are modified.
- Modified data in ordinal columns appear in the same order as in the original data table.
- Data in continuous columns are not modified.
- Column names in column properties are modified.

**Note:** Table scripts and some table variables cannot be anonymized. If your data table contains content that cannot be anonymized, a warning message appears in the log.

“The Notes” column properties are removed. Other column properties are modified based on changes in the data table. For example, Value Order properties are renamed. Formulas except for prediction formulas are updated. Some column properties might no longer have the desired effect on the column.
To rename data, do one of the following:

- To rename data in specific columns, select the columns and then select **Tables > Anonymize**.
- To rename data in the entire data table, select **Tables > Anonymize**.

The data appear in a new data table.

DISCLAIMER: The Anonymize Data utility is provided merely to assist Users in removing certain unique identifiers from a data table as described above. The Anonymize Data utility might not remove all sensitive or personally identifiable information from a data table. Users should not rely exclusively on the Anonymize Data utility to remove such information where complete anonymization, pseudo-anonymization, or de-identification of data is desired or required by law or policy (such as where data are or might be disclosed to other parties). SAS does not represent, and specifically disclaims, that use of the Anonymize Data utility will by itself result in the User’s compliance with any national, state, local or international laws, regulations, or policies that pertain to the privacy, de-identification, or anonymization of sensitive or personally identifiable information.
Use the JMP Formula Editor to create a column whose values are computed by a formula and store that formula as part of a column’s information. Formulas can be simple assignments of numeric, character, or row state constants, or they can contain complex evaluations based on conditional clauses. The Formula Editor window operates like a calculator with buttons, displays, and a list of functions.

For more information about the functions that are available in the Formula Editor, see the “Reference for JMP Functions in Formulas” chapter on page 727.

Overview of Formulas

Formulas are an integral part of a data table for the following reasons:

- They are stored as part of a column’s information when you save the data table.
- You can examine or change them at any time by opening the Formula Editor.
- Their values can be linked to, or dependent on, the values in other columns. Their values are automatically recomputed whenever you edit the values in the columns to which the formula is linked.
- Their values are locked in the data table so that they cannot be manually edited.

This chapter describes the Formula Editor and shows how to build formulas. For more information about each function, see the “Reference for JMP Functions in Formulas” chapter on page 727.

Build Formulas

A formula is an expression stored in a column that performs operations in order to insert values into that column. Formulas can perform mathematical operations, such as addition and multiplication, or they can compare column values or join values by referring to other areas in the same data table. Formulas can consist of any JMP Scripting Language (JSL) command. Once you insert a formula into a column, the column is locked: its values can be edited only by changing or removing the formula.

There are three basic steps to building a formula:

1. Open the Formula Editor by right-clicking the column name to which you want to apply the formula and selecting Formula.

   or

   Double-click the column name to which you want to apply the formula, select Formula from the Column Properties menu, and then click Edit Formula.

   In the Formula Editor, the empty formula is selected (highlighted in blue). You can start typing or select a column or function.

   When you type, a small text editor window appears, which enables you to edit the formula. You can click the Maximize editor button if you need more room. Long formulas open in the maximized editor by default.

   When you select a column or function, that item is added to the selected blue box.

   You can also drag a column from the Columns list into the selected box.
Note: An element is selected when there is a blue outline around it. All terms within the smallest nesting box relative to the place that you clicked become selected. The subsequent actions apply to those combined elements.

2. Add expressions, functions, and terms. Then they appear in the highlighted blue box. The following sections in this chapter provide detailed instructions on how to add constants, elements, operators, and functions.

Figure 7.2 Building a Formula

See “Use Basic Features in the JMP Formula Editor” on page 422, for an example of how to use the Formula Editor.

Notes:

- In a formula, when you reference a column using value labels, hover over the value label to see the actual data value.
- The Formula Editor recognizes the Excluded state and removes those rows from calculations. Here’s an example using the Col Maximum() function:
  
  Col Maximum( :height, :sex, Excluded( Row State() ) )

- JMP automatically removes trailing spaces in formulas.
- You can also use the Formula Editor to define a custom format. For example, you might want to convert a number from inches to centimeters using the calculation Char( :height
* 2.54 ) || " cm". Realize that the underlying data, which you see when double-clicking a data table cell, would still be the value of :height.

- To move the cursor from one field to another in a formula, select the field and press an arrow key.
- For aggregated functions such as Col Mean, the formula might evaluate faster if you separate the formula into two columns. One column should contain an expression that represents the target for the aggregated function. The second column should contain the aggregated function itself referencing the new target column. Here’s an example of the original formula:

  \[ \text{:Y} - \text{Col Mean( If( :Status == "nonsmoker", :Y, . ), :Cycle )} \]

  In a new Y2 column, create this formula:

  \[ \text{If( :Status == "nonsmoker",} \]

  \[ \text{:Y, .} \]

  \[ \text{)} \]

  In another column, create this formula:

  \[ \text{:Y} - \text{Col Mean( :Y2, :Cycle )} \]

Refer to Data Table Values in Formulas

You can create a formula that refers to values found in other parts of the data table, such as other columns and table variables.

When a formula uses values in other columns, the values in the column with that formula are dependent on the values in those other columns. Whenever a column that the formula refers to changes, the dependent column also changes. If you delete the referenced column, empty terms appear in the column containing the formula.

If you create a formula that refers to values found in table variables, those table variables must already exist in the data table. Table variables are character strings that are available to the entire table. Their names are displayed in the table panel at the left of the data table. See “Use Data Table Variables” on page 283 in the “Enter and Edit Your Data” chapter.

**Tip:** To create a table variable from a value in the Formula Editor, right-click the value and select **Create Table Variable from Value**.

The following example shows how to re-create a formula column in the Companies.jmp sample data table.

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. Right-click the last empty column and select **New Columns**.
The Column Info window appears.

3. Type “Profit by Sales” next to Column Name.
   You are re-creating the formula found in the existing %profit/sales column.

4. In the Column Properties list, select Formula.
   The Formula Editor opens. The blue outline around the box in the editing window indicates that the box is selected.

5. With the box selected, select **Profits ($M)** from the Columns list.

**Figure 7.3** Adding the Profits ($M) Column

6. With the box selected, click the Divide button \( \div \).

**Figure 7.4** Adding the Division Symbol

7. With the box selected as shown, select **Sales ($M)** from the Columns list.

**Figure 7.5** Adding the Sales ($M) Column
8. Select the outer box in the formula editing area by clicking it.

**Figure 7.6** Selecting the Formula

\[
\frac{\text{Profits (SM)}}{\text{Sales (SM)}}
\]

9. Click the Multiply button \( \times \).

**Figure 7.7** Adding the Multiplication Symbol

\[
\frac{\text{Profits (SM)}}{\text{Sales (SM)}} \times
\]

10. With the new box selected, type “100” and press Enter.

**Figure 7.8** Multiplying the Formula by 100

\[
\frac{\text{Profits (SM)}}{\text{Sales (SM)}} \times 100
\]

11. Click **OK**.

The column is filled with the calculated numbers.

12. Right-click the last column and select Column Info.

13. In the Column Info window, select **Fixed Dec** from the Format list, type “10” next to Width, and type “2” next to Dec.

   The column width and number of decimal places are specified.

14. Click **OK**.

   The new formula column matches the %profit/sales formula column.

**Tips:**

- Pressing Alt (Option on macOS) and clicking a column replaces both empty and non-empty selected fields with that column.
- The right-click menu for the Columns list has two replacement options: **Replace all occurrences of selected subexpression** replaces all occurrences of the selected expression with the currently selected column. **Replace the selected subexpression with columns** replaces the selected expression with multiple columns for functions that support it (for example, Sum or Plus).
- Define your own functions and transform columns by writing a JSL script. See the *Scripting Guide*. 
Use Local Variables in Formulas

You can create and use temporary numeric variables in expressions. You can use ordinary local variables or you can use parameters, which are special types of local variables. Local variables exist only for the evaluation of the formula in which they are defined. They appear in formulas as bold italic terms.

Local variables are most often used with Assignment functions, which can assign expressions to local variables that are used in a complex equation. See “Assignment Functions” on page 781 in the “Reference for JMP Functions in Formulas” chapter. This technique can sometimes simplify building an equation and improve the efficiency of its evaluation.

To build a formula that references values found in local variables, follow these steps:

**Step 1: Create the Local Variable**
1. Open the Formula Editor by right-clicking a column name in the data table and selecting Formula.
2. Select a box in the formula editing area by clicking it. (It is selected when there is a blue outline around it.)
3. In the middle pane of the Formula Editor, select Local Variables from the list.
4. Click New Local.
5. Enter a name for the local variable. By default, local variables have the names t0, t1, and so on, and have missing values.
6. Assign a starting value, and click OK.
7. (Optional) To copy, edit, or delete a local variable, right-click (Ctrl-click on the macOS) its name and select Copy, Edit, or Delete.

**Step 2: Insert a Local Variable into a Formula**
1. Select a term in the formula editing area by clicking it. (It is selected when there is a blue outline around it.)
2. Click the local variable name in the Local Variables list. It appears in the formula as a bold italic term.

**Notes:**
- Double-clicking or pressing Alt and clicking the local variable replaces the portion of the formula that is selected.
- Another way to create local variables is to use the Make Temporary Variable button on the Formula Editor keypad. The button automatically creates and displays local variables and places a semicolon after it. See “Add Operators to JMP Formulas” on page 404.
You can also create a local variable from an expression. Right-click the expression in the Formula Editor and select **Create Local Variable from Expression**.

Pressing Alt+Shift and then clicking enables you to edit the selected variable in place instead of in a new window.

See “Use Local Variables Formulas” on page 424 for an example of referencing local variables in a formula.

Incorporate Parameters in Formulas

Parameters are special types of local variables that are recognized as model parameters in some platforms, such as Nonlinear fitting. They can be used in formulas just as ordinary local variables can.

To view examples of parameters

1. In the sample data folder that was installed when you installed JMP, open the Nonlinear Examples folder and then US Population.jmp.
2. Right-click the column name x-formula and select **Formula**.
3. In the middle pane of the Formula Editor, select **Parameters** from the list.

Notes:

- After completing a nonlinear fit or after clicking the Reset button in the nonlinear control panel, the parameter’s value is the most recent value computed by the nonlinear platform.
- Each time the fitting algorithm takes a step, the updated parameter values are shown in the Nonlinear report.
- When you paste a formula with parameters into a column, the parameters are automatically created for that column unless it has existing parameters with the same names.
- Double-clicking or pressing Alt and clicking the parameter replaces the portion of the formula that is selected.
- Pressing Alt+Shift and clicking enables you to edit the selected parameter in place instead of in a new window.

To build a formula that references values found in parameters

**Step 1: Create the Parameter**

1. Open the Formula Editor by right-clicking a column name in the data table and selecting **Formula**.
2. Make sure the formula is selected in the formula editing area. (It is selected when there is a blue outline around it.)

3. In the middle pane of the Formula Editor, select **Parameters** from the list.

4. Click **New Parameter**.

5. Enter a name for the parameter. By default, parameters have the names $b_0$, $b_1$, and so on, and have missing values.

6. Assign a starting value. It is important to enter this value when using a parameter in a model for the nonlinear platform. After completing a nonlinear fit, the parameter’s value is the most recent value computed by the nonlinear platform.

7. (Optional) To add several parameters (one for each level of a categorical variable, for example) at once, select **Expand into categories, selecting column**. Then select the column for which you want to expand the parameter.

8. Click **OK**.

9. (Optional) To copy, edit, or delete a parameter, right-click (Ctrl-click on the macOS) its name and select **Copy**, **Edit**, or **Delete**.

**Step 2: Insert a Parameter into a Formula**

1. Select a term in the formula editing area by clicking it. (It is selected when there is a blue outline around it.)

2. Click the parameter name in the Parameters box. The parameter appears in the formula as bold type.

**Tip:** Pressing Alt+Shift and clicking enables you to edit the selected parameter.

---

**Insert Constants in Formulas**

Formulas can be simple assignments of numeric, character, or row state constants, or they can contain complex evaluations based on conditional clauses. Constants include commonly used numeric terms, such as $e$, $\pi$, -1, 0, 1, and 2. There are two ways to add a constant value to a formula:

- Enter them manually using the keyboard
- Select them from the list in the middle pane, as shown in Figure 7.9.
To add constants to a formula, follow these steps:

1. Open the Formula Editor by right-clicking a column name in the data table and selecting **Formula**.

2. Select a box in the formula editing area by clicking it. (It is selected when there is a blue outline around it.)

3. Either type in a number or select **Constants** in the middle pane, as shown in Figure 7.9. Then click a value in the list that appears: 0, 1, 2, -1, pi, e. The value appears in the outlined box.

4. Complete the remainder of the formula using the keypad and functions. (See “Refer to Data Table Values in Formulas” on page 397, “Add Operators to JMP Formulas” on page 404, and “Use Functions in Formulas” on page 406.)

**Note:** Double-clicking or pressing Alt and clicking the constant replaces the portion of the formula that is selected.
Add Operators to JMP Formulas

You can add operators to a formula using the keypad, which contains buttons that help build formulas. It includes common operators (also referred to as functions).

To build a formula using keypad operators at the top of the window, follow these steps:

1. Open the Formula Editor by right-clicking a column name in the data table and selecting Formula.
2. Select a box in the formula editing area by clicking it. (It is selected when there is a blue outline around it.) The operator performs its action on the area that is highlighted.
3. Select the column or variable that you want to use in your formula.
4. Click the keypad button(s).

Keypad Reference for the Formula Editor

Table 7.1 describes the keypad buttons.

</tbody>
</table>
Use Functions in Formulas

Tip: Hover over a function to learn more about the function.

You can add many types of functions to a formula. All of these functions are organized in the Functions list. The browser groups collections of functions in lists organized by topic. The list contains functions that are commonly used in formulas. Use the Functions list to specify the type of calculation that you want to perform on the elements in a formula.

To create a formula that contains a function, follow these steps:

1. Open the Formula Editor by right-clicking a column name in the data table and selecting Formula.
2. Select an expression in the formula editing area by clicking it. (It is selected when there is a blue outline around it.) The function performs its action on the area that is highlighted.
3. In the Functions list, select a group of functions to view. See Table 7.2.
   The functions that belong to that group are then displayed in the list below the menu. The function groups are briefly described in the following list.
4. Click any function in the Functions list to apply it to the selected item. When you click some items, you reveal a submenu from which you should make a selection.
5. Continue to build the formula by highlighting terms and clicking items in the formula element browser, keypad, or Functions list.

Tips:

- Pressing Alt and selecting the function replaces the selected function in a formula with the function that you select from the Functions list or the button that you select from the keypad.
- Pressing Alt (Option on macOS) and clicking a column or other element replaces the item even if it is non-empty.
- Most functions give hints about appropriate arguments through gray words inserted in the boxes in the formula editing area. Functions also show a small caret in the argument area if additional arguments can be added.
- To find out what a function does, right-click the function in the Functions list or in the formula and select Show in Scripting Index.
- Define your own functions by writing a JSL script. See the Scripting Guide.
## Table 7.2 Groups of Functions

Find Frequently Used Functions in the Formula Editor

You can customize the Functions list to make it easier to find the functions that you typically work with. The functions appear at the top of the list. Show frequently used functions at the top of the list, create your own function categories, delete functions, delete categories, and move functions up and down in the list.

Figure 7.10 Customizing the Functions List

To quickly bookmark a favorite function

1. Right-click the function in the Functions list.
2. Select Add as favorite.

To bookmark a favorite and specify the location

1. Select Customize Functions List from the red triangle menu above the formula editor area.
2. Select the function in the Available Functions list.
3. Click the right arrow button to place it in the Functions list.
4. Click the up or down button to rearrange the favorite.

To rearrange or delete favorites
1. Select Customize Functions List from the red triangle menu above the formula editor area.
2. Select Favorite Functions in the Categories list.
3. Select the favorite function that you want to rearrange and click the up or down button.
4. Select the favorite function that you want to delete and click the X button.

To add functions to a category
If a function is in a formula but the function is not in the Functions list, you can add it to your list by adding it to a category.

1. Select the function that you want to add to a category in the Functions list.
2. Right-click the function and select Add to Category.
3. Select the category.
4. Click OK.

To rearrange, add, or delete categories
1. Select Customize Functions List from the red triangle menu above the formula editor area.
2. In the Categories list, select a category and rearrange, add, or delete the category.

To rearrange or delete functions
1. Select Customize Functions List from the red triangle menu above the formula editor area.
2. In the Categories list, select the category that contains the function you want to rearrange or delete.
3. Click the up, down, or X buttons to rearrange or delete the selected function.

Note: Deleting a function only deletes it from the Functions list. You can still type the function in a formula.
Copy and Replicate Formulas

The Standardize Attributes option in the Cols menu provides a way to replicate a column formula while incrementing each column reference in the formula. This option is an alternative to manually creating new column formulas whose columns increment by one in each of the subsequent columns. For example, if column B contains the formula $A \times 2$, then the standardized column C would contain the formula $B \times 2$, and the standardized column D would contain the formula $C \times 2$.

1. Select Help > Sample Data Library and open Semiconductor Capability.jmp.
2. Select Cols > New Columns.
3. Type 3 next to Number of columns to add and click OK.
4. Select the first new column, select Cols, and then select Formula.
5. Create the formula $NPN1/PNP1$ and click OK.

Figure 7.11 Create the Formula NPN1/PNP1

6. Select the three new columns and then select Cols > Standardize Attributes.
7. In the Standardize Properties section, select Formula from the list.
8. Select Substitute Column Reference and leave NPN1 and PNP1 selected.
Note: In this example, we want to change both NPN1 and PNP1. You can deselect the column that you do not want to change in the subsequent formulas.

9. Click OK.

A formula that is relative to the formula in the first new column is copied to the second and third selected columns.

The formulas in the second and third selected columns increment by one column.

- Original formula in the first column: NPN1/PNP1
- Relative formula in the second column: PNP1/PNP2
  In the data table, PNP2 comes after PNP1.
- Relative formula in the third column: PNP2/NPN2
  In the data table, NPN2 comes after PNP2.

Note: Some columns in Semiconductor Capability.jmp were deleted to show the new columns X, Y, and Z in Figure 7.13.

See “Example of Standardizing a Formula” on page 333 in the “Set JMP Column Properties” chapter for another example.
Order Expressions in Formulas

As you build a formula, keep in mind that all functions have an order of precedence shown in the following table, where level one is the highest order of precedence. Expressions with a high order of precedence are evaluated before those at lower levels. When an expression has operators of equal precedence, it is evaluated from left to right. You can use parentheses to override other precedence rules when necessary because any expression within parentheses is always evaluated first. Terms have no order of precedence because they cannot be evaluated further. Table 7.3 shows the first six levels of the order of precedence.

Table 7.3 Order of Precedence of Operators in Formulas

<table>
<thead>
<tr>
<th>Level</th>
<th>Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Parentheses</td>
</tr>
<tr>
<td>2</td>
<td>Functions in the Functions lists, And, Or, Not</td>
</tr>
<tr>
<td>3</td>
<td>*, ÷, Modulo</td>
</tr>
<tr>
<td>4</td>
<td>+, -</td>
</tr>
<tr>
<td>5</td>
<td>Comparisons: &lt;, ≤, =, ≠, ≥, &gt;, ≤ x ≤, &lt; x &lt;</td>
</tr>
<tr>
<td>6</td>
<td>Logical Operators &amp;,</td>
</tr>
</tbody>
</table>

Note: When a function has an expression as its argument, the argument has a higher order of precedence than it would if enclosed in parentheses outside the function.

Build a Formula in Order of Precedence

It is best to build a formula starting with any expression that serves as an argument. This is because functions have a high order of precedence and are always grouped with their corresponding arguments. It is also a good idea to create expressions working from highest to lowest order of precedence when possible. If you need parentheses, be sure to enter the open parenthesis before entering the expression to be enclosed.

For example, given a data table with the columns A, B, and C, use the following steps to compose the expression \( A(B + C) \). Note that this expression is not the same as \( A \times B + C \), which evaluates as \( (A \times B) + C \).

To enter the expression, follow these steps:
1. Click column A in the Columns list. A
2. Click the multiplication button \( \times \) in the Formula Editor keypad. A \( \times \)
3. Enter an open parenthesis. $A \cdot (\phantom{B})$
4. Click column B in the Columns list. $A \cdot (B)$
5. Click the addition button $+$ in the Formula Editor keypad. $A \cdot (B + C)$
6. Click column C in the Columns list. $A \cdot (B + C)$

Because the order of precedence determines which arguments are affected by each functions, it also affects the grouping of expressions. Select functions in the formula to verify how the order-of-precedence rules have been applied.

**Structure Formulas for Efficient Evaluation**

Usually, it is not necessary to structure formulas with efficient evaluation in mind. Most formulas evaluate almost instantaneously regardless of their structure. This is because statistical functions and constant expressions are evaluated only once when a column’s values are calculated.

However, when you are creating conditional expressions, keep in mind that Match evaluates faster and uses less memory than an equivalent Condition function, If. (Note that Match ignores trailing spaces and If does not.)

For example, using Big Class.jmp, you can predict a child’s height from his age as shown in Figure 7.14. There is a base height of 58.125 inches to which a quantity is added depending on the value of the age variable.

**Figure 7.14** The Match Conditional Evaluates Faster Than the If Function

![Figure 7.14](image)

The Match conditional evaluates faster than the If function because the age variable is evaluated only once for each row in the data table. The If condition must evaluate the age variable at each If clause for each row until a clause evaluates as true.
JMP Formula Editor Options

The Formula Editor provides robust options for creating and managing formulas.

- “Calculate Derivatives of JMP Functions”
- “Simplify Complex Formulas”
- “Evaluate Formulas”
- “Ignore Errors in Formulas”
- “View Formulas in JSL”

Calculate Derivatives of JMP Functions

The JMP Formula Editor can find and display the derivative of a function. The derivative is found with respect to the function argument (a single variable name) you highlight. Therefore, in order to differentiate with respect to \( x \), \( x \) must be one of the arguments in the expression. The red triangle menu next to the keypad contains the Derivative command.

To calculate a derivative, follow these steps:
1. Enter a function.
2. Highlight a variable.
3. Select Derivative from the menu.

Figure 7.15 Using the Derivative Option

Simplify Complex Formulas

When the Formula Editor contains a complex formula, JMP can simplify it using various algebraic rules. It can find constant expressions, distribute multiplication over addition, combine terms, and more.
To simplify complex formulas, follow these steps:

1. Select a portion or all of the formula.
2. Click the red triangle next to the keypad.
3. Select **Simplify** from the list as shown in Figure 7.16.

**Figure 7.16** Selecting Simplify (Left) Produces a Simplified Formula (Right)

---

**Evaluate Formulas**

By default, JMP evaluates each formula that you create. You can turn this evaluation off, or you can use it before you have finished creating a formula.

**Suppress Evaluation**

Turning off evaluation is a useful formula development mode for building complex formulas. You can turn off evaluation and build sections of a formula, and evaluate only to test it. In particular, you can close the Formula Editor and reopen it at a later time to continue building a formula without JMP evaluating it.

To suppress formula evaluation, click the red triangle next to the keypad and select **Suppress Eval**. When evaluation is suppressed, the formula icon appears dimmed.

Note the following:

- If the icon appears to the right of the red triangle in the Formula Editor, it indicates that formula evaluation is suppressed for that formula.
- If the icon appears beside the column name in the Columns panel, it indicates that the values in the column result from a formula. When formula evaluation is suppressed, this formula icon appears dimmed. See “Icons Representing Column Characteristics and Properties” on page 41 in the “Get Started with JMP” chapter.
• To turn off formula evaluation for all formulas, click the red triangle next to the data table name and select **Suppress Formula Eval**. To re-evaluate formulas, click the red triangle next to the data table name and select **Rerun Formulas**. You can also click the **Apply** button in the Formula Editor for each column that contains a pending formula.

• When you turn off formula evaluation, edit a formula, and click **Apply**, you are prompted for whether to evaluate the formula. To allow formula evaluation once, click **Evaluate formula this time**.

### Ignore Errors in Formulas

Once you construct a formula and click **OK**, JMP checks behind the formula for error and alerts you of any errors that it finds. An error message appears for each error and asks whether you want to ignore further errors.

Sometimes you might want to suppress error messages while a formula is under development. For example, you might want the evaluated values for some rows without seeing an error message for each row that causes errors.

To ignore errors, follow these steps:

1. Create a formula.
2. Click the red triangle next to the keypad and select **Ignore Errors**.

### View Formulas in JSL

You have the option of entering or changing any part of a formula in *text mode*. Text mode displays the formula in the JMP Scripting Language (JSL). The entire formula (or any of its terms) appears in the Script Editor when you double-click the formula. If the formula is long, it opens in a maximized Script Editor window. Otherwise, you can click the **Maximize editor** button to maximize the window.

Any element of a formula can be displayed in the Script Editor and then edited. After editing formula scripting commands, click outside the formula (or click **OK** below the maximized window) to see its formatted form and to save the change. To enter an If statement in text form, add pairs of arguments for each If/Then clause in the statement, and a single last argument for the else clause if needed. In text form, the If statement in Figure 7.17 looks like this: `If(:total!=0, (:count/:total)*100, 0)`.

**Figure 7.17** An If Statement in Formula Mode
Edit Formulas

Edit formulas by using the keypad; using arrows to select expressions; cutting, copying, and pasting; deleting functions, and dragging expressions.

- “Correct Mistakes in Formulas”
- “Select Expressions in Formulas”
- “Delete Functions Formulas”
- “Cut, Copy, and Paste Formulas”
- “Click and Drag Formulas”

Correct Mistakes in Formulas

If you make a mistake while entering a formula in the JMP Formula Editor, press Ctrl+Z. This reverses the effect of the last (undo-able) command.

Other commands to help modify formulas include the following:

- Click the delete button (-delete) on the Formula Editor keypad to remove the selected expression.
- Use the cut, copy, and paste keyboard shortcut commands or right-click a highlighted part of the formula and select Cut, Copy, or Paste from the menu.
- Drag portions of the formula to rearrange them.

Select Expressions in Formulas

Use the keyboard arrow keys to select expressions for editing in the JMP Formula Editor. You can also use the arrow keys to view the formula’s order of precedence when either parentheses or the boxing option are not present. (See “Hide and Show Outlines Formulas” on page 420.)

Clicking an operator (+, −, *, ÷) in an expression selects the operator and its operands. A blue box appears around the items. Once an operator is selected:

- The left and right arrow keys move the selection across other associative operators having equal precedence within the expression.
- The up arrow extends the current selection by adding the operand and operator of higher precedence to the selection.
- The down arrow reduces the current selection by removing an operand and operator from the selection.
Delete Functions Formulas

Deleting a function also deletes its arguments; deleting a required argument or missing term from a function sometimes deletes the function as well. In the JMP Formula Editor, you can peel a function to delete it from its argument.

To peel a function from a single argument, follow these steps:

1. Select the function.
2. Click the peel button \( \text{Peel} \) in the Formula Editor keypad. Or use the hand tool to drag the argument on top of its function.

3. Complete formula changes.
4. Click **Apply**, and the new values fill the data table column automatically.
5. Once you have created a formula, you can change values in columns that are referenced by your formula. JMP automatically recalculates all affected values in the formula’s column.

Cut, Copy, and Paste Formulas

You can cut or copy any expression or an entire formula and paste it into another formula in the JMP Formula Editor. Use the cut, copy, and paste shortcut commands or right-click a highlighted part of the formula and select **Cut, Copy, or Paste** from the menu. The following aspects apply when you cut, copy, and paste a formula:

- When you paste it into another formula display, the formula appears in formatted form.
- The formula is saved on the clipboard as a JSL statement. Thus, if you copy it into other applications, it appears as a JMP Scripting Language (JSL) statement.

**Note:** Press Shift and click the red triangle to reveal a command called **Copy As SAS Formula**.

Click and Drag Formulas

In the JMP Formula Editor, you can drag any part of a formula that can be selected to any other location that can be selected.
To click and drag in a formula, follow these steps:

1. Place the arrow cursor inside an expression.
2. Click the expression.
3. Drag across the formula. Destination expressions have a dotted outline.

**Figure 7.19** Dragging an Expression

4. Drag the selected expression to the new desired location. The selected expression is moved to the new location, where it replaces the existing expression.

**Customize Formulas in the JMP Formula Editor**

There are several ways that you can customize formulas in the JMP Formula Editor.

- “Hide and Show Outlines Formulas”
- “Change the Font Size Formulas”
- “Specify the Matrix Size Formulas”
- “Change the Orientation of a JMP Formula”
- “Open and Close Arguments Formulas”

**Hide and Show Outlines Formulas**

By default, JMP outlines specific terms within the formula. This is called boxing. Boxing is useful when you want to select and modify a specific portion of a formula, or need to determine the order of evaluation that takes place.

To turn boxing on or off, follow these steps:

1. Build a formula.
2. Click the red triangle next to the keypad and select **Show Boxing**. When a check appears on the menu beside **Show Boxing**, the outline appears in the formula. When it does not, the outline does not appear.
Change the Font Size Formulas

To incrementally increase or decrease the font used to display the formatted formula, follow these steps:

1. Click the red triangle next to the keypad.
2. Select Larger Font or Smaller Font.
3. Repeat this process to further increase or decrease the font size.

Specify the Matrix Size Formulas

You can set the maximum width and height of matrices by selecting Max matrix size to show from the red triangle menu. If the width or height is greater than the specified size, the matrix dimensions show instead of the data. You can still see the data by editing the formula in the text editor window.

Change the Orientation of a JMP Formula

By default, JMP determines the size of a formula and displays it in the Formula Editor in the best orientation (horizontally or vertically). However, if you create a long formula, you might want to display it in a different layout.

To change a formula’s orientation, follow these steps:

1. Build a formula.
2. Highlight an argument or formula.
3. Right-click what you have highlighted.
4. Select Orientation.
5. Select from the Orientation options: Best, Horizontal, or Vertical.

Open and Close Arguments Formulas

When a formula is too large to fit on the screen, you can close formulas and arguments.

To close an argument, follow these steps:

1. Build a formula.
2. Highlight an argument or formula.
3. Right-click what you have highlighted.
4. Select Close or Close Arguments from the menu that appears.
Examples of Building Formulas in the JMP Formula Editor

To better familiarize yourself with building formulas, review the following examples and tutorials.

- “Use Basic Features in the JMP Formula Editor”
- “Use Local Variables Formulas”
- “Use the Munger Function Formulas”
- “Use the Match Conditional Function Formulas”
- “Use the Delete Expression Button Formulas”

Use Basic Features in the JMP Formula Editor

The following example uses the Big Class.jmp sample data table to walk you through using the basic features of the Formula Editor. You can find Big Class.jmp in the sample data folder, which was installed when you installed JMP.

Big Class.jmp has a column called weight. Suppose you want a new column that computes standardized weight values.

To create this column using a formula to obtain its values, follow these steps:

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Cols > New Columns.
3. Type the new name, standard weight, in the box beside Column Name.
4. Select Formula from the Column Properties menu.
5. Click the empty formula element in the formula editing area to select it.

When you create a formula and Show Boxing is checked, the selected portion of the formula is outlined with a thin blue line. See “Hide and Show Outlines Formulas” on page 420. All terms within the smallest nesting box relative to the place that you clicked become selected, and the subsequent action applies to those combined elements.

Next, enter the formula that standardizes the weight values.

1. While the initial missing term is selected, click weight in the Columns list.
2. Click the minus button in the Formula Editor keypad.
   A new missing term appears after the minus sign as shown in Figure 7.20.
3. Click weight again.
4. Click the Functions list, and select Statistical.
5. Select **Col Mean** from the Statistical list.
6. Select the entire expression.
   
   The blue box should now enclose the whole formula.
7. Click the division button **÷** in the keypad.
   
   The result gives a selected missing denominator for the whole expression.
8. Click **weight** again from the column selector list.
   
   It becomes selected in the denominator.
9. Select **Col Std Dev** from the Statistical list.

**Figure 7.20** Building a Formula

10. Close the Formula Editor by clicking **OK**.
11. Close the Column Info window by clicking **OK**.

In the data table, the new **Standard Weight** column fills with values. When a weight value changes, the calculated **Standard Weight** value automatically recalculates.
Use Local Variables Formulas

Suppose you want to compute the slope in a simple linear regression of \( y \) on \( x \) using the standard formula shown in Figure 7.21. One way to do this is to create two local variables, and name them \( XY \) and \( Xsqrd \). (See “Use Local Variables in Formulas” on page 400.) Then assign them to the numerator and the denominator calculations of the slope formula. Delimit each assignment with a semicolon, as shown in Figure 7.21. (Statements in the Formula Editor are actually JSL programming statements. Multiple statements in a formula must be separated by a semicolons.) The slope computation is simplified to \( \frac{XY}{Xsqrd} \).

**Figure 7.21** Local Variables in a Standard Slope Formula

\[
\frac{\sum (x - \bar{x})(y - \bar{y})}{\sum (x - \bar{x})^2}
\]

**Note:** You can also create local variables using the \( \equiv \) button on the on-screen keypad. Clicking this button creates a local variable with a default name in an expression and places a semicolon after it. The default name is \( t1 \), and additional local variables are named \( t2, t3 \), and so on. You can change these default names by double-clicking and editing the name. However, you must be careful to rename each instance of the variable to avoid errors.

Use the Munger Function Formulas

The following examples show uses of the Munger function. In these examples, assume that there is a character column of names with “Veronica Layman” as one of its values. To simplify the examples, the literal name “Veronica Layman” is the search string instead of a column name.

For instructions on how to incorporate Character functions, such as Munger, into a formula, see “Character Functions” on page 737 in the “Reference for JMP Functions in Formulas” appendix.
Insert Characters

This Munger example finds the blank between the first and last name, and inserts the middle initial “J.” The formula Munger("Veronica Layman", 1, " ", " J. ") inserts the middle initial J., and evaluates as Veronica J. Layman.

Double quotation marks are required by the Munger function for literal strings, including strings that consist of a blank or when leading or trailing blanks are part of a string.

Delete Characters

To delete one or more characters from a string, follow these steps:

1. Designate the characters to delete as the Find string in the Munger function.
2. Enter an empty Replace string: two quotation marks with nothing between them.

For example, the function, Munger("Veronica Layman", 1, "onic", "") removes the “onic” from Veronica and evaluates as Vera Layman.

**Note:** A Replace field with a null (no value) string enclosed in quotation marks is different from a Replace field with no value. If you delete the Replace string altogether, Munger shows the argument name (“Replace”) in the Formula Editor window and behaves as if that optional argument does not exist. The resulting data type can also change from character to numeric, depending on the value of the Find/Length argument.

Find the Position (Index) of a Value

When the Find/Length field contains characters, Munger behaves like an index function and returns the numeric position of the first instance of the search string if it exists. For example, Munger("Veronica Layman", 1, " ") searches for a single blank and finds it in position nine. If the search string is not found, Munger returns a zero. This use of Munger produces the same result as the Contains function, as shown in “Character Functions” on page 737 in the “Reference for JMP Functions in Formulas” appendix.

Find a Substring

Munger can extract substrings. For example, to extract only the first name, Munger("Veronica Layman", 1, 8,) starts at position one and reads through position eight. The remaining characters are ignored because the replace argument is not defined. This yields “Veronica” and produces the same result as the Substring, as shown in “Character Functions” on page 737 in the “Reference for JMP Functions in Formulas” appendix.

An alternative way to find a substring is with a start value, any negative find value, and a **no replace** argument. Munger("Veronica Layman", 9, –1,) returns “Layman”.

Use the Match Conditional Function Formulas

This example walks you through using the Match conditional function.

Suppose that you want a Match conditional for the nominal variable Type from the Hot Dogs.jmp sample data table.

1. In the Formula Editor, select Type from the Columns list.
2. Select Conditional from the Functions list.
3. Select Match.
4. Select Add Match Arguments from Data.
   The values are automatically filled in.

---

**Note:** Rather than complete step 2 through step 4, press Shift, select Conditional from the Functions list, and then select Match.

---

**Figure 7.22** Automatically Filling a Match Conditional Statement

![Match conditional example](image)

If you do not want the values filled in for you, select **Do Not Add** from the Match list instead of **Add Arguments from Data**.

Use the Delete Expression Button Formulas

The following steps illustrate the results of repeatedly clicking the delete expression (or peel) button:

1. Start with a formula.
   ![Formula example](image)

2. Select a formula element.
   ![Formula example](image)

3. Click the delete expression button.
   ![Delete expression button](image)
4. Click the delete expression again.

5. Click the delete expression again.

6. Click the delete expression again.

7. Click the delete expression again.

8. Click the delete expression again.

9. Click the delete expression again.

**Keyboard Shortcuts for the JMP Formula Editor**

Table 7.4 describes the keyboard shortcuts that you can use in the JMP Formula Editor.

Glossary of Terms for the JMP Formula Editor

The following terms are used in the Formula Editor:

**Element** The name of a constant, table variable, local variable, or parameter that appears in the element browser list.
**Argument**  Any element or an entire expression (including mathematical operands) that is operated on by a function. Arguments are always grouped with functions. To find which expressions serve as a function’s arguments, select that function in the formula.

\[
\text{Sine} (\text{name})
\]

**Term**  Indivisible parts of an expression, such as constants and variables.

\[
\text{Trim} (\text{first name} | \text{last name})
\]

**Expression**  Any part of a formula that can be selected as a single unit, including terms, missing terms, and functions grouped with their arguments, as well as the entire formula.

\[
\frac{10}{(A + B + C)}
\]

**Clause**  A complete segment in a conditional function.

\[
\text{if} (\text{expr} \Rightarrow \text{then clause}) \text{ else } \text{else clause}
\]

**Function**  A mathematical or logical operation that performs a specific action on one or more arguments. Functions include most items in the Functions list and all keypad operators. Functions always operate upon selected expressions, and arguments are always grouped with functions. To find which expressions serve as a function’s arguments, select that function in the formula.

The boxed groupings also show how order-of-precedence rules apply and show which arguments are deleted when you delete a function. See “Order Expressions in Formulas” on page 413.

\[
\text{Col Std Dev} (\text{weight})
\]

**Missing term**  Any empty place holder for an expression, represented by an empty box.

\[
A + \square + D
\]

**Missing value**  Excluded or null data consisting of the missing value mark (●) for numeric data or null character strings for character data.

Add a Statistics Column to an Existing Summary Table .............. 437
Explanation of Summary Statistics ......................................... 438
Example of Creating a Summary Table with Groups .................. 440
Summarize Columns

The Tables > Summary command calculates various summary statistics, including the mean and median, standard deviation, minimum and maximum value, and so on.

Summary tables have the following characteristics:

- A single row exists for each level of a grouping variable that you specify. If no grouping variable is specified, a single row exists for the full data table.
- When there are several grouping variables, the table contains rows for each combination of levels of all the grouping variables.
- In addition to one column for each grouping variable, the table contains frequency counts in a column named N Rows with counts for each grouping level.
- The summary table can be linked to its source table. When you select rows in the summary table, the corresponding rows are highlighted in its source table.
- If the source table’s column(s) contain value labels, the value labels are displayed in the new table.
- A summary table is not saved when you close it unless you select File > Save As to give it a name and location.

Summary Launch Window

Statistics  Defines the summary statistics (such as mean, standard deviation, and median) for a numeric column in the source table. See “Add Summary Statistics” on page 434.

Group  Summarizes the statistics by group. See “Use One or More Grouping Columns” on page 435.

Subgroup  Summarizes the statistics by subgroup. See “Create a Two-Way Table of Summary Statistics by Adding a Subgroup Variable” on page 437.

Freq  Identifies a column whose values assign a frequency to each row.

Weight  Identifies a column whose values assign a weight to each row.

Create a Summary Table

To create a summary table, follow these steps:

1. Open a data table.
2. Select Tables > Summary.
3. Highlight the columns that you want to summarize.
4. Add summary statistics, groups, subgroups, frequency variable, weight variable, and select any options needed:
   - “Add Summary Statistics” on page 434
   - “Use One or More Grouping Columns” on page 435
   - “Use Quantile Statistics” on page 436
   - “Change the Format of the Statistics Column Name” on page 436
   - “Link to the Original Data Table” on page 436
   - “Prompt to Save When Closing Linked Summary Tables” on page 437
   - “Keep the Summary Window Open” on page 437
   - “Create a Two-Way Table of Summary Statistics by Adding a Subgroup Variable” on page 437
4. Name the summary table by typing a name in the box beside **Output table name**.
6. Click **OK**.

**Notes:**

- When the summary table is linked to the original data table, you cannot edit the data in the summary table, because that would modify and compromise the original data. To edit the data, create a subset of the summary table or save the table, close the table, and reopen it.
- When you select a column that has a Units column property, that value is included in the column header.

**Add Summary Statistics**

You can add columns that display summary statistics (such as mean, standard deviation, median, and so on) for any numeric column in the source table.

1. In the Summary window, highlight the column that you want to use in calculating the statistics.
2. Click the **Statistics** button.
3. Select one of the standard univariate descriptive statistics from the Statistics list. The statistics are described in “Explanation of Summary Statistics” on page 438.
Use One or More Grouping Columns

If you want the statistics summarized by group, highlight the column(s) that you want to be your grouping variables and click Group to move the variable into the grouping variables list. See “Example of Creating a Summary Table with Groups” on page 440, for an example. If you add only grouping variables, the summary table shows a count for each group.

To change the order of the grouping variables

To change the order of the grouping variables (ascending or descending order), select a variable in the grouping variable list and click the ascending or descending button (↑ or ↓). The icon beside the variable changes to indicate the sorting order.

You can also change the order of the grouping variables using the Value Order column property. See “Value Order” on page 308 in the “Set JMP Column Properties” chapter.

To include marginal statistics

To add marginal statistics (for the grouping variables) to the output columns, click the box beside Include marginal statistics. In addition to adding marginal statistics for each grouping variable, JMP adds rows at the end of the table that summarize each level of the first grouping variable.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Tables > Summary.
3. Select Profits ($M) and click Statistics.
4. Select Mean.
5. Select Type and Size Co and click Group.
6. Select Include marginal statistics.
7. Click OK (or Create). See Figure 8.2 at left.

Figure 8.2 Summary Table with and without Marginal Statistics
Summarize Your Data
Chapter 8
Using JMP

Compare the summary table with marginal statistics (at left) to the summary table without marginal statistics (at right). You can see that the marginal statistics are added, and a row showing that there are 32 total Computer and Pharmaceutical companies.

Use Quantile Statistics

To add specific quantile statistics, follow these steps:

1. In the box under **For quantile statistics, enter value (%)** type the desired quantile value (%) for the first quantile (for example, 25).
2. Select the applicable column and click **Statistics**.
3. Select **Quantiles**.
4. (Optional) Repeat this process for any additional quantiles.

Change the Format of the Statistics Column Name

To change the format of the statistics column name in the summary table, select from one of the formats in the **statistics column name format** menu. Table 8.1 illustrates the available options. Assume that you are creating a summary table of the mean profits for a company. Your original column name is **Profits ($M)**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>stat (column)</td>
<td>Mean (Profits ($M))</td>
</tr>
<tr>
<td>column</td>
<td>Profits ($M)</td>
</tr>
<tr>
<td>stat of column</td>
<td>Mean of Profits ($M)</td>
</tr>
<tr>
<td>column stat</td>
<td>Profits ($M) Mean</td>
</tr>
<tr>
<td>stat</td>
<td>Mean</td>
</tr>
</tbody>
</table>

**Table 8.1** Statistics Column Name Format Options and Examples

Link to the Original Data Table

You can select whether to link the summary table to the original data table. By default, the **Link to original data table** option is selected. If you want to edit the data in the summary table, deselect the **Link to original data table** option. When the summary table is linked to the original data table, you cannot edit the data in the summary table, because that would modify and compromise the original data. To edit the data, create a subset of the summary table or save the table, close the table, and reopen it.
Within linked tables, if you drag columns from the summary table into the column heading of a new column in the original data table, the values are expanded as if they were matched by grouping columns.

**Prompt to Save When Closing Linked Summary Tables**

To be prompted to save an unsaved linked summary table when you close it, select `Prompt to save when closing summary tables`. When you select this option in the Summary window, it is selected in the Tables preferences. If you do not want to be prompted to save linked summary tables in the future, deselect the preference.

**Keep the Summary Window Open**

If you select the `Keep dialog open` option, the Summary window remains open after you click `Apply`. Notice that once you select this option, the OK button is replaced by a Create button.

**Create a Two-Way Table of Summary Statistics by Adding a Subgroup Variable**

1. Highlight the column(s) that you want to be the nested variable(s). These are your “subgroup variable(s).”
2. Click `Subgroup` to move the variable(s) into the subgroup list.
3. Highlight the column for which you want statistics summarized by subgroup.
4. In the Statistics list, select the specific statistic that you want.
5. Click `OK`.

For more information about the types of statistics, see “Explanation of Summary Statistics” on page 438.

**Add a Statistics Column to an Existing Summary Table**

After you have created a summary table, you can add columns of descriptive summary statistics for any numeric column in the source table. To do so, from an existing summary table, click the upper red triangle in the data grid and select `Add Statistics Column`.

**Example of Adding a Statistics Column to an Existing Table**

Suppose that you have already created a summary table, and you want to add more statistics to the existing summary table.

1. Select `Help > Sample Data Library` and open `Companies.jmp`.
2. Select `Tables > Summary`.
3. Select Type and Size Co and click `Group`.
4. Click **OK**.
5. Click the red triangle in the Columns panel, select **Add Statistics Column**.

**Figure 8.3** Creating a Summary Statistics Column from Within a Data Table

A modified version of the Summary window appears.

6. Select the column that you want, click **Statistics**, and select the specific statistic that you want. For this example, select **profit/emp** and click **Statistics**, and then select **Mean**.
7. Click **OK**.

**Figure 8.4** Example of a Summary Table with a Summary Statistics Column

The **Mean(profit/emp)** column is added to the existing summary table.

---

**Explanation of Summary Statistics**

You can add columns of descriptive summary statistics for any numeric column in the source table by clicking the Statistics button and making a selection from the menu.

The Statistics menu gives these summary statistics for numeric columns:

- **N**  The number of nonmissing values.
Mean  The arithmetic mean of a column’s values. It is the sum of nonmissing values (and if defined, multiplied by the weight variable) divided by the Sum Wgt.

Std Dev  The sample standard deviation, computed for the nonmissing values and calculated with the specified weight variable. It is the square root of the sample variance. The formula follows:

\[ s = \sqrt{s^2} \quad \text{where} \]
\[ s^2 = \frac{\sum_{i=1}^{N} w_i(y_i - \bar{y}_w)^2}{N - 1} \]
\[ \bar{y}_w = \text{weighted mean} \]

Min  The smallest nonmissing value in a column.

Max  The largest nonmissing value in a column.

Range  The difference between Max and Min.

% of Total  The percent of the total count for each group. Or, if you have so specified, the percent of nonmissing values of the column to the total count for each group.

N Missing  The number of missing values.

N Categories  The number of distinct categories.

Sum  The sum of all values in a column.

Sum Wgt  The sum of all weight values in a column. (See “Column Properties in JMP” on page 303 in the “Set JMP Column Properties” chapter.) Or, if no column is assigned the weight role, Sum Wgt is the total number of nonmissing values.

Variance  The sample variance, computed for the nonmissing values. It is the sum of squared deviations from the mean, divided by the number of nonmissing values minus one.

Std Err  The standard error of the mean. It is the standard deviation divided by the square root of N. If a column is assigned the role of weight, then the denominator is the square root of the sum of the weights.

CV (Coefficient of Variation)  The measure of dispersion, which is the standard deviation divided by the mean multiplied by one hundred.

Median  The 50th percentile, which is the value where half the data are below and half are above or equal to the 50th quantile (median).

Median Absolute Deviation  The median of the absolute deviation from the data’s median.
**Geometric Mean**  The \( n \)th root of the product of the data. For example, geometric means are often used to calculate interest rates. The statistic is also helpful when the data contains a large value in a skewed distribution.

*Note:* Negative values result in missing numbers, and zero values (with no negative values) result in zero.

**Interquartile Range**  The difference between the third and first quartiles.

**Quantiles**  the value at which the specific percentage of the argument is less than or equal to. For example, 75% of the data is less than the 75th quantile. The summary window has an edit box for entering the quantile percentage that you want.

**Histogram**  Generates histograms for different groups. Images of the histograms are saved in data table Expression columns.

---

### Example of Creating a Summary Table with Groups

Suppose a researcher is working with Companies.jmp, which groups companies by Type and Size. Follow along with this next example by opening Companies.jmp from the sample data folder that was installed when you installed JMP.

Suppose that the researcher wants to perform the following tasks:

- Create a table that shows the average profit per employee for small, medium, and big computer and pharmaceutical companies. In other words, create a table that contains a row for each size company and a column for the mean profit per employee of each type of company.
- Create it so the cells hold the mean for the subgroup (defined by the intersection of the row and column).

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. Select **Tables > Summary**.
3. Select Size Co and click **Group**.
   - The researcher selects Size Co as the grouping variable because he wants the values in that column to become rows in the new table.
4. Select profit/emp and click **Statistics**.
5. Select **Mean**.
6. Select Type and click **Subgroup**.
   - This tells JMP to create a column for the average profit per employee (Mean(profit/emp)) for each level (computer, pharmaceutical) of subgroup variable (type).
Figure 8.5 Summary Statistics for a Subgroup

Note: The summary table is named after the Group column name. If the column name contains characters that are not allowed in file names, a hyphen is substituted for the special character.

JMP Reports

Navigate and Customize Report Windows

Most JMP platforms present the results of your analyses in a report window. The report window consists of graphs and statistical reports that are often linked to the data table. When you select data in the graph or report, the data is highlighted in the data table. Figure 9.1 shows an example of selected data in a report window and in a data table.

This chapter describes how to customize the colors, lines, data points, and other graphical elements in a report window.

<td>and drag the cursor to scroll along the axis or to rescale the axis.</td>
</tr>
<tr>
<td></td>
<td>See “Scroll and Scale Axes in Graphs” on page 495.</td>
</tr>
</tbody>
</table>
**Tip:** Consider setting the *Autosave timeout* value in the General preferences to automatically save open reports at the specified number of minutes. This autosave value also applies to data tables, journals, scripts, projects, and reports.

### Use the Hand Tool

Select the hand tool using the Tools > Grabber option. There are many functions that you can use with the hand tool (also known as the grabber tool) in a report. Here are some examples of how the hand behaves in graphs and plots:

- On histograms, for continuous variables, use the hand tool to change the number of bars or to shift the boundaries of the bars.
- In all report tables, use the hand tool to click and drag columns for rearranging.
- Use the hand tool to change the displayed range of axis values. See “Scroll and Scale Axes in Graphs” on page 495.

### Display Options for JMP Reports

Right-click a disclosure icon to show a menu that lets you rearrange the report and gives you control over report outline levels. The resulting menu has the following report formatting options:

**Close** Closes (hides) that section of the report. This can also be accomplished by clicking the disclosure icon.

**Horizontal** If available, the option switches the outline of the report between a vertical and horizontal layout.

**Open All Below** Opens all outline levels beneath the level where this command is selected, including that level.

**Close All Below** Closes all outline levels beneath the level where this command is selected, including that level.

**Open All Like This** Opens all of the same type of reports as the one that is present in the analysis window. If you analyze several variables at a time, you often want to open many of the same type of report tables all at once. You might also want to open all of the same type of report tables at once when you select multiple options on a single analysis.

**Close All Like This** Closes all of the same type of reports as the one that is present in the analysis window.
Close Where No Outlines  Closes all parts of the report that do not have sublevels. This command is usually used at the top level of the report outline. It is a quick way to see a nesting structure overview of a report.

Outline Close Orientation  Specifies the orientation of the outline box when the disclosure icon is clicked closed. Available options are Auto, Horizontal, or Vertical. Default orientation is Auto.

Append Item  Displays a submenu, which lists ways that you can add structural items to the report. Items include text, outline title bars, references to other JMP files and windows, a list of all open JMP files, URLs, and scripts.

Add Text Item  Opens a window that enables you to add up to six text items. You can select whether the text items appear with a bullet or initially appear hidden. Note: You must click exactly on a hidden text box for the text item to become visible.

Add Outline Item  Open a window that enables you to add a titled outline box. Note: The appended outline box contains a red triangle menu listing the append menu items.

Add Window Reference  Opens a window that enables you to select an open JMP window for adding as a link to the selected outline box.

Add File Reference  Displays the Open Data File window that enables you to select a file for adding as a link to the selected outline box.

Add Directory of Files  Displays the Choose directory window that enables you to select a directory for adding as a link to the selected outline box. Note: Links to each file in the selected directory are appended to the outline box.

Add All Open Files  For each file open in JMP, a new outline box is added. It contains a link to the file.

Add URL Reference  Opens the Create Link to URL window that enables you to add a Link Name and URL. The URL reference link is added to the selected outline box.

Add Script Button  Opens the Add Script Button window that enables you to add a named link to the selected outline box. Clicking the added link runs the specified script.

Size to Fit  Resizes the outline to fit the width of the inside graph or report.

Show Properties  Enables you to modify the formatting of display boxes in the report. Properties include graph axis elements such as tick lines,

Tip: You can modify some properties directly in the report by selecting one or more display boxes with the Selection tool and hovering over the display box until a popup property editor appears.
Edit Displays a submenu that contains the following options, which affect all reports at the outline level where they are used:

Select Highlights all reports for that outline level.

Deselect Deselects all selected reports for that outline level.

Journal Duplicates the report in a separate window titled Journal so that you can edit it or append other reports to it. See “Create Journals” on page 607 in the “Save and Share Your Data” chapter.

Copy Picture Copies the report to the clipboard. You can then open another application and paste it.

Page Break Inserts a page break for printing purposes.

Show Tree Structure Opens a window that shows the display boxes that make up the report. This is mainly used by JSL programmers who are manipulating or reading parts of the report. See the Scripting Guide.

Restore Window Size (Appears only if the window size has been modified from its original size.) Returns the selected window to its original size.

An alternative way to access these options is to press Alt and right-click the disclosure icon. This displays a window, as shown in Figure 9.3, with check boxes for commands and options so that you can select multiple actions at the same time. You can also do the same for the menu under a red triangle menu.

Figure 9.3 Outline Box Menu Items Window
Show and Hide Parts of a JMP Report

JMP reports are organized in a hierarchical outline. Each level of the outline has a triangle-shaped disclosure icon. Click the disclosure icon to open and close that section of the report.

You can also change which columns appear in a report. Right-click the report and select the column from the Columns list. To select more than one column at once, press Alt before right-clicking.

Combine Several Reports

Suppose that you perform multiple analyses and want to show all of the results (and the data table) in one window. You can select and combine the reports and the data table in several ways. See “Example of Combining Windows to Create a Dashboard” on page 631 in the “Combine and Present Reports Using Dashboards” chapter.

Rename Titles in Reports

To rename a title in a report, double-click any of the following titles:

- a title next to a red triangle menu
- a title next to a disclosure icon
- a column title

Increase Font Sizes in Reports

On Windows, change the font size that JMP uses in reports and data tables by selecting Window > Font Sizes. Then choose from one of the submenu items:

Increase Font Size Increases the font size. Select again to increase the font size again.

Decrease Font Size Decreases the font size. Select again to decrease the font size again.

On macOS, select View > Make Text Bigger or View > Make Text Smaller.

Resize a Report Window

Report windows are automatically sized to fit the contents of the window. On Windows, you can automatically resize a window after manually resizing it. Press Ctrl and click the lower right corner of the window.
Red Triangle Options in JMP Reports

Click the red triangle menu in a report to access a list of options that apply for that particular report. In addition to clicking the red triangle menu, you can also:

- Select multiple actions at the same time. Press Alt and click the red triangle menu. A panel of all commands and options appears with check boxes.

- Apply a command to all similar reports in the report window. Press Ctrl and click the red triangle menu. For example, in a One-way analysis, if you press Ctrl, click the icon, and select Means/Anova/Pooled t Test, an analysis of variance is performed for all One-way analyses in the active report window.

The red triangle options applicable to each platform in the Analyze and Graph menus are described in the following JMP documentation:

- Basic Analysis
- Consumer Research
- Essential Graphing
- Fitting Linear Models
- Multivariate Methods
- Profilers
- Quality and Process Methods
- Reliability and Survival Methods
- Predictive and Specialized Modeling

Local Data Filters in Reports

Local Data Filters limit the scope of the filter to the output of the platform that you are in. For example, suppose that you have data on the profits of 30 different computer and pharmaceutical companies. You want to examine profits by company type. You can run a distribution and then use the Local Data Filter to narrow the results in the Distribution platform to the type of company.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Profits ($M) and click Y, Columns.
4. Click OK.
5. Click the Distributions red triangle and select Local Data Filter.
6. Click Type and click Add .
7. In the Type box, click **Pharmaceutical** to see only their profits and then click **Computer** to see only their profits.

**Figure 9.4** Local Data Filter Showing Pharmaceutical Profits

---

**Note:** The red triangle menu next to a variable contains options such as inverting the selection and displaying the values in a list of check boxes. See “Red Triangle Options for Variables in Data Filters” on page 470 for more information.

**Local Filtering**

When you use a Local Data Filter, it only filters in the platform, not in the data table (as the Data Filter does). For example, if you exclude rows in a Local Data Filter, these rows are not excluded in the data table. And, if you have row states in your data table, they are not impacted by the Local Data Filter.
Saving a Filter

You can script and therefore save a Local Data Filter, so that you can access your filter settings again quickly. To save a filter, click the red triangle next to Local Data Filter and select one of the Save Script options.

Counting Excluded Rows

The counts for each level of a variable (including excluded rows) are shown in the Local Data Filter by default. To omit the excluded rows from the count, click the Local Data Filter red triangle and deselect **Count Excluded Rows**.

Figure 9.5 shows the difference between counting and omitting excluded rows. When the excluded rows are counted, the Local Data Filter shows 20 rows that contain the value “Computer”. Also, there are nine “big” values. When the excluded rows are omitted, only 16 rows contain “Computer”.

**Figure 9.5** Counting (Left) and Omitting (Right) Excluded Rows
Note: The counts are not shown when Display Options is set to Blocks Display (Figure 9.4 on page 452).

For more information about advanced scripting with Local Data Filters, see the Scripting Guide.

Using By-Groups and Subset Reports

If your analysis uses by-groups or combines together reports using linked subsets of the same table, a local data filter on the parent table can be shared between all the different by-groups and subset reports.

Using Local Data Filters in Dashboards and Applications

You can incorporate Local Data Filters into dashboards or applications:

- For an example using dashboards, see “Example of Creating a JMP Query Dashboard and Add-In” on page 635 in the “Combine and Present Reports Using Dashboards” chapter.
- For an example using applications, see the Scripting Guide.

Zoom In on Time Series Data

After you filter time series data, you can zoom in closer on the Local Data Filter histogram to see smaller time increments. Suppose that one year of data are selected on the histogram. To view smaller increments of time within that year, select **Zoom to Selection** from the red triangle menu next to the variable. Select **Reset Zoom** from the Local Data Filter red triangle menu to reset the histogram.

Redo Menus in Reports

After performing an analysis, you might want to run the analysis again using different options or variables. You might also want to perform the analysis again if data in the data table have changed. The Redo red triangle menus contain the following options:

**Column Switcher**  Lets you interactively exchange one column for another on a graph. See “Column Switcher” on page 456.

**Redo Analysis**  Duplicates the analysis based on the previous launch window settings. The analysis appears in a new report window. This option is helpful if the data have changed.

**Relaunch Analysis**  Opens the launch window and recalls the settings used to create the report.

**Automatic Recalc**  Automatically updates analyses and graphics when data table values change. See “Automatic Recalc” on page 455.
Save Script Menus in Reports

After completing an analysis and receiving a report, you might want to save the process that you used to create the report as a JSL script. You do this by selecting an option from the Script red triangle menu. Most of the Save Script options are the same throughout JMP. A few platforms add extra options that are described in the specific platform chapters. The following Save Script menu options are common to all platforms.

**To Clipboard**  Saves the script to your computer’s clipboard. You can then copy the script to a script or another document.

**To Data Table**  Saves the script to the data table that was used to produce the report. This enables you to run the script again from the data table to re-create the results. Select this option to save a script to the data table.

**To Journal**  Saves a link in a journal window that runs the script for the analysis. If a journal window is already open, the script is added to that journal window. The script contains the path to the data table. Note that if the data table cannot be found, the script does not run.

**To Script Window**  Opens a script editor window and adds the script to it. If a script window is already open, the script is added to the bottom of that open window.

**To Report**  Adds the script to the top of the report window.

**Script All By-Groups**

If you specified a By variable in the launch window, the Save By-Group Script menu enables you to save a script for all levels of the By variable to the data table or script window.

In the Save Script menu, **To Data Table (All Objects)** and **To Script Window (All Objects)** save a script for all levels of the By variable.

**Automatic Recalc**

The Automatic Recalc feature immediately reflects changes that you make to the data table in the corresponding report window. You can make any of the following data table changes:

- exclude or unexclude data table rows
- delete or add data table rows

This powerful feature immediately reflects these changes to the corresponding analyses, statistics, and graphs that are located in a report window.

To turn on Automatic Recalc for a report window, click the platform red triangle and select **Redo > Automatic Recalc**. To turn it off, deselect the same option. You can also turn on Automatic Recalc using JSL.
Platforms that support Automatic Recalc include a preference in the Platforms preferences.

**Note:** For some platforms, the Automatic Recalc feature is not appropriate and therefore is not supported. These platforms include the following: DOE, Profilers, Choice, Partition, Nonlinear, Neural, Neural Net, Partial Least Squares, Fit Model (REML, GLM, Log Variance), Gaussian Process, Item Analysis, Cox Proportional Hazard, Response Screening, and Control Charts (except Run Chart).

**Column Switcher**

Within a report, use the Column Switcher to quickly analyze different variables without having to re-create your analysis. To activate the Column Switcher, from a report window, click the red triangle and select **Redo > Column Switcher**.

If you have multiple columns, use the buttons to animate the column switching or step through each column manually. Move the slider control to change the speed of the animation.

**Note:** You cannot copy or move the column switcher within a report. Also, a column switcher cannot be saved to a JMP journal.

**Example of the Column Switcher**

You have data about nutrition information for candy bars. You want to examine different factors, to see which factors best predict calorie levels.

1. Select **Help > Sample Data Library** and open Candy Bars.jmp.
2. Select **Graph > Graph Builder**.
3. Click **Total fat g** and drag to the **X** zone.
4. Click **Calories** and drag to the **Y** zone.
5. Click **Cholesterol g** and drag to the **Wrap** zone.
6. Click the Graph Builder red triangle and select **Show Control Panel**.
7. Click the Graph Builder red triangle and select **Redo > Column Switcher**.
8. Select **Cholesterol g**.
   This chooses the initial column to switch.
9. Select **Saturated fat g**, **Cholesterol g**, **Sodium mg**, **Carbohydrate g**, **Dietary fiber g**, and **Sugars g**.
   This chooses the replacement columns.
10. Click **OK**.
11. Click the **Play** button to cycle between the different factors. Use the slider to control the speed of the animation. Alternatively, you can step through each factor individually.

Click the Looping button to specify the behavior of the animation when it reaches the last column in the Columns list.

You can see that the relationship between calories and fat is relatively strong for each level of carbohydrate. Therefore, **Carbohydrate g** appears to be the best predictor of calorie levels.

**Notes:**

- To keep axis settings constant when switching columns, select **Retain Axis Settings** from the Column Switcher red triangle menu. This is useful when you have customized an axis, for example, by adding a reference line.
- If a report has multiple column switchers, you can adjust the layout of the column switchers using the Layout options in the Column Switcher red triangle menu.
- To add new columns, do one of these options:
  - In the Column Switcher, click the plus button, choose columns, and click **OK**.
  - In Graph Builder, drag columns from the Columns list into the Column Switcher list.
  - From a data table, drag columns from the Columns panel into the Column Switcher list.
- To remove columns, click the minus button, choose the columns to remove, and click **OK**. Or, you can select the column and press the Delete key.
- To revert changes, select **Reset** from the Columns red triangle menu.
- The Record and Save buttons in the Column Switcher record the animation and then save it as an animated GIF. This feature is available only on Windows.
The Data Filter

The Data Filter in JMP provides a variety of ways to identify subsets of data. You can interactively select complex subsets of data, hide these subsets in plots, or exclude them from analyses.

1. Select Rows > Data Filter.

**Tip:** In addition to the main Data Filter, you can also launch a local Data Filter within a platform report. Click the Local Data Filter icon  from the Report toolbar, or select Local Data Filter from the red triangle menu in a report. See “Local Data Filters in Reports” on page 451 for more information.

2. Select the columns that you want to use as filters, and then click Add.

**Notes:**

- To restore your current row states when the Data Filter window is closed, select the **Save and restore current row states** option.
- If you have a long list of columns, you can sort, show, hide, or search for columns in the list. Use the options in the Add Filter Columns red triangle menu.
- By default, the Data Filter window is attached to the data table. You can detach it temporarily or permanently:
  - Detach it temporarily by deselecting the Use Floating Window option from the Data Filter red triangle menu.
  - Detach it permanently by selecting File > Preferences > Data Filter and deselecting Use Floating Window.
Types of Filter Columns

There are four types of filter columns:

**Continuous columns** Filters numeric columns whose modeling type is set to continuous. A continuous filter column is represented by a histogram that spans the data range. You can adjust vertical lines on the histogram that represent the minimum and maximum filtered values. For options, see “Options for All Types of Variables” on page 470 and “Options for Continuous Variables” on page 470.

**Categorical columns** Filters nominal and ordinal columns. For each categorical column, the Data Filter generates a set of distinct categories. These categories can be displayed in different forms. For options, see “Options for All Types of Variables” on page 470 and “Options for Nominal or Ordinal Variables” on page 470.

*Note:* For categorical columns with value labels, if you want to include responses that are not present in the data, select the **Include Responses Not in Data** option from **File > Preferences > Platforms > Categorical.**

**Multiple Response columns** Filters character columns that have the Multiple Response column property or Multiple Response modeling type assigned. Each data cell of the column generally consists of multiple categories, separated by some common separator, like a comma. Since each data cell can contain more than one category, multiple response columns have a richer set of filtering options. For options, see “Options for All Types of Variables” on page 470 and “Options for Variables with the Multiple Response Modeling Type or Column Property” on page 471.

**Unstructured Text** Filters text columns whose modeling type is set to Unstructured Text. Type words or phrases into the filter text edit box to add them to the filter text list. You can then filter the rows based on these words and phrases. For options, see “Options for All Types of Variables” on page 470 and “Options for Unstructured Text” on page 472.

Filtering Modes

There are three modes of filtering: **Select**, **Show**, and **Include**. You can set and clear these modes using the corresponding check boxes in the Data Filter.

**Select** (Not available for the Local Data Filter.) Shows the selected rows in the data table in a highlighted state.

You can turn off the automatic selection of this option using the **Data Filter Select Check** preference. See also “Changing the Row State in the Data Table After Making Data Filter Selections” on page 461.
Show  Shows the unselected rows with the Hide icon . You can turn on the automatic selection of this option using the Data Filter Show Check preference. For more information about row states, see the “Store Information in Row State Columns” on page 300 in the “Set JMP Column Properties” chapter.

Include  Shows the unselected rows with the Exclude icon . You can turn on the automatic selection of this option using the Data Filter Include Check preference. For more information about row states, see the “Store Information in Row State Columns” on page 300 in the “Set JMP Column Properties” chapter.

There are two additional options when filtering: Auto clear and Conditional. These options are available from the red triangle menu for the Data Filter. See “Red Triangle Options for the Data Filter” on page 463.

The Data Filter Control Panel

Once you have added columns in the initial window, the Data Filter control panel appears.

Figure 9.8  Data Filter Control Panel

The main controls in the Data Filter include the following:

Clear  Clears all selections that you have made on variables in the Data Filter window.

Favorites  Saves your current data filter criteria as a favorite. Once you have created a favorite, selecting it resets the current conditions to the criteria in the favorite. You can also
remove the favorite. To retain favorites once the current session ends, save the data filter script by selecting one of the Save Script options from the Data Filter red triangle menu.

Select, Show, and Include  See “Filtering Modes” on page 459.

Inverse  Inverts the current selection state of the rows in the data table.

Note: Only the rows in the data table are inverted, not the selection in the Data Filter. To invert the selection in the Data Filter, from the column’s red triangle menu, select Invert Selection.

AND  The AND button opens the Add to Selected Group list. The and operator restricts the selection. You can add variables to the filter process at any time.

OR  The OR button opens the Add new OR Group list. The or operator extends the selection. You can add variables to the filter process at any time.

Changing the Row State in the Data Table After Making Data Filter Selections

If you have made selections in the Data Filter and subsequently alter row states in the data table, or select points in a graph or plot, the selections in the Data Filter might not match the selections in the data table. The Data Filter contains a warning message that says: “Your selection was changed in another window”. The Reset Selection button appears. Clicking the Reset Selection button changes the data table selections back to reflect the selections in the Data Filter.

Example of Modifying Selections

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Distribution.
4. Click OK.
5. Select Rows > Data Filter.
6. Select sex and click Add.
7. In the Data Filter control panel, select all of the males by clicking on the M block.
Figure 9.9  Rows Containing Males Highlighted in Data Table and Histograms

![Image](image_url)

You can see that all of the rows containing males are highlighted in the data table and in the histograms. Now you decide that you want to see only the students who are age 12.

8. In the age histogram, select the bar representing age 12.

Now the selection does not match the Data Filter selection. A warning message and a **Reset selection** button appear in the Data Filter window.

Figure 9.10  Data Filter Warning Message and Reset Button

![Image](image_url)
Red Triangle Options for the Data Filter

The red triangle menu next to Data Filter contains the following options:

**Auto clear**   If you have more than one nominal or ordinal column selected in the Data Filter, this option clears any other selections before making a new selection. For example, using Big Class.jmp, suppose that you have the columns sex (nominal) and age (ordinal) in your Data Filter. If you have males (M) selected for sex, and you click an age group, say age 12, your selection of males will be automatically cleared. This means that selecting age 12 is not conditional on selecting males. Conversely, if you turn off Auto clear, you can then select both males and age 12 at the same time. Auto clear is off by default.

**Conditional** Limits the categories displayed for the selected filter column. See “Conditional Data Filters” on page 464.

**Grouped by AND**   Enables you to control the AND and OR behavior of multiple groups of column filters. See “Grouped by AND in Data Filters” on page 465.

**Show Histograms and Bars** Shows or hides the histogram and bars in the data filter.

**Show Counts** Shows or hides the counts in the categorical column data filters.

**Use Floating Window** Keeps the Data Filter window on top of its associated data table. If you do not want the Data Filter window to remain on top, deselect this option.

**Start Over** Closes the current Data Filter session and shows the original Data Filter window.

**Show Controls** Shows or hides all buttons and checkboxes in the Data Filter window except Clear and Inverse.

**Show Modes** Shows or hides the filtering mode checkboxes in the Data Filter window.

**Animation** Sequentially highlights the values of a single variable in the data table. See “Animation in Data Filters” on page 467.

**Subset** Creates a new data table that contains only the following:

- The rows identified by the Data Filter.
- The columns selected in the active data table. If no columns are selected, then all columns are included.

This option is similar to the Tables > Subset command, only without subsetting options.

**Save Where Clause** Builds a Where clause based on the value selections that you make.

**Tip:** Selecting To Formula Column creates an indicator column. You can use the indicator column in many platforms as a By role, Group or ID in Graph Builder, and so on.
Save Script  Provides options for saving scripts. See “Save Script Menus in Reports” on page 455.

Copy Local Data Filter  (Available only for the Local Data Filter.) Copies the script for the local data filter to the clipboard. You can then apply this local data filter to a new report by using the Paste Local Data Filter option in the report’s red triangle menu.

Remove Local Data Filter  (Available only for the Local Data Filter.) Removes the Local Data Filter from the report.

Conditional Data Filters

For filter columns with hierarchy, you can use the Conditional option to filter what appears in the column lists. For example, you could filter by region so that only the states in the selected region appear in the list.

Note: If there is more than one OR group, the conditional filter is not available.

The following example illustrates how the Conditional option helps show the subcategories clearly, without the extra categories that do not belong.

1. Select Help > Sample Data Library and open Cities.jmp.
2. Select Rows > Data Filter.
3. In the Data Filter window, select city, State, and Region, and then click Add.
   The Data Filter window appears, showing a list for each variable.
4. Click the Data Filter red triangle and select Conditional.
5. Select MW in the Region list.
6. Select OH from the State list.
   The cities that are in Ohio and in the Midwest region are selected in the data table. In the Data Filter window, only Midwestern states appear in the State list, and only cities in Ohio appear in the cities list.
The circled number in front of the column name indicates the order in which the column values were selected. In Figure 9.11, Region was selected first, so it has a circled “1” in front of the column name. State was selected second, so it has a circled “2” in front of the column name.

When you rearrange hierarchical filters that are in ascending order, the filter number changes to match the ascending position in the hierarchy.

To clear the selections and reset the order of the hierarchy, click **Clear**.

### Grouped by AND in Data Filters

When you add a filter column, click AND, and add another filter column, you create a filter group. Within that group, columns that meet all criteria are selected in the data table.
When you then click OR and add one or more filters, you create a second filter group. With Grouped by AND deselected, this is the default behavior.

If you select Grouped by AND, you reverse the behavior.

The following example shows what happens when Grouped by AND is selected.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Rows > Data Filter.
3. Click the Data Filter red triangle and select Grouped By AND.
4. In the Data Filter window, select the age column and click Add.
5. Click OR and add the sex column.
   sex is added to the same group as age.
6. Select 14 from the age filter, and select M from the sex filter.
   age and sex are in the same group. In the data table, rows that meet either the age OR sex conditions are selected. That is, all 14-year-olds and all males are selected in the data table.
7. Click AND and add the weight column.
   A new group is added.
8. Move the left weight slider to approximately 112.
   Another filter group has been added. The second filter group limits the selection to those rows where weight is greater than 112.
   The two filter groups together select rows that satisfy the condition in the first group AND the condition in the second group, that is, a student who is 14 or any male but must weigh more than 112.
Animation in Data Filters

The animation feature sequentially highlights the values of a single variable. The variable’s values are highlighted in the data table. However, patterns are more interesting if you first create a plot and then animate a variable using the Data Filter to see how it behaves on the plot.

To use the animation feature, click the Data Filter red triangle and select Animation. Then select the variable that you want to animate. The highlighted frame around the variable indicates which variable is selected for animation.
The Animation Control panel contains the following controls:

- The middle button ( ) starts and pauses the animation. After you start the animation cycles, the button changes to a pause button ( ). By default the animation begins with the first value of the topmost variable.

- The backward arrow ( ) moves the animation backward one cycle. Click more than once to go backward more than one cycle.

- The forward arrow ( ) moves the animation forward one cycle. Click more than once to go forward more than one cycle.

- The square button ( ) hides the Animation Control section on the Data Filter window. Select Animation from the menu on the Data Filter title bar again to see the Animation Control.

- The looping button ( ) enables looping and is on by default. If you turn the looping button off, the animation will cycle through the sequence of values one time and then stop.

- The record button ( ) starts recording the animation. After you start the recording, the button changes to a stop recording button ( ).

- The save button ( ) saves the recorded animation.

Use the slider to adjust the speed of the animation (slower to faster).

The Animate drop-down menu contains the following options:

- **Forward** Highlights values from first to last.

- **Backward** Highlights values from last to first.

- **Bounce** Highlights forward and then backward repeatedly.
Save Where Clause in Data Filters

Once you have filtered variable values in the Data Filter, that information can be expressed as a JMP Where clause. The Where clause is used in JSL (JMP Scripting Language) programs to identify specific rows of data for processing or analysis. The Data Filter builds a Where clause based on the value selections that you make.

The options in the Save Where Clause menu include the following:

**To Clipboard**  Creates a Where clause from the filter criteria and puts it on the clipboard.

**To Row State Column**  Creates a row state column in the data table that has a formula equivalent to the filter criteria.

**To Formula Column**  Creates a formula column in the data table that has a formula equivalent to the filter criteria.

**To Data Table**  Creates a Where clause from the filter criteria and saves it as a JSL command with the current data table in a table property called Filter.

**To Script Window**  Creates a Where clause from the filter criteria and appends it to the current script text window, or creates a new script if one does not exist already.

**To Journal**  Creates the Where clause from the filter criteria and appends it to the current journal, or creates a new journal if one does not already exist.

Example of Saving a Where Clause

1. Select **Help > Sample Data Library** and open **Big Class.jmp**.
2. Select **Rows > Data Filter**.
3. Select **age**, **sex**, and **height** and click **Add**.

Select all females who are twelve and fourteen years old and whose height is between 56 and 60 inches:

4. Click the 12 and 14 blocks and the F block.
5. Click 51 and type 56.
6. Click 70 and type 60.
7. Click the Data Filter red triangle and select **Save Where Clause > To Script Window**.

The Where clause that is created from this example appears in a script window:

```
Select Where(
  (:age == 12 | :age == 14) & :sex == "F" & (:height >= 56 & :height <= 60)
);
```
Red Triangle Options for Variables in Data Filters

After you add a column to the data filter, a red triangle menu appears. Some of the red triangle options for a variable can vary, depending on the type of variable.

Options for All Types of Variables

The red triangle menu next to any type of variable contains the following generic options:

Clear Selection  Clears any selection in effect for that variable only.

Invert Selection  Deselects any selected values, and selects all values previously not selected, for that variable only.

Modeling Type  Shows a submenu of modeling types for the column filter. By default, the column filter type is set to the column’s modeling type. You can change the filter type by selecting a different modeling type in the submenu.

Options for Continuous Variables

For continuous variables, values appear in a histogram with vertical lines at the minimum and maximum values. You can adjust the selected range by clicking on the vertical lines and dragging. The updated range is highlighted in blue.

The following options are available for continuous variables only:

Select Missing  Selects rows that contain missing values.

Include Minimum Value  Includes or excludes the minimum value in the selected range.
  When the minimum value is excluded, the solid vertical line in the histogram becomes a dashed vertical line.

Include Maximum Value  Includes or excludes the maximum value in the selected range.
  When the maximum value is excluded, the solid vertical line in the histogram becomes a dashed vertical line.

Set Number of Bins  Sets the number of bins for the histogram.

Zoom to Selection  Shows only the selected range in the histogram. The menu item changes to Reset Zoom after you select it. Reset Zoom resets the display.

Options for Nominal or Ordinal Variables

For nominal and ordinal variables, values appear in blocks, in a list, or in a menu. If the variable contains only a small number of categories, the values appear in blocks. If the variable contains a large number of categories, the values appear in a list or in a menu. However, you can change these default settings.
The following options are available for nominal or ordinal variables only:

**Display Options**  Changes the appearance of the display. Options can include the following:

- **Blocks Display**  Shows each level as a block.
- **List Display**  Shows each level as a member of a list, followed by its frequency.
- **Single Category Display**  Shows each level, followed by its frequency, in a menu.
- **Check Box Display**  Adds a check box next to each value. To make this the default setting, select the **Check Box Display** option in **File > Preferences > Data Filter**.
- **Radio Box Display**  Adds a radio button next to each value.

**Order by Count**  Orders the values in decreasing sort order by count.

**Find**  Provides a text box where you can enter a search string for the selected column. Press Enter to perform the search.

### Options for Variables with the Multiple Response Modeling Type or Column Property

The following options are available for variables with the Multiple Response modeling type or column property:

**Display Options**  Changes the appearance of the display. Options can include the following:

- **List Display**  Shows each level as a member of a list, followed by its frequency.
- **Single Category Display**  Shows each level, followed by its frequency, in a menu.
- **Check Box Display**  Adds a check box next to each value. To make this the default setting, select the **Check Box Display** option in **File > Preferences > Data Filter**.
- **Radio Box Display**  Adds a radio button next to each value.

**Match None**  Selects only rows containing values that do not match any of the selections.

**Match Any**  Selects all rows that contain values that match any of the selected values. By default, this option is selected.

**Match All**  Selects only rows with values that include all of the selected values.

**Match Exactly**  Selects only those rows with values that exactly match the checked values.

**Match Only**  Selects only those rows with contents exactly matching the checked values.

**Match At Least**  Selects at least $n$ of the selected values.

**Match At Most**  Selects a maximum of $n$ of the selected values.
**Match Between**  Selects between \( n \) and \( m \) of the selected values.

**Find**  Provides a text box where you can enter a search string for the selected column. Press Enter to perform the search.

**Note:** For more information about the Multiple Response property, see the “Multiple Response” on page 319 in the “Set JMP Column Properties” chapter.

### Options for Unstructured Text

The following options are available for variables with the Unstructured Text modeling type:

**Case Sensitive**  If this box is checked, the filter based on the word or phrase typed in the filter text edit box is case sensitive.

**Regular Expression**  Assumes the string typed into the filter text edit box is a regular expression instead of a literal string.

**Display Options**  Changes the appearance of the display. Options can include the following:

- **List Display**  Shows each word or phrase as a member of a list, followed by its frequency.

- **Single Category Display**  Shows each word or phrase, followed by its frequency, in a menu.

- **Check Box Display**  Adds a check box next to each word or phrase. To make this the default setting, select the **Check Box Display** option in File > Preferences > Data Filter.

- **Radio Box Display**  Adds a radio button next to each word or phrase.

**Add Missing**  Adds a filter for entries that do not contain any text.

**Clear Filter Texts List**  Removes any words or phrases that had been added to the filter text list.

**Show Filter Text Edit Box**  Shows or hides the filter text edit box.

**Order by Count**  Orders the words or phrases in decreasing sort order by count.

**Match None**  Selects only rows containing text that does not match any of the selected words or phrases.

**Match Any**  Selects all rows that contain text that matches any of the selected words or phrases. By default, this option is selected.

**Match All**  Selects only rows with text that includes all of the selected words or phrases.
Reformat Tables in Reports

There are many ways to change the formatting of a report table. Right-click a report table to access the following formatting options:

**Table Style**  Adds borders, shading, and dividing lines to the table. Select from the following options:

- **Underline Headings**  Shows the preference setting for Underline Table Headings.
- **Shade Headings**  Shows the preference setting for Shade Table Headings.
- **Heading Column Borders**  Shows divider lines between columns in headings.
- **Column Borders**  Contains borders outside columns and divider lines between columns.
- **Row Borders**  Contains borders outside rows and divider lines between columns.
- **Shade Alternate Rows**  Shades alternate rows.
- **Shade Cells**  Shades the body of the table. When used with Shade Alternate Rows, a darker shade is used on alternate rows.

**Note:** Change the format of all report tables by selecting the preceding options in the JMP preferences. On Windows, the Report Tables options are in File > Preferences > Styles. On macOS, select the Report Tables options in JMP > Preferences > Styles.

**Columns**  Shows or hides columns in the table.

**Note:** Columns whose names begin with a tilde (~), such as ~Bias, are not applicable to the analysis that you ran and do not appear in the table, even if you place checks next to their names.

**Sort by Column**  Sorts the columns in descending or ascending order by the selected column. You can also select Numerical Order to sort a sorted string column numerically. After you do that, the Numerical Order option is available when you right-click the column. For more information about the sorting rules used by the Numerical Order option, see “Numerical Order” on page 309 in the “Set JMP Column Properties” chapter.

**Make into Data Table**  Creates a JMP data table from the report table. The data table script recreates the report and the data table generated by Make into Data Table.

**Make Combined Data Table**  Searches the report for other tables like the one you selected and combines them into a single data table. The data table contains a column that identifies the original data table. The data table script recreates the report and the data table generated by Make Combined Data Table.
### Make Into Matrix
Creates a JMP matrix from a report table. See “Turn a Table in a JMP Report Into a Matrix” on page 475.

### Select Where
(Available only for categorical columns) Creates a Where clause using the selected columns or a complex expression.

### Show Properties
Enables you to modify the formatting of display boxes in the report.

### Format Columns
Changes the numeric formatting of one or more columns in the table.

### Copy Column
Copies the contents of the right-click column to the clipboard for pasting into another window or application.

### Copy Table
Copies the right-click table to the clipboard for pasting into another window or application.

### Simulate
Provides simulated results for the selected column of statistics in a report.

### Bootstrap
Approximates the sampling distribution of a statistic. See *Basic Analysis*.

---

**Modify Display Box Properties in a JMP Report**

For each display box in a report, you can change properties such as the font, text color, padding, and alignment. Your changes are included when you save the report as a script, a graphic, or a journal.

To modify display box properties, follow these steps:

1. Right-click the disclosure icon next to the report and select **Show Properties**.
   The Properties pane appears.
2. Modify the report properties.
3. Click the report to view your changes.

**Tips:**
- In the Properties pane, use the arrow buttons to navigate among display boxes in the display tree.
- After you open the Properties pane, select a specific report and change its properties.

**Modify the Format of Numeric Columns**

In the Show Properties pane, you can modify the appearance of a report, including modifying the format of selected numeric columns. For example, you might want to specify two decimal places for all numeric columns. Your changes are included when you save the report as a script, a graphic, or a journal.
To modify the numeric formats, follow these steps:

1. Right-click the disclosure icon next to the report and select **Show Properties**. The Properties pane appears.
2. Press Shift and select the columns whose format you want to change.
3. From the Format list in the Properties pane, select the Format properties.

**Tips:**
- To select all display boxes of a specific type (for example, all NumberColBoxes), select one of the boxes in the report. From the Select list in the Properties pane, select **Boxes of type ‘NumberColBox’**.
- To select all columns that have a specific format, select one of the boxes in the report. From the Select list in the Properties pane, select **Columns with matching format**.

**Turn a Table in a JMP Report Into a Matrix**

You can create a JMP matrix from a report table. For example, when working with JMP Scripting Language (JSL), you might want to access a report’s table that has been stored into a JSL variable. Or, you might want to store a report table’s values into a table property as either a table property or as a JSL assignment, which is stored within the data table and is accessible via a script or the Formula Editor.

To store a table in matrix form into a global variable, into a table property, or into a table property as an assignment:

1. Right-click anywhere in a report table.
2. Select **Make into Matrix**.
3. In the window that appears, tell JMP how you want to store the table.
4. (Optional) Rename the variable or property by entering a new name into the box beside Name.

**Use Conditional Formatting in Reports**

**Note:** You must enable **Show conditional formatting** in the Reports preferences for your conditional formatting to appear in JMP reports.

To configure reports to use conditional formatting, you must first set your report preferences to enable showing conditional formatting. See “Preferences for JMP Reports” on page 672 in the “JMP Preferences” chapter.
To configure conditional formatting, follow these steps:

1. Open the JMP Preferences window.
2. Select the Reports preference group.
3. Click **Manage Rules**.

The Conditional Format Rule window appears.

**Figure 9.14** Conditional Format Rule Window

All rules are enabled by default. The PValue rule is applied to columns that contain probability values.

From this window you can add, edit or delete a rule.

**Disable or Enable a Rule**

To disable or enable a rule:

1. Open the JMP Preferences window.
2. Select the Reports preference group.
3. Click **Manage Rules**.

The Conditional Format Rule window appears.

4. Select the rule from the list.
5. If **Rule enabled** is selected, select to disable.
6. If **Rule enabled** is not selected, select to enable.
Add a Rule

To add a rule:
1. Open the JMP Preferences window.
2. Select the Reports preference group.
3. Click Manage Rules.
   The Conditional Format Rule window appears.
4. Click Add.
   The Conditional Format Rule window appears. A placeholder rule appears on the left.

Figure 9.15  Adding a Conditional Format Rule

5. Add and format conditions as described in “Add a Condition” on page 478.
6. Click OK to save the new rule and return to the previous Conditional Format Rule window.
7. Select Rule enabled to enable the rule.

Edit a Rule

To change the conditional formatting of a rule:
1. In the Conditional Format Rule window, select the rule from the list.
2. Click Edit.
   The Conditional Format Rule window appears, showing the selected rule’s current conditions.
The default rule for PValue includes two conditions. The order of the list indicates the order that the rules are applied. For example, a $p$-value of 0.04 would not invoke the first rule ($x < 0.01$) but would invoke the second rule ($x < 0.05$).

**Note:** You cannot edit an existing condition within a rule. To edit an existing condition, you must delete the condition and then add it. See “Edit an Existing Condition” on page 480.

**Add a Condition**

To add a condition to a rule:

1. Open the rule to view the Conditional Format Rule window.
2. In the Condition area, select a relation from the list and enter a value in the text box.
   
   Or
   
   If you want the condition to include a value range:
   
   - Select > or ≥ from the relation drop list and enter the value in the text box.
   
   - Select the check box, select the < or ≤ relation, and enter the value.
3. Format the condition using the procedure described in “Format a Condition” on page 479.

**Tip:** When you click **Add new condition**, the condition and its format settings are immediately added to the bottom of the condition list and the Condition and Format areas return to their default settings. Verify your settings before you click **Add new condition**.

4. After verifying your settings, click **Add new condition** to add the condition to the rule.
5. Use the and buttons to position the condition within the list.
6. Click **OK** to save your changes and return to the previous Conditional Format Rule window.

**Delete a Condition**

To delete a condition from a rule:

1. In the Conditional Format Rule window, select the condition and click **Delete**.
2. Click **OK** to save your changes and return to the previous Conditional Format Rule window.
3. Click **OK** to return to the Preferences window.

**Format a Condition**

To format values that fall within a condition:

1. With a Condition entered, select a Text Color from the drop list:
   - **Default** The value appears without color.
   - **Solid** The value appears in the specified color.
   - **Dimmed** The value appears dimmed by the specified transparency.
   - **Color Range** For ranged conditions, the values appear in color gradients within the specified color range.
   - **Dimmed Range** For ranged conditions, values appear in dimmed gradients by the specified transparency range.
2. To specify a text color, click the color swatch and select a color.
3. To specify a transparency, enter the percent value (for example, ‘60%’). The Sample area displays a preview of the appearance of the text column.

4. Select a Background Color from the drop list:
   - **Default** The value appears without a color background.
   - **Solid** The value appears with the specified color background.
   - **Color Range** For ranged conditions, the values appear with background color gradients within the specified color range.

5. To specify a background color, click the color swatch and select a color. The Sample area displays a preview of the appearance of the text column.

6. To have condition values noted, select an Annotation from the drop list:
   - **None** No notation is used on the value.
   - **Box** The value appears in the table with a box around it.
   - **Circle** The value appears in the table with an ellipse around it.
   - * (asterisk) An asterisk (*) appears to the right of values in the table. The Sample area displays a preview of the appearance of the text column.

7. To style the value text, select the **Font Style** from the drop list:
   - **None** No style is used to format the value.
   - **Plain** No style is used to format the value.
   - **Bold** The value appears bolded in the table.
   - **Italic** The value appears italicized in the table.
   - **Bold Italic** The value appears bolded and italicized in the table.

See Figure 9.17 for an example of condition formatting.

**Note:** After configuring the formatting, remember to click **Add new condition** to add the new condition to the rule.

**Edit an Existing Condition**

To change the formatting for an existing condition:

1. In the Conditional Format Rule window, select the condition and click **Delete**.
2. Re-create the condition by using the procedure described in “Add a Condition” on page 478.
3. Format the conditional using the procedure described in “Format a Condition” on page 479.

**Tip:** When you click Add new condition, the condition and its format settings are immediately added to the bottom of the condition list and the Condition and Format areas return to their default settings. Verify your settings before you click Add new condition.

4. After verifying your settings, click Add new condition to add the condition to the rule.
5. Use the Up and Down buttons to position the condition within the list.
6. Click OK to save your changes and return to the previous Conditional Format Rule window.

---

**Select Points in Graphs**

To select a point in a graph, click the point. This selects the point as well as the corresponding row in the current data table. To select multiple points, press Shift while you select points. A point’s label appears when you place the cursor over the point with or without clicking.

**Figure 9.18** Label for a Data Point

![Bivariate Fit of height By weight](image)

**Tips:**

- You can paste the contents of a label into another document. Right-click the label and select Copy. Paste the text into the other document.
- A photo can be displayed in the label if you store the image in an Expression role column. See “Expression Role” on page 326 in the “Set JMP Column Properties” chapter.
Select Rows in Graphs

All graphs and plots that represent the same data table are linked to each other and to the corresponding data table. When you click points in plots or bars of a graph, the corresponding rows highlight in the data table. The example in Figure 9.19 shows a histogram with the SPEEDYTYPE bar highlighted, and the corresponding rows highlighted in the table. You can also extend the selection of bars in a histogram by pressing Shift and then making your selection.

Figure 9.19  Highlighting Rows in a Histogram

Select a Rectangular Area of Points in a JMP Graph

You can select all points that fall in a rectangular area using the cursor. Click and drag the arrow to highlight points. Alternatively, you can use the brush tool. As you move the brush over the graph, points that fall within the rectangle are selected. Any points marked in the data table as hidden are not selected. See “Hide Rows in Data Tables” on page 217 in the “Enter and Edit Your Data” chapter.

To select points using the brush tool, follow these steps:

1. Click the brush tool in the toolbar.
2. Click and hold the brush tool in a plot. A rectangle appears.
3. Move the rectangle over points. As it passes over them, they appear highlighted both in the plot and in the active data table.

   To keep all points selected as you move the brush tool over points, press Shift before you click a point in the plot. The selected points are also selected in the data table.

**Figure 9.20** Using the Brush Tool

4. Release the mouse. The points within the rectangle and the data table remain selected.
   - To change the size of the selection rectangle, press Alt before you click in the plot. Drag the cursor to resize the selection box. This shape acts like a slicing tool that can traverse and highlight slices of points across either axis. **Note:** The size of the selection box is remembered for the next time you use the brush tool.
   - If you press Ctrl and click the brush tool on selected points, the points within the selection rectangle are deselected. Points outside the selection rectangle remain selected.

**Select an Irregularly Shaped Area of Points in a JMP Graph**

You can use the lasso tool to select points that fall in an irregularly shaped area. Any points marked in the data table as hidden are not selected. See “Hide Rows in Data Tables” on page 217 in the “Enter and Edit Your Data” chapter.

To select points within an irregularly shaped area, follow these steps:

1. Click the lasso tool in the toolbar.
2. Click and hold the lasso tool in a plot.
   
   **Note:** To keep all points selected as you drag the lasso around several sets of points, press Shift before you click in the plot.

3. Drag the lasso around any set of points.
Figure 9.21 Using the Lasso Tool

4. Release the mouse. JMP automatically closes the lasso and highlights the points within the enclosed area.

Use Markers in Graphs

Markers are points on a graph that represent data. Once they are changed from their default setting, they also appear next to rows in the data table.

- “Change the Shape of Markers”
- “Change the Color of Markers”
- “Change the Size of Markers”
- “Work with Crowded Markers”
- “Add Outlines Around Markers”
- “Change the Selection Mode of Markers”
- “Specify the Transparency of Markers”
- “Exclude and Hide Markers”
- “Use Images as Markers”
- “Change the Shape or Color of Markers Based On Values”

Change the Shape of Markers

You can assign a character from the JMP markers palette to replace the standard points in scatterplots. These markers also appear next to row numbers in the data table.

1. Highlight one or more markers whose shape you would like to change.
2. Right-click anywhere in the graph. In a histogram, right-click the box plot area on the right.
3. Select **Row Markers**.
4. Select a marker shape from the options that appear, or click **Other** to enter a character to use as a marker.

### Change the Color of Markers

You can assign any color to highlighted rows. When you do this, the points in scatterplots appear in the color that you select from the colors palette. The active color assigned to a row appears next to the row number in the data grid.

To change the color of markers (or points) on a graph:
1. Highlight one or more markers whose color you would like to change.
2. Right-click anywhere in a graph. In a histogram, right-click the box plot area on the right.
3. Select **Row Colors**.
4. Select one of the colors, or click **Custom** to apply a custom color.

### Change the Size of Markers

To increase or decrease the size of markers on a graph:
1. Right-click anywhere in a graph. Press Ctrl and right-click to broadcast the command and apply it to all plots of the same type located in the same window. In a histogram, right-click the box plot area on the right.
2. Select **Marker Size**.
3. Select one of the marker sizes listed.
   * The default value, Preferred Size, is selected on the Graphs page in the JMP preferences.

**Note:** When the drawing speed is set to Fast, the smallest marker size (Dot) is applied. See “Work with Crowded Markers” on page 485.

### Work with Crowded Markers

A large number of markers on a graph can appear crowded on a graph. You might need to alter the transparency to gain a better view. Altering the transparency might also affect the marker drawing mode, which is the mode JMP uses when it refreshes a report window. As markers are drawn on a plot, JMP uses one of two speeds: normal or fast.
To change the marker drawing speed

1. Right-click anywhere in a graph. In a histogram, right-click the box plot area on the right.
2. Select Marker Drawing Mode, and then select either Normal or Fast.

Normal  If JMP is in normal drawing mode and the number of markers on a graph are more than the specified threshold number, JMP automatically switches to fast mode. See “Preferences for JMP Reports” on page 672 in the “JMP Preferences” chapter, for more information about setting the marker threshold.

Fast  Graphs that display a large number of markers appear faster if you set the marker drawing speed to Fast. Note that when the drawing speed is set to Fast, the smallest marker size (Dot) is applied, and marker transparency settings revert to the default opaqueness.

Outlined  See “Add Outlines Around Markers” on page 486.

To fill hollow markers

In the JMP preferences, select Graphs and then select Fill Hollow Markers. Hollow markers on all graphs are filled with an opaque background.

Add Outlines Around Markers

You can add a black outline, or frame, to markers in a plot. Outlined markers are available at the medium, larger, XL, XXL, and XXXL marker size. See “Change the Size of Markers” on page 485.

To add outlines

1. Right-click a plot or graph.
2. Select Marker Drawing Mode.
3. Select Outlined.

To use an outline effectively, it is best if your marker is a color other than black.

To change marker colors

1. Highlight the markers whose color you want to change.
2. Right-click anywhere in the graph.
3. Select Row Colors.
4. Select a marker color from the options that appear.
Change the Selection Mode of Markers

When you select markers on a graph, only the selected markers are highlighted. You can change how markers are highlighted on the current graph. The options are applied to the top two triangles in the following figure.

Figure 9.22 Examples of Highlighted Triangular Markers

To change the marker highlighting on the current graph, follow these steps:
1. Right-click anywhere in a graph and select Marker Selection Mode.
2. Select one of the following options:
   - Preferred Mode: The Marker Selection Mode that is selected on the Graphs page in the JMP preferences. The default value is Unselected Faded.
   - Unselected Faded: Only the selected markers are highlighted. Everything else is dimmed by the percent specified by Faded amount for unselected markers in Preferences > Graphs.
   - Selected Larger: The selected markers are larger than the deselected markers.
   - Selected Haloed: The edges of the selected markers are outlined in blue.
   - Selected Outlined: The selected markers are outlined in black.
   - Selected Same Color: The selected markers are shaded with the Marker Selection Color that is selected in the Graphs preferences.
Specify the Transparency of Markers

You can change the transparency of markers (points) on a graph. For example, this enables you to control the visibility of overlapping points.

**Note:** When the drawing speed is set to Fast, the default marker transparency is applied. See “Work with Crowded Markers” on page 485.

1. In a graph, right-click anywhere and select **Transparency**. In a histogram, right-click the box plot area on the right and select **Transparency**.
2. Enter the level of transparency that you want the markers (points) to have on the graph, and click **OK**.
   
   A value of 1 indicates total opaqueness and 0 indicates invisibility. Values between 1 and 0 are semi-transparent.

Exclude and Hide Markers

Use the **Rows > Hide and Exclude** command to suppress the appearance and exclude from statistical analyses the highlighted rows. Data remains hidden and excluded until you select **Rows > Hide and Exclude** again.

Using the **Exclude/Unexclude** command, you can exclude highlighted rows from statistical analyses. Data remains excluded until you select **Rows > Exclude/Unexclude** for those highlighted rows.

**Note:** Excluded data are not automatically hidden in plots even though they are excluded from calculations in text reports and graphs.

Using the **Hide/Unhide** command, you can suppress (hide) the appearance of highlighted points in scatterplots. For example, you can exclude points from analysis and then hide those same points in scatterplots. The data remain hidden until you select **Rows > Hide/Unhide** for highlighted hidden rows.

**Note:** Hidden points are not automatically excluded from statistical computations that affect text reports and graphs, even though they are not displayed in the plots. To exclude hidden observations from analyses, you must highlight them and select **Rows > Exclude/Unexclude** characteristic.

To exclude or hide markers (points) from analyses, follow these steps:

1. Highlight the marker(s) that you would like to exclude or hide.
2. Right-click anywhere in a graph.
3. Select **Row Exclude** or **Row Hide**.

**Use Images as Markers**

Place images in an expression column to use those images as markers on graphs. Then you indicate which column to use for markers. This feature prevents the need to look at a marker color and refer to the legend for its meaning, which is particularly helpful with data that contain many levels.

If you use a character or numeric column as the marker, the data value is used for the marker.

1. Create a new column in your data table.
2. Right-click the column, select **Column Info**, and select the **Expression** data type.
3. Click **OK**.
4. Drag graphics from your computer into each cell of the column. You can also import data that contains a column of images.
5. Select the column, select the **Cols** menu, and then select **Use for Marker**.
6. Create a graph that uses markers. Figure 9.23 was created in Graph Builder.
7. (Optional) To resize the markers, right-click the graph, and select **Graph > Marker Size** (or right-click and select **Marker Size** in some platforms). Medium markers are selected in this example.
8. Click the Graph Builder red triangle and deselect **Show Legend**.
Figure 9.23 Pictures Used as Markers

Notes:

- In the Big Class Families.jmp sample data table, the picture column used for markers on graphs.
- This feature is not supported in Bubble Plot.

**Change the Shape or Color of Markers Based On Values**

In some plots, you can change marker shapes or colors based on the values of points by adding a row legend. It is called a row legend because JMP automatically inserts a legend using row color or row marker settings. When you assign markers or colors in this way, it assigns the characteristic(s) to all points in a graph, regardless of what points you have selected. All previous marker and color settings are overwritten.

To add shapes or colors based on column values, follow these steps:

1. Right-click anywhere in a graph. In a histogram, right-click the box plot area on the right.
2. Select **Row Legend**.
3. In the window that appears, highlight the column whose values you want to color or mark. A preview of the legend is shown on the right.
4. Refine your row legend using the following options:

**Colors**  Lets you choose among several pre-defined color schemes.

**Tip:** If you already applied a color scheme in the data table, select None to maintain it. Colors should be consistently applied and uniquely grouped.

**Continuous Scale**  Assigns colors on a spectrum that corresponds to the ascending or descending order of the values. Use this option when the highlighted column contains continuous values.

**Reverse Scale**  Reverses the scale of colors.

**Markers**  Lets you choose among several marker schemes.

**Tip:** If you already applied a marker scheme in the data table, select None to maintain it. Markers should be consistently applied and uniquely grouped.

**Make Window with Legend**  Creates a separate legend window that tells you what colors and shapes correspond to which value.

**Save to Column Property**  Adds a column property that stores the selected color theme.

**Save to Table Property**  Adds a table property that preserves the selected color and marker configuration.

**Excluded Rows**  Assigns colors or markers to rows that are excluded.

Most legends have one column. However, the following platforms have multi-column legends when there are more than 20 levels:

- Recurrence
- Oneway (for CDF Plot and all three Densities red triangle commands)
- Fit Model (for the Regression Plot in Standard Least Squares)
Remove the Row Legend

Delete a row legend by right-clicking it and selecting **Remove**.

---

**Change the Appearance of Graphs**

There are many ways that you can format your report to meet your needs. The sections that follow detail how to make changes to the graphical portions of your output reports.

**Tip:** If you have a touchscreen, you can pan and zoom most graphs and axes in JMP. Graphs and axes change scale and zoom out if pinched, and zoom in if stretched.

- “Resize Graphs”
- “Zoom In on Graphs”
- “Change Line Widths in Graphs”
- “Change the Background Color in Graphs”
- “Change the Color of Histogram Bars”
- “Display Coordinates and Temporary Reference Lines in Graphs”
- “Scroll and Scale Axes in Graphs”
- “Customize Axes and Axis Labels in Graphs”
- “Change the Order of Values in Reports”
- “Change the Pattern and Format of Selected Objects in Graphs”
- “Add a Graph to a Data Table”
- “Customize Markers, Lines, Text, and More in Graphs”

---

**Resize Graphs**

There are two main ways to resize graphs in JMP: using the click and drag method or resizing it according to pixel size.

**Note:** You can also change the default size of a graph using the Graph Height option in File > Preferences > Graphs.
Use Click and Drag

To resize a plot or graph using the click and drag method:

1. Place the cursor on the right edge, bottom edge, or lower right corner of the plot frame. The cursor changes to a small double-arrow.
2. Click and drag to change the size of the plot. When you resize, the height and width of all plots in that frame adjust independently of other frames in the same report window. Table 9.2 describes how to adjust the plot.

Table 9.2 Resizing Actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adjust the plot frame but preserve the proportions (aspect ratio)</td>
<td>Press Shift and click and drag the corner of the frame.</td>
</tr>
<tr>
<td>Adjust a plot in 8-pixel increments</td>
<td>Press Alt and click and drag the corner of the frame.</td>
</tr>
<tr>
<td>Adjust all plots of the same type simultaneously</td>
<td>Press Ctrl and click and drag the corner of one of the plots. If you do this for one scatterplot, the action is broadcast to all scatterplots in the window, and they resize together. Any other types of plots remain unchanged.</td>
</tr>
</tbody>
</table>

Specify Graph Size in Pixels

To resize a plot or graph to a specific pixel size:

1. Right-click the plot or graph.
2. Select Size/Scale > Frame Size.
3. Enter the number of pixels for the frame’s height and width.

Note: For more information about the other options in the Size/Scale menu, see “Scroll and Scale Axes in Graphs” on page 495.
Zoom In on Graphs

The magnifier lets you automatically zoom in on any area of a plot. When you click the magnifier, the point or area where you click becomes the center of a new view of the data. The scale of the new view enlarges, giving you a closer look at interesting points or patterns. You can perform any of the following actions:

- Click and drag the magnifier to focus in on a particular region of the plot.
- On a ternary plot, drag the magnifier to zoom the triangular axes.
- Zoom repeatedly to look closer at the data.
- Press Ctrl and click the magnifier to return to your previous state before the last zoom.
- Double-click or press Alt and click the magnifier to restore the original plot.

On Windows, you can also zoom by pressing Ctrl and using the mouse wheel.

On macOS, zoom by pressing Option and clicking the area.

**Note:** You can zoom in and still see a center point by dragging from the axis to inside the graph. For a vertical axis, click a position and drag right into the graph. This zooms in on the scale, adjusting both endpoints of the scale but keeping the clicked value in about the same position. Dragging left zooms out.

Change Line Widths in Graphs

After fitting a line to a graph, or producing a graph with a line already present, you can adjust the width of the line:

1. Right-click anywhere in a graph.
2. Select Customize.
3. Select Smoother (for example, if the graph contains a smoother).
4. Change the line width. The value is in pixels.
5. Click OK.

Change the Background Color in Graphs

To change the background color in a graph, follow these steps:

1. Right-click anywhere in a graph. (To change only the color of a box plot, right-click the box plot area.)
2. Select Background Color.
3. Select one of the predefined colors, or create your own color.
4. Click **OK**.

**Change the Color of Histogram Bars**

To change the color of histogram bars, follow these steps:

1. Right-click anywhere in a histogram and select **Histogram Color**.
2. Click a color, or click **Other** and create your own color.

See your operating system documentation for more information about creating your own colors.

**Display Coordinates and Temporary Reference Lines in Graphs**

You can measure points and distances in graphs, or easily find the exact value, or coordinates, of points and distances on plots and graphs. To do this, click the crosshairs tool ( ) and click and hold anywhere on a graph. The coordinate values appear where the crosshairs intersect the vertical and horizontal axis as you drag the crosshairs within a plot.

**Figure 9.25** Using the Crosshairs Tool

On a fitted line or curve, the crosshairs identify the response value for any predicted value. On a ternary plot, this tool displays triangular crosshair lines.

**Scroll and Scale Axes in Graphs**

The hand tool (also known as the grabber tool) ( ) provides a way to change the axes and view of a plot:

- On a y-axis, dragging ( ) scrolls the y-axis; dragging ( ) or ( ) scales the y-axis.
• On an $x$-axis, dragging $\text{rients}$ scrolls the $x$-axis; $\text{orent}$ or $\text{ent}$ scales the $x$-axis.

**Tip:** When you drag an axis to change its scale, JMP automatically updates the major and minor tick increments based on the new axis width. To prevent this (retaining your original increments), press Shift while dragging.

You can also right-click in a plot or graph, and select **Size/Scale** (or **Graph > Size/Scale**). Choose one of the following options:

• To adjust the scale of the $X$ axis, select **X Axis**. To adjust the scale of the $Y$ axis, select **Y Axis** or **Right Y Axis**. For more information about this window, see “Customize Axes and Axis Labels in Graphs” on page 496.

• For more information about the Frame Size option, see “Specify Graph Size in Pixels” on page 493.

• Select **Size to Isometric** when the $x$- and $y$-axes are measured in the same units and you want distances on the graph to be represented accurately regardless of direction.

**Customize Axes and Axis Labels in Graphs**

Double-click a numeric axis to customize it using the Axis Settings window. Or, right-click the axis area and select **Axis Settings** to access the window.

**Note:** In the Graph Builder and Distribution platforms, you can also customize nominal axes using the Axis Settings window.

Customization features in the window depend on the data type of the axis and the specific platform JMP uses to create the plot or chart. Figure 9.26 shows a typical Axis Settings window for numeric (continuous) axes.
Figure 9.26 Axis Settings Window for a Numeric (Continuous) Axis

The Axis Settings window contains the following panels:

- “Scale” on page 497
- “Tick/Bin Increment” on page 500
- “Axis Label Row” on page 502
- “Reference Lines” on page 505
- The Preview panel shows how your current selections will appear on the axis.

**Scale**

In the Scale panel, you can do the following:

- “Change the Axis Scale Type” on page 497
- “Change the Numeric Format of an Axis” on page 498
- “Establish Minimum and Maximum Axis Values” on page 499

**Change the Axis Scale Type**

When viewing a graph with a numeric axis, you can change the axis scale to one of the following types:

- Linear
• Log
• Power
• Geodesic
• Geodesic US
• Probability Scales (Normal, Weibull, Fréchet, Logistic, Exponential, Gamma, Beta, and Mixtures)

Notes:
• Specific platforms might use other scale types that are fixed and cannot be changed. For example, Destructive Degradation, Degradation, and the X axis in Fit Y by X scatterplots use custom scales. Do not change the scale in these graphs through the Axis Settings window.
• If you selected a scale type of Log, enter the Base to use.
• If you selected a scale type of Power, enter the Power to use.
• Power works similarly to log scale, but instead of the scale conversion being log(x), it is \( x^p \), where \( p \) is a customizable axis option. For example, Power = 2 creates an \( x^2 \) axis.

To set a default scale type for a variable, which avoids making this change every time you run an analysis, see “Axis” on page 312 in the “Set JMP Column Properties” chapter.

Change the Numeric Format of an Axis

For plots and charts that contain a numeric axis area, you can change the format of the axis. For more information about numeric formats, see “Numeric Formats” on page 295 in the “Set JMP Column Properties” chapter.

Notes:
• If you selected Date, Time, or Duration, you need to specify the format of the increments. See “Add and Remove Axis Labels” on page 506. You can also specify label row nesting. See “Label Row Nesting” on page 501.
• If you selected Fixed Dec, enter the number of decimal places that you want JMP to display in the Dec box.
• If you selected Precision, select whether you want to keep trailing zeros and all whole digits.
• To add commas to values that equal a thousand or more, select the Use thousands separator option. You must account a space for each comma in the Width box, or else they might not appear. This option is available for the Best, Fixed Dec, Percent, and Currency formats.
• For a numeric axis, you can adjust the width of the tick mark labels using the Width box.
Note: When you change the numeric format of an axis, you do not change the numeric format of the way the values appear in the corresponding data table. To change how a date or time appears in a data table, see “Numeric Formats” on page 295 in the “Set JMP Column Properties” chapter.

Selecting a date interval from the date increment drop-down menu divides the JMP date (number of seconds) into the appropriate units. This gives the plot scale that you want for your data. The date axis must be a column with a JMP date value and appear in the Axis Settings window in the date format found in the Column Info window. However, you can use the Axis Settings window to format the date’s appearance in the plot.

Establish Minimum and Maximum Axis Values

For plots and charts that contain a numeric axis area, you can change the minimum and maximum values that you want the graph to display.

Note the following:

- To restore the default minimum and maximum axis settings of a numeric axis, right-click a numeric axis and select Revert Axis.
- Select Reverse Order to reverse the axes by reversing the minimum and maximum values. Note that this option is not supported for ternary plots.

Tip: To set a default minimum and maximum axis value for a variable, which avoids making this change every time you run an analysis, see “Axis” on page 312 in the “Set JMP Column Properties” chapter.

The example on the right in Figure 9.27 is an enlargement of the point cluster that shows between 80 and 140 in the plot to the left. The enlarged plot is obtained by reassigning the maximum and minimum axis values.

Figure 9.27  Rescale Axis to Enlarge a Plot Section
Tick/Bin Increment

In the Tick/Bin Increment panel, you can do the following:

- “Change Axis Increments” on page 500
- “Add Minor Tick Marks” on page 501
- “Change the Tick Offset” on page 501
- “Label Row Nesting” on page 501

Change Axis Increments

While viewing a graph, you can change the axis increments.

If the axis Format is set to Date, Time, or Duration, a format menu appears beside Increment (Figure 9.28). Select the format for the increments.

Figure 9.28 Selecting the Format for Date and Time Increments

Tip: To set a default axis increment for a variable, which avoids making this change every time you run an analysis, see “Axis” on page 312 in the “Set JMP Column Properties” chapter.
Add Minor Tick Marks

You can add tick marks to a numeric axis, or change the number of minor tick marks that appear on a numeric axis. In the Axis Label Row panel, be sure to select the Minor Tick Marks box so that the tick marks appear on the axis.

**Tip:** To set default minor tick marks for a variable, which avoids making this change every time you run an analysis, see “Axis” on page 312 in the “Set JMP Column Properties” chapter.

Change the Tick Offset

To change the starting point of the tick marks, enter a number in the Tick Offset box. For example, if the Tick Offset is currently set to 0, setting it to 1 will move all the values on the axes up by 1.

Label Row Nesting

This option appears only if you have selected Date, Time, or Duration as the axis Format. Label row nesting enables you to split a date axis into multiple rows based on the format. For example, you might put the year on the outermost row, then the month, then the day:

1. Select **Help > Sample Data Library** and open Stock Prices.jmp.
2. Select **Graph > Graph Builder**.
3. Drag Date into the X zone.
4. Drag Open into the Y zone.
5. Double-click the X axis.
6. For **Format**, select **Date > ddMonyyyy**.
7. Increase the value for **Label Row Nesting** to 3.
8. Click **OK**.
9. Click **Done** to see the finished graph.
Axis Label Row

In the Axis Label Row panel, you can do the following:

- “Change the Axis Label Font” on page 502
- “Add Tick Marks, Grid Lines, or Labels” on page 503
- “Change the Orientation for Tick Labels” on page 504

**Note:** In Graph Builder, if you have nested labels in an axis, tabs appear in the Axis Label Row panel. You can modify each row of labels separately in its own tab.

**Change the Axis Label Font**

You can modify the axis label font on any axis type. Your changes only apply to the active graph. To set the default axis label font, see “Fonts Preferences” on page 703 in the “JMP Preferences” chapter.
To change the current font type and size, double-click an axis, select **Axis Settings**, and then click **Font**.

**Notes:**

- Select **Automatic Font Size** to have JMP attempt to decrease the font size (down to a certain minimum) if all of the labels cannot fit at the default size.
- To change the axis label font color, right-click the axis and select **Show Properties**. In the Edit options on the right, change the text color.

**Add Tick Marks, Grid Lines, or Labels**

These options can vary depending on whether your axis is continuous or categorical. Figure 9.30 shows axis settings for a categorical axis. **Figure 9.26** on page 497 shows axis settings for a continuous axis.

**Figure 9.30** Axis Label Row for a Categorical Axis

Options for continuous axes:

- Select **Automatic Tick Marks** to turn on tick marks only if one or more labels are hidden due to insufficient space.
• Add major or minor tick marks, grid lines, or labels, by selecting the corresponding check boxes.
• Click the color box to change the color of grid lines.
• Select **Tick Marks Inside Graph Frame** to move the tick marks inside the graph.

Options for *categorical* axes:
• The default is to not show tick marks if all of the labels are visible. To add tick marks, select **Automatic Tick Marks**. Change the tick mark style by selecting one of the options.
• Select **Automatic Tick Marks** to turn on tick marks only if one or more labels is hidden (due to insufficient space).
• Add grid lines by selecting **Show Grid**.
• Click the color box to change the color of grid lines.
• Select **Tick Marks Inside Graph Frame** to move the tick marks inside the graph.
• Select **Lower Frame** to add a frame around the labels.
• Change the number of lines that text wraps.
• Modify the labels by entering different values in the Label boxes.

**Tips:**
• To set default tick marks for a variable, which avoids making this change every time you run an analysis, see “Properties That Control the Display of Columns” on page 312 in the “Set JMP Column Properties” chapter.
• For additional axis customizations, select **Show Properties** from the axis right-click menu.

**Change the Orientation for Tick Labels**
To change the orientation for tick labels, select an option from the Label Orientation list.

**Automatic**  Tick labels are oriented automatically to be readable, depending on the tick increment and length of the labels.

**Horizontal**  Baseline at the bottom.

**Vertical**  Vertical with the baseline on the right.

**Perpendicular**  Horizontal for vertical axes and vertical for horizontal axes.

**Note:** Parallel and Perpendicular are useful with paired axes, like in Multivariate plots.

**Parallel**  Vertical for vertical axes and horizontal for horizontal axes.

**Angled**  Angled at about 45 degrees.
Reference Lines

Add reference lines to graphs:

1. Double-click a numeric axis. Or, right-click a numeric axis and select **Axis Settings**.
2. In the Value text box, enter the value to which you want the reference line to correspond. This is the position on the graph at which the line is placed.

   **Note:** If you opened the Axis Setting window by double-clicking on the graph, the default value corresponds to the point on the graph that you clicked.

3. Enter a Label for the line.
4. You can further customize the reference line by choosing either of these options:
   - **Allow Ranges** Enables you to enter a minimum and a maximum value, which define the beginning and the end of the reference line. The reference line appears over a range of data.
   - **Line Color** Changes the line color. You can also specify the opacity.
   - **Line Style** Specifies the line style (when Allow Ranges is not selected). You can also specify the line width.
   - **Font** Enables you to adjust the font for the reference line label.
   - **Label Position** Enables you to select a position for the reference line label. Options are outside or inside the graph frame.
   - **Label Axis Side** Enables you to select the side of the graph for the reference line label.

5. Click **Add**. The value moves into the box to the right of the Add button, indicating that it will be placed on the graph. Your changes appear in the Preview window.
6. To add more lines, repeat the above steps.
7. To modify an existing reference line, make your changes, and then click **Update**.

**Tip:** To set a default reference line for a variable, which avoids making this change every time you run an analysis, see “Properties That Control the Display of Columns” on page 312 in the “Set JMP Column Properties” chapter.

Extend Divider Lines and Frames for Categorical Axes

Extending the vertical divider line(s) between tick labels is useful when there are many levels of a nominal or ordinal (categorical) variable.

To extend the divider line to the x-axis labels, follow these steps:

1. Double-click a nominal or ordinal axis to show the axis settings.
2. Select **Show Tick Marks > Short Divider** of **Show Tick Marks > Long Divider** to add the divider lines, or **Lower Frame** to add a frame around the axis area.

**Figure 9.31** Divider Lines

---

**Add and Remove Axis Labels**

You can add or remove labels in a numeric axis. To add an axis label:

1. Right-click a numeric axis and select **Add Axis Label**.
2. Enter a name for the axis label. The axis area enlarges to hold the number of label lines that you enter.

This command can be used multiple times to add multiple labels. To edit the label after it has been added to the axis, click it and it will turn into an edit box.

To remove an axis label, right-click a numeric axis and select **Remove Axis Label**. The last label added is removed.

**Rotate Axis Labels and Tick Marks**

You can modify the axis label on any axis type.

To rotate an axis label, follow these steps:

1. Double-click an axis to show the axis settings.
2. From the Label Orientation list, select which direction to rotate the text.

**Tip:** To set a default axis label position for a variable, which avoids making this change every time you run an analysis, see “Properties That Control the Display of Columns” on page 312 in the “Set JMP Column Properties” chapter.
You can rotate tick marks on a nominal axis by right-clicking the tick label and selecting Rotated Tick Labels.

Copy and Paste Graph Contents

After customizing a graph by adding elements such as a fitted line, you can copy and paste the contents from one graph to another compatible graph:
1. Right-click the graph that you have customized.
2. Select Edit > Copy Frame Contents.
3. Right-click the graph to which you would like to copy the settings.
4. Select Edit > Paste Frame Contents.

Tip: If you are having difficulty pasting histogram bars, see the JSL workaround the Scripting Guide.

Copy and Paste Axis Settings

After customizing an axis (as described in “Customize Axes and Axis Labels in Graphs” on page 496), you can copy and paste your new settings to another axis:
1. Right-click the axis that you have customized.
2. Select Edit > Copy Axis Settings.
3. Right-click the axis to which you would like to copy the settings.

Tip: To broadcast the axis settings to multiple graphs, press Ctrl when you right-click the axis and select Edit > Paste Axis Settings.

Change the Order of Values in Reports

Data in a JMP report might not appear in the order that you prefer. To give data a specific order so that it appears that way in a report, assign the column the Value Order property before running the analysis, as described in “Value Order” on page 308 in the “Set JMP Column Properties” chapter.

If your values include any of the following, they automatically appear in the appropriate order in reports:
- January, February, March, April, May, June, July, August, September, October, November, December
- Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec
• Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday
• Very Low, Low, Medium Low, Medium, Medium High, High, Very High
• Strongly Disagree, Disagree, Neutral, Indifferent, Agree, Strongly Agree
• Failing, Unacceptable, Very Poor, Poor, Bad, Acceptable, Average, Good, Better, Very Good, Excellent, Best

**Change the Pattern and Format of Selected Objects in Graphs**

Patterns appear on some objects such as bars and maps when you select them. You can change the pattern for a specific object in the legend.

Right-click the item in the legend and select **Fill Pattern** to select a new pattern.

To remove the pattern, right-click the item again and select **Revert**.

**Modify the Format of Selected Objects in All Graphs**

Select **File > Preferences > Graphs** (Windows) or **JMP > Preferences > Graphs** (macOS) to change the Filled Areas preferences.

- To change the highlight on selected objects, select one of the following Filled Selection Mode preferences:
  - **Selected Patterned**  Striped pattern (the default setting)
  - **Selected Darker**  Solid darker color
  - **Selected Outlined**  Outline
  - **Selected Same Color**  The Fill Selection Color in the preferences formats the selected object.

- To change the color of selected rows in graphic objects when the Fill Selection Mode is “Selected Same Color”, click the Fill Selection Color bar. The default color is red.

**Add a Graph to a Data Table**

You can add a graph to a new data table. Right-click a graph and select **Edit > Make table of graphs like this**. The graph and the variables appear in a new data table. You then resize the row and column to enlarge the graph.
Customize Markers, Lines, Text, and More in Graphs

Graphs consist of markers, lines, text, and other graphical elements that you can customize. For example, in a Scatterplot Matrix graph, you might want to highlight data points in one of the bivariate graphs with a pink solid marker. In a Contour Plot graph, you can increase the width or transparency of the contour lines.

Example of Customizing a Contour Plot

1. Select Help > Sample Data Library and open Little Pond.jmp.
2. In the Table panel, click the green triangle next to the Contour Plot script.
3. Click the red triangle next to Contour Plot for Z and deselect Fill Areas.
4. Right-click the plot and select **Customize**.
   The Customize Graph window appears.

5. Click **Shape**.

6. Change the **Line Width** to 2.0.

7. Click the color next to **Line Color** and select a shade of green.

8. Click **OK**.

**Figure 9.34** Customized Contour Plot

The graphical elements that you can customize differ on each graph. For example, in a Control Chart graph, there are three line elements (Lower Limit, Upper Limit, and Connect Line). In other graphs, the line element might be named Line or Custom.

To customize graphical elements in the current graph, follow these steps:

1. Right-click the graph and select **Customize**.
2. Select the element that you want to change, and then modify the properties.
   Your changes are immediately shown on the graph.
3. Click **OK** to save your changes to the current graph.

**Note:** The Customize settings do not override those shown in the legend. For example, if you set the fill area in a bar chart to red, and the legend is blue, the legend will remain blue.

Each element can include properties for line color, marker style and size, text style, and so on. Here are some common properties:

**Line Color**  Changes the color of the line. Click to select any color in the window. Right-click to choose from more colors.
Line Style  Changes the style of the line. Click to select one of five different styles.

Line Width  Changes the width of the line. Click in the box and enter the desired line width in points.

Marker  Changes the marker shape. For more information about markers, see “Use Markers in Graphs” on page 484.

Marker Size  Changes the size of the marker.

Arrow  Adds an arrowhead to a line at either None, Start, End, or Both ends of the line.

Line of Fit  Changes the color, width, or style of the line.

Text Color  Changes the color of the text.

Font  Changes the font, style, and point size of the text.

Text Style  Changes the text alignment to centered, left-aligned, or right-justified. The Fill option applies the selected color to the background.

Fill Color  Changes the color of objects such as box plots and Fit Confidence regions.

Fill Pattern  Changes the pattern of filled objects.

Transparency  Changes the marker or label transparency. Enter the level of transparency to draw markers (points) on the graph. The degrees of opacity ranges from 0 (clear) to 1 (opaque). For more information about changing the transparency of markers, see “Specify the Transparency of Markers” on page 488.

Clip Shape  Crops the object (such as contours) around the boundary according to the selected Clip Shape. The display segs that make up the object then conform to the boundaries of the map. Select a sub-boundary to display the objects only over a portion of the boundary. For example, you might want to display the objects only over New York.

About Clip Shape Options

Graphical elements (display segs such as reference, grid lines, and contours) can be clipped to conform to the boundaries of a geographical map. The Customize Graph window provides Clip Shape options, where you can select a boundary around which to clip the shape. Figure 9.35 shows reference lines clipped around a map of the United States.
Figure 9.35 Unclipped (Left) and Clipped (Right) Reference Lines

Tips:
- See Essential Graphing for an example of creating the maps shown in Figure 9.35.
- The Clip Shape option in the Customize window was also set to clip the contours to the boundaries of the map. See “Clip Shape” on page 511.
- Scripting provides additional options such as specifying the clipping path in a matrix or string. See the Scripting Guide.

Create Scripts for Graphical Elements

In addition to customizing graphical elements, you can write JSL scripts that add elements. These scripts run when you display the graph. You can write the scripts from scratch, or you can select from the following lists of commands and scripts, accessed by clicking on the Add a new script button:

- Use the Templates list to insert a single JSL command. For example, the Polygon option inserts the Polygon command. The text enclosed in underscores are placeholders for point values, which you replace with your own values.
  \[
  \text{Polygon}(\text{[}_x0, \text{x}_1, \ldots], \text{[}_y0, \text{y}_1, \ldots])
  \]
- Use the Samples list to insert a script that creates elements such as bubble plots and sine waves. In this list, the Polygon sample script shows examples of the Transparency, Fill Color, and Polygon values, which you replace with your own values.
In some graphs, you can view the JSL that creates graphical elements. Figure 9.37 shows the Group Label script for a Discriminant Analysis graph. The script defines markers and text for group labels. The commands included in these built-in scripts cannot be modified or deleted. You can insert commands from the Templates or Samples list, but you cannot click in the window and type new commands.

For information about JSL, see the *Scripting Guide* and the *JSL Syntax Reference*.

To create a graphics script, follow these steps:

1. Right-click the graph and select **Customize**.
2. Click the **Add a new script** button ( ) to create a new script.
   
   The default name, Script, is highlighted.

3. With the default name highlighted, type a more descriptive name, and then press Enter. (If you already moved the cursor and the name is no longer highlighted, double-click Script, and then enter the new name.)

4. Do one or more of the following:
   
   – Enter JSL in the Properties window.
– Select one or more JSL commands from the Templates list, and modify the placeholder text. For example, change the Pen Color option from “blue” to “red.”
– Select one or more sample scripts from the Samples list and modify, if necessary.

5. (Optional) Click **Apply** to update the graph with your changes without closing the window. Unlike other property changes, script changes to not take effect until you click **Apply** or **OK**.

6. Click **OK** to save your changes.

   One of the following occurs:
   – The element that you created appears on the graph.
   – An error message appears if the script contains an error. Select **View > Log** to read about the error, and then correct the script.

To delete a script that you created, select the script and then select the **Delete selected object** button (删除).

### Change the Drawing Order of Graphical Elements

The graphical elements are drawn in the order in which they are listed. The first element on the list is drawn first, so it appears *behind* all other graphical elements. If one element hides another, you can rearrange the order of the elements.

**To rearrange graphical elements**

1. Right-click the graph and select **Customize**.
2. Select the element that you want to move.
3. Click the **Move up in drawing order** button (↑) or **Move down in drawing order** (↓) button one or more times until the elements are in the order in which you want them drawn.
4. Click **OK**.

### Save Your Customizations

The graph customizations apply to the current graph and are also used when you redo an analysis. To re-create your graph at a later time with its customizations, select **Save Script** from the red triangle menu, and then select one of the Save options. For example, you can save the script to the data table, which applies your customized properties each time you run the script. See “Save a JMP Analysis as a Script” on page 593 in the “Save and Share Your Data” chapter.
Copy Your Customizations

You can copy your customizations from one graph to another. All objects that you created or modified, such as colored text or lines, are pasted to the other graph.

To copy lines from one graph to another, see “Copy and Paste Graph Contents” on page 507.

To copy other objects

1. Right-click in the graph with custom elements and select Edit > Copy Customizations.
2. Right-click in the destination graph and select Edit > Paste Customizations.

The objects appear on the current graph and are added to the list of customized elements.

Notes:

- The customizations are pasted into all similar graphs when you press Ctrl, click, and then paste.
- The copy customizations feature copies only the elements that you added or modified. It does not copy the other contents of the graph.

Add Images to a JMP Graph or Report

To enhance your analyses with logos and other types of graphics, paste or drag and drop graphics into the graph or report. .bmp, .emf, .jpeg, .png, and .rtf graphic formats are supported.

- “Paste a Background Image into a JMP Graph”
- “Paste an Image at the End of a JMP Report”
- “Drag and Drop an Image into a JMP Graph”
- “Add Geographical Images and Boundaries to JMP Graphs”
- “Extract Data from an Image”

Paste a Background Image into a JMP Graph

1. Open the graphic file in a graphics program and select the graphic. Copy it to the computer’s clipboard.
2. Right-click inside a graph.
3. Select Edit > Paste Background Image. The graphic is inserted at the point in the graph that you right-clicked.
**Paste an Image at the End of a JMP Report**

You can also add the graphic to the end of a report window. Copy the graphic from a graphics program onto your computer’s clipboard, display the report window, and select **Edit > Paste**.

**Drag and Drop an Image into a JMP Graph**

To add an image that you created, generate your report and then drag and drop the image from your computer’s file system onto the graph in the report. After you add the image, JMP provides several options such as resizing, formatting, and rotating an image. Right-click the image and select **Image** to see these options.

The following example shows a bivariate plot of wind speeds in the Chicago area. The plot on the left includes arrows to illustrate the wind direction and speed. A map image was dropped onto the plot and resized to line up the markers with the stations that provided the wind data (each dot representing a station).

![Figure 9.38 Example of a Custom Map Image](image)

**Image Processing**

JMP includes a variety of image processing options. Image processing includes filters that can sharpen, blur, resize, and enhance. JMP also allows flipping, rotating, and locking images. This section describes the processing options.

**Notes:**

- Repeated changes to images can degrade the image quality. If you are not happy with the results of sizing, scaling, or applying filters to the image, remove the image and start again.
- All JMP image filters are supported at the operating system level; images might be processed differently on Windows and macOS.
Lock

Locks the image in place so that it cannot be moved.

Size/Scale

- **Fill Graph**: Resizes the image proportionately to fit the graph.
- **Specify Size**: Resizes the image according to the values that you enter. (The units for these values are the same as your graph axes.)
- **Crop**: Crops the image according to the values that you enter. (The units for these values are the same as your graph axes.) For example, the left edge might be positioned at 50. You enter 60 next to Left, and the portion of the image between 50 and 60 is removed from the image.

Flip

- **Flip vertical**: Flips the image top to bottom.
- **Flip horizontal**: Flips the image left to right.
- **Flip both**: Flips the image both horizontally and vertically.

Rotate

Rotates the image the specified number of degrees. Enter a negative value to rotate the image counterclockwise.

Transparency

Changes the image transparency level. Enter a value between 0 and 1 (where 1 is completely opaque).

Filter

Provides filters found in many graphic editing programs to change the appearance of the image. Select a filter repeatedly to increase its effects on the image.

- **Contrast**: Optimizes the light and dark colors. Larger values lighten the image.
- **Despeckle**: Removes pixels that do not blend with surrounding pixels. For example, a black pixel surrounded by white pixels is converted to a white pixel.
- **Edge**: Darkens everything but the outlines of objects.
- **Enhance**: Reduces the contrast between pixels in a noisy image.
- **Gamma**: Balances the brightness of an image and the red, green, and blue (RGB) ratios. Larger values create a lighter image.
• **Gaussian Blur**: Blurs pixels by the specified radius. Larger radii create a smoother image. (In JSL, you can also specify the sigma value. Larger sigma values create a smoother image.)

• **Median**: Replaces each pixel color value with the median value of the surrounding pixels.

• **Negate**: Converts each pixel to its complementary color (such as pink to green and white to black).

• **Normalize**: Removes a percentage of the top and bottom color values. The color values are then stretched to fill the remaining image. This process increases the intensity of the colors.

• **Reduce Noise**: Finds the minimum and maximum color values and replaces them with values more consistent with the surrounding pixels. Larger values create a smoother image.

• **Sharpen**: Makes the edges of pixels more distinct.

**Remove**

Removes the image from the report.

### Add Geographical Images and Boundaries to JMP Graphs

Adding map images and political boundaries to graphs provides visual context to geospatial data. For example, you can add a map to the graph that displays an image of the U.S. Another option is displaying the boundaries for each state (when data includes the latitudes and longitudes for the U.S.).

The data should have latitudinal and longitudinal coordinates. Otherwise, the map has no meaning in the context of the data. The x and y axes also have range requirements based on the type of map. These requirements are described in the following sections.

Two tools are especially helpful when you are viewing a map:

• The grabber tool ( ) lets you scroll horizontally and vertically through a map.

• The magnifier tool ( ) lets you zoom in and out.

For more information about adding maps, see *Essential Graphing*.
Extract Data from an Image

JMP provides the ability to extract information from images into a data table and then analyze that information. Researchers at WildTrack.org analyze digital footprint photos in JMP to track endangered species. They drag and drop a footprint image into a JMP report and draw data points to capture the size and shape of the print. A JMP Scripting Language (JSL) script extracts those measurements into a data table. At that point, the researchers can analyze the data and determine whether the footprint is from a new animal. This method helps them track populations of endangered species in specific regions of the world.

Figure 9.39 Example of Extracting and Analyzing Data

Analysis shows that the footprint above is from a tiger whom WildTrack has already cataloged.

The details for implementing this feature are beyond the scope of Using JMP, because the needs of the user vary widely. For more information about writing JSL scripts, see the Scripting Guide and the JSL Syntax Reference.
Add Annotations and Shapes to JMP Reports and Graphs

You can add text notes, lines, polygons, ovals, and rectangles to a report or graph using graphics tools found in the toolbar.

Add Annotations to JMP Reports or Graphs

You can add editable text notes to a JMP report or graph using the annotate tool. To add an annotation:

1. Select the annotate tool from the Tools menu or toolbar.
2. In the report or graph, click where you want to add the annotation. Or, click and drag to size the annotation note. A white editable text box appears.
3. Enter text.
4. Click outside the annotation.
5. (Optional) To add a tag line, right-click the annotation and select Tag Line.

You can also edit any of the following options:

- **Background Color** Select the background color for the annotation.
- **Text Color** Select the text color. The color of the text also defines the color of the annotation outline.
- **Font** Change the font type, style, and size. To change the default font, see “Fonts Preferences” on page 703 in the “JMP Preferences” chapter.
- **Tag Line** Draws a line between the annotation and the point or text it is anchored to.
- **Filled** Removes the background color from the annotation so that it looks transparent. A transparent note is handy for putting titles and footnotes on a graph.
- **Editable** Makes the annotation editable by double-clicking on it.
- **Fixed Size** Avoids resizing the annotation box when you add text to the box.
- **Reanchor** (Available only when the annotation is moved.) Annotations are anchored to a location within the report, but can be moved around independently of the anchor location. The behavior of an annotation depends on the anchor position. For example, annotations anchored inside a graph move with the axes, and annotations anchored inside an outline show or hide when the outline is opened or closed. To reanchor an annotation, turn off the tag line, move the annotation to a new location, and right-click to reanchor it.
Delete  Deletes the entire annotation.

**Note:** When adding multiple annotations, press Shift when selecting the annotation tool for the first time. This causes subsequent clicks to add an annotation, and you do not have to select the annotate tool from the toolbar before the addition of each annotation.

Once you have added an annotation, you can do the following:

**Table 9.3 Using Annotations**

<table>
<thead>
<tr>
<th>Action</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add to or edit an annotation</td>
<td>Click inside the text box.</td>
</tr>
<tr>
<td>Move an annotation</td>
<td>Click inside the annotation box and drag it. When an annotation is moved, it becomes selected, as indicated by a double blue line with handles around the perimeter.</td>
</tr>
<tr>
<td>Resize an annotation</td>
<td>Place the cursor on the handle of a selected note (showing in the middle of the edges and in the corners). The cursor appears as a single crossed arrow; drag to resize the annotation.</td>
</tr>
<tr>
<td>Delete an annotation</td>
<td>Highlight the annotation by clicking the handle of a note and then press Delete or Backspace.</td>
</tr>
<tr>
<td>Move an annotation’s tag line</td>
<td>1. Right-click the annotation and deselect <strong>Tag Line</strong>.</td>
</tr>
<tr>
<td></td>
<td>2. Drag the annotation to where you want the tag line to start (the attachment point).</td>
</tr>
<tr>
<td></td>
<td>3. Right-click the annotation and select <strong>Tag Line</strong>.</td>
</tr>
<tr>
<td></td>
<td>The tag line now starts at the point where you moved the annotation.</td>
</tr>
<tr>
<td></td>
<td>4. Move the annotation where you want it to appear.</td>
</tr>
<tr>
<td>Move the tag line with the annotation</td>
<td>Press Ctrl and drag the annotation to move the tag line endpoint with the annotation.</td>
</tr>
</tbody>
</table>

**Add Shapes to JMP Reports**

You can add editable lines, polygons, and simple shapes (ovals or rectangles) to a JMP report using the drawing tools  ToAdd Annotation. The following sections describe how each of these tools can be used.
Note: Each graphics tool remembers the most recent options chosen. This is useful if you need many annotations or other graphics with the same characteristics. For example, suppose you want many thick green lines with an arrow on one end. Create a line the way you want it, set the options, and subsequent lines appear with those options in effect. The options persist until you change them.

Add a Line

Add a line annotation to a report window:

1. Click the line tool in the tool palette.
2. Click and drag where you want to insert the line. The line appears selected, showing handles on both ends.
3. Click and drag the line to move it.
4. Click a handle and drag to rotate the line.
5. Right-click a line for options to customize the appearance of the line:
   - **Point to and Point from**  Places arrows on either end (or both ends) of the line.
   - **Thick**  Changes the width of a line to thick. Lines are thin by default.
   - **Dashed**  Changes the line to dashed. Lines are solid by default.
   - **Color**  Displays the JMP color palette to change the color of the shape.
   - **Reanchor**  Line annotations are anchored to a location within the report but can be moved around independently of the anchor location. The behavior depends on the anchor position. For example, line annotations anchored inside a graph move with the axes, and line annotations anchored inside an outline show or hide when the outline is opened or closed. To reanchor a line annotation, move the line to a new location and right-click to reanchor it. Available only when the annotation is located outside the graph.
   - **Delete**  Removes the shape from the report surface. You can also remove the shape by selecting it and then pressing Delete or Backspace.

Add a Polygon or Bezier Curve

To add a polygon (or Bezier curve) annotation to a report window:

1. Click the polygon tool in the tool palette.
2. Click to create the beginning point for the first side of a polygon.
3. Click again at the location where you want to complete the first side and begin an adjacent side. A square selection box with handles appears around the polygon area.
4. Click a third time to complete the second side.
5. Continue this process until the polygon is the way you want it. Each time a side is complete, the selection box adjusts to encompass the polygon sides.
6. Double-click to release the polygon tool.

Once you have added a polygon, you can perform the following actions:

### Table 9.4 Working with Polygons

<table>
<thead>
<tr>
<th>Action</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select or deselect the polygon</td>
<td>Click the edge of a completed polygon.</td>
</tr>
<tr>
<td>Resize the polygon</td>
<td>Select it and drag one of the selection box’s handles.</td>
</tr>
<tr>
<td>Move the polygon</td>
<td>Click between the box’s handles and drag the selection box.</td>
</tr>
<tr>
<td>Change the number of sides of the</td>
<td>Click and drag the sides to form the new shape.</td>
</tr>
<tr>
<td>polygon</td>
<td></td>
</tr>
</tbody>
</table>

Right-click a polygon for options to customize its appearance:

**Filled**  Fills or empties the area of the shape.

**Raised**  Displays thick shaded lines around the shape. If the shape is also filled, the lower edge of the figure appears raised, giving it a three-dimensional look.

**Smooth**  Smooths the vertices of a polygon to produce a Bezier curve. The smoothed figure is reshaped and resized the same way as the polygon, and can be filled and raised.

**Closed**  Opens or closes the last segment of a polygon.

**Color**  Displays the JMP color palette to change the color of the shape’s sides, and its fill color when the **Filled** option is in effect.

**Reanchor**  Polygon annotations are anchored to a location within the report, but can be moved around independently of the anchor location. The behavior depends on the anchor position. For example, polygon annotations anchored inside a graph move with the axes, and polygon annotations anchored inside an outline show or hide when the outline is opened or closed. To reanchor a polygon annotation, move the polygon to a new location and right-click to reanchor it.

**Delete**  Removes the shape from the report. You can also remove the shape by selecting it and then pressing Delete or Backspace.
Add an Oval or Rectangle

To add an oval or rectangle annotation to a report window:
1. Click the simple shape tool \( \text{◯} \) in the tool palette.
2. Click and drag where you want to insert the shape. An oval appears with a selection box around it.
3. (Optional) To turn the oval into a rectangle, right-click the oval and select \textbf{Shape > Rectangle}.
4. Double-click to release the simple shape tool.

Once you have added the shape, you can do the following:
- Select the shape and drag one of the selection box handles to reshape or resize.
- Click and drag an edge of the selection box (located between the handles) to move it.
- Select the shape, and then right-click it for options to customize its appearance:
  - **Filled**: Fills or empties the area of the shape.
  - **Raised**: Displays thick shaded lines around the shape. If the shape is also filled, the lower edge of the figure appears raised, giving it a three-dimensional look.
  - **Shape**: Displays a submenu whose options transform the shape into either an oval or a rectangle when selected.
  - **Color**: Displays the JMP color palette to change the color of the shape’s sides and its fill color when the Filled option is in effect.
  - **Reanchor**: Shape annotations are anchored to a location within the report, but can be moved around independently of the anchor location. The behavior depends on the anchor position. For example, shape annotations anchored inside a graph move with the axes, and shape annotations anchored inside an outline show or hide when the outline is opened or closed. To reanchor a shape annotation, move the shape to a new location and right-click to reanchor it.
  - **Delete**: Removes the shape from the report. You can also remove the shape by selecting it and then pressing Delete or Backspace.

---

**Customize Hover Labels in Graphs**

When you hover over a visual element in a graph, usually you see a basic description of the data point in a hover label. Customize what appears in the hover label in any of these ways:
<table>
<thead>
<tr>
<th>Description</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add interactive graphs or images using <em>graphlets</em>.</td>
<td>See “Add Graphs or Images to Hover Labels” on page 526.</td>
</tr>
<tr>
<td>Add formatted text using <em>textlets</em>.</td>
<td>See “Add Rich Text to Hover Labels in Graphs” on page 540.</td>
</tr>
<tr>
<td>Add, remove, or update names and values using <em>gridlets</em>.</td>
<td>See “Update Names and Values in Hover Labels” on page 543.</td>
</tr>
<tr>
<td>Learn more about using the Hover Label Editor.</td>
<td>See “Edit Hover Labels in Graphs” on page 553.</td>
</tr>
<tr>
<td>Update names and values in hover labels or add labels to graphs.</td>
<td>See “Add Images from Data Tables to Hover Labels” on page 558.</td>
</tr>
<tr>
<td>Add images from data tables.</td>
<td>See “Add Images from Data Tables to Hover Labels” on page 558.</td>
</tr>
<tr>
<td>Pin hover labels on graphs.</td>
<td>See “Pin Hover Labels in Graphs” on page 559.</td>
</tr>
<tr>
<td>Format hover labels and access additional options.</td>
<td>See “Right-Click Options for Hover Labels” on page 560.</td>
</tr>
</tbody>
</table>

**Figure 9.40** Examples of Graphs, Text, Names, and Values in Hover Labels

Male patient, 19 years old, 25.3 BMI, has **Medium** disease progression (200).

Text created using *textlets*

Names and values updated using *gridlets*

Hover graph created using *graphlets*
Add Graphs or Images to Hover Labels

You can add a thumbnail of a graph or an image to a hover label using graphlets.

- Preset graphlets: Preset graphlets are predefined and editable. They are easy to add, simply right-click on a graph and select Hover Label > graph type, or you can add them from the Hover Label Editor.

  **Note:** Graphs based on synthetic data (such as data used in simulations) that are not connected to a data table do not support preset graphs.

- Paste graphlet: Create a graph in Graph Builder. Copy the script by saving it to your clipboard, and then paste it as a graphlet into a baseline graph.

Once you add the hover graph, put your cursor over an element in the baseline graph. A thumbnail preview of the hover graph appears for that element. For example, for aggregate data, you can see a hover graph of the underlying data distribution.

Some JMP platforms have built-in hover label graphs, such as Principal Components, Process Screening, Model Driven Multivariate Control Charts, and Functional Data Explorer. You do not need to do anything to add these graphs to your visualizations. When you hover over them, the graph automatically appears in the hover labels.

You can also customize hover label graphs using JSL. For details, see the Scripting Guide.

Hover Graph Actions

- Click a hover graph to launch it in a new window, or click an image to open a related link.
- Press Ctrl and click on a hover label graph to replace the baseline graph with the hover label graph.
- Press Alt and click on a hover label graph to replace the contents of the last launched window, instead of opening a new one.

Example of Adding a Preset Graph to a Hover Label

In this example, you create a graph, add preset graphs to hover labels, and then customize the hover label graphs.

Create the Original Graph

1. Select Help > Sample Data Library and open JMP Man Dozen.jmp.
2. Select Graph > Graph Builder.
3. Select X and Y and drag them to the Y zone.
4. Select Data Set and drag it to the X zone.
5. Click the Bar element.  
6. For the Error Interval, select **Standard Deviation**.

**Figure 9.41** Original Graph for JMP Man Dozen.jmp

You can see that the mean and standard deviation for these observations are the same, so this graph does not tell you much. Use preset graphs to get more insight into the data.

**Add Preset Graphs**

1. In the graph, right-click and select **Hover Label > Histogram**.  
   This adds preset histograms to the hover labels.
2. Point to some of the bars. In this example, point to the red bars for dots and star.

   **Tip:** To make the hover label remain so that you can compare it with other hover labels, click the Pin icon in the top right corner. See “Pin Hover Labels in Graphs” on page 559.
You can see that the distribution for the measurements is clearly different. But you want to see another type of graph, a scatterplot.

3. In the graph, right-click and select **Hover Label > Points**.

   This changes the preset graphs from histograms to scatterplots.

4. Hover over the blue bar for `down_parab` and the red bar for `down_parab`. Notice that the Y and X variables on the axes are reversed.

   You want to use the same X and Y role assignments for all graphs (assigning the X variable to the X axis, and the Y variable to the Y axis). You also want to change the smoother to a line of fit, and add a caption box with summary statistics to the scatterplot.

   You can customize a graph in Graph Builder and then copy the graph as a template and apply it to all of the hover labels in this graph.

**Customize Graphs**

1. Hover over the blue bar for `down_parab` and click the graph to open it in a new window.

   The graph opens in Graph Builder.

**Note:** Notice that when you launch a preset graph, you see a Local Data Filter at left. You can use the Local Data Filter to expand and modify the graph. For details, see “**Local Data Filters in Reports**” on page 451.
2. Click the Graph Builder red triangle and select **Show Control Panel**.
3. Click the Line of Fit element .
4. Click the Caption Box icon .
5. Under Caption Box, change the Summary Statistic to **5 Number Summary**.
6. Click **Done**.

**Figure 9.43** Customized Graph for down_parab

7. Click the Graph Builder red triangle menu and select **Save Script > To Clipboard**.
8. Close this Graph Builder window.
9. In your original graph, right-click and select **Hover Label > Paste Graphlet**.

This applies the customized graph as a template to all hover label graphs. Hover over a few bars to see the changes.

**Tip:** To better compare original graphs and graphs launched from hover labels, use projects. See Chapter 10, “Save and Share Your Data”.

**Example of Specifying Drill-Down Column Hierarchies in Hover Labels**

In preset graphs that use categorical columns, you can specify which columns to filter by.
Create the Original Graph

1. Select Help > Sample Data Library and open San Francisco Crime.jmp. These data show crime statistics for police districts in San Francisco.
2. Select Graph > Graph Builder.
3. Select Police District and drag it to the X zone.
4. Click the Treemap element .
   You can see a treemap of the different police districts in San Francisco.
5. Right-click on the graph and select Hover Label > Treemap.
6. Put your cursor over Central to see the hover label graph.

Figure 9.44 Initial Hover Label Graph for Central

The hover label graph is showing the number of incidents in each district by the day of the week. Instead, in this example, you want to see the number of incidents in each district by category.

Specify the Drill-Down Column Hierarchy

1. In the San Francisco Crime.jmp data table, right-click the Police District column heading and select Column Properties > Next in Hierarchy.
2. Under Next in Hierarchy, click Category.
3. Click **OK**.

4. Add a second level of the hierarchy that appears if the first hover label graph is launched:
   a. In the *San Francisco Crime.jmp* data table, right-click the *Category* column.
   b. Select **Column Properties > Next in Hierarchy**.
   c. Under Next in Hierarchy, click Incident Description.
   d. Click **OK**.

5. In Graph Builder, put your cursor over Central again to see the updated hover label graph.
The hover label graph is now showing the number of incidents in each district by category.

6. Click the hover label graph to launch it.
7. Put your cursor over Other Offenses.
Figure 9.47  Second Level Hover Label Graph for Other Offenses Category

The second level of the hover label graph is showing the number of incidents in the Other Offenses category by the incident description.

Example of Removing a Filter Column from a Hover Label Graph

In some cases, the hover label graph might be filtering on a column that you want to remove. For example, the filter column might be too granular to be useful. You can remove it using the Hover Label Editor.

Create the Original Graph

1. Select Help > Sample Data Library and open CrimeData.jmp. These data show crime rates for regions and states in the U.S.
2. Select Graph > Graph Builder.
3. Select Population and drag it to the Y zone.
4. Select Year and drag it to the X zone.
5. Select Region and drag it to the Overlay zone.
6. Click the Line element .
This graph shows the mean population in each U.S. region that were impacted by different crime rates over different years. In the hover label graphs, you want to see a more granular view that shows the impacts by U.S state instead of region.

7. Keep this window open.

Copy and Paste a Graph
1. Click the Graph Builder red triangle and select **Redo > Redo Analysis**. A copy of the original graph appears.
2. In the copy of the graph, select State and drag it to the **Overlay** zone. This replaces Region with State.
3. Click **Done**.
4. Click the Graph Builder red triangle and select **Save Script > To Clipboard**.
5. Close this graph.
6. In the original graph, right-click and select **Hover Label > Paste Graphlet**.
7. Hover over the Pacific line and click to launch the hover label graph.
Because we are still filtering by year, this view is too granular to be useful. You want to remove the year filter, so the graph filters only by region.

8. Close the hover label graph for the Pacific region.

**Remove a Filter Column**

1. Right-click the original graph and select **Hover Label > Hover Label Editor**.
2. In the Graphlet window, click the **Filters** tab.
3. Select **Year**, the column you no longer want to filter by.
Figure 9.51 Skip Filters in the Hover Label Editor

4. Click **OK**.

5. Hover over the Pacific line and click to launch the hover label graph.
You can see that the hover label graphs are no longer filtering by year, but by region only, creating a more useful visualization.

**Example of Displaying Multiple Images in a Hover Label**

For labeled columns, hover labels can contain an image from the first labeled image column and up to four values from labeled text columns. To show more labeled images or text observations, use the Label Viewer.

1. Select **Help > Sample Data Library** and open Big Class Families.jmp.
2. Select **Graph > Graph Builder**.
3. Select weight and drag it to the **Y** zone.
4. Select height and drag it to the **X** zone.
5. Click the Bar element.
6. Hover over the bar for the height of 65 inches and click **Pin**.
Although five names are included in this bar, only the first image (Henry) appears in the hover label. You want to see more images in the hover label.

7. Right-click in the graph and select **Hover Label > Label Viewer**.
Figure 9.54 Hover Label with Multiple Images

The maximum of four images now appear in the hover label.

8. To see the additional image, in the hover label, click a thumbnail.
9. In the Label Viewer, click the Forward arrow to see the fifth image.

Add Rich Text to Hover Labels in Graphs

A textlet is a hover label extension that adds formatted text to a hover label. You might use a textlet to describe data in an explanatory paragraph, or to call out important information by making it bold or drawing it in a different color.

Example of Adding Text to a Hover Label

Create the Original Graph

1. Select Help > Sample Data Library and open Diabetes.jmp.
   These data show measurements for diabetes patients that track the progression of the disease.
2. Select Graph > Graph Builder.
3. Select LDL and drag it to the Y zone.
4. Select Age and drag it to the X zone.
5. Click the Line of Fit element.
6. Click **Done**.
7. Hover over the point in row 345.

**Figure 9.55** Initial Hover Label for Content for Row 345

For the data point in row 345, you can see the row number, age of the person, and their LDL measurement. Change what appears in the hover labels:

- Add the patient’s level of disease progression in a sentence.
- Assign different colors to the levels of the disease progressions, based on severity.

**Add Text**

1. Put your cursor over the hover label for row 345 and click **Pin**.
   Pinning the hover label enables you to see your changes as you apply them.
2. Right-click in the graph and click **Hover Label > Hover Label Editor**.
3. On the left, click **Textlet**.
4. In the JSL Variables box, define the variables using JSL. Copy and paste the following JSL script:

```julia
// gets the value for the Y Ordinal column for the underlying visual element
local:YOrdinal = As Column( "Y Ordinal" )[local:__firstRow];
// maps the value to HTML color names that are used to style the text
local:color = Match( local:YOrdinal,
                    "Low", "Medium Dark Green",
                    "Medium", "Medium Dark Blue",
                    "High", "Medium Dark Red" );
```

5. Under HTML Markup, write your text using HTML and the JSL variables that you just defined. Copy and paste the following code:

```
Patient has <font color='{local:color}'>{local:YOrdinal}</font> disease progression.
```

**Figure 9.56** JSL Variables and HTML Markup for Textlet

6. Click OK.
You can see the new sentence appearing in the hover label indicating the level of disease progression. Since the disease progression for this patient is medium, it is color coded blue.

**Update Names and Values in Hover Labels**

When you hover over an element in a graph (such as a point, bar, and so on), you see content in the hover label for that element. By default, the hover label contains name and value pairs that are in a grid. The value can come from the data table, or can be an arbitrary calculation or JSL expression. You can customize these names or values using gridlets. For example, here are some things that you can do:

- Remove a name and its associated value
- Add a name and its associated value
- Change a name
- Change the style of a name (for example, bold) or a value (for example, decimal places)
Tip: Another way to customize hover label grid entries is using labels. See “Add Images from Data Tables to Hover Labels” on page 558.

Example of Updating Names and Values in a Hover Label

In this example, you create a graph and update content in the hover label using gridlets.

Create the Original Graph

1. Select Help > Sample Data Library and open Movie Inventory.jmp. These data show movie rental data.
2. Select Graph > Graph Builder.
3. Select Length and drag it to the Y zone.
4. Select Year and drag it to the X zone.
5. Click Done.
6. Hover over the point in row 34 (Figure 9.58).

Figure 9.58 Initial Hover Label Content for Row 34

For the data point in row 34, you can see the row number, the year in which the movie was made, and the length of the movie (in minutes). Change what appears in the hover labels:

• Remove the row number and the length entry.
• Add the movie name and genre.
• Create a new entry that shows the length of the movie in hours and minutes.
• Make the genre name bold.

**Update Names and Values**

1. Hover over the hover label for row 34 and click Pin .
   *Pinning the hover label enables you to see your changes as you apply them.*

2. Right-click in the hover label and click **Edit**.

3. At left in the thumbnail, click **Row**.

4. In the Delete tab, click **Add**.
   *“Row” appears under the entries to delete.*

5. Click **Apply**.
   *In the graph window, you can see that Row is removed from the hover label.*

**Figure 9.59  Hover Label with Row Removed**

6. At left in the thumbnail, click **Length** (the other entry that you want to remove).

7. In the Delete tab, click **Add**.
   *“Length” appears under the entries to delete.*
8. Click **Apply**.

In the graph window, you can see that **Length** is removed from the hover label, leaving only **Year**.

9. Add the movie name and genre:
   a. Click the **Append** tab. Type should be set to **Name**.
   b. Under Target, type **Name** (the name that you want to add).
   c. Under Value, copy and paste the following JSL expression: `:Name[local:_firstRow]`

   Name is the column reference. Brackets indicate to get the corresponding column value for the given index. `local:_firstRow` is the index, which is a Hover Label Execution Context (HLEC) variable. For details, see the *Scripting Guide*.
   d. Click **Add** and then click **Apply**.

   In the thumbnail and in the graph hover label, you can see that the name of the movie is added.

**Figure 9.60** Hover Label with Name Added

**e.** Under Target, type **Genre** (the next name you want to add).

**f.** Under Value, copy and paste the following JSL expression:

   `:Genre[local:_firstRow]`

**g.** Click **Add** and then click **Apply**.
In the thumbnail and in the graph hover label, you can see that the genre of the movie is added.

10. Convert the Length data from minutes to hours and minutes:
   a. On the **Append** tab, in the Target box, type `Duration` (the name of the new hover label that you want to add).
   b. Under Value, copy and paste the following JSL expression: `local:_Length * 60`
      
      `local:_Length` is an HLEC variable, with the value of the grid entry `Length`. `Length` is in the graph, so we have access to this value in the hover label context. For details, see the *Scripting Guide*.
      
      `* 60` converts the duration from minutes to seconds. In order to apply the hours:minutes format, the duration needs to be in seconds.
   c. Click **Add** and then click **Apply**.
      
      In the thumbnail and in the graph hover label, you can see the `Duration` label is added. But the value needs to be formatted correctly.

**Figure 9.61** Hover Label with Duration Added

d. Click the **Reformat** tab.

e. Under Target, type `Duration` (the name of the hover label entry that you want to reformat).

f. Click **Edit**.
g. Next to Format, select **Duration** > hr:m and then click **OK**.

h. Click **Add** and then click **Apply**.

On the hover label, you can see that the Duration is now in hours and minutes.

**Figure 9.62** Hover Label with Duration in Hours and Minutes

11. Make the Genre values bold:
   a. Click the **Style** tab.
   b. Under Target, type **Genre** (the name of the hover label entry that you want to make bold).

   Notice that Scope is set to **Values**. This bolds the Genre values instead of the name Genre.
   c. Click **Font**.
   d. Under Font style, click **Bold** and then click **OK**.
   e. Click **Add** and then click **Apply**.

   On the hover label, you can see that the Genre value, Romance, is now bold.
Figure 9.63 Hover Label with Genre Value in Bold

Hover over the other labels to see that they are all updated.
Use Labels in Data Tables

In addition to gridlets, you can also do some basic customization of hover labels by adding Labels to columns in data tables.

- If your hover label contains a Row entry, you can replace it with values in columns by adding a Label.
- Once you add a Label, you can make it persist on the graph. You can also move the label’s location on the graph. A tag line might be added to connect the label to its point.

Example Using Labels in Data Tables

1. Select Help > Sample Data Library and open iris.jmp.
2. Select Graph > Graph Builder.
3. Select Sepal length and drag it to the Y zone.
4. Select Sepal width and drag it to the X zone.
5. Click Done.
6. Hover over the point in row 109.
You can see that a Row entry appears in the hover label. You want to replace it with a column and its value from the data table called Species.

7. In the data table, right-click the Species column and select Label/Unlabel.

   A label icon appears beside the column name in the Columns panel.

8. In Graph Builder, hover over the same data point.

![Figure 9.65 Hover Label for Row 109](image)

You can see that the Row entry is replaced by the Species column.

**Note:** If you specify multiple labeled columns, their values appear alphabetically in the hover label.

Now, you want to make some of the labels persist on the graph.
9. Click the same data point to highlight it.
10. Right-click anywhere and select **Rows > Row Label**.

**Note:** In a histogram, right-click the box plot area on the right.

Figure 9.67  Species Label Showing on Graph

You can see that the label containing the Species value for this data point appears on the graph.

11. Click and drag the label to move its position.

A tag line is added to connect the label to the point.

Figure 9.68  Reposition the Species Label

In the data table, a label icon 📊 appears beside the row number.
Data remains labeled until you highlight the column or row and select **Label/Unlabel** again.

### Edit Hover Labels in Graphs

Use the Hover Label Editor to customize and add graphs, images, formatted text, names, and values in hover labels.

*To interactively edit hover labels*

1. In a graph, hover over data to show a hover label.
2. In a hover label, right-click and select **Edit**.

In the Hover Label Editor, a thumbnail of the hover label appears at left. Click an area in the thumbnail to edit it at right. Changes that you make apply to all hover labels in the graph.

**Figure 9.69  Interactively Edit a Hover Label**

In this example, the Incident Address data is clicked and the Delete tab appears, so you could delete the Incident Address entry from all hover labels in the graph. You could also rename it, reformat it, or change the font style.

To add or edit hover labels generally, launch the Hover Label Editor. Right-click on a graph and select **Hover Label > Hover Label Editor**.
Figure 9.70 Hover Label Editor

On the left, you can choose **Textlet**, **Gridlet**, or **Graphlet**, depending on what you want to do in hover labels:

**Textlet**  Add formatted text to hover labels using JSL. For an example, see “Example of Adding Text to a Hover Label” on page 540. For details about this window, see the Scripting Guide.

**Gridlet**  Delete, add, rename, reformat, or choose a style for names and values that appear in hover labels. For an example, see “Example of Updating Names and Values in a Hover Label” on page 544. For details about this window, see “Gridlet Tabs” on page 556.

**Graphlet**  Add an interactive graph or image to hover labels. For an example, see “Example of Adding a Preset Graph to a Hover Label” on page 526. For details about this window, see “Graphlet Tabs” on page 558.

**Textlet Tabs**

**Markup**  Define HTML markup used to create rich text on the hover label.

**Presets**  Examples of a preconfigured textlet.

- The Showcase textlet is an example of how to add color and style to the textlet content based on the underlying data. “Add Rich Text to Hover Labels in Graphs” on page 540 for an example.
- The Tabulate textlet is an example of how to add summary statistics for the underlying data to the textlet content.
- The Context textlet is an example of how to display the evaluation context variables in the textlet (for debugging purposes). Evaluation context variables define the environment in which your graphlet and textlet scripts are executed. See the Scripting Guide for details.
**JSL Variables**  (Optional) Enables you to assign the result of expressions to local JSL variables. The variables are used in the HTML Markup field to create dynamic, data-driven rich text.

**HTML Markup**  Specifies a rich text paragraph template based on a subset of HTML tags. The markup can contain JSL variable references enclosed in delimiters. The default delimiters are braces ({}). Table 9.5 describes the supported HTML tags:

<table>
<thead>
<tr>
<th>HTML Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;b&gt; &lt;/b&gt;</td>
<td>bold text</td>
</tr>
<tr>
<td>&lt;i&gt; &lt;/i&gt;</td>
<td>italicized text</td>
</tr>
<tr>
<td>&lt;u&gt; &lt;/u&gt;</td>
<td>underlined text</td>
</tr>
<tr>
<td>&lt;font&gt; &lt;/font&gt;</td>
<td>stylized font with any of the following attributes:</td>
</tr>
<tr>
<td></td>
<td>• color=color: The quoted foreground color value. Can be a color name or a hexadecimal RGB color value.</td>
</tr>
<tr>
<td></td>
<td>• face=family: The quoted name of an installed font family.</td>
</tr>
<tr>
<td></td>
<td>• size=size: The quoted font size.</td>
</tr>
<tr>
<td>&lt;background&gt;</td>
<td>background color value</td>
</tr>
<tr>
<td></td>
<td>• color=color: The quoted color name or hexadecimal RGB color value.</td>
</tr>
</tbody>
</table>

**Other**  Specify the delimiters and width of text on the hover label.

**Delimiters**  Select the delimiter that indicates variables for replacement in the Markup area. For example, you might use square bracket delimiters for JMP variables if the script contains C++ code or other code that also uses braces.

**Width**  Specify the preferred width in pixels for the hover label.
Note: After you make changes to the textlet configuration, you can click Apply to see your changes on a pinned hover label. When you are satisfied with the updated hover label, click OK to save your changes.

Gridlet Tabs

Gridlet tabs include Delete, Append (add), Rename, Reformat, and Style. In all of these tabs, you specify the Matching Criteria, which identifies the hover label entry that you want to modify.

Type and Target

Matching Criteria Specify the hover label entry that you want to modify:
Choose the type of entry to select and the target entry.

Note: Not all choices appear in all tabs.

Name Enter the exact name of the entry that you want to modify. For example, if the entry name is Mean(height), enter this target value: Mean(height).

Index Enter the index of the entry in the grid that you want to modify. For example, if the third entry in the hover label is Mean(height), enter 3 as the Target value.

Column Enter the column name of the entry that you want to modify. For example, if the entry is Mean(height), enter this target value: height.

Regex Enter a regular expression matched against the name that you want to modify. For example, if the entry is Mean(height), enter this target value: ^.*\(height\)$ (The Pat Regex, parenthesis, and quotations are automatically added.)

All Changes the style for all hover label entries.

Gridlet Buttons

Add Adds a specified Target value under Entries. Click Apply to apply your changes to the hover label.

Remove Removes a specified Target value under Entries. Click Apply to apply your changes to the hover label.
Replace  Replaces a selected Target value under Entries. Click an entry, enter a new target value, and click Replace. Click Apply to apply your changes to the hover label.

Gridlet Tabs

Delete  Specify entries to delete from hover labels.

**Note:** If you are using JSL, Delete is the Expunge command.

Append  Specify entries to add to hover labels.

Value  Specify the JSL to add the value to the hover label. For an example, see “Update Names and Values” on page 545.

Click  Add an action to the entry that will appear as a link. Specify the script to be executed when the link is clicked. For example, the script can create a visualization, open a web page, or launch a platform. Here are a few ways that you can copy and paste a script:

Create a visualization to link to: In Graph Builder, create the visualization that you want. Click the Graph Builder red triangle menu and select Save Script > To Clipboard. Paste the script under Click.

Link to a preset graph: In Graph Builder, from the underlying graph that has the preset hover label graphs, right-click > Hover Label > Hover Label Editor. Under Graphlet, in the Picture tab, copy the script. Paste the script under Click.

Click Apply to apply your changes to the hover label.

**Note:** If you are using JSL, Append is the Annex command.

Rename  Specify entries to rename in hover labels. Enter a new name to replace the current Target value.

Reformat  Specify a different format for entry values in hover labels. For example, you can change the date or duration format, or change the number of decimal points. Click Edit to choose a different format. For details about the Edit options, see “Numeric Format Options” on page 295

Style  Specify a background color, text color, or font details (such as bold, and so on) for entries in hover labels.

Scope  Specify if the style updates should be made to the names of the entries, the values, or both. For example, if you are applying a style change to all the matching criteria, you can easily align all the names to the left, or all the values to the right.
Background color  Specifies the background color for the Target value, name, or both in hover labels.

Text color  Specifies the text color for the Target value, name, or both in hover labels.

Font  Specifies font details, such as font, font style, and size for the Target value, name, or both in hover labels.

Alignment  Specifies how to align the text for the Target value, name, or both in hover labels.

Graphlet Tabs

Presets  Click a preset graph to add it to hover labels. For details about preset graphs, see “Add Graphs or Images to Hover Labels” on page 526.

Picture  Add a JSL script to define the type of graph or image to add to hover labels.

Click  Add a JSL script that is executed when a user clicks on the thumbnail (or hover graph) that is defined by the Picture script. If nothing is defined here, the Picture script is reused, so that the image or graph defined under Picture is launched in a new window.

Filters  Remove a filter column from your hover graph. Click a column that you want to remove, or add a “1” under Skip Filters Flag. See “Example of Removing a Filter Column from a Hover Label Graph” on page 533.

Thumbnail  Specify the size of the graph thumbnail and whether to include axis values.

Other  Use JSL to specify the following information:

  Title  Sets the title of the new window that is created when a hover graph is launched.

  Reapply  Defines whether the current hover label graph customizations are applied to a new window launched when clicking on a hover graph.

Add Images from Data Tables to Hover Labels

You can add images to hover labels using graphlets, but you can also add them from a data table.

Tip: For details about adding JMP graphs or images using graphlets in a hover label, see “Customize Hover Labels in Graphs” on page 524.

1. Create a new column in your data table.
2. Right-click the column, select Column Info, and select the Expression data type.
3. Click OK.
4. Drag graphics from your computer into each cell of the column. You can also import data that contains a column of images.

5. Right-click the column in the data table and select **Label/Unlabel** to apply a label.

6. Create a graph using your data table (for example, in Graph Builder or Distribution).

7. Hover over a data point or a histogram bar.

   The image appears on the label. To see an example, run the Graph Builder script in the SAS Offices.jmp sample data table.

**Figure 9.72 Image on Hover Label**

![Image on Hover Label](image)

**Tips:**

- Images in an expression column can also be used as markers. See “Use Images as Markers” on page 489.

- You can pin the hover label so that the label always appears on the graph. See “Pin Hover Labels in Graphs” on page 559.

**Pin Hover Labels in Graphs**

When you hover over data on a graph, a hover label that contains data values appears. You can pin the hover label so that it always appears on the graph as a label. This is helpful if you want to compare several labels, or if you want to show the label information. When you save the graph, the label is saved. When you print the graph, the label is printed.
Note: The hover label remains pinned after you redo an analysis. However, if the data changed, you might have to reposition the label.

Figure 9.73 Pinned Hover Labels

To pin a hover label, hover over the data point until the label appears. Click the pin icon in the upper right corner of the label. You can then drag the label to reposition it.

Right-Click Options for Hover Labels

**Background Color**  Applies the selected color to the label background.

**Frame Color**  Applies the selected color to the label border and tag line.

**Text Color**  Applies the selected color to the text.

**Filled**  Applies the background color and frame color to the label. Selected by default.

**Use Gradient**  Shades the background color vertically from light to dark. Selected by default.

**Font**  Applies the selected font family to the text. The default font is determined by your JMP Font preferences.

If a script with a pinned label refers to a font that is not on the computer, the script does not run.

**Add Text**  Adds text to the bottom of the label.

**Replace Text**  Change the text on the tooltip. If you redo the analysis, the tooltip text remains updated.

**Tag Line**  Draws a line between the label and the data point. The Frame Color is applied to the line.
Copy  Copies the hover label contents to the clipboard.

Subset  Opens a data table with the subset data associated with the hover label.

Edit  Opens the Hover Label Editor, where you can further edit the contents of the hover label. See “Edit Hover Labels in Graphs” on page 553.

Close  Removes the label. You can also remove the label by clicking the X in the upper right corner of the label.

Note: To return to the default label formatting, remove the label and add it again.
This chapter covers the following topics:

- saving data tables as text files, SAS data sets, Excel files, and other formats
- saving reports as interactive HTML and PowerPoint
- emailing reports and data tables
- saving analyses as scripts
- saving parts of a report as a graphic
- printing reports
- copying and pasting reports
- creating JMP journals or projects
- saving JMP sessions
- saving log windows

The method that you choose depends on how you want to interact with your analyses in the future:

- If you want to interactively present your data, you might choose to create a JMP journal.
- If you want to send data tables, linked reports, and other items to someone, you might choose to create a JMP project.
- If you want to continue to explore a report later, you might choose to create a JMP report.
- If you want to send a report to a non JMP user, you might convert the report to interactive HTML or a web report.
## Contents

**Save and Share Data Tables** 566
- Save Data Tables as Microsoft Excel Files 567
- Save JMP Data as a CSV File 568
- Save JMP Data as a Text File 569
- Save JMP Data as a JSON File 570
- Save JMP Data as a SAS Transport File 570
- Save JMP Data as a Google Sheet 572
- Save JMP Data as a SAS Data Set 573
- Save Data Tables to a Database 574
- Replace a Database with a Data Table 575

**Save and Share Reports** 576
- Share Reports as Interactive HTML 578
- Publish Reports to JMP Live or JMP Public 582

**Save Reports as PDF Files** 590
- Save Reports as PowerPoint Presentations 591
- Setting the Graphic DPI for Exported Graphics 592

**Save a JMP Analysis as a Script** 593

**Save Parts of a Report in a Graphic Format** 593

**Print Reports** 594

**Copy and Paste Reports** 595

**Work with Projects** 596
- Create a New Project 597
- Open Files in a Project 597
- Rearrange Files in Projects 598
- Save a Project 599

Save JMP Sessions .............................................................................................. 616
  Save Sessions upon Exiting JMP ................................................................. 617
  Save Sessions Manually .............................................................................. 617
Save a Log Window ......................................................................................... 618
Save and Share Data Tables

Select **File > Export** or **File > Save As** to save a data table in another format such as Microsoft Excel or CSV.

**Note:** To save a data table as a journal, select **Edit > Journal** and then **File > Save As**.

JMP saves data tables in the formats listed in Table 10.1.

**Table 10.1** Supported File Types for Saving Data Tables

<table>
<thead>
<tr>
<th>File Type(s)</th>
<th>OS Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>JMP Data Table (.jmp)</td>
<td>All</td>
</tr>
<tr>
<td>Excel Workbook (.xls, .xlsx)</td>
<td>All</td>
</tr>
<tr>
<td>Text Export File (.txt)</td>
<td>All</td>
</tr>
<tr>
<td>Comma-delimited File (.csv)</td>
<td>Windows</td>
</tr>
<tr>
<td>Tab-delimited File (.tsv)</td>
<td>Windows</td>
</tr>
<tr>
<td>SAS Data Set (.sas7bdat)</td>
<td>All</td>
</tr>
<tr>
<td>SAS Data Set with Extended Attributes (.sas7bxat)</td>
<td>Windows</td>
</tr>
</tbody>
</table>

**Note:** JMP can save column properties and table properties as extended attributes in a SAS 9.4 .sas7bxat file. Select **File > Export**, select the **SAS** file type, and then select the check box for saving extended attributes. JMP names the file with the .sas7bxat extension. The SAS Integration preferences also include this option, which is off by default.

<table>
<thead>
<tr>
<th>File Type(s)</th>
<th>OS Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAS Transport File (.xpt, .stx)</td>
<td>All</td>
</tr>
<tr>
<td>JSON Data File (.json)</td>
<td>All</td>
</tr>
</tbody>
</table>

You can also save files for types that have a corresponding ODBC driver. See “**Save Data Tables to a Database**” on page 574.

**Notes:**

- The maximum length of the data table’s name depends on your computer’s operating system. See your operation system documentation for details.
- JMP tries to save any modified files when a crash is detected.
Save Data Tables as Microsoft Excel Files

There are two options for saving data tables as Microsoft Excel files:

- Save one data table in Microsoft Excel format (.xls or .xlsx). Data from a single table is saved in a workbook named after the data table.
- Generate a workbook in .xlsx format from multiple tables. Data from each table appear on a different worksheet in the workbook.

Saving an .xlsx file retains data table cell colors, hidden data, and excluded data. Formulas and most formatting are not included.

The maximum length of the Excel filename is determined by your computer’s operating system.

Save One Data Table as a Microsoft Excel Workbook

To save a data table as a Microsoft Excel workbook, follow these steps:

**Windows**

1. Select **File > Export**.
2. Select **Microsoft Excel** and click **Next**.
3. Enter a name for your file in the File name box.
4. (Optional) To save the file as an .xls file, select **Use Excel 97-2003 Format (*.xls)**.
5. (Optional) To avoid opening the file in the default spreadsheet program after saving, deselect **Open the file after saving** on the Export window.
6. Click **Save**.

**macOS**

1. Select **File > Export**.
2. Select **Microsoft Excel** and select the format.
3. Click **Next**.
4. Enter a name for the file in the **Save As** box.
5. (Optional) To avoid opening the file in the default spreadsheet program after saving, deselect **Open the file after saving**.
6. Click **Export**.

**Note:** On Windows, data is split among several worksheets when the number of columns or rows exceeds the number that Excel supports.
Save Multiple Data Tables as a Microsoft Excel Workbook

To save multiple data tables in a new or existing Microsoft Excel workbook, follow these steps:

1. Open the data tables.
2. (Windows) Select File > Export > Microsoft Excel, select Export Multiple Data Tables, and then click Next.
3. (macOS) Select File > Export, select Export Multiple Data Tables from the Excel list, and then click Next.
4. In the JMP Data Table column, select only the data tables that you want to save.
5. In the Worksheet Name column, specify the name of the worksheet tab if necessary.
6. Enter a name for the workbook in the Workbook Name box.
   The workbook is named after the current data table by default.
7. Click Choose and browse to select a directory to save the file in.
   You can overwrite an existing workbook. Worksheets that already exist in the workbook are replaced. Worksheets that are not in the existing workbook appear at the end of the sheets.
8. Click Save (or Export on macOS).
   The file is saved as an .xlsx file.

Save JMP Data as a CSV File

On Windows, JMP can convert data from a JMP data table to a comma-separated values (CSV) file. To save a data table as a CSV file:

1. With the specific data table open in JMP, select File > Save As.
2. Select CSV (Comma delimited) (*.csv) from the Save as type list.
3. Enter the filename.
4. Select the location for the CSV file.
5. Click Save.

Note: Exporting a data table to a CSV file uses the comma and carriage return line feed character (CRLF) as file delimiters. Use a different extension and later rename the file with the CSV extension if you need to use different delimiters.
Save JMP Data as a Text File

JMP can convert data from a JMP data table to standard text format with rows and columns.

Text Formatting Options

Export Column Names to Text File  To save column headings in the first line of text, and to save labels or header information with the data, select Export Table Headers.

Add quotation marks to all column names, Add quotation marks to all character values, Add quotation marks to all numeric values  Select an option to add quotation marks even when they are not required. Some programs that import CSV files might need the quotation marks to display the text correctly. Quotation marks are always added to fields that contain special characters such as the field delimiter (typically a comma or tab), the line separator (typically a carriage return), or quotation marks.

End of Field  Select the radio button next to the character that marks the end of a field (or cell). Select Other and enter a character if the appropriate character is not listed.

End of Line  Select the radio button next to the character that marks the end of a line (or row). Select Other and enter a character if the appropriate character is not listed.

Notes:

• If a double quotation mark is found when importing text data, the delimiter rules change, and JMP looks for an end double quotation mark. Other text delimiters, including spaces embedded within the quotation marks, are ignored and treated as part of the text string.
• When you import text data, columns that contain image data are assigned the Expression data type.

Windows

1. Select File > Export.
2. Select Text and then click Next.
3. Enter the file name in the File name box.
4. Click the Options button and specify end-of-line and end-of-field characters, and choose whether to export column headings as text.
5. Click OK.
6. (Optional) To avoid opening the file in the default text editor after saving, deselect Open the file after saving.
7. Click Save.
8. Click Yes.
macOS

1. Select **File > Export**.
2. Select **Text** and then click **Next**.
3. Enter a name for the file in the Save As box.
4. Specify end-of-line and end-of-field characters, and choose whether to export column headings as text.
5. (Optional) To avoid opening the file in the default text editor after saving, deselect **Open the file after saving**.
6. Click **Export**.

Save JMP Data as a JSON File

You can save a data table as a JSON file, which consists of name and value pairs. JSON files are often used to exchange data between applications.

To save a data table as a JSON file, follow these steps:

**Windows**

1. Select **File > Export**.
2. Select **JSON Data** and click **Next**.
3. Enter the file name in the File name box.
4. Click **Save**.

**macOS**

1. Select **File > Export**.
2. Select **JSON Data** and click **Next**.
3. Enter a name for the file in the Save As box.
4. Click **Export**.

Save JMP Data as a SAS Transport File

You can save a JMP data table in SAS transport file format. JMP replaces spaces in filenames and column names with underscores, converts column headings to uppercase SAS variables, and makes other changes to follow the transport file specifications.
When you save the data table as a transport file, you can opt to append it to an existing transport file. When you reopen the transport file in JMP, the two data tables open in separate windows.

**Notes:**
- The maximum length for SAS transport filenames is 8 characters. JMP warns that characters beyond that limit are omitted.
- Images in Expression columns cannot exceed 200 characters, otherwise they are not supported.

**Windows**
1. Select **File > Export**.
2. Select **SAS Transport File**.
3. Click **Next**.
4. Enter the file name in the File name box.
5. Click **Save**.
6. Click **OK**.
   Alerts appear regarding other SAS format modifications.
7. Click **OK** on each alert.
8. (Optional) Append the data table to an existing SAS transport file. Select **File > Export**, select the **Append** check box, and then click **Next**. Select the file to which you want to append the data table and then click **Save**.

**macOS**
1. Select **File > Export**.
2. Select **SAS Transport**.
3. Click **Next**.
4. Enter a name for the file in the **Save As** box, and then click **Export**.
   Alerts appear regarding SAS format modifications.
5. Click **OK** on each alert.
6. (Optional) Append the data table to an existing SAS transport file. Select **File > Export**, select the **Append** check box, and then click **Next**. Select the file to which you want to append the data table and then click **Append**.
Save JMP Data as a Google Sheet

A Google Sheet is a spreadsheet (which consists of sheets, like tabs) that is saved in your Google account. Exporting a JMP data table to Google Sheets enables you to share the data with others and edit the data outside of JMP.

You can export a JMP data table to an existing Google spreadsheet or create a new one.

To export a JMP data table as a Google spreadsheet, follow these steps:

1. If you are exporting to an existing spreadsheet, perform these steps first. Otherwise, go to step 2.
   b. Open the existing spreadsheet.
   c. Copy the URL from the browser’s address bar.
2. In JMP, open the data table with the data you want to export.
4. Under Spreadsheet Type, choose either Existing or New Spreadsheet.
5. Type your Google account name. (@gmail.com is unnecessary.)
6. (Existing spreadsheets only) Next to Spreadsheet Name, paste the URL of the Google spreadsheet you copied in step 1.
7. (New spreadsheets only) Enter a name for the new spreadsheet.
8. Enter the name of the sheet (the tab name).
9. Click Save.
10. If you have already exported a data table from JMP, the data will appear in Google Sheets. Go to your Google spreadsheet to see the data in the specified sheet.
    or
    If you are exporting data using the specified Google account for the first time, you are prompted to give JMP access to your Google account.
    a. Click Allow.
    b. Go to your Google spreadsheet to see the data in the specified sheet.
   Depending on the size of the data table, the save operation might take some time.

About Exporting Google Sheets

- JMP features such as formulas and List Check column properties are not supported in Google Sheets.
- If the spreadsheet is empty, look in the JMP log for error messages. On Windows, select View > Log. On macOS, select Window > Log.
• If a Google Sheet has only one sheet, you cannot replace the sheet with a new sheet. Add a second sheet with a unique name and then delete the original sheet. In the Export to Google Sheets window, select Existing Spreadsheet and export the data table again. The sheet name that you specified appears in the sheet.

• See “About Importing Google Sheets” on page 177 in the “Import Your Data” chapter for more information about security, country restrictions, and more.

• If Display intranet sites in Compatibility View in Internet Explorer on Windows is selected, the Google Sheet cannot be exported. To avoid this issue, follow these steps:
  1. In Internet Explorer, select the Tools button and then select Compatibility View settings.
  2. Deselect Display intranet sites in Compatibility View.

Save JMP Data as a SAS Data Set

You can save data tables as SAS version 7 and higher data sets. JMP writes columns as SAS variables, writes rows as SAS observations, and makes other changes to follow the SAS data set specifications.

When you export data to a SAS data set, JMP date columns become SAS date values with the appropriate SAS format.

On Windows, JMP can save column properties and table properties as extended attributes in a SAS 9.4 .sas7bxt file. The option is available in the Save JMP As window and in the SAS Integration preferences.

Windows

1. Select File > Export.
2. Select SAS Data Set and click Next.
3. Enter the file name next to File name.
4. (Optional) To save SAS variable names or SAS formats, select the Preserve SAS variable names or Preserve SAS formats check boxes.
5. (Optional) To store JMP metadata as extended attributes for SAS 9.4, select Store table and column properties in SAS 9.4 extended attributes. JMP automatically assigns the .sas7bxt file extension.
6. Click Save.
7. Click Yes.
8. If other alerts appear, click OK on each alert.
macOS

1. Select **File > Export**.
2. Select **SAS** and click **Next**.
3. Enter the filename and select export options.
   - To avoid exporting rows that have the Excluded row state, select **Honor Excluded Rows**. The other options are described in the preceding section.
4. Click **Export**.

### Save Data Tables to a Database

You can save a data table to any database on your system that has a compliant ODBC (Open Database Connectivity) driver.

When exporting a data table to a database using ODBC, JMP exports the data as either character (CHAR or NCHAR) or numeric (FLOAT or DOUBLE PRECISION) data types. If a column is defined as a JMP date or time, the column exports as character data. The receiving database handles changing the data type to a proper date format.

1. First, connect to the database. See “To add a new database connection” on page 575.
2. Select **File > Database > Save Table**.

**Figure 10.1** The Database Save Table Window

1. In the Connections box, highlight the name of the database to which you want to save the file (Figure 10.1). The Connections box contains a list of databases to which your system is connected.
2. From the **JMP data table to be saved** menu, select the open JMP data table that you want to save to the database.
5. In the **Save to database table** box, enter the name that you want the table to have when you save it in the database.

6. Click **Save Table**.

**To add a new database connection**

1. Click **Connect**.
2. Select the data source that you want and click **OK**. Or, to create a new source, click the **New** button (Windows) or **Choose DSN** button (macOS).
   
   Depending on which data source you select (and which database drivers you have installed on your computer), you might be presented with a variety of windows. Use them to create the database source.

3. Select the database to which you want to save the file.

**Replace a Database with a Data Table**

To replace a database with a data table, follow these steps:

1. First, connect to the database. See “**To add a new database connection**” on page 575.

2. Select **File > Database > Save Table**.

3. In the Connections box, select the name of the database to which you want to replace the file. The Connections box contains a list of databases to which your system is connected.

4. In the Schemas - Tables box, select the database table that you want to replace.

   **Note:** Remember the name for the database table. You use this same name for the replacement database table.

5. Click **Drop Table**.
   
   The database table is deleted from the database.

6. From the **JMP data table to be saved** list, select the JMP data table that you want to save to the database.

7. In the **Save to database table** box, enter the name for the deleted database table.

8. Click **Save Table**.
   
   The data table is saved to the database.

9. Click **Disconnect**.

10. Close the Database Save Table window.
Save and Share Reports

To save a report, select File > Export.

- On Windows, you can save the report as any of the file types listed in Table 10.2.
- On macOS, the report is saved as a JMP report (.jrp). Note the following:
  - You can save the report as a journal by selecting Edit > Journal and then File > Save.
  - If you want to save the report as a text, image, HTML, PowerPoint, or RTF file, select File > Export. Supported image files include .png, .emf, .jpg, .gif, .tiff, .svg, and .eps.

Table 10.2 Windows Supported Report File Types

<table>
<thead>
<tr>
<th>File Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Word (.doc)</td>
<td>Word processing format; mixture of pictures, text, and tables.</td>
</tr>
<tr>
<td>Enhanced Metafile (.emf)</td>
<td>Can contain both vector and bitmap components.</td>
</tr>
<tr>
<td>Encapsulated PostScript File (.eps)</td>
<td>Line drawing (or vector image) that can show a bitmap preview of the image.</td>
</tr>
<tr>
<td>CompuServe Graphics Interchange Format (.gif)</td>
<td>Compressed bitmap pictures.</td>
</tr>
<tr>
<td>Hypertext Markup Language (.htm, .html)</td>
<td>Browser format; marked up text and references to separate picture files. Save pictures within the HTML file by selecting one of these formats: PNG, JPEG, SVG, or GIF.</td>
</tr>
<tr>
<td>HTML or Interactive HTML with Data (.htm, .html)</td>
<td>Saves the data, reports, and graphs in an interactive web page, so non JMP users can explore the data. See “Share Reports as Interactive HTML” on page 578.</td>

</tbody>
</table>
Share Reports as Interactive HTML

Interactive HTML enables you to share JMP reports that contain dynamic graphs so that even non JMP users can explore the data. JMP reports are saved as an interactive web page that you can share with others (for example, on a shared network drive, by email, or on a website). Users then explore the data as they would in JMP.

Interactive HTML Contains Data

When you export or publish a report as interactive HTML, your data are embedded in the HTML. The content is unencrypted, because web browsers cannot read encrypted data. To avoid sharing sensitive data, export your results as a non-interactive web page instead by selecting File > Export > HTML.

Which Features Are Supported Interactively

Interactive HTML provides a subset of features from JMP:

- If the features in your report are fully supported, the web page is created with no warnings.
- If your report contains unsupported features, you see a message in the export or publish window that interactive HTML is partially implemented. For details, see the JMP log (View > Log).
- Partially or unsupported features appear static in the web page. If you hover over an unsupported feature in the web page, a tooltip says that the feature is not yet interactive.

For information about exploring interactive HTML output, visit https://www.jmp.com/interactive.

Export a Single Report as Interactive HTML

To export a single JMP report as interactive HTML, use the Export as Interactive HTML with Data option to create a single web page.

1. In JMP, create the report and make it the active window.

   **Note:** If a report contains a Local Data Filter, it is static in the web report and users cannot change the selections. To make the Local Data Filter interactive, deselect the Include mode. (In Graph Builder, to see the Include mode, select Show Modes from the Local Data Filter red triangle menu.)

2. Select File > Export, select Interactive HTML with Data and click Next.
3. Name the file.
4. (Optional) To open the HTML file in your default browser after exporting it, select Open the file after saving.
5. Click **Save**.

The output is saved in the selected folder.

**Figure 10.2** Web Page for Single Interactive HTML Report

---

**Publish Multiple Reports as Interactive HTML**

To publish multiple JMP reports as interactive HTML, use the Publish to File option, which creates an index page that contains the reports.

**Tip:** When you publish multiple JMP reports, you specify where to save the index page and report files. You can choose a shared network folder and provide the location to others, or choose a folder on your computer and zip the files before sharing. This is particularly helpful if you are sharing with non JMP users.

1. In JMP, create the reports.

**Note:** If a report contains a Local Data Filter, it is static in the web report and users cannot change the selections. To make the Local Data Filter interactive, deselect the **Include** mode. (In Graph Builder, to see the **Include** mode, select **Show Modes** from the Local Data Filter red triangle menu.)
2. From a report window, select File > Publish > Publish to File.
3. Select the reports that you want to publish.
4. (Optional) Change where the parent folder resides or change the name of the subfolder that will contain the reports.
5. Click Next.
6. Enter a title for the index page. You can also update the report titles.
8. Click Publish.

Figure 10.3 Index Page for Multiple Interactive HTML Reports

9. Click a thumbnail to open a report.

For details about working with interactive reports, from an HTML report, click ☰ > Help. This opens the help at https://www.jmp.com/interactive.

Interactive HTML Report Options

**Title** Add a title for the index page (multiple reports only) or the reports.

**Description** (Optional) Add a description to the index page or the reports. The description will appear under the titles.
**Customize**  (Appears for multiple reports only) Change the appearance of the web page. You can change the style, theme, font, logo, and whether the date or time appears. See [Customize Index Page Options](#).

**Publish Data**  Select this for interactive reports. If you deselect this option, the reports are static.

**Note:** To avoid sharing sensitive data, save your results as a non-interactive web page. (Select **File > Export > HTML**.)

**Add Image**  Adds an image to the bottom of the web page.

**Open published web report**  Opens the web page in a browser once you click Publish.

**Close reports after running**  Closes the reports in JMP once you publish the web report.

**Delete icon**  (Appears for multiple reports only) Deletes a report.

**Arrow icons**  (Appears for multiple reports only) Changes the order of reports.

**Customize Index Page Options**

**Style Format**  Determines the layout of the reports.

- **Large List**  Shows the reports in a column with large thumbnail graphics.
- **Small List**  Shows the reports in a column with small thumbnail graphics.
- **Grid**  Shows the reports in rows.

- **Custom CSS**  Enables you to specify a CSS file to format the web page. The CSS file is copied into a subfolder called `_css`. The link to the CSS file is relative so that you can send the report and support files to another user and maintain the CSS formatting.

**Color Theme**  Specifies the color of the web page, headings, and borders. The default web page has a white background, orange headings, and blue borders.

**Change Font**  Change the font applied in the reports.

**Change Logo**  Specifies an image to display along with the reports. Click the up or down arrow next to the image to move it above or below the reports.

**Show date/time**  Shows or hides the date and time at which the web page was generated.
Publish Reports to JMP Live or JMP Public

JMP Live is a website purchased by your company for sharing JMP content privately. JMP Live can be hosted by SAS or your company. JMP Public is a website using the same technology as JMP Live, where anyone can share JMP content with the public.

JMP Live and JMP Public are platforms for sharing JMP data, visualizations, and dashboards. Prepare your reports in JMP and publish them as posts to collaborate with your colleagues, even those who might not have JMP.

JMP Live and JMP Public offer the visual interactivity of JMP to explore your data, and let you do the following:

- Store all of your reports in one location.
- Control sharing of individual reports with those who need to see them.
- Maintain up-to-date reports for your team in an easily accessible location.
- Extend the functionality of reports to other locations: embed and interact with your reports in web pages, blogs, social media posts and more.

Register and Sign Into a SAS Profile (JMP Public Only)

Before you can publish posts to JMP Public, you must register and sign in using a SAS profile.

**Note:** If you are not signed in to JMP Public, you see only featured posts.

1. In a browser, go to [https://public.jmp.com](https://public.jmp.com).
   Supported browsers include Chrome, Firefox, Safari, and Edge (based on Chromium).
2. At the top right, click **Sign in**.
3. If you already have a SAS profile, log on using those credentials, then click **Submit**.
4. If you do not have a SAS profile:
   a. Click **Register**. Complete the form and click **Create profile**.
   b. Follow the instructions in the email to set your password and activate your profile.

Add a JMP Live Server

Before you can publish to JMP Live, you must add a JMP Live server.

1. In JMP, select **File > Publish > Manage Connections**.
2. Click **Add New**.
3. Enter an identifying name for the connection, such as JMP Live.
4. Enter the server URL, formatted like this: https://jmpliveserver.com:3501 (where 3501 is the default web server port).
5. (Optional) To use JSL to create JMP Live reports, enter an API key.
6. Click **Next**.
7. Sign in to the JMP Live server with your user name and password.
8. Once the connection is created successfully, click **Save**.
   - The server name appears under Select a connection.
9. Click **Exit**.

**Create and Publish JMP Reports**

1. In JMP, create the reports.
   - You can create a single report, which appears as its own post in JMP Live or JMP Public, or multiple reports which appear in a folder.
2. (Skip if your report does not contain a Local Data Filter.) If the report contains a Local Data Filter, add columns before you publish, otherwise the Local Data Filter will be static instead of active. To add columns, select them in the Local Data Filter and click the Add icon.
3. Select **File > Publish > Publish to JMP Live** or **Publish to JMP Public**.
   - (JMP Live only) If you have not added a JMP Live server, add one now. See “Add a JMP Live Server” on page 582.
   - You might need to sign in to JMP Live or JMP Public.

   **Note:** To register for a SAS login, visit [https://www.jmp.com](https://www.jmp.com) and click **Sign In** near the search box at the top of the page.

**Figure 10.4 Select Reports Window**
4. (JMP Live only) Next to **Publish to**, select a JMP Live server.
5. Select the open reports that you want to publish.
6. Choose your action and then click **Next**:
   - “Create a New Post” on page 584
   - “Add Reports to an Existing Folder” on page 585
   - “Replace an Existing Report in a Post” on page 587 (if a post with the exact name exists)

**Create a New Post**

Figure 10.5 Create a New Post with Multiple Reports

> **Note:** If you are publishing a single report, the window and options in Figure 10.5 are slightly different.

1. (Multiple posts only) Enter a title for the folder and an optional description.
2. (Optional) Update the title for each report and add descriptions.
3. Choose how to share the post:
   - **Only Me** keeps your post private and visible to you only.
   - **Everyone** shares your post with everyone on JMP Public or JMP Live.
   - **Groups** shares your post with groups that you select. Groups that you can publish to appear below this option.
5. Click **Publish**.
6. Click **OK** to dismiss the informative window.
Figure 10.6 JMP Live Folder Containing Reports

Add Reports to an Existing Folder

Figure 10.7 Select an Existing Folder

Note: You see only folders that you have permission to update. These are folders that you own or folders in a group that you are a member of.

1. Select a folder. Do one of the following:
   – Click a folder in the list and click Next.
Search for a folder—in the Keyword Search box, enter a word that appears in the folder name or description and then click a folder. Click Next.

**Figure 10.8** Add a Report to an Existing Folder

**Note:** If you are publishing multiple reports, the window and options in Figure 10.8 are slightly different.

2. (Optional) Update the title for each report and add descriptions.
3. Change additional options. See “Post Options” on page 589.
4. Click Publish.
5. Click OK to dismiss the informative window.
Figure 10.9  Report Added to Existing JMP Live Folder

![Image](image1.png)

Replace an Existing Report in a Post

Figure 10.10  Select an Existing Post

![Image](image2.png)

Note: You see only posts that you have permission to update.

1. Select a post. Do one of the following:
   - Click a post in the list and click Next.
   - Search for a post—In the Keyword Search box, enter a word that appears in the post name or description and then click a post. Click Next.
2. Choose one of the following options:
   - To use the same title and description (if one exists) from the existing post, click **Copy to New**.
   - To use an updated title and description, enter a new title and description.

4. Click **Publish**.

5. Click **OK** to dismiss the informative window.
Figure 10.12  Report Replaced in JMP Live

My Web Report  Bivariate Fit of weight By height

Post Options

Title  Add a title for the web page. You can also change the report titles.

Description  (Optional) Add a description to the web page that appears under the title. You can also add report descriptions that appear under the report titles.

Publish Data  Select this for interactive reports. If you deselect this option, the reports are static. When selected, the data behind the report and a JSL script of the report are published.

Note: To avoid sharing sensitive data, save your results as a non-interactive web page. (For a single report, select File > Export > HTML. For multiple reports, select File > Publish > Publish to File and deselect Publish Data.)

Enable Warnings  (Applicable for platforms that support control charts only.) Notifies interested parties when the post has control chart warnings. Interested parties include the publisher of the post and any groups the post is shared with that have warning notifications enabled.

Add Image  Adds an image as an image-only report.

Allow data and scripts to be downloaded  Allows data tables and scripts associated with the reports to be downloaded. If you do not select this option, in JMP Live there is no
download option next to the data table names and no JSL script to re-create the report. See “Note on Data Accessibility” on page 590.

Open published web report  Opens the web page in a browser once you click Publish.

Close reports after running  Closes the reports in JMP once you publish the web report.

Delete icon  Deletes a report.

Arrow icons  Changes the order of reports.

JMP Live and JMP Public Help

For help with using JMP Live or JMP Public, click > Help. This opens one of these help pages:

- JMP Live: https://www.jmp.com/jmplive
- JMP Live (administrator): https://www.jmp.com/jmpliveadmin
- JMP Public: https://www.jmp.com/jmppublic

Note on Data Accessibility

The data that is represented in your published reports will exist online in HTML5 files as well as in the JMP data table format.

Disabling the Allow data to be downloaded option prevents any user who has access to the JMP Live page from being able to download the data in the JMP data table format, but it does not prevent a user from being able to get the HTML file containing the data in XML format. Enabling the Allow data to be downloaded option allows a user who has access to the JMP Live page to get the data in either way. The JMP format is only useful to users who have access to the JMP Live page who also have a separate license of JMP software or a third-party software that knows how to read JMP files, but a user of the JMP Live page only needs a web browser to see the data in the HTML file.

Save Reports as PDF Files

You save reports as PDF files by selecting File > Save As > PDF File (*.pdf) (Windows) or File > Export > Image > PDF (macOS).

Windows

- You can control pagination features such as headers, footers, and margins when you export the file.
  - Select File > Export, select PDF, and click Next.
– Name the file, click **Save**, and then change settings in the Page Setup window.

- You can also control pagination by selecting **File > Page Setup**. Note that you can click **Set as Default** to apply the settings to future page setups.

- You can also control pagination by selecting **File > Print Preview**.

**macOS**

- Select **File > Export > Image > PDF**. The resulting PDF file contains a single PDF image with no headers or footers.

- You can also select **File > Print** and then select **Save as PDF** from the PDF window. The resulting PDF file is paginated into multiple pages as needed, with headers and footers, and using the page size, orientation, scaling, and margins that you selected in the Print and Page Setup windows.

**Windows and macOS**

Through JSL, you can control pagination on both Windows and macOS. See *JSL Syntax Reference* for more information about **Set Page Setup**, **Set Print Headers**, **Set Print Footers**, and **Save PDF**.

### Save Reports as PowerPoint Presentations

Create a presentation by saving JMP results as a Microsoft PowerPoint presentation (.pptx). Rearrange JMP content and edit text in PowerPoint after saving as a .pptx file. Sections of a JMP report are imported into PowerPoint differently. Report headings are imported as editable text boxes, and graphs are imported as images. Certain graphical elements, such as legends, can be imported as separate images. Images resize once opened in PowerPoint to fit the slide. Typically, each outline in the JMP report appears on separate PowerPoint slides. If an outline in the report is closed when saving as a .pptx file, it is excluded from the PowerPoint. Larger content can spread across multiple PowerPoint slides. Delete unwanted content from the PowerPoint file.

**Note:** On Windows, PowerPoint 2007 is the minimum version required to open .pptx files created in JMP. On macOS, at least PowerPoint 2011 is required.

1. In JMP, create the report.
2. Select **File > Export > Microsoft PowerPoint** and click **Next**.
3. Select a graphic file format.
   - On Windows, EMF is the default format. On macOS, PDF is the default format.
4. (Optional) To avoid opening the file in the default presentation program after saving, deselect **Open the file after saving**.
5. Name and save the file (or export on macOS).

Tips:

- The native EMF graphics produced on Windows are not supported on macOS. The native PDF graphics produced on macOS are not supported on Windows. For cross-platform compatibility, change the default graphics file format by selecting File > Preferences > Third Party Data (Windows) or JMP > Preferences > Third Party Data (macOS). Then, change the Image Format for PowerPoint to either PNG or JPEG.
- It is sometimes necessary to auto-resize column widths using PowerPoint. PowerPoint often sizes objects differently from JMP, which can lead to abnormally sized table columns.
- Drag the column separators in PowerPoint to adjust column widths for a nicer layout. You can also double-click a column border to decrease the amount of white space in the column.
- A default PowerPoint template is installed in the JMP directory’s pptx folder. You can save a copy of this PowerPoint template and replace the default template with your own if you want to always use an alternate template when exporting. For example, you might want to create a German PowerPoint template that has German default fonts. See Custom PowerPoint Templates.

Custom PowerPoint Templates

PowerPoint presentations use the default JMP template. You can use a custom template by overwriting the default template file. To do this, open JMPExportTemplate.pptx located in one of the following locations:

C:/Program Files/SAS/JMP/16/pptx/
C:/Program Files/SAS/JMPPro/16/pptx/

Then, choose your own PowerPoint template, and select File > Save. The next time you save JMP content as a PowerPoint, it opens with your custom template. Alternatively, create your custom template in PowerPoint first, and save it as JMPExportTemplate.pptx.

Notes:

- The custom PowerPoint template on macOS cannot be edited.
- To use the JMP default template later, make a duplicate copy on your machine before overwriting the file.

Also, you can use a custom template with a JSL script. For more information, see the JSL Syntax Reference.

Setting the Graphic DPI for Exported Graphics

On Windows, there are several ways to set the resolution (or DPI) for exported graphics:
• To change the default DPI for all graphics, set the DPI to in the Windows Specific preferences. The Default option uses the default setting of your operating system.

• The following script lets you set the default DPI to a different value. Change the number if you want a different DPI and then run the script.

```julia
Pref( Save Image DPI( 600 ) );
```

To verify the default DPI after you run the preceding script, run the following script:

```julia
Get Preferences( Save Image DPI );
```

The Windows Specific preferences and Save Report As window show Default as the DPI after you run this script. The setting applies until you change it. On the Save Report As window, select Always use this setting to save your choice across multiple JMP sessions.

• For a specific graphic, set the DPI in the Save Report As window.

On macOS, you cannot change the default DPI, which is 72.

### Save a JMP Analysis as a Script

After completing an analysis and receiving a report, you might want to save the process that you used to arrive at the report as a JSL script. You can save the script inside the data table, inside the report, or in a separate script window. To do this, click the red triangle in the report title and select the Save Script option that you prefer. See “Save Script Menus in Reports” on page 455.

Non-English versions of JMP can save scripts in either English or your local language. See “General JMP Preferences” on page 667 in the “JMP Preferences” chapter.

### Save Parts of a Report in a Graphic Format

You can save part of an analysis report window as a graphic. You can save the selection in .png, .jpg, .gif, .eps, .emf, .pdf, .tiff, and .svg formats. On macOS, you can save the selection in .png, .jpg, .gif, .svg, .eps, .pdf, and .pptx formats.

To save a selection, follow these steps:

1. Click the selection tool ( ).
2. Highlight the area that you want to save.
3. On Windows, select Edit > Save Selection As. On macOS, press Control and select File > Save Selection As.

   The Save Selection As window appears (or the Save window on macOS).

4. Enter the filename for the graphic.
On macOS, change the file extension to save the file in a format other than .png, the default format.

**Note:** If you use Save Selection As and create a PDF file from the selection, the PDF file has headers and footers. With JSL, you can control pagination on both Windows and macOS. See the *JSL Syntax Reference*.

5. Change options on Windows:
   - Select the graphics file format type to which you want to save the selection. See “Save and Share Reports” on page 576.
   - Select the Image DPI Setting. 300 or higher is best for graphics that must be stretched or printed.
   - To keep your selected DPI Setting for the current session, select **Always use this setting**.
   - To avoid opening the file in the default graphics program after saving, deselect **Open the file after saving**.
   - Select **Select this filter the next time this window is invoked** to save your file type selection for the current session.

**Note:** If you cannot see the Select this filter option, select a folder location for saving the graphic file.

6. Click **Save**.

**Tips:**

- You can change the default DPI setting selection in the Windows Specific preferences from 96 to 300 DPI. The following script lets you set the default DPI to a different value. Change the number if you want a different DPI and then run the script.

  ```julia
  Pref( Save Image DPI( 600 ) );
  ```

- On macOS, you cannot change the default DPI, which is 72.

- When you export a graph or report that contains a bitmap image to an .svg file, the image is embedded in the .svg file. The exported content is then easier to reuse in other documents.

---

**Print Reports**

To print the report in the active window, select **File > Print**. This command displays the standard window for printing. The appearance of the window depends on your operating system and printer driver.
To insert a page break for printing purposes, follow these steps:

1. Right-click the disclosure icon in the report window.
2. Select **Edit > Page Break**.

## Copy and Paste Reports

When you need to use JMP reports or data tables in another program, you can paste or drag parts of a report or table into another program. For example, you might want to send a colleague a copy of a JMP report in a Microsoft Word file.

1. Click the selection tool .
2. Click and drag (or press Shift and click) to select items in a report window or data table. Clicking near the edge of the report window selects the entire report.
3. Click the selected items and drag them from JMP to the other program. Or, copy the selected items in JMP and paste them into the other program. When you paste an element into another application, the format used depends on the application into which you paste. If you use the applications’ Paste Special command, you can select a format to use, such as text (.rtf), unformatted text (.txt), or bitmap (.bmp).

### Notes:

- To copy all text (no graphs) from the active report window as unformatted text, select **Edit > Copy As Text**. On macOS, select **Paste > Special** in Microsoft Word or **Paste and Match Style** in other macOS apps.
- To copy a graph, which includes labels and axes, right-click the graph and select **Edit > Copy Graph**.
- To copy anything other than a graph, right-click and select **Edit > Copy Picture**. For example, to copy a report, right-click the bar containing the report title and select the option.
- To copy text from a text box onto the clipboard, right-click the text and select **Copy Text**.
- To copy text from one column onto the clipboard, right-click the column and select **Copy Column**.
- To copy and entire table onto the clipboard, right-click the table and select **Copy Table**.
- The Reports preference **Transparent background in report PNG images** determines whether reports that are saved as PNG images have transparent backgrounds. The preference is deselected by default.
Work with Projects

With JMP projects, you can do the following:

- Explore your data more efficiently with a single, tabbed JMP window
- Quickly save and reopen a set of related files and reports
- Easily share your work by embedding your tables and scripts in a self-contained project file

Figure 10.13  Project File with Data Tables and Reports
This section contains the following information:

- “Create a New Project”
- “Open Files in a Project”
- “Rearrange Files in Projects”
- “Save a Project”
- “Project Workspace”
- “Project Bookmarks”
- “Project Contents”
- “Recent Files in Projects”
- “Project Log”
- “Move Files into Projects”
- “Write a Project On Open Script”
- “Example of Creating a New Project”

## Create a New Project

To create a new, empty JMP project, select File > New > Project (Windows) or File > New > New Project (macOS).

## Open Files in a Project

In a JMP project, you can open data tables and then run analyses on the data. Each data table and analysis report opens in a new tab.

1. From a project window, select File > Open and navigate to the data tables that you want to open.
2. From a data table, run an analysis.

If a data table is updated on your computer, any associated reports in your project update when you reopen the project.
Figure 10.14 Initial Project

Tip: You can use JMP keyboard shortcuts in projects, such as Ctrl+S to save a file, or Ctrl+W to close the active window pane. For a full list, select Help > Quick Reference Card.

Rearrange Files in Projects

In a JMP project, data tables and reports appear in individual tabs. You can rearrange tabs by dragging them into a dock zone.

Tip: To undo or redo a docked item, select Project > Undo Layout or Project > Redo Layout. To return all tables and reports to individual tabs, select Project > Reset Layout.

Example of Rearranging Project Files

1. Select File > New > Project (Windows) or File > New > New Project (macOS).
2. Select Help > Sample Data Library and open Car Physical Data.jmp and Car Poll.jmp.
3. In the Car Poll.jmp data table, run the Distribution script.
4. In the Car Physical Data.jmp data table, run the Contingency script.
5. Drag the Car Poll - Distribution report tab to the right and drop it into the Dock right zone.
   The Distribution report pane appears at the right of the project window. The report is docked and stays visible when you switch between tabs.
6. Drag the Car Physical Data - Contingency tab to the middle of the Car Poll - Distribution report and drop it into the Dock tab zone.
**Tip:** You can adjust the size of the data table window to fully show both reports.

**Figure 10.15** Reports and Data Tables Grouped into Tabs

![Image of reports and data tables grouped into tabs]

The Distribution and Contingency reports are now tabbed together, as are the two data tables.

**Save a Project**

If you want to share, distribute, or archive your project, create a self-contained project by saving all your data tables and scripts to the project contents. This embeds all project files and folders into a single project file that you can share with other JMP users.

1. (Optional) To save the project as a self-contained project, save each data table and script in the project by selecting **File > Save As** and then select **Project Contents**. You can click **New Folder** to create a folder in the project contents.

**Note:** You do not need to save reports as these are automatically saved to the project.
2. Select **File > Save Project** to save the project file.

### Project Workspace

In a JMP project, you can see all currently open files in the Workspace tool pane. Reports appear under the corresponding data table. The active data table appears in bold.

**Tip:** To hide or show the Workspace tool pane, select **Project > Show Workspace**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.

In the Workspace tool pane, you can do the following:

- Double-click a file to make it active.
- Right-click a file to close it, hide it (removes the tab and dims the file name), bookmark it, and more.

### Project Bookmarks

In a JMP project, you can create a shortcut to a file or folder in the Bookmarks tool pane. You can also organize your bookmarked files and folders by creating a bookmark group.
Chapter 10  
Save and Share Your Data  
Using JMP  
Work with Projects  

**Tip:** To hide or show the Bookmarks tool pane, select **Project > Show Bookmarks**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.

**Bookmark an open file in the project**

- Right-click a tab and select **Bookmark**.
- To bookmark all open files, right-click a tab and select **Bookmark All**.

**Bookmark a file or folder on your computer**

Drag a file or folder from your computer into the Bookmarks tool pane, or click the Bookmarks red triangle menu and select **Add Files** or **Add Folder**.

**Note:** If you add or remove files from a bookmarked folder on your computer, the folder contents automatically update in the project.

**Open a bookmarked file**

In the Bookmarks tool pane, double-click a file.

**Remove a bookmark**

In the Bookmarks tool pane, right-click a file and select **Remove Bookmark**.

**Create a bookmark group**

1. Click the Bookmarks red triangle menu and select **New Group**.
2. Name the group and click **OK**.
3. Drag new or existing bookmarks into the group, or in the Bookmarks tool pane, right-click the group and select **Add Files** or **Add Folder**.

**Project Contents**

In a self-contained JMP project, any files you save to the project contents appear in the Contents tool pane.

**Tip:** To hide or show the Contents tool pane, select **Project > Show Contents**. To specify which tool panes appear by default when you create a project, select **File > Preferences > Projects** and choose the initial tool panes.
Open a file from the project contents

In the Contents tool pane, double-click a file.

Create a folder in the project contents

1. Click the Contents red triangle menu and select New Folder.
2. Name the folder and click OK.

Move files into folders

In the Contents tool pane, drag a file into a folder.

Copy a file or folder from your computer into the project contents

1. Click the Contents red triangle menu and select Copy Files into Project or Copy Folder into Project.
2. Navigate to the file and click Open, or navigate to the folder and click Select.

Rename a file in the project contents

In the Contents tool pane, right-click a file and select Rename.

Delete a file in the project contents

In the Contents tool pane, right-click a file and select Delete.

Recent Files in Projects

In a JMP Project, you can open a file from the Recent Files tool pane.

**Tip:** To hide or show the Recent Files tool pane, select Project > Show Recent Files. To specify which tool panes appear by default when you create a project, select File > Preferences > Projects and choose the initial tool panes.

Open a file

In the Recent Files tool pane, double-click on a file or drag it into a project.

**Note:** Open files that are saved to the project contents do not appear in the Recent Files tool pane.
Project Log

In a JMP Project, you can see log messages in the Log tool pane.

Tips:

- To hide or show the Log tool pane, select Project > Show Log. To specify which tool panes appear by default when you create a project, select File > Preferences > Projects and choose the initial tool panes.
- By default, log messages that occur in projects appear only in the project log, not in the main JMP log. To change this setting, select File > Preferences > Projects and update Use Project Log Pane to If Open or Never.

Move Files into Projects

In JMP, you can move files into a project, out of a project, or between projects.

1. Select Help > Sample Data Library and open Big Class Families.jmp.
2. Run the Distribution, Text Explorer, and Graph Builder scripts.
3. From any window, select Window > Move to/from Project.
4. Leave the Source Project as (None) to see files that are not open in any project.
5. Leave the Destination Project as (New Project) to move the selected files into a newly created project.
6. Select the check box next to Big Class Families.jmp. The graphs associated with the data table are also selected.

Figure 10.18 Move Windows To/From Project

7. Click OK. A new project is created with the selected table and reports.
Write a Project On Open Script

In the Project On Open Script box, you can add a JSL script that will run each time this specific project is opened. For example, you can create a script that creates or modifies reports, prompts the user for information, or writes usage information to the log window.

1. Select Project > Project Settings.
2. Paste the JSL script and click OK.

Tips:

- See the Scripting Guide, which explains how to create a start-up script when any project is opened (instead of a specific project).
- To use an existing project as a template for new projects, specify the existing project as a new project template under File > Preferences > Projects.

Example of Creating a New Project

In this example, you create a project, import data, generate an analysis and dock the report in the project window, create a subset table, and then save, close, and reopen the project.

1. Select File > New > Project (Windows) or File > New > New Project (macOS).
2. From the project window, select File > Open.
3. Open the sandwiches.xlsx file, located here by default:
   C:/Program Files/SAS/JMP/16/Samples/Import Data

   Tip: At the bottom, you might need to change All JMP Files to Excel Files.

4. Click Import.
5. Select File > Save.
6. Make sure Project Contents is selected.
7. Change the file name to Sandwiches.jmp and click Save.
8. Select **Analyze > Fit Y by X**.
9. Select Calories and click **Y, Response**.
10. Select Weight and click **X, Factor**.
11. Click **OK**.
12. Drag the **Sandwiches - Fit Y by X** tab to the right and drop it into the **Dock right** zone.

**Tip:** To show the entire report, you can drag the line between the data table and the report to the left.
13. Select Tables > Subset.
14. Under Rows, select Random: sampling rate 0.5.
15. Click OK.

16. Select File > Save Project.
17. Navigate to the folder where you want to save your project, name the project file, and click Save.
18. Close the project.
19. Select File > Open and open your project file.
Notice that the subset table that you did not save has been saved automatically to the project file.

Create Journals

Create a JMP journal when you want to store results and present them. One of the benefits of journaling is that you can capture an analysis and not depend on external files. Another benefit is the ability to copy and paste specific reports or graphs into the journal. This enables you to create a custom report to present to other users.

There are two types of presentations that you can create using journals:

- A static presentation embeds the output of one or more JMP reports, fixed at a moment in time. The output is similar to what you get when you save output as a PDF file. There is no data table, points cannot be selected, colored, hidden, excluded, and so on. Only cosmetic changes (fonts, axes, sizes) can be made. The benefit is that there is no dependency on external files.

- A dynamic presentation is built from outlines containing text and buttons (or links) that help you organize, hide, or reveal a set of data tables and reports. This type of journal is dynamic because you can open reports and tables and interact with them, selecting points, subsetting data, making more graphs, or rerun an analysis.

Figure 10.22 shows some of the items that you can add to a journal.

Figure 10.22 Example of a Journal

Notes:

- When you’re finished creating the journal, select Edit > Lock Journal. To unlock the journal for editing, select Edit and deselect Lock Journal.
You can save journals to other formats, such as Microsoft Word, HTML, PDF, and so on. See “Save Journals in Other Formats” on page 615.

- Journals support GZ compression to reduce file size. See “General JMP Preferences” on page 667 in the “JMP Preferences” chapter. This can be particularly helpful if large data tables are embedded in the journal.

- Consider setting the *Autosave timeout* value in the General preferences to automatically save open journals at the specified number of minutes. This autosave value also applies to data tables, scripts, projects, and reports.

**Example of Making a Journal for a Presentation**

Most people use a presentation application like PowerPoint to give presentations. With JMP journals, you can avoid using a presentation application: all your bullet points can be combined with live links and buttons to help automate the analyses that you want to show. Interactivity is also maintained in reports.

Follow this example to create a presentation using a journal.

1. Select **File > New > Journal**.
2. Right-click in the journal. Start your outline by selecting **Add Outline Item**.
3. Enter the title of the presentation “My Bivariate Demo.”

![Add an Outline Item](image)

A presentation should have outline nodes. The nodes are nested, opened, and closed in sequence, as you give the presentation.

4. To add bullet points into the outline, click the red triangle in the My Bivariate Demo title bar and select **Add Text Item**.
5. Enter the text shown in Figure 10.25.
6. Select the **Bullet Point** check box and click **OK**.

   **Tip:** A horizontal flashing line appears at the top of the journal. Use the arrow keys to move the line to where you want to insert an object.

Now add a window reference as a link. These links lets you open a file with one click during the presentation.

7. Select **Help > Sample Data Library** and open Big Class.jmp.
8. Click the red triangle in the My Bivariate Demo title bar and select **Add Window Reference**.
9. Select Big Class and click **OK**.

**Figure 10.26 Add a Window Reference**

10. Click the window reference to verify the link.
11. Display the window reference as a button by right-clicking the link and selecting **Style > Normal**.
12. Select **Edit > Lock Journal** to see the final journal.

When you lock the journal, the journal toolbar and insertion cursor no longer appear. And when you select Save Script > To Journal from a platform, the journal is not appended to the open locked journal.

**Tip:** You can also add objects to the journal by dragging them from the journal toolbar or putting your cursor where you want the object and double-clicking the object in the journal toolbar. The toolbar is available when you place your cursor over it.

**Create New Journals**

1. Close all open journals, and do one of the following:
   - To create an empty journal, select **File > New > Journal**. Or, from the JMP Starter window, select **New** in the Journal section.
   - To create a journal from an entire report or data table, select **Edit > Journal**.
   - To create a journal from a specific report or text in a report, click and drag the selection tool to select adjacent items in a report or data table. To select discontinuous items, press Shift and click the items with the selection tool. Then select **Edit > Journal**.
   - To create a journal from specific text in a data table, select the text, and then select **Edit > Journal**.
   - To create a journal from most graphs, right-click the graphic, and then select **Edit > Journal**. (Not available for surface plots and 3-D scatterplots.)
Tip: If you prefer keyboard shortcuts, press Ctrl+J (Windows) or Command+J (macOS) to create the new journal.

2. Select File > Save and save the journal in .jrn format.

Manage Links in Shared Journals

When you insert a link to a data table on your computer, the entire path to that data table is embedded in the journal. To share the journal or move it to another computer, store the linked files in the same directory as the journal or on a shared network drive. Because the files are in the same directory, the full pathname is unnecessary. Then the links are intact no matter where the journal is opened.

Tips:

- Zip the journal and supporting files so that another user can extract them to a directory. If the files remain in that directory, the links work.
- If you create a link to a sample data table, consider using the $SAMPLE_DATA variable in the path. Likewise, you can use $DESKTOP if the files are on your desktop or $DOCUMENTS for your personal documents folder.
- You can edit several links at once within an outline. There is also an option to replace strings in the links. Right-click the disclosure icon next to the outline, and then select Append Item > Edit Links.

To create portable links in a journal

1. Put the data tables and other files that you want to reference in the same folder.
2. Save the journal in that folder.
3. Right-click at the bottom of the journal, select Add File Reference, select the file, and then click Open.
4. Right-click the link in the journal and select Edit > Set Script.
   Notice the full file path.
   Open("C:\Users\shlori\journals\San Francisco Traffic.jmp")
5. Delete everything in the string except for the file name.
   Open("San Francisco Traffic.jmp")
To embed a data table in a journal

To avoid linking to an external data table, copy the data table into a script and place it in the journal. The advantage is that other users always have access to your data, and you do not need to edit links. The disadvantage is that, if you want to edit the data, you must edit the script.

1. In the data table, click the red triangle next to the data table name and select Copy Table Script.

Figure 10.29 Copying a Table Script

2. In the journal, right-click and select Add Script Button.
3. Enter a script name in the Name box.
4. Paste the table script into the Script box and click OK.
5. Right-click the link and deselect Underline Style display the link as a button.

Add and Edit Outlines to Journals

You can group text and links in an outline and then click the gray disclosure icon to expand and collapse the group.

- To add an outline, right-click in the journal, and then select Append Item > Add Outline Item. You can also add nested outline levels to outline levels that you have created. (When you click the red triangle menu of a graph that you have journaled, the Add Outline Item option is unavailable.) Click the outline’s red triangle and select Add Outline Item.
• To edit the outline heading, double-click the heading, enter the new name, and press Enter.

• To add text or links within an outline, click the outline’s red triangle and select an option described in “Right-Click Options in Journals” on page 613. Note that these options are not available when you click a scripted item’s red triangle.

• To add text or links outside an outline, right-click the journal and then select one of the options described in “Right-Click Options in Journals” on page 613.

• To edit a link, right-click the link, select Edit > Set Script, edit the path, and then click OK.

• To edit the name of the link displayed in the journal, right-click the link, select Set Button Name, enter the new name, and then click OK.

Right-Click Options in Journals

Add Outline Item  Groups text and links into collapsible and expandable lists.

Add Text Item  Enter up to six paragraphs with the option to add a bullet or hide the text. To unhide, right-click the hidden text and deselect Hide.

**Note:** To add text outside an outline level, you can also double-click at the end of the journal and enter text in the box that appears. Click outside the box to exit the editing mode.

Add Window Reference  Creates a link to a window already opened in JMP.

Add File Reference  Creates a link to a file on your computer.

Add Directory of Files  Creates links to all files (including non JMP files) in the selected directory.

Add Open Files  Creates outline levels and links to open files in JMP (except for the log). For example, a link to the open Big Class.jmp data table and chart is displayed below a collapsible heading named Big Class. Files such as journals, scripts, and tutorials are grouped below a collapsible heading called Other Files.

Add URL Reference  Creates a link to files that are delivered through an internet protocol such as HTTP, FTP, or FILE:///.

Add Script Button  Creates a link to a JSL script. Right-click the link and deselect Underline Style to display the link as a button.

Add Script Box  Adds a box in which you type a script.

Lock  Hides the journal toolbar and insertion cursor. If you select Save Script > To Journal from a platform, the results are not appended to a locked journal.
Edit Links Enables you to rename file links (for example, to remove a hardcoded path). An option to test links is also provided. If the path is valid, nothing happens when you click Test Links. If it is not valid, an error message appears in the log. To update an invalid link, click Replace.

Size to Fit Resizes the window to ensure that button names are fully displayed.

Control the Display of Outline Levels in Journals

You can instantly control which outline levels are displayed (for example, closing all sublevels below the selected level). Click the red triangle for that level, select OutlineBox, and then select one of the Open or Close commands. For more information about the Open and Close commands, see “Display Options for JMP Reports” on page 447 in the “JMP Reports” chapter.

Tip: On Windows, show the OutlineBox options by pressing Alt and right-clicking the outline level’s gray disclosure icon.

Add a Graph or Graphic to Journals

PNG, GIF, JPG, BMP, and TIF files are supported in journals. Do one of the following to add a graphic to a journal:

- Copy a graph from within JMP or a graphic from another application and then select Edit > Paste. JMP places the graphic at the end of the journal.
- Drag and drop the graph or graphic from another window to the journal. (See “Paste a Background Image into a JMP Graph” on page 515 in the “JMP Reports” chapter.) A blue line indicates where you can drop the graphic.

Tip: Consider resizing the graphic in an external program. Then you can insert the graphic at 100% resolution in the journal without dragging to resize the graphic.

Customize Items in Journals

- To click and drag journal items to different positions, select the selection tool ( ), select the item, and then drag the item to the new position. A line indicates where you can drag the item.
- To adjust text wrapping, right-click the text and select Set Wrap. Enter the number of desired pixels per line and click OK. To apply the wrap to all text items, select Set Wrap, select Extend this to other text boxes, and then click OK.
- To modify a plot axis, double-click or drag the axis. See “Customize Axes and Axis Labels in Graphs” on page 496 in the “JMP Reports” chapter.
• To add text or shapes anywhere in the report, use the drawing tools (Annotate, Line, Polygon, and Simple Shape). For more information about the drawing tools, see “Add Annotations and Shapes to JMP Reports and Graphs” on page 520 in the “JMP Reports” chapter.

• To resize plots and graphs, do one of the following:
  – Click and drag the edge.
  – Right-click the plot or graph, and then select **Size/Scale > Frame Size**. See “Resize Graphs” on page 492 in the “JMP Reports” chapter.

• To modify the format of a numeric column, you edit the Properties pane for the display box. See “Modify the Format of Numeric Columns” on page 474 in the “JMP Reports” chapter.

### Prevent Modifications to Journals

When a journal is opened, and you then journal another report or data table, the second report or data table is added to the end of the open journal.

To prevent modifications to a journal, right-click the blank area at the bottom of the journal and select **Lock**. Additional reports are not added to the journal (as described in the following section). JMP instead finds an open unlocked journal or creates a new journal when you select the **Edit > Journal** command again.

To unlock the journal, right-click the blank area at the bottom of the journal and deselect **Lock**.

### Append Reports to Journals

To append other reports to a report that you already journaled, open the journal and select **Edit > Journal**. If an area of an analysis window is selected, **Edit > Journal** saves only the selected area instead of the entire window.

**Notes:**

• The journal window has the same functions as the report window: you can click icons, click and drag, and right-click to access menus.

• When a report is journaled, the journaled copy is no longer connected to the data table. To maintain that connection, save the report as JMP report and insert a link to it in the journal.

### Save Journals in Other Formats

You can save a journal in another format (such as HTML or PDF). When you save the journal as HTML, buttons and links are active when the file is viewed in a web browser.
Windows

1. Select File > Export.
2. Select the format. See “Save and Share Reports” on page 576.
3. Click Next.
4. Name and save the file.

macOS

1. Select File > Export.
2. Select the format. See “Save and Share Reports” on page 576.
3. Click Next.
4. Name and export the file.

Delete Items from Journals

1. Click the selection tool ( ).
2. Select the item that you want to delete and press Delete.

Save JMP Sessions

Each time you use JMP is called a session. A saved session is a JSL script that re-opens documents and re-runs analyses to restore JMP’s state when the session script was saved. A saved session can help get you back to a previous state without having to manually re-open files and re-run analyses.

If you are an advanced user, it is important to understand what session information is preserved in a saved session. Any documents (such as data tables, scripts, and journals) that have been saved are re-opened. JMP windows that support script saving are re-run (equivalent to clicking the red triangle in a report and selecting Redo > Redo Analysis). Side effects of running scripts, such as global variable values or custom windows, are not saved. The state of highly interactive analyses is also not saved.
Save Sessions upon Exiting JMP

The most common use of saved sessions is to save the state when JMP exits so that it can be restored when JMP restarts. By default, JMP asks whether you would like to save the state of your session each time you exit the program (Figure 10.30). This enables you to quit JMP, and then return to it later without having to open the files with which you were previously working.

Figure 10.30  Saving Session upon Exiting

![Saving Session upon Exiting](image)

To always save the session upon exiting, select **Do not ask me again about saving the session** and click **Yes** or **No**. This option also prevents JMP from saving the session upon exiting.

You can change this option later in Preferences:

1. Choose **File > Preferences**.
2. Select the **General** icon.
3. Next to the **Save the session when exiting** option, choose when you want JMP to save the session. Always, never, and prompt whether you want to save are the options.

Save Sessions Manually

You can also save a session to a location of your choosing and continue working, so you can restore the saved state whenever you like. Manually saving sessions is useful when you want more control of session saving and restoring. This option is especially helpful when you want to maintain multiple independent session states. Each state has a different set of files and analyses.

*To create a script of a JMP session*

1. Select **File > Save Session Script**.
2. Enter the name of your script in the window and click **Save**.

Another way of manually saving a session is by creating a journal of each session. A journal can be a notebook-style or project-style file. With it, you can collect references to files in a project, develop presentation launch pads, document projects, and store many scripts in one place. See “Create Journals” on page 607.

*To create a journal of a JMP session*

1. Open the files that you would like to include in the journal.
2. Select **File > New > Journal**. Or, to append your open files to an existing journal, open that journal.

3. Right-click in the empty journal and select **Add All Open Files**.

---

**Save a Log Window**

Selecting **View > Log** displays a window that monitors JMP activities, such as JSL statements as they execute and script errors. You might also encounter instances where running a formula, matrix, or another operation writes information of interest to the log window.

*To save a log*

1. Open the Log window.
2. Select **File > Save As**.
3. (Windows only) To open the log automatically when text is added to it, select **File > Preferences > Windows Specific**. In the **Open the JMP Log window** list, select **whenever text is added**.
Combine and Present Reports Using Dashboards

JMP is an extensible program that lets you broaden its functionality to create your own JMP components. With Dashboard Builder, you combine reports into a dashboard, a visual tool that lets you run and present reports on a regular basis. No JSL knowledge is required. Start with a template, click report components, insert graphs and pictures, and the dashboard is done. You can also combine windows outside Dashboard Builder to create dashboards.

Combine JMP Reports by Creating a Dashboard

With Dashboard Builder, you combine reports to create your dashboards without writing JSL scripts. Similar to Application Builder, Dashboard Builder has a drag-and-drop interface but with pre-configured display boxes. In Dashboard Builder, the display boxes do not require customization as they do in Application Builder. You can put reports and graphs in tabs, embed database queries, save the dashboard as an add-in, and more.

You can also quickly create dashboards by combining several open windows using the Window > Combine Windows option. For example, you might combine two reports and a data table to arrange them on a dashboard. See Example of Combining Windows to Create a Dashboard for an example.

Example of Creating a Dashboard with Two JMP Reports

Suppose that you created two reports and want to run the reports again the next day against an updated set of data. This example shows how to create a dashboard from the reports.

2. To create the reports, run the table scripts named “Distribution: Profitability by Lead Studio and Genre” and “Graph Builder: World and Domestic Gross by Genre”.
3. From any window, select File > New > Dashboard.
   Templates for common layouts appear.
4. Select the 2x1 Dashboard template.
   A box with room for two reports appears on the workspace.
5. In the Reports list, double-click the report thumbnails to put them on the dashboard (Figure 11.3).
6. Click the Dashboard Builder red triangle and select Preview Mode.
   A preview of the dashboard appears. Notice that the graphs are linked to each other and the data table. They also have the same red triangle options as the Distribution and Graph Builder platforms.
7. Click **Close Preview**.

8. In Dashboard Builder, select **File > Save**, and then save the file as a .jmpapp file.

   Users who have JMP can open the data table and double-click this file to display the dashboard. Note that the .jmpapp file cannot be edited.

9. Return to the Dashboard Builder window, select **File > Save As**, and then save the file as a .jmpappsource file.

   The dashboard is saved in a file that you can edit in the future.

**Note:** You might also want to save the dashboard as an add-in. Users then view the dashboard by selecting a menu item in the main Add-Ins menu instead of opening the .jmpapp file. See “Example of Creating a JMP Query Dashboard and Add-In” on page 635.

### Using the Dashboard Builder

Figure 11.3 shows a dashboard in development. The two reports in the left pane were generated from the Hollywood Movies.jmp sample data table. Those reports were added to the right pane. “Hollywood Movies.jmp” is displayed in a text box that was added to the dashboard and centered using the toolbar buttons.
Red Triangle Options in the Dashboard Builder

The Dashboard Builder red triangle menu provides options such as running the dashboard, previewing the dashboard, and saving the dashboard as an add-in.

**Run Dashboard**  Starts the dashboard.

**Preview Mode**  Displays a preview of the dashboard. Click **Close Preview** on the dashboard to return to the dashboard mode.

**Start Over**  Remove objects from the workspace and select a new template.

**Show Grid**  Displays dotted grid lines on the workspace. Selected by default.

**Show Properties**  Shows or hides the Objects and Properties panels for editing display boxes. See the Scripting Guide for more information about editing properties.

**Auto Scroll**  Automatically scrolls horizontally or vertically as you drag an object near the edges of the workspace. Selected by default.
Combine and Present Reports Using Dashboards

Chapter 11
Combine JMP Reports by Creating a Dashboard

**Dashboard Mode**  Deselect to display the dashboard in Application Builder, where you can fully customize the application and write scripts. See the *Scripting Guide.* Select **Dashboard Mode** to return to the dashboard.

**Source Panel**  Shows or hides the Sources panel (the left column in which report components are displayed) and categorizes the icons. Show Sources is selected by default.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

- **To Data Table**  Saves the script to the data table that was used to produce the report. This enables you to run the script again from the data table to recreate the results.

- **To Journal**  Saves a link in a journal window that runs the script for the analysis. If a journal window is already open, the script is added to that journal window. The script contains the path to the data table. Note that if the data table cannot be found, the script does not run.

- **To Script Window**  Opens a script editor window and adds the script to it. If a script window is already open, the script is added to the bottom of that open window.

- **To Add-In**  Lets JMP users install the application and launch it from a JMP menu. See the *Scripting Guide.*

- **To Template**  Saves the application as a template from which you can create new dashboards. The templates are saved in the following locations based on your operating system and JMP version:
  - Windows (JMP):
    
    
    `"C:/Users/<username>/AppData/Roaming/SAS/JMP/16/DashboardTemplates"
  
  - Windows (JMP Pro):
    
    
    `"C:/Users/<username>/AppData/Roaming/SAS/JMPPro/16/DashboardTemplates"
  
  - macOS:
    
    
    `"/Users/<username>/Library/Application Support/JMP/16/DashboardTemplates"

**Start with a Sample Dashboard**

Examples of dashboards are shown when you open Dashboard Builder. You can modify these samples instead of starting with an empty dashboard. The dashboards are also installed in the JMP Samples/Dashboards folder.

The following sample dashboards are available:

**Instant Dashboard.jmpappsource**  Combines two Multivariate reports (Principal Components/Factor Analysis and T Square with All Principal Components).
Six Quality Graphs Dashboard.jmpappsource  Creates three Control Charts, a Distribution report, and a Capability Analysis report.

Edit a Dashboard

“Example of Creating a Dashboard with Two JMP Reports” on page 621 shows how to create a dashboard from two reports. This section shows how to arrange those reports and preview the final dashboard.

Rearrange Reports in Dashboard Edit Mode

To help you rearrange reports while editing a dashboard, the outline around a report includes drop zones. When you drag the report into a different area of the box, a portion of the box is highlighted. The highlight shows where you can drop the box.

Figure 11.4 shows how to create tabbed reports. To put the Distribution report inside a tab, drag the report over the other report until the upper right corner of the bar chart report is highlighted. The Distribution report appears in a tab on top of the other report.

To remove a tabbed report, click the middle of the report and drag it outside of the tab.

Figure 11.4 Working with Tabbed Reports in Dashboard Edit Mode

Figure 11.5 shows an example of placing a data table inside the bottom border of the report. To display the data table below the report instead of inside it, drag the Data Table box onto the dashboard below the report. The box snaps inside the bottom border of the report.
Figure 11.5 Displaying a Data Table Inside a Report

Figure 11.6 shows a data filter that appears to the left of a report.

Figure 11.6 Adding a Data Filter to the Left of a Report
Format Text in a Dashboard

When you edit a dashboard, you can format text in a text box. Drag the text box to the dashboard and click the middle of the text box. Formatting options appear.

Figure 11.7 Formatting Options for a Text Box

Preview a Dashboard

When you edit a dashboard, you can see a preview of the final dashboard by selecting **Preview Mode** from the Dashboard Builder red triangle menu. Previewing a dashboard is particularly helpful when testing interactive elements such as column switchers, data filters, and tabbed reports.

**Note:** If you resize panes in preview mode, your changes are not saved.

**Tips:**

- The column switcher initially shows all columns in the table, but it does not actively make changes to reports in the dashboard or application.
- You can switch into preview mode to do the following:
  - Select the initial column to be switched in all reports.
  - Remove any columns that you do not want to appear in the column switcher, including any other columns that are used in the reports.
- When you run the dashboard or application, the column switcher automatically connects to all platforms in the dashboard that use the same data table.
View a Running Dashboard

When you view a running dashboard, the same red triangle options that you find in JMP platforms are available in the reports. Dashboard Builder also provides several other options.

View a Report Summary

A report that contains graphs and statistics can grow fairly large. To view only the graphs while running the report, select the top red triangle in a report and then select \textbf{Report View > Summary}. The report shown in Figure 11.8 originally showed parameter estimates. In the Summary view, only the graphs are shown.

Figure 11.8 Viewing a Summary of the Report
Rearrange Reports in a Running Dashboard

You rearrange reports in a running dashboard by dragging the reports into highlighted drop zones. The drop zones indicate where you can place the report. Figure 11.9 shows an example of moving a report into a tab. The Distribution report is dropped inside the “Dock tab” drop zone to place it on the first tab.

Figure 11.9 Creating Tabbed Reports in a Running Dashboard

To remove a tabbed report, click the middle of the report and drag it outside of the tab.
Maximize a Report in a Running Dashboard

To see only a specific report while running a dashboard, select the report’s **Maximize Tab** box.

**Figure 11.10** Maximizing a Tab

To restore the report to its original size, select the **Restore Tab** box.

**Figure 11.11** Restoring a Maximized Report

Resize Reports in a Running Dashboard

The thick gray line that appears between reports in a dashboard is called a **splitter**. Drag the splitter to resize the panes. When the pane is too wide to display the enclosed report, the pane closes. Drag the splitter from the outer edge of the dashboard to see all reports again. **Figure 11.12** shows the collapsed and expanded reports.
Using JMP Combine JMP Reports by Creating a Dashboard

Chapter 11

Combine and Present Reports Using Dashboards

Using JMP Combine JMP Reports by Creating a Dashboard

Figure 11.12 Resizing Panes in a Running Dashboard

You can also drag the edge of a graph. The graph widens as far as the width of the window and the other reports allow.

Share Reports with Users Working Outside JMP

You can share reports with users working outside JMP by saving a dashboard as interactive HTML. First, click the Dashboard Builder red triangle and select Run Dashboard to run the dashboard. In the running dashboard, select File > Save As and then select Interactive HTML with Data from the list. The reports are saved in a web page that also contains the data. Email the web page to users or publish the page on a website. Users then explore the data as they would in JMP. See Share Reports as Interactive HTML.

Edit a JMP Platform Script

A dashboard consists of a JSL script, which you can edit in Dashboard Builder. For example, you might edit the script for the Multivariate platform to show the scatterplot matrix or to use different columns.

Right-click the object for a platform in the dashboard and select Edit Platform Script. The script opens in a script editor window.

After you edit the script and click OK, the object on the workspace is updated.

Example of Combining Windows to Create a Dashboard

You can quickly create dashboards by merging several open windows in JMP. Combining windows provides options to view a summary of statistics and include a selection filter.

1. Select Help > Sample Data Library and open Birth Death.jmp.
Combine and Present Reports Using Dashboards

Combine JMP Reports by Creating a Dashboard

2. Run the Distribution and Bivariate table scripts.
3. From one of the report windows, select **Window > Combine Windows**. The Combine Windows window appears.

   **Tip:** On Windows, you can also select Combine Windows from the Arrange Menu option in the lower right corner of JMP windows.

4. Select **Summary Report View** to display the graphs and omit the statistical reports.
5. In the Combine column, select **Birth Death - Bivariate of death by birth** and **Birth Death - Distribution**.
6. In the Filter By column, select **Birth Death - Distribution**.

   **Figure 11.13** Combine Windows Options

   ![Combine Windows Options](image)

7. Click **OK**.

   The two reports are combined into one window. Notice the filter icon at the top of the Distribution report. When you select a bar in one of the histograms, the corresponding data in the Bivariate graph are selected.

**Notes:**

- To combine reports on Windows, you can also select Combine Windows from the Arrange Menu option in the lower right corner of JMP windows.
- In the Combine Windows window, select **Summary Report View** to see only the graphs in a report and omit the statistics.
Example of Adding Selection Filters to a Dashboard

In a dashboard that contains several reports, you can select data in a report and then view only that data in other reports contained in the same window. This example shows how to add selection filters to the primary report when you edit a dashboard.

Open Reports and Create a Dashboard

2. To create the reports, run the table scripts named “Distribution: Profitability by Lead Studio and Genre”, “Graph Builder: World and Domestic Gross by Genre”, and “Bubble Plot: Theaters Open Week by Domestic Gross”.
3. From any window, select File > New > Dashboard.
   Templates for common layouts appear.
4. Select the 2x1 Dashboard template.
   A box with room for two reports appears on the workspace.
5. In the Reports list, double-click the Graph Builder and Distribution report thumbnails to put them on the dashboard.
Add and Use Selection Filters

1. Right-click the center of the left report (Graph Builder) and select **Use As Selection Filter**.
2. To add another report as a second selection filter, click the Bubble Plot thumbnail and drag it into the blue line around the Graph Builder graph.

**Figure 11.15** Dragging the Bubble Plot into the Graph Builder Graph

A filter icon appears on both thumbnails.

3. Click the Dashboard Builder red triangle and select **Preview Mode**.
4. Select one of the bars for the Fantasy genre in the left report.
In the right report, you can see that Warner Bros and Independent studios produced the most fantasy movies. In the bottom report, you can see that Harry Potter was the most profitable fantasy movie.

**Example of Creating a JMP Query Dashboard and Add-In**

Suppose that you used JMP Query Builder to import portions of two data tables into JMP. A dashboard displays reports of the data. You want to create an add-in that queries the data and shows the updated reports on a dashboard.

**Build the Query**

1. Select **Help > Sample Data Library** and open Hollywood Movies.jmp.
2. Select **Tables > JMP Query Builder**.
3. Click **Build Query**.
4. In the Available Columns list, double-click t1.Movie Name, t1.Rotten Tomatoes Score, t1.Audience Score, and t1.Theaters Opening Wknd to add them to the Included Columns tab.
5. Click **Run Query**.
The queried data appears in a new data table. Note the Source table script. When you open the dashboard, JMP runs this Source script to query the data in Hollywood Movies.jmp.

6. In the new data table, run the **Graph Builder: Scores by Opening Weekend** table script to create a report.

### Create the Dashboard

1. From the report window, select **File > New > Dashboard**.
2. Select the **Blank Dashboard** template.
3. Double-click the **Data Filter(Local)** box in the left pane to add it to the dashboard.
4. Double-click the **Graph Builder** report in the left pane to place it next to the local data filter.

**Figure 11.17** Dashboard for Hollywood Movies

### Create and Run the Add-In

1. Click the Dashboard Builder red triangle and select **Save Script > To Add-In**.
   
   Add-In Builder opens.
2. Next to Add-In name, type Hollywood Movies Dashboard (the add-in filename).
3. Click the **Menu Items** tab and type Hollywood Movies Dashboard next to **Menu item name** (the name of the add-in menu item).
4. Click **Save** and save the add-in to your desktop.
   
   The add-in is saved and installed in your Add-Ins menu.
5. Click **Close** on the Add-In Builder window.
6. From the JMP main menu, select Add-Ins and select Hollywood Movies Dashboard. The Hollywood Movies.jmp data table is queried, and the dashboard opens to show the local data filter and updated report.

**Figure 11.18 Hollywood Movies Add-In**

![Hollywood Movies Add-In](image)

**Example of Creating a Dashboard from Two Data Tables**

The graphs or reports in a dashboard can be created from multiple data tables. The data table used for the first graph on the dashboard is considered the current data table by default. This gives the user the flexibility to use any current data table to create the graph or report. The dashboard author can also hard-code the path. Specifying the name gives the dashboard author control over which data table is used.

1. Select Help > Sample Data Library, open Big Class.jmp, and run the Bivariate script.
3. From any JMP window, select File > New > Dashboard.
4. In Dashboard Builder, select the 2 x 1 Dashboard template.
5. Double-click the Distribution graph to add it to the dashboard first.
   By default, this graph uses whatever data table is the current data table. In this example, Hollywood Movies.jmp stored in the Samples/Data folder is the current data table.
6. Double-click the Bivariate graph to add it to the dashboard.
   You are prompted to determine whether the first graph uses the current data table or whether you want to hard-code the path to the data table (reference the table by name) in the dashboard.
7. Select **Reference table by name** to make sure the specified data table is always used to create the graph.

8. Click **OK**.

   In this example, Hollywood Movies.jmp in the Samples/Data folder will always be used as the current data table for the first graph, despite the current data table that is open.

**Tip:** Sometimes a named data table cannot be found when the dashboard is run. This is particularly common when the dashboard is moved to a different computer. You can either open the data table before running the dashboard or run the dashboard and select the data table when prompted.

---

**To Change the Location of the Data Table**

After you assign the location of the data table (current data table or name), you can change the setting in the dashboard Objects and Properties panes.

1. Click the Dashboard Builder red triangle and select **Show Properties**.

**Figure 11.19 The Objects and Properties Panes**

2. In the Objects pane, select **DataTable1**.

3. In the Properties pane, change the Location as shown in Figure 11.19.
For example, if you change the Name location to Current Data Table, the selected graph on the dashboard is based on the current data table.

**Note:** The Location value of Current Data Table applies only when you are running the dashboard. When you are editing the dashboard, Dashboard Builder uses the full path to locate the data table.
This chapter describes how to customize JMP menus and toolbars to show only the commands that you need. For example, you might remove the SAS option in the File menu if you do not use SAS. Or you might assign a shortcut key to the Run Script command.

Customizing JMP also lets you set up JMP for groups with special interests. If one group does not design experiments, you could remove DOE from the JMP menu.

**Note:** When you upgrade to JMP 16 Subscription, changes to preferences are maintained.

Personalize JMP Toolbars and Menus on Windows

Toolbars consist of buttons that execute commands and dividers that help you organize the buttons. In Windows, there are many ways to personalize toolbars. For example, you can create, rename, hide, and modify toolbars or buttons. You can also rearrange or delete toolbars and buttons that you create.

Menus consist of commands, submenus, and separators. As with toolbars and buttons, you can create, rename, hide, and modify menus. You can also rearrange or delete menus and menu items that you create.

You personalize toolbars and menus in the Menu Editor. The names of modified items are formatted to indicate which items were created, modified, or hidden, and which items are unsaved.

Figure 12.1 Menu Editor Options

- Customization set options.
- Item definition.
- Boldface text indicates that the item or an indented item below has been modified.
- Blue boldface text indicates a new item.
- Green boldface text indicates a modified built-in item.
- Asterisks mark unsaved items.
- Hidden items are marked out.
Customization Set Options

Customization Set to Modify

**Current User**  Only you see the changes. The customization file is called *usercust.jmpcust*. Modifying this file manually might cause unexpected results.

**All users**  All users who open JMP on the computer see the changes. The customization file is called *admindcust.jmpcust*.

**JMP Add-In**  Those who use the selected JMP Add-in, and select **JMP Add-In customizations** as the Starting Set, see the changes. When you modify the customization set for a disabled add-in, those changes do not appear until you enable the add-in.

**Other file**  Changes appear when the selected *.jmpcust* file is chosen as the customization set. You create this file in a text editor.

**New**  Changes appear when this new customization is selected. (After you make your changes, click **Save** to name the new file in the selected folder.)

Starting Set

**JMP built-in items**  The selected customization set is based on the default JMP toolbars and menus. (Applies to all customization sets and cannot be deselected.)

**All Users customizations**  The selected customization set is based on the All users customization set. (Available for the Other file or New customization sets. Cannot be deselected from the Current user customization set.)

**JMP Add-In customizations**  The selected customization set is based on the JMP Add-In customizations. The add-in customizations are typically installed with the add-in. (Available for all customization sets except for All users.)

**Current User customizations**  The selected customization set is based on the Current user customization set. (Available only for Other file and New customization sets.)

### Personalize Toolbars

JMP includes toolbars that you can add new buttons to, or you can create your own toolbars. By default, the JMP window type determines which bars appear. For example, the File_Edit toolbar is in all windows. In data tables, the Data Tables toolbar also appears.

**Project**  Shows icons for projects.
**File>Edit**  Shows icons for commands found in the File and Edit menus.

**Analyze**  Shows icons for common commands found in the Analyze menu.

**Graph**  Shows icons for commands found in the Graph menu.

**Tools**  Shows icons of tools that you can click and use as your cursor. In some windows, the toolbar is hidden. A blue line appears instead. Hover over the blue line to show the toolbar.

**Data Table List**  Shows a list of open data tables. You select a data table in this list to make it the current table. Note that the current table is not necessarily the front window. To bring a table (or any window) to the front, select its name from the list in the Window menu.

**Tables**  Shows icons for commands in the Tables menu.

**DOE**  Shows icons for commands in the DOE menu.

**SAS**  Shows icons for accessing and browsing SAS data and folders, opening SAS Query Builder, creating a new SAS program, submitting data to SAS, opening the SAS log window and output window, and viewing server connections.

**Application Builder**  Shows icons for commands in Application Builder.
Create your own toolbars for frequently used commands that are not included in the default toolbars. You assign a command to the button and can add other properties such as shortcut keys, icons, and JMP Scripting Language (JSL) scripts.

When you want to create a toolbar based on an existing toolbar, make a copy of the existing toolbar and then change settings as necessary. See “Copy and Paste Menus, Menu Items, Toolbars, and Buttons” on page 653.

Step 1: Create the Toolbar
1. Select View > Customize > Menus and Toolbars.
   The Toolbars list appears on the left.
2. (Optional) Change the customization set to control which users see your customizations. See “Customization Set Options” on page 644.
3. With the Menu Editor still opened, right-click one of the toolbars, such as File_Edit.
   Select any toolbar, because all new toolbars appear at the end of the Toolbars list.
   The toolbar is inserted at the end of the list. The toolbar includes an untitled button, because all toolbars must have at least one button.
Step 2: Specify the Caption and Internal Name

Toolbars have several basic properties:

- The caption appears in the View > Toolbars list, which lets you show or hide the toolbar. Give each toolbar a unique name. JMP merges toolbars with the same name after you close and reopen the Menu Editor.
- The internal name, which is case insensitive. JMP identifies the location of an item by its internal name rather than its caption.

To specify these toolbar properties, follow these steps:

1. With the Menu Editor still opened, select the toolbar. The General properties appear on the right.
2. Enter the internal name next to Internal name.
3. Enter a unique name for the toolbar or button in the Caption box.
4. (Optional) To specify the translation for the caption, do the following:
   - Click the Localize button for the item that you want to customize.
   - Select the language.
   - Enter the translation next to Text.
   - Click OK.
5. (Optional) Click Hidden to keep the toolbar hidden after creation.
6. Customize the untitled button as described in “Create Menu Items and Toolbar Buttons” on page 648.
7. Click Save to save your changes.

Personalize the Main Menu Bar

Add your own menu items to the main menu bar in JMP. These menus appear before or after menus such as File, Edit, and Tables. An untitled command is inserted automatically in the menu, because all menus must have at least one command.

When you want to create a main menu based on an existing menu, make a copy of the existing menu and then change settings as necessary. See “Copy and Paste Menus, Menu Items, Toolbars, and Buttons” on page 653.

To create a main menu

1. Select View > Customize > Menus and Toolbars.
   The Main Menu list appears on the left.
Personalize Menus and Toolbars

Chapter 12
Personalize JMP Toolbars and Menus on Windows

2. (Optional) Change the customization set to control which users see your customizations. See “Customization Set Options” on page 644.

3. Right-click the menu next to which you want to add a new menu.

4. Select Insert Before or Insert After.

   An untitled menu and a menu item are added to the list.

5. Complete “Step 2: Specify the Caption and Internal Name” on page 647 to rename the main menu.

6. Customize the menu item as described in “Create Menu Items and Toolbar Buttons” on page 648.

7. Click Save to save your changes.

Create Menu Items and Toolbar Buttons

Menus consist of the following menu items:

- Commands are the items that you click to execute a command (such as Data Table and Script).

- Submenus are menu items that you click to reveal more menu options. An example of a submenu is New inside the top-level File menu. New is also a submenu because it contains commands (such as Data Table and Script).

- Separators (———) are lines that divide or group commands and submenus.

The button on a toolbar is considered a type of command, so you also complete the following steps to create new toolbar buttons.

When you want to create a menu item or button based on an existing item, make a copy of the existing item and then change settings as necessary. See “Copy and Paste Menus, Menu Items, Toolbars, and Buttons” on page 653.

Step 1: Create a New Menu Item or Button

1. Select View > Customize > Menus and Toolbars.

   The Menu Editor appears.

2. (Optional) Change the customization set to control which users see your customizations. See “Customization Set Options” on page 644.

3. Right-click where you want to add the menu item or button.

   A list of possible locations appears.

4. Select Insert Before or Insert After.

   The Specify Type window appears.
5. Do one of the following:
   – To create a button, select **Command**.
   – To create a menu within a menu, select **Submenu**. (Not available for buttons.)
   – To create divider between menu items or toolbar buttons, select **Separator**.
6. Click **OK**.
   The new untitled button, submenu, or separator is added.

**Step 2: Specify the Caption, Tooltip, and Internal Name**

Buttons have several basic properties:

- The caption appears in the View > Toolbars list, which lets you show or hide the toolbar. Give each toolbar a unique name. JMP merges toolbars with the same name after you close and reopen the Menu Editor.
- The tooltip appears when you place the cursor over a menu item or button.
- The internal name, which is case insensitive. JMP identifies the location of an item by its internal name rather than its caption.

Submenu items include many of the same General properties as buttons, except that submenu items do not have tooltips.

To specify these properties, follow these steps:

1. With the Menu Editor still opened, select the menu item or button.
   The General properties appear on the right.
2. Enter the internal name next to **Internal name**.
3. Enter a unique name for the menu item or button in the Caption box.
4. Enter a description for button in the Tip box.
5. (Optional) To specify the translation for the caption or tip, do the following:
   – Click the **Localize** button for the item that you want to customize.
   – Select the language.
   – Enter the translation next to Text.
   – Click **OK**.
6. Customize the untitled button or menu item as described in the following procedure.
Step 3: Assign Functionality

Clicking a menu item or button either executes a predefined command or runs a JSL script. The script can be stored in a separate file, or you can enter the JSL in the Run this JSL area of the Menu Editor. If users have access to a central location, such as a network, you typically want to run the script from that location. This also simplifies giving users access to updated scripts. Otherwise, store the JSL in the menu item or button definition.

To associate a menu item or button with an add-in JSL script, you have two options:

- Select Run JSL in this file, and then browse to find the external file.
- Type the relative path to the JSL script, and select the add-in from the Use add-in home folder list. For example, the following command runs the mds_application.jsl script from the selected add-in:
  
  `$ADDIN_HOME(com.jmp.mdswithr)/mds_application.jsl`

In addition, you can select Use the “Here” namespace for unqualified JSL variable names if you include namespaces in the internal or external JSL script. See the Scripting Guide for more information about namespaces.

To assign this functionality, follow these steps:

1. With the Menu Editor still opened, select the menu item or button that you want to modify.
   
   The Action properties appear on the right.
2. Select the action that you want to execute.
3. To run an internal JSL script, delete the placeholder text `print("Not implemented.");` in the Run this JSL area and enter the JSL.
4. (Optional) If your internal or external JSL script includes namespaces, select Use the “Here” namespace for unqualified JSL variable names.
5. Click Save to save your changes.

Step 4: Show an Icon on the Menu Item or Button (Optional)

New menu items have no icon next to the item. New buttons show up as blue squares on the toolbars. You can assign a descriptive icon to the menu item or button. The graphic can reside on your computer or in an add-in folder. .ico, .png, .jpg, and .bmp graphics are supported.

Assigning an icon to a button is particularly important. Otherwise, the user must view the button’s tooltip to see what the button does.

To show an icon on the menu item or button, follow these steps:

1. With the Menu Editor still opened, select the menu item or button.
   
   The Icon properties appear on the right.
2. Select one of the following options:

   **None**   Select this option to show a blue square instead of an icon.

   **Built-in icon**   Select this option to show an icon that JMP provides, and then select the icon from the list.

   **Use image from file**   Select this option to show an image that you created. Click **Browse**, select the graphic, and then click **OK**.

   **Use add-in home folder**   Select this option to display an icon from an add-in to the left of the menu item. After you select the checkbox, select the add-in, click **Browse**, and then select the icon. The path to the image is displayed in the **Use image from file** field. The image can be an ICO, PNG, JPG, or BMP graphic.

3. Click **Save** to save your changes.

**Step 5: Assign a Shortcut Key (Optional)**

A shortcut key executes an action so that you do not have to select the menu item or click the button on the toolbar. This option is also helpful when the button’s toolbar is not shown, but you still want to execute the action.

Shortcuts begin with Ctrl, Ctrl+Shift Ctrl+Alt and end with a number, letter, or symbol that appears on the keyboard. The Function keys (such as F1) are also supported. Many Ctrl + letter and Function shortcuts are already assigned in JMP, but you can reassign them to your buttons if you want.

Shortcut keys appear in menus next to each menu item.

To assign a shortcut key, follow these steps:

1. With the Menu Editor still opened, select the menu item or button.
   The Shortcuts properties appear on the right.

2. Do one of the following:
   
   - To assign a new shortcut, click in the **New shortcut** area and press the shortcut keys. If the keystrokes then appear in the **Currently assign to** box, press another combination of shortcut keys. (You do not have to delete the keystrokes before pressing the shortcut keys.)
   
   - To change a shortcut that you previously specified, click **Remove**, click in the **New shortcut** area and press the shortcut keys.

3. Click **Assign**.
   The shortcut appears in the **Current shortcuts** list.

4. Click **Save** to save your changes.

To remove a shortcut, select the shortcut and click **Remove**.
Set User Permissions for Customized Toolbars and Buttons

Use the JMP Menu Editor to specify which users can see your customized toolbars and buttons. Your changes are saved in a text file with the .jmpcust extension called a customization set. By default, your customizations are shown only to the current user; other users who log on to the computer and open JMP do not see your personal toolbars and menus.

All customization sets include the built-in JMP buttons and menus. You can also base customization sets on other customization sets. For example, you might create a new customization set that shows the JMP add-in menus and toolbars along with your modifications.

When you modify the Current user customization set, JMP creates a backup file of the set. The file is located in your Windows Users folder within the JMP or JMPPro folder.

C:/Users/<user name>/AppData/Roaming/SAS/JMP/16/

When you modify the All users customization set, JMP creates a backup file of the set. The file is located in the Windows All Users folder within the JMP or JMPPro folder.

C:/Users/All Users/SAS/JMP/16/

The All Users folder does not appear when you try to browse for it, so you must type the path into the Windows Explorer address field.

Note: To find the customization set files in Windows Explorer, show all hidden files in the Windows Explorer Folder Options. See your operating system documentation for details.

To change the customization set, follow these steps:

1. Select View > Customize > Menus and Toolbars.
   The Menu Editor appears.
2. Click Change.
   When you try to change the customization set, and changes to the selected set are not saved, you are prompted to save the changes. Click Save Changes.
3. Select the customization set in the Customization Set to Modify area. (By default, changes apply only to the Current user customization set.) “Customization Set Options” on page 644 describes the options.
4. (Optional) To change the set on which the selected customization set is based, select the set in the Starting Set area. (Not available for the All users customization set.) “Customization Set Options” on page 644 describes the options.
5. Click OK.
Rearrange Toolbars

On Windows, there are two ways to rearrange toolbars:

- To rearrange toolbars quickly for the current user, drag the toolbar above, below, to the left, or to the right of the adjacent toolbar.
- To specify the new location rather than drag the toolbar, right-click the toolbar and select a position from the Location menu. This method lets you move toolbars to the top or bottom of the window. You can also position the toolbars vertically on the left or right side of the window.

In some windows, the toolbar is hidden by default. Specifying a new location shows the toolbar in all windows of that type. On Windows, you can change the toolbar preferences to always show toolbars. See “Windows Preferences” on page 698 in the “JMP Preferences” chapter.

To drag a toolbar

1. Point to the left corner of the toolbar until the Move cursor appears.
2. Drag the toolbar to the new location. When a toolbar is too wide to show completely, click the arrow to show all of the buttons, as shown in Figure 12.3.

![Figure 12.3 Expanding a Toolbar](image)

To position the toolbar

1. Right-click the toolbar that you want to move.
2. Select Location, and then select the new position.

Note: After you move a toolbar to the left, right, or bottom positions, you can add other toolbars to the same position. For example, you might relocate the File_Edit toolbar to the right side of the JMP window. To add other toolbars on the right side, right-click the bar and select the toolbar that you want to add.

Copy and Paste Menus, Menu Items, Toolbars, and Buttons

Copying existing items is a shortcut to creating new items in a menu or toolbar. This option lets you change only a few settings in the new item when possible.
To copy and paste menus and menu items

1. Select View > Customize > Menus and Toolbars.

   The Menu Editor appears.

2. (Optional) Change the customization set to control which users see your customizations. See “Customization Set Options” on page 644.

3. Right-click the menu or menu item that you want to copy and select Copy.

4. Right-click the menu or menu item before, after, or into which the item will appear and select Paste.

   One of the following occurs:
   - A list of possible locations appears.
   - The menu or menu item appears below the selected item. Skip to step 7.

5. Select the location of the menu by doing one of the following:
   - To paste the item before the selected menu, select Paste before.
   - To paste the menu after the selected menu, select Paste after.
   - To paste the menu inside the selected menu, select Paste into. (Available only when you select a menu as the new location.)
   - To cancel the action, select Cancel.

   The item appears as you indicated.

6. Modify the item.

7. Click Save to save your changes.

See “Personalize the Main Menu Bar” on page 647 and “Create Menu Items and Toolbar Buttons” on page 648 for more information about modifying the items.

To copy and paste toolbars and buttons

1. Select View > Customize > Menus and Toolbars.

   The Menu Editor appears.

2. (Optional) Change the customization set to control which users see your customizations. See “Customization Set Options” on page 644.

3. Right-click the toolbar or button that you want to copy and select Copy.

4. Do one of the following:
   - To paste a toolbar, right-click Toolbar and select Paste. The toolbar appears at the end of the list of toolbars.
   - To paste a button, right-click the button before or after which you want the new button, and select Paste. If you selected the first button on the toolbar, select the location of the button. Otherwise, the button is pasted below the selected button.
5. Modify the item.
6. Click **Save** to save your changes.

See “Personalize Toolbars” on page 644 and “Create Menu Items and Toolbar Buttons” on page 648 for more information about modifying the items.

### Rearrange Custom Menus, Menu Items, and Buttons

On Windows, you can rearrange the order of menus, menu items, and buttons that you create. For example, under the **File > New** menu, you could move your custom menu before the **Data Table** command.

In the item’s General properties, the Source determines whether you can move the item. You can move items if the Source is **Custom Item**. Built-in items cannot be moved. Items that are defined in other customization sets can be moved only in that customization set. See “Customization Set Options” on page 644.

**Note:** The right-click menu has options for cutting and pasting items. To cut an item, you can also press Ctrl+X, or press Shift+Delete. To paste, press Ctrl+V, or press Shift+Insert.

**To rearrange custom menus and menu items**

1. Select **View > Customize > Menus and Toolbars**.

    The Main Menu list appears on the left.

2. Do the following:
   - Select the item that you want to move.
   - Verify that the Source is **Custom Item**.
   - If the Source is **All Users** or **JMP Add-In**, select the specified customization set and verify that the Source is **Custom Item**.

3. Right-click the custom menu or menu item that you want to move and select **Cut**.

4. Right-click the new location of the cut item and select **Paste**.

    One of the following occurs:
    - A list appears with the possible locations of the cut item. This occurs when you select a menu (such as **File** or **New**) or the first item in a menu (such as **Data Table** in the **File > New** menu).
    - The cut menu item appears below the selected menu item. Skip to step 6.

5. Select the location of the cut item by doing one of the following:
    - To paste the cut item **before** the selected item, select **Paste before**.
    - To paste the cut item **after** the selected item, select **Paste after**.
To rearrange custom buttons
1. Select View > Customize > Menus and Toolbars.
   The Toolbars list appears on the left.
2. Do the following:
   – Select the custom button that you want to move.
   – Verify that the Source is Custom Item.
   – If the Source is All Users or JMP Add-In, select the specified customization set and verify that the Source is Custom Item.
3. Right-click the custom button that you want to move and select Cut.
4. Right-click the new location of the cut button.
   One of the following occurs:
   – A list appears with the possible locations of the cut button. This occurs when you select the first button on the toolbar (such as New Data Table in the File_Edit toolbar).
   – The button is pasted at the end of the toolbar. This occurs when you select the name of the toolbar. For example, when you select File_Edit and paste, the button appears after the last button, Run Script. Skip to step 6.
   – The cut button appears after the selected button. Skip to step 6.
5. Select the location of the cut button by doing one of the following:
   – To paste the cut button before the selected button, select Paste before.
   – To paste the cut button after the selected button, select Paste after.
6. Click Save to save your changes.

Delete Custom Items
Rather than temporarily showing or hiding toolbars, buttons, menus, and menu items, you can delete items that you created to remove them permanently from JMP. The Source determines whether you can delete the item and which customization set contains the item. Figure 12.4 shows examples of customization Source types.
Empty menus are not supported. When you delete the only item in a menu, the entire menu is deleted, not just the selected item.

**Note:** Make sure that you really want to delete custom items. They are removed immediately without confirmation.

To delete a custom item, follow these steps:

1. Select **View > Customize > Menus and Toolbars**. The Menu Editor appears.
2. Select the item that you want to delete.
3. Verify whether the item can be deleted, and change the customization set, if necessary.
4. Right-click the selected item and select **Delete**. The item is immediately deleted.
5. Click **Save**. Your changes are saved.

**Show or Hide Custom Items**

In the Menu Editor, you show or hide toolbars, buttons, menus, and menu items in specific customization sets. The item’s Source determines where you show or hide the item. For example:

- When the Source is *All Users*, change the customization set to **All users** to hide the item from all users.
- When the Source is *JMP Add-In*, change the customization set to **JMP Add-In** followed by the name of the add-in. The item is shown or hidden in all sets that include the selected JMP add-in.
If you do not change the customization set, the item is shown or hidden only in the currently selected set. See “Customization Set Options” on page 644 for more information about customization sets.

**Note:** To quickly hide or show toolbars for the current user, select or deselect them from the **View > Toolbars** list.

To show and hide items in a customization set, follow these steps:

1. Select **View > Customize > Menus and Toolbars**.
   The Menu Editor appears.
2. Select the customization set that you want to modify.
3. Select the item that you want to show or hide.
4. Select or deselect **Hidden** in the General properties. See “Step 2: Specify the Caption and Internal Name” on page 647 for more information about the General properties.
5. Click **Save** to save your changes.

**Import Customizations**

Changes to toolbars and menus are stored in customization sets, or plain text files. You open a customization set in JMP to import your modified toolbars and menus. The customizations are then shown in the Menu Editor. See “Customization Set Options” on page 644 for more information about the menu customization files.

To import customizations, follow these steps:

1. Select **File > Open**.
2. In the File name list, select **All JMP Files** (or **JMP Menu Files**) and then select the customization set.
3. Click **Open**.
   A confirmation is displayed, stating that the customizations have been imported. The Menu Editor is also opened.
4. Display the Menu Editor and click **OK** to save the changes, or click **Cancel** to discard them.

**Remove Customizations from JMP**

As you modify items, you discard unsaved changes by clicking the Menu Editor’s **Cancel** button and clicking **Yes** to confirm. After saving customizations, you can also remove all customizations and revert to the original menus and toolbars.
To remove all of the current user’s customizations

1. Select **View > Customize > Revert to Factory Defaults**.
2. Click **Yes** to remove the current user’s customizations.
   
   When JMP finds customizations from a previous version of JMP, a confirmation appears.
   
   Do one of the following:
   
   – Select **No** to avoid adding those customizations to the current installation of JMP.
   
   – Select **Yes** to add those customizations to the current installation of JMP.

To remove customizations from another customization set

1. Select **View > Customize > Menus and Toolbars**.
   
   The Menu Editor appears.

2. Click **Change**.

3. Select the customization set, and click **OK**.

4. Click **Revert All**.
   
   A confirmation window appears.

5. Click **Yes** to remove your customizations.

To remove customizations from the selected item

1. Select **View > Customize > Menus and Toolbars**.
   
   The Menu Editor appears.

2. (Optional) Select the customization set that contains the item.

3. Select the item that you want to modify.

4. Do one of the following:
   
   – To restore the *previous* properties of an *unsaved* item, click **Reset**.
   
   – To restore the *original* properties of a *built-in* item, click **Revert All**, and then click **Yes** to confirm.

5. Click **Save** to save your changes.
Personalize JMP Toolbars on macOS

On macOS, you can set up toolbars to display only the icons that you need. Icons are available based on the type of window. For example, in a script window, icons for options such as reformatting, encrypting, and running the script are available. Table icons are available only for data table toolbars.

You can specify whether the icon, icon and icon name, or just the name appear on the toolbar. Displaying small icons is also an option.

To add, remove, or rearrange toolbar icons

1. Open the type of window whose toolbar you want to customize.
2. Select View > Customize Toolbar.
   A window appears that shows icons relevant to the current type of window.
3. Do any of the following:
   - To add an icon to the toolbar, drag the icon from the window onto the toolbar.
   - To move an icon on the toolbar, drag the icon to its new location onto the toolbar.
   - To remove an icon from the toolbar, drag the icon from the toolbar onto the window.
   Your changes are applied to the current window and all open windows of the same type.

Figure 12.5 Add, Rearrange, and Remove Toolbar Buttons on macOS

4. Click Done.
   When a toolbar is too wide to display completely, click the right arrows on the toolbar to show and then select other icons. Alternatively, you can click and drag the window until the entire toolbar appears.
To change the appearance of toolbar icons

1. Open the type of window whose toolbar you want to customize.
2. Select **View > Customize Toolbar**.
   
   A window containing toolbar icons appears.
3. At the bottom of the window, select one of the following options from the Show list:
   
   - To display only an icon, select **Icon Only**.
   - To display an icon and its name, select **Icon and Text**.
   - To display only the icon name, select **Text Only**.
4. To display small or standard icons, select or deselect **Use small size**.
   
   Your changes are applied to the current window and all open windows of the same type.
5. Click **Done**.

**Personalize JMP Menus on macOS**

Customize JMP menus to quickly access files or modify existing menu items. Selecting a menu item runs a JSL script from your computer or executes the JSL commands that you specify. For example, you can create a menu item to open a frequently used script. This option is an alternative to adding the script as a favorite on the Home Window.

Features include adding and renaming menu items, hiding menu items, inserting menu item separators, and associating a menu item with JSL.

JMP customizations are stored in `<username>/Library/Application Support/JMP/16/usercust.jmpcust`.

**Note:** You cannot delete default JMP menus or delete submenus (which open to reveal other menu items). Default and custom submenus also cannot be renamed.

**Example of Adding a Menu Item**

In this example, create a menu item that runs a script.

1. Select **View > Customize Menus**.
2. In the JMP Menu Editor, select **File** and then **Open**.
3. Press Control and then select **Add New Menu Item after**.
4. Type *What is the Current Time?* in the Menu Label box.
5. Select **Run JSL in this file:** and select *Library/Application Support/JMP/16/Samples/Scripts/timeAnnouncer.jsl*.
6. Click **Add** and close the Menu Editor window.
7. Select **File > What is the Current Time?**.
   The Scheduler window appears, and the current time is spoken.

**Example of Adding a Submenu Item**

A submenu opens to reveal submenu items. In this example, create a submenu item that opens a data table.

1. Select **View > Customize Menus.**
2. In the JMP Menu Editor, select **File** and then **Open**.
3. Press Control and select **Add New Submenu after**.
4. Type **Open My Data Tables** and select **JSL Commands**.

   **Note:** Selecting **JSL Script** lets you select a JSL script from your computer.

5. Click **Add**.
6. Select **Open My Data Tables**, delete **Subitem placeholder** in the Menu Label box, and then type **Open Napoleons March.jmp**.
7. In the Run this JSL box, type **Open("$SAMPLE_DATA/Napoleons March.jmp")**;
8. Click **Save Changes**.
9. Select the **File** menu to see the new menu item.

**Tip:** If the new menu item appears in the menu but not the menu editor, close the menu editor window and reopen it.

**To delete a custom menu or submenu item**

- Delete one custom menu item by selecting the item and selecting **Delete Selection** from the options list.
- Delete all custom menu items by selecting **Revert All** from the options list.
- To delete items within a submenu, you must delete the entire submenu. Empty menus are not permitted. Select the submenu and select **Delete Selection** from the options list.
To add new features to JMP, you can write the scripts and compile files to create an add-in. One way to compile the scripts is to use Add-In Builder as described in the *Scripting Guide*.

Add-In Builder provides a menu editor that enables you to create menu items in the Add-Ins menu. You can also use the JMP Menu Editor to create menu items and add toolbar buttons for an add-in.
JMP preferences enable you to specify general and specific settings and save the settings.

To change preferences

1. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS). The window in Figure 13.1 appears. The previous preferences page that you selected appears.
2. Click a category and make selections. Click **Apply** to see the results, and then click **OK**.

**Note:** When you upgrade to JMP 16 Subscription, changes to preferences are maintained. In other JMP versions, you must customize the preferences after each upgrade.

To search preferences

1. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS).
2. In the Filter box at the top, enter your text.
   - Text matches are highlighted.
3. Under Preference Group, click a category to see its results.

A search term can show up in these places:
- the preference itself
- a tooltip for the preference
- a list of options for a preference

To reset preferences to the default settings

1. Select **File > Preferences** (Windows) or **JMP > Preferences** (macOS).
2. Click **Reset All**, and then click **OK**.

Overview of JMP Preferences

The Preferences command on the File menu (on the JMP menu on macOS) displays the Preferences window. See Figure 13.1. Each category is described in this chapter.

On Windows, changes that you make to preferences are stored in a version-specific JMP.PFS file located in one of the following folders:

C:/Users/<user name>/AppData/Roaming/SAS/JMP/16/
C:/Users/<user name>/AppData/Roaming/SAS/JMPPro/16/

On macOS, the preferences are stored in com.sas.jmp.plist, which is located in

~/Library/Preferences/.

JMP looks for this file when you open the program and considers your changes to be the factory defaults. And all subsequent changes are stored in this file.

General JMP Preferences

Most General preferences customize your JMP session at start-up. Others set preferences for file handling and the general appearance of the JMP workspace.
### Figure 13.1 General Preferences

- Show Tip of the Day at startup
- Initial Splash Window
- Initial Log Window

**Initial JMP Window**  
- **Home Window**

- Reopen the initial JMP window on last window close
- Show menu tips
- Report JSL warnings and errors interactively
- Show log warnings for JSL compatibility changes in JMP 12

**Allow Unquoted Strings in JSL**  
- Yes (no warning)

- Save Journals GZ Compressed
- Save Data Table Columns GZ Compressed
- Allow 16 Bit List Check Compression
- Save Scripts in English
- JSL save column groups with group name
- Display indexes in English
- Report Invalid Display Box Messages
- Add files opened by scripts to the Recent Files list

**Autosave timeout**  
- 0

**Autosave maximum data table rows**  
- 10000

**Autosave maximum data table columns**  
- 1000

**Save the session when exiting**  
- Prompt

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Home Window</strong></td>
<td><em>(macOS only)</em> Select this option to show the JMP Home window when you start JMP on macOS. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Reopen the initial JMP window on last window close</strong></td>
<td><em>(Windows only)</em> Select this option to open whichever window you have set as the Initial JMP Window when you close the last JMP window. If this option is turned off, closing the last JMP window also quits JMP. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Show menu tips</strong></td>
<td><em>(Windows only)</em> Select this option to see tooltips on main menu options and options in red triangle menus. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Report JSL warnings and errors interactively</strong></td>
<td>Shows script errors in a new window rather than only in the log. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Show log warnings for JSL compatibility changes in JMP 12</strong></td>
<td>Select this option to print warnings about JSL compatibility to the log. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Allow Unquoted Strings in JSL</strong></td>
<td>Select this option to print a warning to the log when a string value in a platform message is unquoted. Quoted string values are preferred over literal names.</td>
</tr>
<tr>
<td></td>
<td><strong>Yes (no warning)</strong> Allows unquoted string values and does not print a warning to the log. This option is selected by default.</td>
</tr>
<tr>
<td></td>
<td><strong>Yes (warning)</strong> Allows unquoted string values and prints a warning to the log.</td>
</tr>
<tr>
<td></td>
<td><strong>No</strong> Ignores the unquoted string value and does not print a warning to the log.</td>
</tr>
<tr>
<td><strong>Save Journals GZ Compressed</strong></td>
<td>Select this option to save JMP journals in a compressed format to save disk space. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Save Data Table Columns GZ Compressed</strong></td>
<td>Select this option to allow JMP to save data tables using GZ compression. For backward compatibility, JMP 10 can read the compressed files but not save them. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Allow 16 Bit List Check Compression</strong></td>
<td>Compresses a column that has less than or equal to 65,535 unique values. Adds the List Check property to the column. This option is deselected by default.</td>
</tr>
</tbody>
</table>
Table 13.1 Preferences on the General Page *(Continued)*

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Save Scripts in English</strong></td>
<td>Non-English versions of JMP can save scripts in either English or your local language. User-specified values (such as column names and text strings) in these scripts appear as they do in the data table. However, command words (such as Distribution and Set Value) appear in English rather than the local language in order for the script to run on JMP in English. JMP properly displays non-Roman characters (such as Japanese variable names) in JMP in English when the fonts support the necessary characters. The option is selected by default. Deselect this option to save scripts in your local language. Note that these scripts run correctly only if JMP is running in the same language.</td>
</tr>
<tr>
<td><strong>JSL save column groups with group name</strong></td>
<td>Specifies the column group name in a JSL script saved from a platform instead of listing all of the column names.</td>
</tr>
</tbody>
</table>
| **Display indexes in English**                  | Shows sections of the JMP Indexes in English or the current locale’s language. The option is selected by default. When you deselect it, the following items are displayed in the current locale’s language:  
  • The message list for objects  
  • The message list for display boxes.  
  • The category list for JSL functions.  
  **Note:** The description of each index item is always displayed in the current locale’s language. Examples are always in English. |
| **Report Invalid Display Box Messages**          | Sends information about invalid display box messages to the log. This option is selected by default. This option can be useful during script development, but can cause unwanted log messages for existing scripts. |
| **Add files opened by scripts to the Recent Files list** | *(Windows only)* Select this option to include files opened by the JSL Open() command in the Home Window Recent Files pane and the File > Recent Files list. This option is selected by default. |
| **Autosave timeout**                            | Automatically saves the contents of opened data tables, journals, reports, projects, and scripts except for untitled files at the specified interval. The default setting is 0 minutes, which indicates no autosave. |
Projects preferences enable you to control how new empty projects are created, which tool windows appear, and more.

**Figure 13.2  Projects Preferences**

<td></td>
</tr>
<tr>
<td>JMP Live Timeout</td>
<td>60</td>
</tr>
<tr>
<td>Transparent background for report PNG images</td>
<td></td>
</tr>
</tbody>
</table>
Table 13.3 Preferences on the Reports Page  (Continued)

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save table with report</td>
<td>Select one of the options from the menu to determine how a table is saved to a report:</td>
</tr>
<tr>
<td>Embed</td>
<td>When you save a report, the table is embedded into the report. Choose this option if you want to share the report with others. The data table that is stored in the report is reopened (unchanged) each time the report is opened. If you make changes to the table, they are not saved into the report unless you re-save the report.</td>
</tr>
<tr>
<td>Separate</td>
<td>When you save a report, the table is referenced in the report.</td>
</tr>
<tr>
<td>Prompt</td>
<td>When you save a report, you are prompted to specify how to save the report: either to embed the table within the report, or to add a reference to the table in the report. This is the default setting.</td>
</tr>
<tr>
<td>Laser pointer</td>
<td>JMP has a built-in laser pointer that enables you to visually emphasize parts of a report. The option is deselected by default. To turn it on, select a color for the laser pointer from the list.</td>
</tr>
<tr>
<td>Show conditional formatting</td>
<td>Conditionally formats the color of the text that represents the values. Available for correlation values, p-values, and factor pattern values.</td>
</tr>
<tr>
<td></td>
<td>Select one of the options from the menu:</td>
</tr>
<tr>
<td>Always</td>
<td>Conditional formatting is always applied to correlation values, p-values, and factor pattern values. This is the default setting.</td>
</tr>
<tr>
<td>Screen Only</td>
<td>Conditional formatting is always applied to correlation values, p-values, and factor pattern values. However, the conditional formatting does not show when the report is printed.</td>
</tr>
<tr>
<td>Never</td>
<td>Conditional formatting is never applied to correlation values, p-values, and factor pattern values.</td>
</tr>
</tbody>
</table>
Table 13.3 Preferences on the Reports Page (Continued)

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Rules</td>
<td>Creates custom conditional formatting rules that can be applied to numeric columns or matrices. See “Use Conditional Formatting in Reports” on page 475 in the “JMP Reports” chapter.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Verify the Use an Asterisk with the PValue Format preference to ensure that the asterisk (*) is or is not used for any p-value conditions.</td>
</tr>
<tr>
<td>Use an Asterisk with the PValue Format</td>
<td>Select this option to display an asterisk (*) next to significant p-values. This option is selected by default.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Verify any conditional formatting rules for PValue to ensure asterisk (*) is not used for any defined conditions.</td>
</tr>
<tr>
<td>JMP Live Timeout</td>
<td>Species the timeout value for publishing to JMP Live. The default time is 60 seconds.</td>
</tr>
<tr>
<td>Transparent background for report PNG images</td>
<td>Select this option to display a transparent background when a report is saved as a PNG file. This option is deselected by default.</td>
</tr>
</tbody>
</table>

Preferences for JMP Graphs

Graph preferences customize the appearance of graphs. See “Style Preferences for JMP Graphs and Reports” on page 680 for more information about configuring the appearance of graphs.
Table 13.4 Preferences on the Graphs Page

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Graph Border</strong></td>
<td>Draws a border line around the area of the graph. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Y-Axis Title Above Graph</strong></td>
<td>Shows the Title for the Y-Axis above the line rather than beside the line. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Hide Overlapping Labels</strong></td>
<td>Select this option to hide overlapping chart labels. This option is selected by default.</td>
</tr>
</tbody>
</table>
### Table 13.4 Preferences on the Graphs Page *(Continued)*

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Graph Height</strong></td>
<td>Sets the default height (in pixels) for a graph. The default setting is 240 pixels. Some platforms take the value and multiply it by a certain amount.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>With Graph Builder windows, specifying the Graph Height enlarges the window proportionally, but the exact value is not applied.</td>
</tr>
<tr>
<td><strong>Line Width</strong></td>
<td>Sets the default width (in pixels) for lines that pertain to content. The default setting is two pixels.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This preference does not apply to grid lines.</td>
</tr>
<tr>
<td><strong>Graph Marker Size</strong></td>
<td>Select a default size for the markers in graphs: Dot, Small, Medium, Large, XL, XXL, or XXXL. This preference is applied when the marker size is set to Preferred on a graph. The default setting is Large. When the number of markers in a graph exceeds the Fast Marker Threshold, the graph’s Marker Drawing Mode is set to Fast, which draws dot-sized markers.</td>
</tr>
<tr>
<td><strong>Graph Marker</strong></td>
<td>Select a default marker shape for the markers in graphs. The default setting is a small dot.</td>
</tr>
<tr>
<td><strong>Graph Marker Theme</strong></td>
<td>Select a default theme for the markers in graphs when you mark by row or column. The default setting is Standard.</td>
</tr>
<tr>
<td><strong>Marker Selection Mode</strong></td>
<td>Select the default formatting for selected markers. The default setting is Unselected Faded. See “Change the Selection Mode of Markers” on page 487 in the “JMP Reports” chapter.</td>
</tr>
<tr>
<td><strong>Marker Selection Color</strong></td>
<td>When the Marker Selection Mode is Selected Same Color, this setting applies the specified color to selected markers. The default color is Red.</td>
</tr>
<tr>
<td><strong>Marker Selection Fade</strong></td>
<td>When the Marker Selection Mode is Unselected Faded, this setting fades the unselected markers by the specified amount (in percent). The default setting is 65%.</td>
</tr>
</tbody>
</table>
Table 13.4 Preferences on the Graphs Page  (Continued)

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Marker Label Color Style</strong></td>
<td>Select the color of the marker label that appears on a graph when you label a column in the data table.</td>
</tr>
<tr>
<td><strong>Marker Color</strong></td>
<td>The marker label is the same color as the marker. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Marker Color Faded</strong></td>
<td>The marker label is faded according to the Marker Selection Fade preference.</td>
</tr>
<tr>
<td><strong>Fixed Color</strong></td>
<td>The marker label color is as specified. The Marker Label Fixed Color preference determines the color.</td>
</tr>
<tr>
<td><strong>Marker Label Fixed Color</strong></td>
<td>Select the color of fixed-color marker labels, an option that you select in the Marker Label Color Style preference. The default color is gray.</td>
</tr>
<tr>
<td><strong>Fast Marker Threshold</strong></td>
<td>When JMP refreshes a report window, it can draw markers or points on a plot at two different speeds: normal and fast. If JMP is in normal drawing mode, and the number of markers on a graph are more than the specified threshold number, JMP automatically switches to fast mode.</td>
</tr>
<tr>
<td></td>
<td>Enter the number of markers that separate normal and fast mode. When the number of markers in a graph exceeds the Fast Marker Threshold, the graph's Marker Drawing Mode is set to Fast. which draws dot-sized markers. The default setting is 50,000.</td>
</tr>
<tr>
<td><strong>Fill Hollow Markers</strong></td>
<td>Select this option to apply an opaque background to markers. This option is deselected by default.</td>
</tr>
</tbody>
</table>
### Table 13.4 Preferences on the Graphs Page (Continued)

Preferences for Data Tables

Table preferences customize JMP data tables, including formula handling, appearance, and compatibility with SAS data sets.
Figure 13.6 Tables Preferences

Evaluate OnOpen Scripts
- Prompt to save when closing summary tables
- Allow short numeric data format
- Print Data Grid as is
- Preserve SAS variable names when exporting to SAS
- Preserve SAS formats when exporting to SAS
- Show Alternate Column Name
- Use Thousands Separator
- Show Search Box on Columns Panel

Default Field Width: 12

Use Numerical Ordering
- Numeric keypad Enter key moves down
- Suppress Formula Eval on Open (Not recommended)

Formula Evaluation: When Idle

ODBC Hide Connection String
- Warn when referenced table name has changed
- Virtual Join Auto Open Linked Table
- Virtual Join Use Linked Column Name

Header Summary Graphs
- Show summary graphs below column names
- Show missing data bars or bins in summary graphs

Summary Graph Colors
- Continuous
- Continuous Missing
- Nominal
- Ordinal
- Other

Table 13.6 Preferences on the Tables Page

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Evaluate OnOpen Scripts</strong></td>
<td>If you save a script to a data table and name it OnOpen or On Open, JMP can automatically run the script whenever you open the data table. On Open scripts that execute other programs are never run.</td>
</tr>
<tr>
<td>Prompt is selected by default. Your choice is remembered each time you open the data table in the current JMP session.</td>
<td><strong>Always</strong>  Allows On Open scripts to run without prompting.</td>
</tr>
<tr>
<td></td>
<td><strong>Never</strong> Prevents On Open scripts from automatically running when a data table is opened.</td>
</tr>
<tr>
<td><strong>Prompt to save when closing summary tables</strong></td>
<td>Prompts you to save an unsaved linked summary table when you close it. Note that, when you select this option in the Summary window, it is selected in the Tables preferences. If you do not want to be prompted to save all linked summary tables in the future, deselect the preference. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Allow short numeric data format</strong></td>
<td>JMP has the ability to store numeric data in as few as 8 bits (one byte). This option makes short-integer formats available to you when you select Cols &gt; Column Info and assign a column a data type. When you use the correct short-integer format for your data, the numbers are not displayed differently, but the data table uses less disk space. See “The Short-Integer Format” on page 294 in the “Set JMP Column Properties” chapter.</td>
</tr>
<tr>
<td><strong>Print Data Grid as is</strong></td>
<td>Select this option to print the JMP data table as it appears on the screen. Clear this option to resize column widths to accommodate the content width. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Preserve SAS variable names when exporting to SAS</strong></td>
<td>Select this option to use variable names that are compliant with SAS when you export a JMP data table to a SAS data set. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Preserve SAS formats when exporting to SAS</strong></td>
<td>Select this option to use formats that are compliant with SAS when you export a JMP data table to a SAS data set. This option is selected by default.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Preferences by JMP Platform

Each analysis report has a variety of plot and table options that are shown by default. However, there might be additional options that you want to see each time you run a particular analysis. For example, a bivariate analysis shows a scatterplot by default, but you might also always want to see a linear fit each time. By selecting the Platforms option in the left panel of the Preferences window, you can set the default options for analyses. (Analyses are run by using platforms, such as the Bivariate platform. Thus, the name of this category is Platforms.)
Highlight an analysis name in the Platforms list. Its available options appear in the Options box with the defaults selected.

Some platform preferences include a Set check box to control whether an option appears in a report.

- To prevent an option from appearing in the report, next to an option, select Set but do not select the option.
- To ensure an option appears in the report, select Set and select the option.

Click **Reset Platform to Defaults** to return the selected platform options to the default settings.

Click **Reset to Defaults** to return all platforms to their default settings.

**Figure 13.8** Platforms Preferences
Print Preferences

The Print pages enables you to configure default print settings such as, margins, header, and footers.

Table 13.9 Preferences for Import Settings for Text Files

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open Text File Charset</td>
<td>Select one of the options from the menu to determine what character encoding JMP uses to open files. The default setting is Best Guess. Note that Windows-1252 is considered ANSI on some systems, and UTF-8-BOM is not supported.</td>
</tr>
<tr>
<td>Save Text Files as Unicode</td>
<td>JMP uses the Unicode character set, which supports special characters such as é and ½. It saves files without special Unicode characters as plain text automatically. This option is selected by default. Deselect this check box to save all your files as plain text.</td>
</tr>
<tr>
<td>Import Settings</td>
<td>Select the strategy JMP uses to open text files. The default selection is <strong>Use these settings</strong>. In that case, you need to ensure that the settings reflect your text files. If you select <strong>Use best guess</strong>, JMP collects statistics in the text file on tabs, commas, blanks, and a few other characters and uses a rule-based system to decide what the file format might be. The rules try to make reasonable field widths and a reasonable number of fields per line. If your data format is too different from what the rules are designed to guess, JMP guesses incorrectly. In that case, either use the wizard or explicitly describe your data in these preference settings.</td>
</tr>
<tr>
<td>End Of Field</td>
<td>Select one or more characters to use as the delimiter that signifies the end of a field when importing text data. Tab, comma, and CSV standard are selected by default. Select the Other option and enter a character to specify a delimiter that is not listed.</td>
</tr>
</tbody>
</table>
Table 13.9 Preferences for Import Settings for Text Files (Continued)

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>End Of Line</strong></td>
<td>Select one or more characters to use as the delimiter that signifies the end of a line (row). <code>&lt;CR&gt;</code>+&lt;LF&gt;, &lt;CR&gt;, and &lt;LF&gt; are selected by default. Select the Other option and enter a character to specify a delimiter that is not listed. Note that if double-quotes are encountered when importing text data, the delimiter rules change to look for an end double-quote. Other text delimiters, including spaces, that are embedded within the quotes are ignored and treated as part of the text string.</td>
</tr>
<tr>
<td><strong>Table contains column headers</strong></td>
<td>Select this option if your text file contains columns names. If you select this option, enter the line number where the column names are located in the field next to Column Names are on line. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Column Names are on line</strong></td>
<td>If you select the Table contains column headers option, enter the line number where the column names are located in this field. Line one is the default setting.</td>
</tr>
<tr>
<td><strong>Data starts on line</strong></td>
<td>Enter the line number where the data starts in your text file. Line two is the default setting.</td>
</tr>
<tr>
<td><strong>When determining column types</strong></td>
<td>Set how long JMP scans a text file to determine data types for the columns. Scan whole file is selected by default. Note that the Scan whole file option can cause importing a text file to be slow for large files. Consider selecting Scan for 5 seconds instead. When your text file contains columns of missing data, select Treat empty columns as numeric to import the columns as numeric rather than character. A period, Unicode dot, NaN, or a blank string are possible missing value indicators. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Two-digit year rule</strong></td>
<td>Select the rule that you want to use to import dates that have two-digit years instead of four. 2000-2099 is the default setting. For more information about these rules, see “Two-digit year rule” on page 90 in the “Import Your Data” chapter.</td>
</tr>
</tbody>
</table>

</thead>
</table>
| **Display Language**                           | Select the language in which you want to run JMP. The locale settings for your operating system normally determine settings for number, date, and currency formats. Select the option below the language menu to use that language to determine these formats instead. Text that appears in windows provided by the operating system (for example, **File > Open**), do not reflect changes in the language setting. **Notes:**  
  - After changing the display language, close and restart JMP to have the language settings fully take effect.  
  - The languages that you selected in the JMP installation program determine which languages are available. To make a language available, rerun the JMP installation program, select **Modify**, and then select the language. |
| **Use JMP language rather than System locale settings for number, data, and currency formats** | Uses the JMP display language to specify number, data, and currency formats.                                                               |
| **Locale Format Settings**                     | Specify the decimal and thousands separators used for numbers and currency values. The Default setting uses the system locale and the settings in the Display Language preferences. If a non-default setting is specified, that setting overrides the Display Language preferences and the system locale. |
| **Copy/Drag Graphic Formats**                  | Select one or more graphic formats to use when copying and pasting (or dragging and dropping) graphics from JMP into other applications. Enhanced Metafile, Windows bitmap, RTF, and PNG are selected by default. The resolution for PNG and JPEG images is Default. |
### Preferences on the Windows Specific Page (Continued)

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
</table>
| Resolution (DPI) for PNG and JPEG Images        | Specify the DPI to be used when you copy a graphic format. Choose from the Default (96) or 300. 300 is better for images that must be stretched, embedded in trade publications, or printed. However, this setting uses more memory and is slower to generate for large images.  

The following script lets you set the default DPI. Change the number to a different DPI if you want and then run the script.

```julia
Pref( Save Image DPI( 600 ) );
```

To verify the default DPI after you run the preceding script, run the following script:

```julia
Get Preferences( Save Image DPI );
```

For more information about specifying a higher DPI, see “Setting the Graphic DPI for Exported Graphics” on page 592 in the “Save and Share Your Data” chapter. |
| Graphics Formats                                 | Select the format to use for graphics when you save a JMP report as an RTF file (EMF, PNG, or JPEG) or an HTML file (PNG, JPEG, GIF, and SVG).  

In the Graphic Scale Factor % box, enter the percentage at which you want graphics to appear in other applications. This feature might not work with all versions of your chosen application. 100% is the default setting. |
| Enable hardware accelerated graphics             | Takes better advantage of the computer’s graphics processing unit (GPU) for better video performance. Consider selecting this option if your computer is sluggish when drawing JMP windows. This is an experimental feature.                                                                                                                                 |
| JSL Scripts should be run only, not opened, when selected from Recent Files or a file browser | Select this option to force all scripts to run when opened. If this is selected, the script window for the script is not opened. This option is deselected by default.                                                                                                                                                                     |
| Show on the Windows task bar                     | Select which JMP windows you would like displayed on the Windows task bar. The default selection is All Windows. You can also choose to show the main JMP window and data table windows.                                                                                                                                                           |

Preferences for the JSL Debugger

The JSL Debugger preferences let you show or hide line numbers, create breaks in scripts, and show warnings.

**Figure 13.21 JSL Debugger Preferences**

- **Show Line Numbers**
- **Break On Multiple Statements Per Line**
- **Break On Throw**
- **Break On Execution Error**
- **Warn On Assignment In Condition**
- **Enter Debugger Upon Termination**
- **Break For Compatibility Warnings**

**Table 13.21 Preferences on the JSL Debugger Page**

<table>
<thead>
<tr>
<th>Preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Show Line Numbers</strong></td>
<td>Shows or hides the line numbers for the script in the debugger. This option is selected by default.</td>
</tr>
<tr>
<td><strong>Break on Multiple Statements Per Line</strong></td>
<td>Stops executing the script between each expression in a single line. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Break On Throw</strong></td>
<td>Breaks when an exception error occurs in a Try() function. For example, the exception error in the Try() function is thrown by a Throw() function. The Debugger breaks on the Throw() instead of continuing through the rest of the codes. This lets you identify where the problem occurred in the script and then return to debugging. This option is deselected by default.</td>
</tr>
<tr>
<td><strong>Break On Execution Error</strong></td>
<td>Stops executing the script when the error occurs rather than closing the Debugger. The option is selected by default</td>
</tr>
<tr>
<td><strong>Warn On Assignment In Condition</strong></td>
<td>Select to show a warning when you enter an assignment expression for the breakpoint condition. For example, if you specify x = 1 instead of x == 1 in the breakpoint condition, you are prompted to verify the specification. The option is selected by default</td>
</tr>
</tbody>
</table>
Menu Preferences

The Menu preferences show and hide menus based on how you use JMP. This gives you fewer menu items to browse through and streamlines the JMP interface. For example, if you never design experiments, deselect Design of Experiments. Other menus are grouped by area of interest, such as quality engineering, advanced modeling, reliability and survival, and SAS options.

Table 13.21 Preferences on the JSL Debugger Page (Continued)

<tr>
<td>Columns</td>
<td>Contains options to control which columns of information appear in the Enhanced Log. You can show or hide the following columns of information: the origin type of the message, the result type of the message, and the time stamp of the message. All options are selected by default.</td>
</tr>
<tr>
<td>Color by Window</td>
<td>Specifies whether the rows in the Enhanced Log are colored by the JMP window that created the row of the log output. This option is selected by default. “JMP Default” is the default color theme.</td>
</tr>
</tbody>
</table>
You can add functions to a formula. All of these functions are available in the Functions list of the Formula Editor. This chapter gives a description of functions in the Formula Editor.

More information about functions is available in the following resources:

- The Scripting Index describes all functions and their arguments, demonstrates how the functions work, and links to online Help. In JMP, select Help > Scripting Index to view this interactive resource.
- The JSL Syntax Reference also provides the arguments for JMP functions, not just those available in the Formula Editor. In JMP, select Help > JMP Help and find JSL Syntax Reference in the left column.

Figure A.1 Functions in the Formula Editor

For instructions on how to create a formula that contains a function, see “Build Formulas” on page 395 in the “Create Formulas in JMP” chapter.

Row Functions

Adding a row function to a formula lets you reference specific rows or cells within specific rows. You can also insert values based on an arithmetic sequence. See the Scripting Guide for more information about syntax.

Col Stored Value

Returns the column value that does not have column properties applied to it. If the row is not specified, the current row is used.

Suppose that the Missing Value Codes column property is assigned to the x1 column to treat “999” as a missing value. Another column includes a formula that calculates the mean. To use the value “999” instead of a missing value to calculate the mean, use Col Stored Value in the formula:

\[
\text{Mean}( \text{Col Stored Value}( :x1 ), :x2, :x3 )
\]

Count

Creates a list of values beginning with the from value and ending with the to value. The number of steps specifies the number of values in the list between and including the from and to values. Each value determined by the first three arguments of the count function occurs consecutively the number of times that you specify with the times argument. When the to value is reached, Count starts over at the from value.

Also, you can add the times argument with the insert button on the keyboard. This argument is one by default, but repeats the count process as many times as you specify, as illustrated by the Count4 column in the data table in Figure A.2. To add any argument to the Count function, highlight the argument preceding the one that you want to enter. Either type a comma or use the insert button on the Formula Editor keypad.

The columns in the data table below result from the following formulas:

- Count (1, 9, 2) gives Count 1
- Count (1, 9, 3) gives Count 2
- Count (1, 9, 9) gives Count 3
- Count (1, 9, 3, 3) gives Count 4
Reference for JMP Functions in Formulas
Appendix A

Row Functions

Figure A.2 Example of the Count Function

<table>
<thead>
<tr>
<th>count1</th>
<th>count2</th>
<th>count3</th>
<th>count4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>

</tr>
<tr>
<td>4</td>
<td>9</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

The **Count** function is useful for generating a column of grid values. For example, the following formulas create a square grid of increment **NRow()**. **NRow()** is the **Row** function that gives the total number of rows in the data table. **NRow()** also creates axes that range from –5 to 5:

\[
\text{Count}(-5, 5, \text{Root( NRow() )}); \\
\text{Count}(-5, 5, \text{Root( NRow() )}, \text{Root( NRow() )});
\]

**Dif**

Returns the difference between the value of the first argument in the current row and its value in the row defined by the current row less the second argument. The default **Dif** is one, which you can change to any number. Note that \( \text{Dif}(X, n) \) gives the same result as \( X_{\text{Row}()} - X_{\text{Row}()} - n \) or as \( X_{\text{Row}()} - \text{Lag}(X, n) \).

**Dim**

Returns a row vector with the dimensions of the current data table, a specified data table, or a matrix. The dimensions are the number of rows and the number of columns and are listed in that order.

**Lag**

Returns the value of the first argument in the row defined by the current row less the second argument. The default **Lag** is one, which you can change to any number. The value returned for any lag that identifies a row number less than one is missing. Note that \( \text{Lag}(X, n) \) gives the same result as the subscripted notation, \( X_{\text{Row}()} - n \).

**NRow**

Returns the total number of rows in the active data table.

**Row**

Returns the current row number when an expression is evaluated for that row. You can use **Row()** in any expression, including column name subscripts. The default subscript of a column name is **Row()** unless otherwise specified.
Subscript

Enables you to use a column’s value from a row other than the current row. After choosing Subscript from the list, enter a numeric expression into the subscript argument. Subscripts that evaluate to nonexistent row numbers produce missing values. Column names with no subscript refers to the current row. To remove a subscript, select the subscript and delete it. Then delete the missing box.

The formula Count_{\text{Row}()} – Count_{\text{Row}() – 1}, where \text{Row()} is the row number as described below, uses subscripts to calculate the difference between each pair of values from the column named Count. This result is the same as that given by the Dif() function. When \text{Row()} is 1, the computation produces a missing value.

The formula below calculates a column called Fib, which contains the terms of the Fibonacci series (each value is the sum of the two preceding values in the calculated column).

\[
\text{If}\left\{\begin{array}{ll}
\text{Row()} & \leq 2 \\
\text{else} & \\
\text{End}
\end{array}\right. \\
= \begin{cases} 
1 \\
Fib_{\text{Row}() – 1} + Fib_{\text{Row}() – 2}
\end{cases}
\]

It shows the use of subscripts to do recursive calculations. A recursive formula includes the name of the calculated column, subscripted such that it references only previously evaluated rows (rows 1 through \((i–1)\)). The calculation of the Fibonacci series shown includes a conditional expression and a comparison. See the sections “Conditional Functions” on page 743 and “Comparison Functions” on page 742.

Sequence

Produces an arithmetic sequence of numbers across the rows in a data table, where the start value, ending limit, and increment are specified as arguments.

Numeric Functions

You can create a formula that contains arithmetic operators that are commonly used in formulas. See the Scripting Guide for more information about syntax.

Abs

Returns a positive number of the same magnitude as the value of its argument. For example, \(|5|\) and \(|–5|\) both result in 5.

Ceiling

Returns the smallest integer greater than or equal to its argument. For example, \(\text{Ceiling}(2.3)\) results in 3, while \(\text{Ceiling}(-2.3)\) results in –2.
Floor

Returns the largest integer less than or equal to its argument. For example, Floor(2.7) results in 2, but Floor(-0.5) results in -1.

Integrate

Integrates an expression with respect to a scalar value, using the adaptive quadrature method from Gander and Gautschi (2000). For example, Integrate( Exp(-x), x, 0, .) results in 0.99999999986846.

Modulo

Returns the remainder when the second argument is divided into the first. For example, Modulo(6, 5) results in 1.

Round

Rounds the first argument to the number of decimal places given by the second argument. For example, Round(3.554, 2) rounds to 3.55 and Round(3.555, 2) rounds to 3.56.

Transcendental Functions

You can create a formula that supports transcendental functions, such as logarithmic functions for any base, functions for combinatorial calculations, the Beta function, and several gamma functions. See the Scripting Guide for more information about syntax.

Exp

Raises e to the power that you specify. Thus, Exp(1) = e.

ExpM1

Returns a more accurate calculation of Exp(x) - 1 when x is very small.

Ln

Calculates the natural logarithm of x.

Log and Log10

Calculates the natural logarithm (base e). To change the default base, highlight the argument and type a comma or click the Insert key on the Formula Editor keypad. The base appears and is editable. The Log argument can be any numeric expressions. The expression Log(e) evaluates as 1, and Log(32,2) is 5. The Log10 function calculates the logarithm of base 10 only.
**Log1P**

Returns a more accurate calculation of $\log(1+x)$ when $x$ is very small.

**Squash**

Computes the function $1 / (1 + e^x)$, where $x$ is any numeric column, variable, or expression.

**Logist**

Also known as Squish or Logistic, is an efficient computation of the function $1 / (1+e^{-x})$, where $x$ is any numeric column, variable, or expression.

**Root (Square Root)**

Calculates the root of its argument as specified by the index. Root initially shows with an index of 2. To change the index, highlight the index argument and enter the value that you want.

**Factorial**

Returns the product of all numbers 1 through the argument that you specify. For example, Factorial(5) evaluates as 120.

**NChooseK**

Returns the number of $n$ things taken $k$ at a time ($n$ select $k$) and is computed in the standard way using factorials, as $n! / (k!(n - k)!)$). For example, NChooseK(5,2) evaluates as 10.

**Beta**

Adds the two parameter Beta function and is written terms of the Gamma function as:

$$B(m, n) = \frac{\Gamma(m)\Gamma(n)}{\Gamma(m + n)}$$

**Gamma**

Adds the Gamma function, denoted $\Gamma(i)$, and is defined as:

$$\Gamma(i) = \int_{0}^{\infty} (x^{i-1})e^{-x}dx$$

Gamma with a single argument is the same as Gamma(x, infinity). The optional second argument changes the upper integer from infinity to the value that you enter. Other interesting gamma function relationships are
• for any $\alpha > 1$, $\Gamma(\alpha) = (\alpha-1) \cdot \Gamma(\alpha-1)$
• for any positive integer, $n$, $\Gamma(n) = (n-1)!$
• $\Gamma(0.5) =$ the square root of $\pi$

**LGamma**

Is the natural log of the result of the gamma function evaluation. You get the same result using the Log (natural log) function with the Gamma function. However, the LGamma function computes more efficiently than do the Log (natural log) and the Gamma functions together. NChooseK is implemented using LGamma functions. The result is not always an exact integer. If the result is close to an integer, it is rounded up using the Floor function.

**Digamma**

The logarithmic derivative of the Gamma function.

**Trigamma**

The derivative of the Digamma function, or the logarithmic second derivative of the Gamma function.

**Arrhenius**

Calculates the non-specific component of the Arrhenius relationship that is then multiplied by the activation energy in the Arrhenius equation.

$$\frac{11604.5181215503}{T + 273.15}$$

**Arrhenius Inv**

The inverse of the Arrhenius function:

$$\left(\frac{11604.5181215503}{y}\right) - 273.15$$

**Logit**

Applies the logit transformation to the argument using:

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right)$$

**Logit Percent**

Calculates the logit as a percent for the argument.
Logist Percent
Calculates the logistic as a percent for the argument.

\[
\text{LogisticPct}(x) = \frac{100}{1 + e^{-x}}
\]

Scheffe Cubic
Is used in fitting certain models. Scheffe Cubic \((X_1, X_2)\) is equivalent to \(X_1X_2(X_1-X_2)\).

SbInv
Johnson Sb inverse transformation. If argument is normal, the result is Johnson Sb.

SbTrans
Johnson Sb transformation from a doubly bound variable to a standard normal \((0, 1)\) distribution.

SHASHInv
Returns a transformation of a standard normal variable into a sinh-arcsinh (SHASH) distributed variable.

SHASHTans
Returns a transformation of a sinh-arcsinh (SHASH) distributed variable into a standard normal distributed variable.

SlInv
Johnson Sl inverse transformation. If argument is normal, the result is Johnson Sl.

SlTrans
Johnson Sl transformation from a doubly bound variable to a standard normal \((0, 1)\) distribution.
SuInv
Johnson Su inverse transformation. If argument is normal, the result is Johnson Su.

SuTrans
Johnson Su transformation from a doubly bound variable to a standard normal (0, 1) distribution.

Trigonometric Functions

You can create a formula that supports trigonometric functions, such as sine and cosine. JMP’s trigonometric functions expect all angle arguments in radians. See the Scripting Guide for more information about syntax.

Sine, Cosine, Tangent
The Sine and Cosine functions calculate the sine and cosine of their respective arguments given in radians. For example, the expression Sine(0) evaluates as 0, and Cosine(0) evaluates as 1. The tangent function calculates the tangent of an argument given in radians. The expression Tan(Pi()/4) evaluates as 1.

ArcSine, ArcCosine, ArcTangent
The ArcSine and ArcCosine functions return the inverse sine and inverse cosine of their respective arguments. The returned value is measured in radians. For example, both expressions ArcSine(1) and ArcCosine(0) evaluate as 1.57080. The ArcTangent function returns the inverse tangent of its argument. The returned value is measured in radians. The expression ArcTangent(1) evaluates as 0.78540 (=3.14159/4).

SinH, CosH, TanH
The SinH and CosH functions return the hyperbolic sine and hyperbolic cosine of their respective arguments. The expression SinH(1) evaluates as 1.175201, and CosH(0) evaluates as 1.0. The TanH function returns the hyperbolic tangent of its argument. The expression TanH(1) evaluates as 0.761594.

ArcSinH, ArcCosH, ArcTanH
The ArcSinH and ArcCosH functions return the inverse hyperbolic sine and inverse hyperbolic cosine of their respective arguments. The expression ArcSinH(1) evaluates as 0.881374, and ArcCosH(1) is 0. The ArcTanH function returns the inverse hyperbolic tangent of its argument. The expression ArcTanH(0.5) evaluates as 0.549306.
Character Functions

You can create a formula that accepts character arguments or returns character strings and converts the data type of a value from numeric to character, or character to numeric. When you create these formulas, note that:

- Character functions can result in either character or numeric data. If you calculate a data type different from the one specified, the data type of the computed column is automatically changed to match the result.
- Arguments that are literal character strings must be enclosed in quotation marks.

See the *Scripting Guide* for more information about syntax.

**Char**

Produces a character string that corresponds to the digits in its numeric argument. For example, `Char(1.123)` evaluates as 1.123. See the *Scripting Guide*.

**Collapse Whitespace**

Trims leading and trailing whitespace and replaces interior whitespace with single space. That is, if more than one white space character is present, the `Collapse Whitespace` command replaces the two spaces with one space.

**Concat**

Concatenates character strings to produce a new string with the function’s second character argument appended to the first. For example, "Dr." || " " || name produces a new string consisting of the title Dr. followed by a space and the contents of the name string.

**Contains**

Returns the numeric position within the first argument of the first instance of the second argument, if it exists. The second argument can contain one or more characters. If the second argument does not exist, `Contains` returns a zero. For example, `Contains("Veronica Layman", "ron")` evaluates as 3. `Contains("Lillie Layman", "L")` evaluates as 1. `Contains("Lillie Layman", "Veronica")` evaluates as 0. The third argument, `offset`, is optional. Offset is a numeric value that specifies the search starting position. `Contains("Lillie Layman", "L", 5)` evaluates as 8 as the search starts at the 5th position, skipping the first “L”. If `offset` is negative, `Contains` searches backward from `offset` from the end of the string.
Munger

Computes new character strings from existing strings by inserting or deleting characters. It can also produce substrings, calculate indices, and perform other tasks depending on how you specify its arguments. The Munger function treats uppercase and lowercase letters as different characters.

Text is a character expression. Munger applies the other three arguments to this string to compute a result.

Offset is a numeric expression indicating the starting position to search in the string. If Offset is greater than the position of the first instance of the find argument, the first instance is disregarded.

Find/Length is a character or numeric expression. Use a character string as search criterion, or use a positive integer to return that number of consecutive characters starting from the Offset position. If you specify a negative integer as the Length value, Munger returns all characters from the Offset through to the end of the string.

Replace (optional argument) can be a string or unspecified. If it is a string and the Find/Offset value is numeric, Munger replaces the search criterion with the Replace string to form the result. If the Find/Offset value is numeric and no string is specified, Munger calculates a substring. If the Find/Length value is a character string, Munger always returns the numeric offset, disregarding the Replace value if it exists. To insert the Replace argument, click any argument in the Munger function and then click the insert button. Press delete or click the Delete button (−) on the Formula Editor keypad to remove the Replace argument.

Lowercase, Uppercase

The Lowercase function converts any uppercase character found in its argument to the equivalent lowercase character. For example, Lowercase("VERONICA LAYMAN") evaluates as veronica layman. The Uppercase function converts any lowercase character found in its argument to the equivalent uppercase character. For example, Uppercase("Veronica Layman") evaluates as VERONICA LAYMAN.

Length

Calculates the length of its argument. For example, Length("Veronica") evaluates as 8. If the argument is

- a string, length returns the number of characters;
- a list, length returns the number of items in the list;
- a blob (binary object), the number of bytes.
**Num**

Produces a numeric value that corresponds to its character string argument when the character string consists of numbers only. If a character string contains a non-numeric value, the result is a missing value. For example, `Num(“1.123”)` evaluates as 1.123.

**Substr**

Extracts the characters that are the portion of the first argument. Begins at the position given by the second argument, and ends based on the number of characters specified in the third argument. The first argument can be either a character column or a literal value. The starting argument and the length argument can be numbers of expressions that evaluate to numbers. For example, to show the first name only, `Substr("Veronica Layman", 10, 6)` starts at position 10 and reads through position 15, which yields **Layman**.

If `start` is negative, `Substr` searches backward from `start` from the end of the string. If `length` is negative or absent, `Substr` returns a string that begins with `start` and continues to the end of the text string.

`Substr` can also be used with lists.

**Titlecase**

Converts the string to title case, that is, an initial uppercase character and subsequent lowercase characters. For example, `Titlecase("Veronica layman")` results in **Veronica Layman**.

**Trim**

Produces a new character string from its argument, removing any leading and trailing whitespace. The second argument determines if whitespace is removed from the **left**, the **right**, or **both** ends of the string. If no second argument is used, whitespace is removed from both ends. For example, `Trim("john ") evaluates as **john**. `Trim(" john ", both)` also evaluates as **john**.

**Word**

Extracts the $n$th word from a character string. One or more spaces define where each word begins and ends unless the optional **delimiters** argument is specified. For example, `Word(2, "Veronica Layman")` returns the word **Layman**.

To insert the **delimiters** argument, click any argument in the **Word** function and then click the insert button  on the Formula Editor keypad. Press Delete or click the Delete button  on the Formula Editor keypad to remove the **delimiters** argument. If you do not specify a delimiter, space is used as the delimiter. If you define the delimiter as an empty string, each character is treated as a separate word.
Most special characters act as single delimiters. You can enter any character or set of characters to act as a word delimiter. For example, to extract the last name in the following example, use a comma and blank together as the delimiting characters and ask for the first word. **Word(1, "Layman, Veronica", ", ")** returns the word **Layman**.

### Words

Extracts the words from *text* according to the delimiters listed in the optional second argument. The default delimiter is space. For example, **Words("the quick brown fox")** returns `{"the","quick","brown","fox"}`.

If you include a second argument, any and all characters in that argument are taken to be delimiters. For example, **Words("Doe, Jane P.",", ",")** returns `{"Doe","Jane","P"}`.

To insert the **delimiters** argument, click any argument in the **Words** function and then click the insert button on the Formula Editor keypad. Press Delete or click the Delete button on the Formula Editor keypad to remove the **delimiters** argument. If you do not specify a delimiter, white space is used as the delimiter. If you define the delimiter as an empty string, each character is treated as a separate word.

### Left, Right

Returns a substring of the left-most or right-most *n* characters of the string *text*, respectively. Both functions also work with lists.

### Starts With, Ends With

Returns 1 if *whole* begins or ends with *part*, respectively. Returns 0 otherwise. Both functions also work with lists.

### Item

Is different than the **Word** function because of the way it treats word delimiters. If a delimiter is found multiple times, or you enter a delimiter with multiple characters, the **Word** function treats them as a single delimiter. The **Item** function uses each delimiter to define a new word position. To compare, suppose a name is of the form lastname, firstname. The delimiter is a comma followed by a blank, such as:

**Item(2, "Layman, Veronica", ", ")**

**Word(2, "Layman, Veronica", ", ")**

The **Item** function returns a missing value because it treats the comma and blank separately and finds nothing between them. The **Word** function treats the comma and blank as a single delimiter and finds **Veronica** as the second word.

If you do not specify a delimiter, white space (blank space) is used as the delimiter. If you define the delimiter as an empty string, each character is treated as a separate item.
Hex and Hex to Number

Converts between hex and hex and numbers.

**Hex** returns the hexadecimal representation of its argument. If the argument is character (in quotes), then the result is a character string twice as long containing the hexadecimal codes for the character values. For example, **Hex("A")** returns the string 41.

If the argument is numeric and “integer” is specified, the Hex function returns an 8-hexadecimal-character representation of the integer returned. For example, **Hex(12, “integer”)** returns the string 0000000C.

**Hex to Number** converts hexadecimals to numbers.

See the *Scripting Guide*.

Repeat

Creates a string that is the first argument repeated the number of times specified by the second argument. The first argument can be either a character literal, a character variable, or a character expression. For example, **Repeat("Katie", 3)** creates KatieKatieKatie.

A third argument applies when **Repeat** is used in a JSL script to repeat a matrix. When the first argument is a matrix, the second argument is the rowwise repeat and the third argument is the columnwise repeat.

Insert

**Insert** inserts a new item into the list or expression at the given position. If position is not given, it is inserted at the end.

Reverse

**Reverse** reverses the characters in the string.

Substitute

The first argument is a string, the second is a pattern, and the third is a replacement string. **Substitute** finds all matches to the pattern in the string, and replaces them with the replacement string.

Regex

The first argument is the source string that Regex searches for a match to the pattern. The second argument is the pattern, in the form of a regular expression. The Formula Editor prompts you for these two required arguments.
Tip: For more information about using regular expressions, search the Internet for regular expression tutorial.

By default, Regex performs a case-sensitive search and returns the parts of the source string that match the pattern that you specified (or returns MISSING if the match fails). There are two optional arguments that you can add. You can type a third argument—the format—that specifies the string to return. If you choose, you can use regular expressions to specify replacement text in the returned string. If you specify the third argument, you can also specify `IGNORECASE` so that Regex ignores capitalization when searching the source string for a match.

Table A.1 Regex Examples

<table>
<thead>
<tr>
<th>Sample Regex function</th>
<th>String that is returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regex( &quot;@ q3 #&quot;, &quot;([a-z])([0-9])&quot; )</td>
<td>q3</td>
</tr>
<tr>
<td></td>
<td>The function is case sensitive, so q3 matches but Q3 would not.</td>
</tr>
<tr>
<td>Regex( &quot;@ Q3 #&quot;, &quot;([a-z])([0-9])&quot;, &quot;\0&quot;,IGNORECASE)</td>
<td>Q3</td>
</tr>
<tr>
<td></td>
<td>Although \0 is the default argument, it is required in this example so that IGNORECASE can be specified.</td>
</tr>
<tr>
<td>Regex( &quot;@ Q3 #&quot;, &quot;([a-z])([0-9])&quot;, &quot;\2\1&quot;,IGNORECASE)</td>
<td>3Q</td>
</tr>
</tbody>
</table>

For more information and an example that you can run, select Help > Scripting Index and do a search for `Regex`.

**Comparison Functions**

You can create a formula that compare the values of two arguments by using the comparison function. Each comparison relationship evaluates as true or false based on numeric magnitudes or character rankings. A true relationship evaluates as one, and false evaluates as zero.

Comparisons are useful when you include them in conditional expressions, but they can also stand alone as numeric expressions if neither term in comparison is missing. A relational symbol’s arguments can be any two expressions. However, both arguments in a comparison function must be of the same data type. Also note that:

- JMP displays an error if you use a single “=” in a conditional where “==” is expected.
Appendix A
Reference for JMP Functions in Formulas
Using JMP

- The Formula Editor uses the International Utilities package when comparing character strings. This package contains different rankings for each international character set and takes diacritical marks into consideration.
- You should not use comparison operators to specifically compare to a missing value. Instead, use the `Is Missing` function to detect a missing value.

See the *JSL Syntax Reference* for more information about syntax.

< Less than

> Greater than

<= Less than or equal to

>= Greater than or equal to

== Equal to

!= Not equal to

\(a < b \leq c\)  \(b\) is greater than \(a\) and less than or equal to \(c\)

\(a \leq b < c\)  \(b\) is greater than or equal to \(a\) and less than \(c\)

**Is Missing**  Returns a one (1) if the value of the argument for the current row is missing, and a zero if the value is not missing.

### Conditional Functions

You can include conditional expressions (called *conditionals* for short) in your formulas. These expressions let you build a sequence of clauses paired with result expressions. Constructing a sequence of clauses is the way you conditionally assign values to cells in a calculated column. Conditionals follow these rules:

- When no clause is true, the Formula Editor evaluates the result expression that accompanies the else clause.
- All result expressions in a conditional expression must evaluate to the same data type.
- A missing term matches any data type.
- By definition, expressions that evaluate as zero are false.
- If an expression evaluates as missing, no clauses are executed and missing is returned. All other numeric expressions are true.

See the *Scripting Guide* and the *JSL Syntax Reference* for more information about syntax.
Use the insert and delete clause buttons on the Formula Editor panel to expand the expression. For maximum efficiency, list the most frequently evaluated clause and result pairs first in the sequence.

**Note:** Interpolate, Step, For, and While are most often used in conjunction with other commands to build a JSL script. You can use the Formula Editor to create and execute a script in that column, but this is not recommended because of dependencies and ambiguities that can result. Most often, scripts are stored as .jsl files, and can be saved with a data table as a table property. For more information about table properties, see “Table Panel in Data Tables” on page 38 in the “Get Started with JMP” chapter. For documentation of scripting commands, see the JSL Syntax Reference.

**If**

Shows a single If condition with a missing expression and a missing then clause. Highlight either expr or then clause and enter a value. For example, to calculate count as a percentage of total when total is not 0, enter the conditional expression (using columns called count and total) in Figure A.3.

**Figure A.3  A Conditional Expression**

![](image)

To add a new condition to the If conditional, highlight then clause and click the insert button (▲) on the Formula Editor keypad. Initially, this changes the existing else condition to an expr clause. Click the insert button again to add an else clause. Highlighting then or else and repetitively clicking the insert button changes the else to expr or adds a new expr clause.

To delete a clause, select the then clause above it and press Delete or click the Delete button (☐) on the Formula Editor keypad.

By definition, expressions that evaluate as zero are false. If an expression evaluates as missing, no clauses are executed and missing is returned. All other numeric expressions are true.

**Match**

Compares an expression to a list of clauses and returns the value of the resulting expression for the first matching clause encountered. You provide the matching expression only once and then give a match value for each clause.

After you select Match in the Formula Editor, a list appears with two options:

- Select Add Match Arguments from Data, and clauses that correspond to all of the levels in your data are added automatically. Alternatively, press Shift, select Conditional, and then
Using JMP Conditional Functions

select **Match**. In Figure A.4, the example on the left shows clauses that were added automatically.

- Select **Don't Add** so that you can add each clause individually. In Figure A.4, the example on the right shows an empty clause, which you fill with the missing expressions.

**Figure A.4** Examples of Using the Match Function

In an automatically filled argument, you should highlight **then clause**, and then enter an expression. In an empty argument, you highlight either expr, value, or then clause, and then enter an expression. (Or, if you highlight an expression and click **Match**, the Formula Editor creates a new Match conditional, with the original highlighted expression as expr and nothing for the value and else clause.) Also, keep in mind that:

- **Match** evaluates faster and uses less memory than an equivalent **If** because the variable is evaluated only once for each row in the data table. The If condition must evaluate the variable at each If clause for each row until a clause evaluates as true. See “Comparison Functions” on page 742, for a comparison of Match and If conditionals.

- With If and Match, the Formula Editor searches down from the top of the sequence for the first true clause and evaluates the corresponding result expression. Subsequent true clauses are ignored.

In the following example, each value is assigned depending on the value of the age variable.

**Figure A.5** An Example of Using the Match Function

**Note**: Match ignores trailing spaces and If does not.

Although Match returns missing for any missing values, you can also specifically match missing values.
Choose

**Choose** is a special case of **Match** in which the arguments of the condition are a sequence of integers starting at one. The value of **clause** replaces the match condition. An example of a **Choose** condition is shown in Figure A.6. With **Choose**, the Formula Editor goes directly to the correct choice clause and evaluates the result expression.

**Figure A.6** Example of a **Choose** Condition

![Diagram of Choose condition](image)

When you highlight an expression and click **Choose**, the Formula Editor creates a new conditional expression with one **clause**. Use the insert (✓) and delete (✗) buttons on the keypad to add new clauses or remove unwanted clauses, as described previously for the **If** conditional.

**Choose** evaluates the **Choose** expression and goes immediately to the corresponding result expression to generate the returned value. With **Choose**, you provide a choosing expression that yields sequential integers starting at 1 only once, and then you give a choice for each integer in the sequence.

**IfMax**

Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the maximum of the expressions. If more than one expression is the maximum, the first maximum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.

**IfMin**

Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the minimum of the expressions. If more than one expression is the minimum, the first minimum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.
And &
Evaluates as 1 when both of its arguments are true. Otherwise, it evaluates as 0 (Figure A.9.) The formula in Figure A.7 labels Group 1 as drivers only if both comparisons are true.

Figure A.7 Creating an And Function

<table>
<thead>
<tr>
<th>sex == &quot;M&quot; &amp; age &gt; 13</th>
<th>Group 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>else</td>
<td>Group 2</td>
</tr>
</tbody>
</table>

Or |
Evaluates as 1 when either of its arguments is true. If both of its arguments are false, then the Or expression evaluates as 0 (Figure A.9.) The formula in Figure A.8 assigns males and all participants who are more than 13 years old to Group 1.

Figure A.8 Creating an Or Function

<table>
<thead>
<tr>
<th>sex == &quot;M&quot; &amp; age &gt; 13</th>
<th>Group 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>else</td>
<td>Group 2</td>
</tr>
</tbody>
</table>

The truth tables on the left in Figure A.9 illustrate the results of the And (&) and Or (|) functions when both arguments have nonmissing values that evaluate to true or false. The table on the right illustrates the result when either the left or right expression (call them a and b) or both have missing values.

Figure A.9 Evaluations of And and Or Expressions

Not !
Evaluates as 1 when its argument is false. Otherwise, Not evaluates as 0. When you apply the Not function, use parentheses where necessary to avoid ambiguity. For example, !(weight==64) can be either true or false (either 1 or 0), but (!weight)==64 is always false (0) because Not can return only 0 or 1. Expressions such as !(weight==64) can also be entered as weight != 64.
Interpolate

Linearly interpolates the y-value between two points, \( x_1, y_1 \) and \( x_2, y_2 \) that corresponds to the arguments that you give. You can insert additional pairs of \( x, y \) arguments with the Insert key. \textbf{Interpolate} finds the pair of \( x, y \) points that correspond to the \( x \)-value and completes the interpolation.

\textbf{Figure A.10} Examples of \textbf{Interpolate}

\begin{center}
\begin{tabular}{l}
\textbf{Interpolate}(x)(x_1 \Rightarrow y_1); \\
\textbf{Interpolate}(x)(x_2 \Rightarrow y_2);
\end{tabular}
\end{center}

Step

Step is like \textbf{Interpolate} except that it returns the \( y \)-value corresponding to the greatest \( x \)-value less than or equal to the \( x \) and \( y \) arguments. That is, it finds the corresponding \( y \) for a given \( x \) from a step function rather than a linear fit between points. Like \textbf{Interpolate}, you can have as many \( x \) and \( y \) argument pairs as you want.

\textbf{Figure A.11} Examples of \textbf{Step}

\begin{center}
\begin{tabular}{l}
\textbf{Step}(x)(x_1 \Rightarrow y_1); \\
\textbf{Step}(x)(x_2 \Rightarrow y_2);
\end{tabular}
\end{center}

For

Repeats the statements in the \textbf{body} argument as long as the \textbf{while} condition is true. The \textbf{init} and \textbf{next} control the iterations.

While

Repeatedly tests the \textbf{expr} condition and executes the \textbf{body} until \textbf{expr} is no longer true.

Break, Continue

\textbf{Break} stops execution of a loop completely and continues to the statement following the loop. \textbf{Continue} ends the current iteration of a loop and begins the loop at the next iteration.

Both are used in \textbf{For}, \textbf{While}, and \textbf{For Each Row} loops.

Statistical Functions

There are two types of Statistical functions that you can use in a formula:

- The functions with names that have the prefix Col. These functions compute statistics for a column of numbers or expressions involving columns.

- The Mean, Std Dev, Number, Sum, Quantile, Maximum, Minimum, and N Missing functions. These functions evaluate across columns or arguments. The statistic is computed for each row across the series of arguments. You can click the Insert key (✓) on the Formula Editor keypad, or type a comma to add arguments to the functions that accept multiple arguments. When there are multiple contiguous arguments, select the function and the first argument, and then press Shift and click the last argument in the group. These functions then automatically show with the complete list.

**Note:** Missing values are ignored in statistical functions.

See the JSL Syntax Reference for more information about syntax.

**Col Cumulative Sum**

Returns the cumulative sum for the current row. Col Cumulative Sum supports By columns, which do not need to be sorted.

**Col Mean**

Calculates the mean (or arithmetic average) of the numeric values identified by its argument. The formula Col Mean(age) calculates the average of all nonmissing values in the age column.

**Col Moving Average**

Returns the moving average over a given interval based at the current row. Missing values are ignored.

**Col Std Dev**

Measures the spread around the mean of the distribution identified by its argument. In the normal distribution, about 68% of the distribution is within one standard deviation of the mean. 95% of the distribution is within two standard deviations of the mean. 99% of the distribution is within three standard deviations of the mean.
Col Number
Counts the number of nonmissing values in the column that you specify. A missing numeric value occurs when a cell has no assigned value or is the result of an invalid operation (such as division by zero). Missing values show on the spreadsheet as a missing value mark (•). Missing character values are null character strings. In formulas for row state columns, an excluded row state characteristic is treated as a missing value.

Col N Missing
Counts the number of missing values in the column that you specify. A missing numeric value occurs when a cell has no assigned value or is the result of an invalid operation (such as division by zero). Missing values show in the data grid with a missing value character (•). Missing character values are null character strings.

Col Sum
Computes the sum of the values in its numeric argument. Missing values are ignored.

Col Minimum and Col Maximum
Takes the minimum of its numeric arguments. Col Minimum ignores missing values. Col Maximum takes the maximum of a numeric column argument and ignores missing values.

Col Quantile
Computes the value at which a specific percentage of the values is less than or equal to that value. For example, the value calculated as the 50% quantile, also called the median, is greater than or equal to 50% of the data. Half of the data values are less than the 50th quantile.

The Col Quantile function’s quantile argument represents the quantile percentage divided by 100. The 25% quantile, also called the lower quartile, corresponds to \( p = 0.25 \), and the 75% quantile, called the upper quartile, corresponds to \( p = 0.75 \).

The Formula Editor computes a quantile for a column of \( n \) nonmissing values by arranging the values in ascending order. The subscripts of the sorted column values, \( y_1, y_2, \ldots, y_n \), represent the ranks in ascending order.

The \( p \)th quantile value is calculated using the formula \( p(n + 1) \), where \( p \) is the percent value and \( n \) is the total number of nonmissing values. If \( p(n+1) \) is an integer, then the quantile value is \( y_{p(n+1)} \). If \( p(n + 1) \) is not an integer, then the value is interpolated by assigning the integer part of the result to \( i \), assigning the fractional part to \( f \), and applying the formula \( (1 - f)y_i + fy_{i+1} \).

For example, suppose a column has values 2, 4, 6, 8, 10, 12, 14, 16, 18, and 20. The 50% quantile is calculated as \( 0.5(10 + 1) = 5.5 \).

Because the result is fractional, the 50% quantile value is interpolated as
(1 – 0.5) × 10 + (0.5) × 12 = (0.5)10 + (0.5)12 = 6 + 5 = 11

The following are example **ColQuantile** formulas:

- **ColQuantile(age, 1)** Calculates the maximum age.
- **ColQuantile(age, 0.75)** Calculates the upper quartile age.
- **ColQuantile(age, 0.5)** Calculates the median age.
- **ColQuantile(age, 0.25)** Calculates the lower quartile age.
- **ColQuantile(age, 0)** Calculates the minimum age.

The **ColQuantile** argument can be any expression that evaluates to a value between (and including) 0 and 1. For example, the first formula in Figure A.12 calculates quantile values of age in ascending order for each row. The column then contains the interpolated values of age in ascending order in the calculated column. The second formula lists the interpolated values of age in descending order.

**Figure A.12** Examples of the Quantile Function

Col Rank

Ranks each row’s value, from 1 for the lowest value to the number of non-missing columns for the highest value. Ties can be broken by reporting the average of the possible rankings, assigning the ranks in the order that they originally appear, giving both values the lowest possible rank, or arbitrarily. (JMP 12 used arbitrary tie breaking.) Distribution’s Normal Quantile output uses average tie breaking.

Col Standardize

Performs the usual standardization on its numeric expression. For each row \( i \), **Col Standardize(height)** is \( \frac{(Height_{\text{row}} - \text{Col Mean(Height)) / Col Std Dev(Height)}}{\text{N Row} - 1} \).

Mean

Calculates the arithmetic average of the nonmissing values in the list of arguments that you specify. The arguments can be constants, numbers, or expressions. The **Mean** function initially shows with a single argument. You add arguments with the insert button ( ) on the Formula Editor keypad or by typing a comma.
**Std Dev**

Computes standard deviation of the nonmissing values in the list of arguments that you specify. The arguments can be constants, numbers, or expressions. The **Std Dev** function initially shows with a single argument. You add arguments by clicking the insert button ( ) on the Formula Editor keypad or by typing a comma.

**Number**

Counts the number of nonmissing values in the list of arguments that you specify.

**Sum**

Returns the sum of the nonmissing values in the list of arguments that you specify.

**Quantile**

Calculates the quantile specified by the first argument for all the nonmissing values in the remaining list of arguments that you specify.

**Summation (Σ)**

Evaluates for an explicit range of values in a column, as given by the summation indices. This behavior is different from all other statistical functions (except **Product**), which always evaluate on every row. The **Summation** function uses the summation notation shown in Figure A.13. To calculate a sum, replace the missing body term with an expression containing the index variable \( i \), or an index variable that you assign. **Summation** repeatedly evaluates the expression for \( i = 1, i = 2, \) through \( i = \text{NRow()} \) and then adds the nonmissing results together to determine the final result.

You can replace \( \text{NRow()} \), the number of rows in the active spreadsheet, and the index constant, \( i \), with any expression appropriate for your formula. For example, the summation formula in Figure A.13 computes the total for each row of all revenue values for rows 1 through the current row number, filling the calculated column with the cumulative totals of the revenue column.

**Figure A.13** Example of the **Summation** function
Appendix A
Using JMP

Reference for JMP Functions in Formulas

Random Functions

Product (Π)

Evaluates for an explicit range of values in a column, as given by the summation indices, as opposed to all other statistical functions (except Summation), which always evaluate on every row. Product uses the notation shown in the formula in Figure A.14. To calculate a product, replace the missing body term with an expression containing the index variable j. Product repeatedly evaluates the expression for i = 1, i = 2, through i = n and multiplies the nonmissing results together to determine the final result.

You can replace NRow(), the number of rows in the active spreadsheet and the index constant, i, with any expression appropriate for your formula.

For example, the product example in Figure A.14 calculates i! (each row number’s factorial).

Minimum and Maximum

Return the minimum and maximum value, respectively, from the list of nonmissing arguments that you specify.

N Missing

Counts the number of missing values in the list of arguments that you specify.

SSQ

Returns the sum of squares of all elements.

Random Functions

You can create formulas that generate random numbers by effectively “rolling the dice” within the constraints of the specified distribution. Each time you click Apply in the Formula Editor window, these functions produce a new set of random numbers.

Note: Random numbers are generated using the Mersenne-Twister technique. This technique has a period length of $2^{19937}-1$. For more information about the generators, see Matsumoto and Nishimura (1998). The new generators are verified to pass all the DIEHARD tests as documented in Marshalled (1996).
See the JSL Syntax Reference for more information about function arguments. See the JSL Syntax Reference for more information about distribution parameterizations.

**Random ChiSquare**

Generates a column of random numbers from a Chi-Square distribution with specified degrees of freedom. The optional noncentrality parameter must be greater than or equal to 0. The noncentrality parameter is 0 by default. For more information about the parameterization of the Chi-Square distribution, see the JSL Syntax Reference.

**Random F**

Generates a column of random numbers from an F distribution with specified numerator degrees of freedom and denominator degrees of freedom. The optional noncentrality parameter must be greater than or equal to 0. The noncentrality parameter is 0 by default. For more information about the parameterization of the F distribution, see the JSL Syntax Reference.

**Random Index**

Returns a $k$ by 1 matrix of random integers between 1 and $n$ with no duplicates.

**Random Uniform**

Generates a column of random numbers from a uniform distribution. If no arguments are specified, the minimum of the uniform distribution is 0 and the maximum is 1. This means that any number between 0 and 1 is as likely to be generated as any other. The result is an approximately even distribution. You can use the optional arguments to specify different values for the minimum and maximum numbers of the uniform distribution.

**Random Normal**

Generates a column of random numbers from a normal distribution with specified mean and standard deviation. If no arguments are specified, the normal distribution has mean of 0 and standard deviation of 1. For more information about the parameterization of the normal distribution, see the JSL Syntax Reference.

**Random Normal Mixture**

Returns a random number from a normal mixture distribution with the specified arguments. For information about the syntax for the Random Normal Mixture function, see the JSL Syntax Reference.
Random Exp

Generates a column of random numbers from an exponential distribution with \( \lambda = 1 \). You can scale the exponential function to use a different \( \lambda \). For example, \( \text{Random Exp()} \times 0.1 \) generates an exponential distribution for \( \lambda = 0.1 \). For more information about the parameterization of the exponential distribution, see the JSL Syntax Reference.

Random Gamma

Generates a column of random numbers from a gamma distribution with specified shape and scale parameters. The default value of the scale parameter is 1. When the scale parameter is 1, the gamma distribution is equivalent to an exponential distribution. For more information about the parameterization of the gamma distribution, see the JSL Syntax Reference.

Random GenGamma

Generates a column of random numbers from an extended generalized gamma distribution with specified location, scale, and shape parameters. If no arguments are specified, the generalized gamma distribution has location of 0, scale of 1, and shape of 0. For more information about the parameterization of the generalized gamma distribution, see the JSL Syntax Reference.

Random LogGenGamma

Generates a column of random numbers from a log generalized gamma distribution with specified location, scale, and shape parameters. If no arguments are specified, the extended generalized gamma distribution has location of 0, scale of 1, and shape of 0. For more information about the parameterization of the log generalized gamma distribution, see the JSL Syntax Reference.

Random Beta

Generates a column of random numbers from a beta distribution with two specified shape parameters and optional threshold and scale parameters. The default threshold is 0, and the default scale is 1. For more information about the parameterization of the beta distribution, see the JSL Syntax Reference.

Random Cauchy

Generates a column of random numbers from a Cauchy distribution with location parameter 0 and scale parameter 1. A Cauchy variate with location parameter alpha and scale parameter beta can be generated with the formula \( \alpha + \beta \times \text{Random Cauchy()} \). For more information about the parameterization of the Cauchy distribution, see the JSL Syntax Reference.
Random Category

Generates a column of random category assignments based on a set of probability and result expressions (for example, Random Category(.2, "A", .3, "B", .4, "C", "D");). A random uniform number is generated and compared to the probabilities to determine which result expression is returned.

Random Johnson Su

Generates a column of random numbers from a Johnson Su distribution with two specified shape parameters, a location parameter, and a scale parameter. For more information about the parameterization of the Johnson Su distribution, see the JSL Syntax Reference.

Random Johnson Sb

Generates a column of random numbers from a Johnson Sb distribution with two specified shape parameters, a location parameter, and a scale parameter. For more information about the parameterization of the Johnson Sb distribution, see the JSL Syntax Reference.

Random Johnson Sl

Generates a column of random numbers from a Johnson Sl distribution with two specified shape parameters, a location parameter, and an optional skewness parameter. The skewness parameter can be +1 for positive skew or -1 for negative skew. The default is +1. For more information about the parameterization of the Johnson Sl distribution, see the JSL Syntax Reference.

Random Seed State

Retrieves or restores the random seed state to or from a BLOB object.

Random Triangular

Generates a column of random numbers from a triangular distribution with specified minimum, maximum, and mode parameters. If you specify only one argument, it represents the mode and the triangular distribution is between 0 and 1. If you specify two arguments, they represent the mode and the maximum, respectively, and the triangular distribution is between 0 and the maximum. If you specify three arguments, they represent the minimum, the mode, and the maximum, respectively, and the triangular distribution is between the minimum and the maximum.

Random Integer

Generates a column of random numbers from a uniform distribution of integers. If you specify one argument, the integers are between 1 and the argument. If you specify two arguments, the integers are between and include the values of the two arguments.
**Random Binomial**
Generates a column of random numbers from a binomial distribution with specified parameters. The first argument is \( n \), the number of trials in a binomial experiment. The second argument is \( p \), the probability that the event of interest occurs. When \( n \) is 1, the binomial function generates a distribution of Bernoulli trials. For more information about the parameterization of the binomial distribution, see the *JSL Syntax Reference*.

**Random Negative Binomial**
Generates a column of random numbers from a negative binomial distribution with specified parameters. The first argument is \( r \), the number of successes of interest. The second argument is \( p \), the probability of success. The random variable of interest is the number of failures that precede the \( r^{th} \) success. In contrast to the binomial variate, where the number of trials is fixed and the number of successes is variable, the negative binomial variate is for a fixed number of successes and a random number of trials. For more information about the parameterization of the negative binomial distribution, see the *JSL Syntax Reference*.

**Random Beta Binomial**
Generates a column of random numbers from a beta binomial distribution with specified parameters. The first argument is \( n \), the number of trials. The second argument is \( p \), the probability of success for each trial. The third argument is optional and represents the overdispersion parameter. The default overdispersion parameter is 0. For more information about the parameterization of the beta binomial distribution, see the *JSL Syntax Reference*.

**Random Frechet**
Generates a column of random numbers from a Fréchet distribution with specified location and scale parameters. If no arguments are specified, the Fréchet distribution has location of 0 and sigma of 1. For more information about the parameterization of the Fréchet distribution, see the *JSL Syntax Reference*.

**Random Geometric**
Generates a column of random numbers from a geometric distribution with specified probability parameter. The argument is the probability that a specific event occurs at any one trial. The random variable of interest is the number of trials until a specific event occurs for the first time.

**Random Poisson**
Generates a column of random numbers from a Poisson distribution with specified shape parameter. For more information about the parameterization of the Poisson distribution, see the *JSL Syntax Reference*. 
Random Gamma Poisson

Generates a column of random numbers from a gamma Poisson distribution with specified shape and overdispersion parameters. If the second argument is not specified, the gamma Poisson distribution has an overdispersion of 1. For more information about the parameterization of the gamma Poisson distribution, see the JSL Syntax Reference.

Random Weibull

Generates a column of random numbers from a Weibull distribution with specified shape and scale parameters. If the second argument is not specified, the Weibull distribution has scale of 1. For more information about the parameterization of the Weibull distribution, see the JSL Syntax Reference.

Random Logistic

Generates a column of random numbers from a logistic distribution with specified location and scale parameters. If no arguments are specified, the logistic distribution has location of 0 and scale of 1. For more information about the parameterization of the logistic distribution, see the JSL Syntax Reference.

Random Loglogistic

Generates a column of random numbers from a loglogistic distribution with specified location and scale parameters. If no arguments are specified, the loglogistic distribution has location of 0 and scale of 1. For more information about the parameterization of the loglogistic distribution, see the JSL Syntax Reference.

Random Lognormal

Generates a column of random numbers from a lognormal distribution with specified location and scale parameters. If no arguments are specified, the lognormal distribution has location of 0 and scale of 1. For more information about the parameterization of the lognormal distribution, see the JSL Syntax Reference.

Random GLog

Generates a column of random numbers from a generalized logarithmic distribution with specified location, scale, and shape parameters. When the shape parameter is 0, the generalized logarithmic distribution is equivalent to a lognormal distribution. For more information about the parameterization of the generalized logarithmic distribution, see the JSL Syntax Reference.

Random Reset

Restarts the random number sequences with a seed that you specify.
Random LEV
Generates a column of random numbers from a largest extreme value (LEV) distribution with specified location and scale parameters. If no arguments are specified, the LEV distribution has location of 0 and scale of 1. For more information about the parameterization of the LEV distribution, see the JSL Syntax Reference.

Random SEV
Generates a column of random numbers from a smallest extreme value (SEV) distribution with specified location and scale parameters. If no arguments are specified, the SEV distribution has location of 0 and scale of 1. For more information about the parameterization of the SEV distribution, see the JSL Syntax Reference.

Random SHASH
Generates a column of random numbers from a sinh-arcsinh (SHASH) distribution with two specified shape parameters, a location parameter, and a scale parameter. For more information about the parameterization of the SHASH distribution, see the JSL Syntax Reference.

Random Shuffle
Generates a randomly ordered column of numbers from the numbers in the matrix argument.

Random t
Generates a column of random numbers from a t distribution with specified degrees of freedom. The optional noncentrality argument may be negative or positive. The noncentrality parameter is 0 by default. For more information about the parameterization of the t distribution, see the JSL Syntax Reference.

Col Shuffle
Selects a row number at random from the current data table. Each row number is selected only once. When Col Shuffle is used as a subscript, it returns a value selected at random from the column that serves as its argument. Each value from the original column is assigned only once as Col Shuffle’s result. For more information about the syntax for the Col Shuffle function, see the JSL Syntax Reference.
Resample Freq
Generates a random selection with replacement frequency counts, suitable for use in bootstrapping. For example, it supports a second Freq Column argument, enabling it to do bootstrap samples relating to a pre-existing frequency column specified in the second argument. Resample Freq() generates a 100% resample. ResampleFreq(rate) generates a rate frequency sample. Resample(rate, column) generates a sample that is calculated by the rate multiplied by the sum of the specified column. For more information about the syntax for the Resample Freq function, see the JSL Syntax Reference.

Date Time Functions

JMP stores dates and times in numeric columns using macOS standard of the number of seconds since January 1, 1904. When a column has date values, you can assign a date format to that column by double-clicking a column name and selecting Date or Time from the Format menu. See “Numeric Format Options” on page 295 in the “Set JMP Column Properties” chapter.

See the JSL Syntax Reference for more information about syntax.

In Minutes, In Hours, In Days, In Weeks, In Years
Converts from the units of the function name to the equivalent number of seconds for the argument. The argument must be a number or numeric expression. For example, In Minutes(2) yields 120, and In Years(1) yields 31,557,600 (60 seconds * 60 minutes * 24 hours * 365.25 days).

Date DMY, Date MDY
Accepts numeric expressions for day, month, and year and return the associated JMP date. For example, Date DMY (20, 3, 1991) and Date MDY(3, 20, 1991) evaluate to 2,752,272,000.

Today
Returns the number of seconds between January 1, 1904 and the current date. For example, at midnight on March 20, 1991 (a Wednesday), the Today function returns 2752272000 (2,752,272,000 seconds) and continues counting. If you evaluate the Today function later in the day, it reflects the additional seconds.

Day, Month, Year
Returns the day of the month, the month (as a number from 1 to 12), a four-digit year, respectively. The argument for these functions is interpreted as a JMP date. For example, on March 20, 1991:
Using JMP Date Time Functions

- **Day(2752272000)** returns the number **20**.
- **Month(2752272000)** returns the number **3**.
- **Year(2752272000)** returns the number **1991**.

**Quarter**

Returns the annual quarter of a *datetime* value as an integer 1-4.

**Hour, Minute, Second**

Returns the hour, the minute, and the seconds of a date-time value, respectively. The argument for these functions is interpreted as a JMP date. For example, on March 20, 1991:

- **Hour(2752572649)** returns the number **11**.
- **Minute(2752572649)** returns the number **30**.
- **Second(2752572649)** returns the number **49**.

**Day of Week, Day of Year, Week of Year, Time of Day**

The argument for these functions is a JMP date. **Day Of Week** returns a number from 1 to 7, where 1 represents Sunday. **Day Of Year** returns the number of days from the beginning of the year. **Week Of Year** returns a number from 1 to 52 based on the rule specified. Rule 1 (default) has weeks start on Sunday with the first Sunday being week 2 and week 1 is a partial week or empty; rule 2 has the first Sunday begins week 1 with any previous days being week 0; rule 3 returns the ISO week number where the week starts on Monday and week 1 is the first week of the year with four days in that year. With ISO weeks, it is possible for the first or last three days of the year to belong to the neighboring year’s week number. **Time Of Day** returns a number from 0 to 86399 (time of day in seconds). For example, on Wednesday, March 20, 1991:

- **Day Of Week(2752272000)** returns the number **4**.
- **Day Of Year(2752272000)** returns the number **79**.
- **Week Of Year(2752272000)** returns the number **12**.
- **Time Of Day(2752272000)** returns the number **0**.

**Informat**

The argument for the Informat function is a date character string. For example, Informat("03/20/1991") returns the appropriate JMP date value, 2752272000. JMP can read all the date formats except for Abbrev Date and Long Date.

**Abbrev Date, Long Date, Short Date**

The argument for these date functions is a JMP date. They return character strings that are the formatted representation of the argument. For example:
• **Abbrev Date(2752272000)** returns **Wed, Mar 20, 1991**.
• **Long Date(2752272000)** returns **Wednesday, March 20, 1991**.
• **Short Date(2752272000)** returns **3/20/91**.

**Format**

The first argument in the **Format** function is a JMP date. This function returns the character string representation of the date by the date format that you specify in the second argument, which is a quoted string. If you apply this formula to a numeric column, JMP automatically changes the column’s data type to character.

You can also supply a column for the first argument and leave the rest blank. The result is the formatted value of the column reference. This can be used to extract value labels of a column when the value labels are turned off.

**MDYHMS**

The argument of **MDYHMS** is a JMP date. This function shows all date and time fields, appending zeros as time fields if no time information is present. This is useful if a date column is formulated such that not all date information is displayed. The **MDYHMS** function can be used to see all available date and time information.

**Date Increment**

Adds 1 or more intervals to a starting datetime value. For example, **Date Increment(Today(), "Day", 3)** adds three days to the current date. **Date Increment(Today(), "Year", 3)** adds 3 years to the current date.

**Date Difference**

Returns the difference of two datetime values. The interval argument can be Second, Minute, Hour, Day, Week, Month, Quarter, Year. The alignment arguments are described here:

- **Start** Used to count the number of times an interval starts.
- **Actual** Used to count whole intervals.
- **Fractional** Used to count fractional intervals.

For example, the following formula returns **207.890243055556**, the number of days between the dates:

```javascript
Date Difference(
01Jan2010:00:00:00,
27Jul2010:21:21:57,
"Day",
"fractional"
)```
The following formula returns 207, the number of completed days between the dates:

\[
\text{Date Difference(}
\quad 01\text{Jan2010}:00:00:00, \\
\quad 27\text{Jul2010}:21:21:57, \\
\quad "Day", \\
\quad "actual"
\quad \text{)};
\]

The following formula returns 9, the number of completed hours between the times:

\[
\text{Date Difference(}
\quad 01\text{Jan2010}:00:00:00, \\
\quad 01\text{Jan2010}:09:22:57, \\
\quad "Hour", \\
\quad "actual"
\quad \text{)};
\]

The following formula returns 1, the number of times a new hour started between the times:

\[
\text{Date Difference(}
\quad 31\text{Dec2010}:23:59:59, \\
\quad 01\text{Jan2011}:00:59:59, \\
\quad "Hour", \\
\quad "start"
\quad \text{)};
\]

Row State Functions

There are six characteristics that rows in a data table can have: selected, hidden, excluded, labeled, colored, and marked. If you give rows one or more of these characteristics and then create row state data table columns, you can then create a formula that computes and saves row state conditions. (See “Column Properties in JMP” on page 303 in the “Set JMP Column Properties” chapter, and “Store Information in Row State Columns” on page 300 in the “Set JMP Column Properties” chapter.) This formula processes row state data just as it would process character and numeric data.

See the JSL Syntax Reference for more information about syntax.

**Note:** A row can be assigned any combination of row states; a row state column can have multiple row states as a value.

Table A.2 describes the type of argument each Row State function requires and what each returns.
Table A.2  Row State Functions

<table>
<thead>
<tr>
<th>Function Name</th>

</tbody>
</table>
**Row State**

Returns the active row state condition of the current row as true or false. You can use this function to conveniently write conditional clauses that depend on the status of the current row. For example, Figure A.15 assigns a 1 to rows that are currently selected and labeled and 0 otherwise.

**Figure A.15  Row State**

As Row State

Converts a numeric argument to a row state or set of row state conditions. Row states are stored internally in JMP as a 16-bit number, with each bit assigned to represent one of the possible row states as illustrated in Figure A.3. For example, the binary representation of 1327 is 0000010100101111. As Row State(1327) would therefore set the row state as selected, excluded, hidden, labeled, with marker 2 and color 10.

**Table A.3  Row States Stored as 16-Bit Numbers: Each Bit Represents a Row State**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Row State</th>

<td>Marker</td>
</tr>
<tr>
<td>8-14</td>
<td>Color</td>
</tr>
</tbody>
</table>

**Combine States**

Generates a row state combination with two or more arguments. Use the insert button (▲) on the Formula Editor keypad or type a comma to add arguments to the Combine States function. The currently selected expression becomes the first argument when you select **Combine States. Replace** each argument with an expression that evaluates to a row state. This formula:
Combine States(
    Selected State( Modulo( Row(), 2 ) ),
    Labeled State( Modulo( Row() + 1, 2 ) )
);

alternately labels or selects each row in the calculated row state column. The Selected State and Labeled State functions are defined later in this section. Use the insert ( ) and delete ( ) buttons on the Formula Editor keypad to add more arguments or remove unwanted arguments.

If you include conflicting row states in a combination, the results are unpredictable.

Excluded State

Interprets a numeric argument as true or false. When an argument evaluates as true, the Excluded State function assigns the excluded condition as the value of the column for that row. For example, Excluded State(Modulo(Row(),2)) assigns the excluded row state as the value of the row state column for each odd numbered row.

Hidden State

Assigns the hidden row state condition when its argument is greater than zero. If the argument is zero, the value in the column for that row is not hidden.

Labeled State

Gives the labeled row state condition when its argument is greater than zero. If the argument is zero the row value in the column for that row is not labeled.

Color State

Returns the color from the JMP color map that corresponds to its integer argument. JMP colors are numbered 0 through 84. Zero maps to black.

Marker State

Returns markers from the JMP marker map that correspond to its integer argument. JMP markers are numbered 0 through 16. The formula Marker State(Row()) assigns all the row state markers in a repeating sequence determined by the current row number to the calculated row state column. A row state column can have multiple row states as a value.

Selected State

Gives the selected row state condition when its argument is greater than zero. If the argument is zero, the value in the column for that row is not selected.
**Hue State**

Returns the color from the JMP hue map that corresponds to its integer argument. JMP hues are numbered 0 through 11 but larger integers are treated as *modulo* 12. The *Hue State* function does not map to black, gray, or white. A hue of zero maps to red, and a hue of 11 maps to magenta. The formula in Figure A.16 assigns row state colors in a chromatic spread based on the value of $z$. The *Hue State* function is used with a row state data type column.

**Figure A.16  Example of Hue State Function**

![Hue State Formula](formula)

**Shade State**

Assigns five shade levels to a color or hue. A shade of –2 is darkest and shade of +2 is lightest. A shade of zero is a pure color. The formula in Figure A.17 assigns shade values based on the value of $z$.

**Figure A.17  Example of Shade State Function**

![Shade State Formula](formula)

To assign all shades of all the colors in the colors palette, you need to use the *Hue State* and *Shade State* assignments together. The formula in Figure A.18 uses the *Combine States* function described at the beginning of this section. The first argument in the *Combine States* function is the *Hue State* formula shown previously, and the second argument is the *Shade State* formula. In addition, the *Marker State* function with an argument of 2 assigns the X marker to each row, and the *Selected State* function with an argument of 1 selects each row.
Figure A.18 Combine States Example For Using Both Hue State and Row State

Excluded, Hidden, Labeled, and Selected

Accepts a row state expression argument (row state column or row state constant) that evaluates as either 1 or 0 (true or false). These characteristics are inactive by default. Often, the \texttt{Row()} function is the argument, which detects the active row state condition of each row. For example, in Figure A.19, the formula assigns 99 whenever a row is actively selected, and 0 otherwise. Note that this formula is used in a column that has a numeric data type.

Figure A.19 Example of a Formula Using the \texttt{Selected} Function

The example in Figure A.20 assigns row state conditions to a row state column. The formula for the row state column (in the column called \texttt{x}) checks to determine whether the active row state is either \texttt{Hidden} or \texttt{Excluded}, and if so, assigns the \texttt{Labeled} row state.

Figure A.20 Calculate Row State Information in a Row State Column
Color Of

Accepts any row state expression or column, or the Row State() function as its argument. Returns a number from the JMP color map that corresponds to the active color state, or zero if there is no assigned color.

Marker Of

Accepts any row state expression or column, or the Row State() function as its argument. Returns a number from the JMP marker map that corresponds to the active marker or zero if there is no assigned marker.

Assignment Functions

Assignment functions work in place. That is, the result returned by the operation (on the right of the operator) is stored in the argument on the left of the operator and replaces its current value.

Assignment statements are most often used in conjunction with other commands to build a JSL script. You can use the Formula Editor to create and execute a script in that column, but this is not recommended because of dependencies and ambiguities that can result. Most often, scripts are stored as .jsl files, and can be saved with a data table. See “Create and Save Scripts in Data Tables” on page 284 in the “Enter and Edit Your Data” chapter. For more information about syntax, see the JSL Syntax Reference.

Note: The first argument of an assignment function must be capable of being assigned. This means you cannot have an assignment such as 3+=4, because 3 is a constant value that cannot be reassigned. You must first create a variable (a table variable or local variable) whose value is 3. (For more information about table variables, see “Use Data Table Variables” on page 283 in the “Enter and Edit Your Data” chapter. For more information about local variables, see “Refer to Data Table Values in Formulas” on page 397 in the “Create Formulas in JMP” chapter). Then use that variable as the left-hand argument of the assignment function.

= (assign) Puts the value of \( b \) into \( a \). For example \( (a=b) \).

+= (add to) Adds the value of \( b \) to \( a \) and puts the result back into \( a \). For example, \( a+=b \).

-= (subtract to) Subtracts the value of \( b \) and puts the result back into \( a \). For example, \( a-=b \).

*= (multiply to) Multiplies \( b \) with \( a \) and puts the result back into \( a \). For example, \( a*=b \).

/= (divide to) Divides \( b \) into \( a \) and puts the result back into \( a \). For example, \( a/=b \).

++ (post increment) Adds one (1) to \( a \), in place, so that \( a++ \). For example, if the initial value of \( a \) is 4, the expression \( a++ \) changes \( a \) to 5.
-- (post decrement) Subtract one (1) from a, in place, so that a– –. For example, if the initial value of a is 4, the expression a– – changes a to 3.

Parametric Model Functions

This category is a short cut to create three parametric models that are linear functions of set of window-selected columns.

Linear Model, Interactions Model, Full Quadratic Model

Selecting each of these opens a column selection box that lets you select one or more columns to be included in the model. The function then creates and populates the chosen model.

Finance Functions

Lets you create formulas to calculate principal payments, interest rate, rate of return, and so on.

Double Declining Balance

Returns the depreciation of an asset for a specified period of time. The function uses the double-declining balance method or some other depreciation factor.

Future Value

Returns the future value of an investment that is based on periodic, constant payments and a constant interest rate.

Interest Payment

Returns the interest payment for a given period for an investment that is based on periodic, constant payments and a constant interest rate.

Interest Rate

Returns the interest rate per period of an annuity.

Internal Rate of Return

Returns the internal rate of return for a series of cash flows in the values argument.
Modified Internal Rate of Return

Returns the modified internal rate of return for a series of periodic cash flows. The cost of investment and the interest received on reinvested cash is included.

Net Present Value

Returns the net present value of an investment by using a discount rate and a series of future payments (negative values) and income (positive values).

Number of Periods

Returns the number of periods for an investment that is based on periodic, constant payments and a constant interest rate.

Payment

Returns the payment for a loan that is based on constant payments and a constant interest rate.

Present Value

Returns the present value of an investment.

Principal Payment

Returns the payment on the principal for a given period for an investment that is based on periodic, constant payments and a constant interest rate.

Straight Line Depreciation

Returns the straight-line depreciation of an asset for one period.

Sum Of Years Digits Depreciation

Returns the sum-of-years’ digits depreciation of an asset for a specified period.
This chapter contains technical details that apply to multiple platforms in JMP and to SAS integration.

JMP Features That Support Multithreading .................................................. 787
Conventions for Mapping JMP Attributes to SAS Extended Attributes ........ 788
JMP Features That Support Multithreading

Some features in JMP are coded to take advantage of multiple central processing units (CPUs) on a machine, allowing these features to run significantly faster. This process is called multithreading.

The following features support multithreading:

- Boosted Trees
- Bootstrap Forest
- Choice
- Covering Arrays
- Capability Analysis in Distribution
- Explore Outliers
- Explore Patterns
- Factor Analysis
- Fit Life by X
- Fit Model: Parametric Survival, Mixed Model, Generalized Regression, and Response Screening
- Functional Data Explorer
- Gaussian (Fast GASP and the use of Categorical variables are only in JMP Pro.)
- K Nearest Neighbors
- Latent Class Analysis
- Life Distribution
- Multivariate
- Neural (Some features are only in JMP Pro.)
- Nominal Logistic
- Nonlinear and Nonlinear Curve
- Normal Mixtures in Cluster Analysis
- Partial Least Squares (Some features are only in JMP Pro.)
- Partition
- Predictor Screening
- Principal Components
- Process Screening
- Profiler (Does not apply to Profilers launched from within other platforms.)
Conventions for Mapping JMP Attributes to SAS Extended Attributes

SAS extended attributes are metadata that you define in SAS code to import information such as table scripts, labels, length, and type. You associate the extended attributes with a data set or variable and define them in name-value pairs, such as _JMP_TABLESCRIPTNAME_2="OnOpen".

This section provides information about SAS extended attributes and their corresponding JMP attributes.

Get the Most from JMP

Whether you are a first-time or a long-time user, there is always something to learn about JMP.

Visit JMP.com to find the following:

• live and recorded webcasts about how to get started with JMP
• video demos and webcasts of new features and advanced techniques
• details on registering for JMP training
• schedules for seminars being held in your area
• success stories showing how others use JMP
• the JMP user community, resources for users including examples of add-ins and scripts, a forum, blogs, conference information, and so on

Basic Analysis describes the initial types of analyses that you often perform in JMP:

- The Distribution platform illustrates the distribution of a single variable using histograms, additional graphs, and reports. Once you know how your data is distributed, you can plan the appropriate type of analysis going forward. See Chapter 3, “Distributions”.

- The Fit Y by X platform analyzes the pair of X and Y variables that you specify, by context, based on modeling type. See Chapter 4, “Introduction to Fit Y by X”. The four types of analyses include:
  - The Bivariate platform, which analyzes the relationship between two continuous X variables. See Chapter 5, “Bivariate Analysis”.
  - The Oneway platform, which analyzes how the distribution of a continuous Y variable differs across groups defined by a categorical X variable. See Chapter 6, “Oneway Analysis”.
  - The Contingency platform, which analyzes the distribution of a categorical response variable Y as conditioned by the values of a categorical X factor. See Chapter 7, “Contingency Analysis”.
  - The Logistic platform, which fits the probabilities for response categories (Y) to a continuous X predictor. See Chapter 8, “Logistic Analysis”.

- The Tabulate platform interactively constructs tables of descriptive statistics. See Chapter 9, “Tabulate”.

- The Simulate feature provides parametric and nonparametric simulation capability. See Chapter 10, “Simulate”.

- Bootstrap analysis approximates the sampling distribution of a statistic. The data is re-sampled with replacement and the statistic is computed. This process is repeated to produce a distribution of values for the statistic. See Chapter 11, “Bootstrapping”.

- The Text Explorer platform enables you to categorize and analyze unformatted text data. You can use regular expressions to clean up the data before you proceed to analysis. See Chapter 12, “Text Explorer”.

Use the Distribution platform to explore the distribution of a single variable using histograms, box plots, and summary statistics. You can perform several types of hypothesis tests, including $t$ tests, $z$ tests, Chi-squared tests, and equivalence tests. You can also construct confidence, tolerance, and prediction intervals, and estimate process capability. The word *univariate* simply means involving one variable instead of two (bivariate) or many (multivariate). However, you can examine the distribution of several individual variables within a report. The report content for each variable depends on whether the variable is categorical (nominal or ordinal) or continuous.

The Distribution report window is interactive. Clicking on a histogram bar highlights the corresponding data in any other histograms and in the data table.

Overview of the Distribution Platform

The treatment of variables in the Distribution platform is different, depending on the modeling type of the variable, which can be categorical (nominal or ordinal) or continuous.

Categorical Variables

For categorical variables, the initial graph that appears is a histogram. The histogram shows a bar for each level of the ordinal or nominal variable. You can also add a divided (mosaic) bar chart.

The Frequencies report show counts and proportions. You can add confidence intervals and test the probabilities from the options in the red triangle menu.

Continuous Variables

For numeric continuous variables, the initial graphs show a histogram and an outlier box plot. The histogram shows a bar for grouped values of the continuous variable. The following options are also available:

- normal quantile plot
- quantile box plot
- stem and leaf plot
- CDF plot

The reports show selected quantiles and summary statistics. Additional report options are available in the red triangle menu for the following:

- saving ranks, probability scores, normal quantile values, and so on, as new columns in the data table (Save options)
- testing the mean and standard deviation of the column against a constant you specify (Test Mean and Test Std Dev options)
- fitting various distributions and nonparametric smoothing curves (Continuous Fit and Discrete Fit options)
- performing a process capability analysis for a quality control application
- confidence intervals, prediction intervals, and tolerance intervals
Example of the Distribution Platform

Learn how to create a distribution in JMP. Suppose that you have data on 40 students, and you want to see the distribution of age and height among the students.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Distribution.
4. Click OK.

From the histograms, you notice the following:

- The ages are not uniformly distributed.
- For height, there are two points with extreme values (that might be outliers).
Click the bar for 50 in the height histogram to take a closer look at the potential outliers.

- The corresponding ages are highlighted in the age histogram. The potential outliers are age 12.
- The corresponding rows are highlighted in the data table. The names of the potential outliers are Lillie and Robert.

Add labels to the potential outliers in the height histogram.

1. Select both outliers.
2. Right-click one of the outliers and select **Row Label**.
   Label icons are added to these rows in the data table.
3. Resize the box plot wider to see the full labels.

**Figure 3.3** Potential Outliers Labeled

Launch the Distribution Platform

Launch the Distribution platform by selecting **Analyze > Distribution**.

**Figure 3.4** The Distribution Launch Window
For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Columns** Assigns the variables that you want to analyze. A histogram and associated reports appear for each variable.

**Weight** Assigns a variable that specifies weights for observations on continuous Ys. For categorical Ys, the Weight column is ignored. Any statistic that is based on the sum of the weights is affected by weights.

**Freq** Assigns a frequency variable to this role. This is useful if your data are summarized. In this instance, you have one column for the Y values and another column for the frequency of occurrence of the Y values. The sum of this variable is included in the overall count appearing in the Summary Statistics report (represented by N). All other moment statistics (mean, standard deviation, and so on) are also affected by the **Freq** variable.

**By** Produces a separate report for each level of the **By** variable. If more than one **By** variable is assigned, a separate report is produced for each possible combination of the levels of the **By** variables.

**Create Process Capability** (Appears only if a column contains a Spec Limits column property.) Adds a Process Capability report for the analysis columns that contain a Spec Limits column property.

**Histograms Only** Removes everything except the histograms from the report window.

For more information about launch windows, see *Using JMP*. 
The Distribution Report

The initial Distribution report contains a histogram and reports for each variable.

**Figure 3.5** The Initial Distribution Report Window

![Distribution Report Window](image)

**Note:** Follow the instructions in “Example of the Distribution Platform” on page 35 to produce the report shown in Figure 3.5.

**Red Triangle Menus**

The red triangle menu next to Distributions contains options that affect all of the variables. See “Distribution Platform Options” on page 46.

The red triangle menu next to each variable contains options that affect only that variable. See “Options for Categorical Variables” on page 47 or “Options for Continuous Variables” on page 48.
Tip: If you hold down the Ctrl key and select a variable option, the option applies to all of the variables in the report that have the same modeling type.

Histograms and Reports

Histograms visually display your data. See “Histograms” on page 39.

The initial report for a categorical variable contains a Frequencies report. See “The Frequencies Report” on page 42.

Replace, Add, or Remove Variables in Histograms

To replace a variable in a histogram, from the Columns panel of the associated data table, drag and drop the variable into the axis of the histogram.

To create a new histogram in a report using a new variable, drag and drop the variable outside of an existing histogram. The new variable and histogram can be added before, between, or after the existing histograms.

To remove a variable from a histogram, select Remove from the red triangle menu.

Hidden and Excluded Rows

If you apply the Hidden row state to rows in the data table, the corresponding points do not appear in plots that show points. However, histograms are still constructed using the hidden rows.

If you want to exclude rows from the construction of the histograms and from analysis results, apply the Exclude row state. Then select Redo > Redo Analysis from the red triangle menu next to Distributions. Any rows that are excluded in the data table are also hidden in plots that show points.

Histograms

Histograms visually display your data. For categorical (nominal or ordinal) variables, the histogram shows a bar for each level of the ordinal or nominal variable. For continuous variables, the histogram shows a bar for grouped values of the continuous variable.

Highlighting data  Click a histogram bar or an outlying point in the graph. The corresponding rows are highlighted in the data table, and corresponding sections of other histograms are also highlighted, if applicable. See “Highlight Bars and Select Rows” on page 41.
Creating a subset  Double-click a histogram bar, or right-click a histogram bar and select Subset. A new data table that contains only the selected data is created.

Resizing the entire histogram  Hover over the histogram borders until you see a double-sided arrow. Then click and drag the borders.

Rescaling the axis  Click and drag on an axis to rescale it.

Alternatively, hover over the axis until you see a hand. Then, double-click the axis and set the parameters in the Axis Settings window.

Resizing histogram bars  (Available only for continuous variables.) There are multiple options to resize histogram bars. See “Resize Histogram Bars for Continuous Variables” on page 40.

Specifying your selection  Specify the data that you select in multiple histograms. See “Specify Your Selection in Multiple Histograms” on page 42.

To see additional options for the histogram or the associated data table:

- Right-click a histogram. See Using JMP.
- Right-click an axis. You can add a label or modify the axis. See Using JMP.
- Click the red triangle next to the variable, and select Histogram Options. Options are slightly different depending on the variable modeling type. See “Options for Categorical Variables” on page 47 or “Options for Continuous Variables” on page 48.

Resize Histogram Bars for Continuous Variables

Resize histogram bars for continuous variables by using the following:

- the Grabber (hand) tool
- the Set Bin Width option
- the Increment option

Use the Grabber Tool

The Grabber tool is a quick way to explore your data.

1. Select Tools > Grabber.

   Note: (Windows only) To see the menu bar, you might need to hover over the bar below the window title. You can also change this setting in File > Preferences > Windows Specific.

2. Place the grabber tool anywhere in the histogram.

3. Click and drag the histogram bars.
Think of each bar as a bin that holds a number of observations. For vertical histograms:

- Moving the hand to the left increases the bin width and combines intervals. The number of bars decreases as the bar size increases.
- Moving the hand to the right decreases the bin width, producing more bars.
- Moving the hand up or down shifts the bin locations on the axis, which changes the contents and size of each bin.

**Note:** If you have changed the histogram orientation to horizontal, reverse these directions. Move the hand down to increase bin width, up to decrease bin width, and left or right to shift bin locations on the axis.

### Use the Set Bin Width Option

The **Set Bin Width** option is a more precise way to set the width for all bars in a histogram. To use the Set Bin Width option, from the red triangle menu for the variable, select **Histogram Options > Set Bin Width**. Change the bin width value.

### Use the Increment Option

The **Increment** option is another precise way to set the bar width. To use the **Increment** option, double-click the axis, and change the Increment value.

### Highlight Bars and Select Rows

Clicking on a histogram bar highlights the bar and selects the corresponding rows in the data table. The appropriate portions of all other graphical displays also highlight the selection. Figure 3.6 shows the results of highlighting a bar in the height histogram. The corresponding rows are selected in the data table.

**Tip:** To deselect specific histogram bars, press Ctrl and click the highlighted bars.
Specify Your Selection in Multiple Histograms

Extend or narrow your selection in histograms:

- To extend your selection, hold down the Shift key and select another bar. This is the equivalent of using an *or* operator.

- To narrow your selection, hold down the Ctrl and Alt keys (Windows) or Command and Option keys (macOS) and select another bar. This is the equivalent of using an *and* operator.

For an example, see “Example of Selecting Data in Multiple Histograms” on page 69.

The Frequencies Report

For nominal and ordinal variables, the Frequencies report lists the levels of the variables, along with the associated frequency of occurrence and probabilities.

For each level of a categorical (nominal or ordinal) variable, the Frequencies report contains the information described in the following list. Missing values are omitted from the analysis.
Tip: Click a value in the Frequencies report to select the corresponding data in the histogram and data table.

**Level**  Lists each value found for a response variable.

**Count**  Lists the number of rows found for each level of a response variable. If you use a Freq variable, the Count is the sum of the Freq variables for each level of the response variable.

**Prob**  Lists the probability (or proportion) of occurrence for each level of a response variable. The probability is computed as the count divided by the total frequency of the variable, shown at the bottom of the table.

**StdErr Prob**  Lists the standard error of the probabilities. This column might be hidden. To show the column, right-click in the table and select \textit{Columns > StdErr Prob}.

**Cum Prob**  Contains the cumulative sum of the column of probabilities. This column might be hidden. To show the column, right-click in the table and select \textit{Columns > Cum Prob}.

### The Quantiles Report

For continuous variables, the Quantiles report lists the values of selected quantiles (sometimes called \textit{percentiles}). For statistical details, see “Statistical Details for Quantiles” on page 78.

### The Summary Statistics Report

For continuous variables, the Summary Statistics report displays the mean, standard deviation, and other summary statistics. You can control which statistics appear in this report by selecting \textit{Customize Summary Statistics} from the red triangle menu next to Summary Statistics.

Tip: You can specify which summary statistics show in the report each time you run a Distribution analysis for a continuous variable. Select \textit{File > Preferences > Platforms > Distribution Summary Statistics}, and select the ones that you want to appear.

- \textit{Description of the Summary Statistics Report} describes the statistics that appear by default.
- \textit{Additional Summary Statistics} describes additional statistics that you can add to the report using the \textit{Customize Summary Statistics} window.
Description of the Summary Statistics Report

**Mean**  Estimates the expected value of the underlying distribution for the response variable, which is the arithmetic average of the column’s values. It is the sum of the nonmissing values divided by the number of nonmissing values.

**Std Dev**  The normal distribution is mainly defined by the mean and standard deviation. These parameters provide an easy way to summarize data as the sample becomes large:
- 68% of the values are within one standard deviation of the mean
- 95% of the values are within two standard deviations of the mean
- 99.7% of the values are within three standard deviations of the mean

**Std Err Mean**  The standard error of the mean, which estimates the standard deviation of the distribution of the mean.

**Upper and Lower Mean Confidence Limits**  The 95% confidence limits about the mean. They define an interval that is very likely to contain the true population mean.

**N**  The total number of nonmissing values.

Additional Summary Statistics

**Sum Weight**  The sum of a column assigned to the role of Weight (in the launch window). Sum Wgt is used in the denominator for computations of the mean instead of \( N \).

**Sum**  The sum of the response values.

**Variance**  The sample variance, and the square of the sample standard deviation.

**Skewness**  Measures sidedness or symmetry.

**Kurtosis**  Measures peakedness or heaviness of tails. See “Kurtosis” on page 80 for formula details.

**CV**  The percent coefficient of variation. It is computed as the standard deviation divided by the mean and multiplied by 100. The coefficient of variation can be used to assess relative variation. For example, it can be used when comparing the variation in data measured in different units or with different magnitudes.

**N Missing**  The number of missing observations.

**N Zero**  The number of zero values.

**N Unique**  The number of unique values.

**Uncorrected SS**  The uncorrected sum of squares or sum of values squared.

**Corrected SS**  The corrected sum of squares or sum of squares of deviations from the mean.
**Autocorrelation**  (Appears only if you have not specified a Frequency variable.) First autocorrelation that tests if the residuals are correlated across the rows. This test helps detect non-randomness in the data.

**Minimum**  Represents the 0 percentile of the data.

**Maximum**  Represents the 100 percentile of the data.

**Median**  Represents the 50th percentile of the data.

**Mode**  The value that occurs most often in the data. If there are multiple modes, the smallest mode appears.

**Trimmed Mean**  The mean calculated after removing the smallest p% and the largest p% of the data. The value of p is entered in the *Enter trimmed mean percent* text box at the bottom of the window. The Trimmed Mean option is not available if you have specified a Weight variable.

**Geometric Mean**  The \( n \)th root of the product of the data. For example, geometric means are often used to calculate interest rates. The statistic is also helpful when the data contains a large value in a skewed distribution.

**Note:** Negative values result in missing numbers, and zero values (with no negative values) result in zero.

**Range**  The difference between the maximum and minimum of the data.

**Interquartile Range**  The difference between the 3rd and 1st quartiles.

**Median Absolute Deviation**  (Does not appear if you have specified a Weight variable.) The median of the absolute deviations from the median.

**Proportion Zero**  The proportion of nonmissing values that are equal to zero.

**Proportion Nonzero**  The proportion of nonmissing values that are not equal to zero.

**Robust Mean**  The robust mean, calculated in a way that is resistant to outliers, using Huber’s M-estimation. See Huber and Ronchetti (2009).

**Robust Std Dev**  The robust standard deviation, calculated in a way that is resistant to outliers, using Huber’s M-estimation. See Huber and Ronchetti (2009).

**Enter (1-alpha) for mean confidence interval**  Specify the alpha level for the mean confidence interval.

**Enter trimmed mean percent**  Specify the trimmed mean percentage. The percentage is trimmed off each side of the data.
Summary Statistics Options

The red triangle menu next to Summary Statistics contains these options:

- **Customize Summary Statistics**  Select which statistics you want to appear from the list. You can select or deselect all summary statistics.

- **Show All Modes**  Shows all of the modes if there are multiple modes.

For statistical details, see “Summary Statistics” on page 79.

Distribution Platform Options

The red triangle menu next to Distributions contains options that affect all of the reports and graphs in the Distribution platform.

- **Uniform Scaling**  Scales all axes with the same minimum, maximum, and intervals so that the distributions can be easily compared.

- **Stack**  Changes the orientation of the histogram and the reports to horizontal and stacks the individual distribution reports vertically. Deselect this option to return the report window to its original layout.

- **Arrange in Rows**  Enter the number of plots that appear in a row. This option helps you view plots vertically rather than in one wide row.

See Using JMP for more information about the following options:

- **Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

- **Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

- **Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

- **Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Options for Categorical Variables

The red triangle menus next to each variable in the report window contain additional options that apply to the variable. This section describes the options that are available for categorical (nominal or ordinal) variables.

**Display Options**  See “Display Options for Categorical Variables” on page 47.

**Histogram Options**  See “Histogram Options for Categorical Variables” on page 47.

**Mosaic Plot**  Displays a mosaic bar chart for each nominal or ordinal response variable. A mosaic plot is a stacked bar chart where each segment is proportional to its group’s frequency count.

**Order By**  Reorders the histogram, mosaic plot, and Frequencies report in ascending or descending order, by count. To save the new order as a column property, use the Save > Value Ordering option.

**Test Probabilities**  Displays a report that tests hypothesized probabilities. See “Examples of the Test Probabilities Option” on page 71.

**Confidence Interval**  This menu contains confidence levels. Select a value that is listed, or select Other to enter your own. JMP computes score confidence intervals.

**Save**  See “Save Options for Categorical Variables” on page 48.

**Remove**  Permanently removes the variable and all its reports from the Distribution report.

**Display Options for Categorical Variables**

**Frequencies**  Shows or hides the Frequencies report. See “The Frequencies Report” on page 42.

**Horizontal Layout**  Changes the orientation of the histogram and the reports to vertical or horizontal.

**Axes on Left**  Moves the Count, Prob, and Density axes to the left instead of the right.

This option is applicable only if Horizontal Layout is selected.

**Histogram Options for Categorical Variables**

**Histogram**  Shows or hides the histogram. See “Histograms” on page 39.

**Vertical**  Changes the orientation of the histogram from a vertical to a horizontal orientation.
**Std Error Bars** Draws the standard error bar on each level of the histogram.

**Separate Bars** Separates the histogram bars.

**Histogram Color** Changes the color of the histogram bars.

**Count Axis** Adds an axis that shows the frequency of column values represented by the histogram bars.

**Prob Axis** Adds an axis that shows the proportion of column values represented by histogram bars.

**Density Axis** Adds an axis that shows the length of the bars in the histogram.

The count and probability axes are based on the following calculations:

\[
prob = (\text{bar width}) \times \text{density} \\
\text{count} = (\text{bar width}) \times \text{density} \times (\text{total count})
\]

**Show Percents** Labels the percent of column values represented by each histogram bar.

**Show Counts** Labels the frequency of column values represented by each histogram bar.

---

**Save Options for Categorical Variables**

**Level Numbers** Creates a new column in the data table called Level <colname>. The level number of each observation corresponds to the histogram bar that contains the observation.

**Value Ordering** (Use with the **Order By** option) Creates a new value ordering column property in the data table, reflecting the new order.

**Script to Log** Displays the script commands to generate the current report in the log window. Select **View > Log** to see the log window.

---

**Options for Continuous Variables**

The red triangle menus next to each variable in the report window contain additional options that apply to the variable. This section describes the options that are available for continuous variables.

**Display Options** See “**Display Options for Continuous Variables**” on page 50.
Histogram Options  See “Histogram Options for Continuous Variables” on page 50.

Normal Quantile Plot  Helps you visualize the extent to which the variable is normally distributed. See “Normal Quantile Plot” on page 52.

Outlier Box Plot  Shows the distribution and helps you identify possible outliers. See “Outlier Box Plot” on page 52.

Quantile Box Plot  Shows specific quantiles from the Quantiles report. See “Quantile Box Plot” on page 53.

Stem and Leaf  See “Stem and Leaf” on page 55.

CDF Plot  Creates a plot of the empirical cumulative distribution function. See “CDF Plot” on page 55.

Test Mean  Perform a one-sample test for the mean. See “Test Mean” on page 56.

Test Std Dev  Perform a one-sample test for the standard deviation. See “Test Std Dev” on page 58.

Test Equivalence  Assesses whether a population mean is equivalent to a hypothesized value. See “Test Equivalence” on page 58.

Confidence Interval  Choose confidence intervals for the mean and standard deviation. See “Confidence Intervals” on page 59.

Prediction Interval  Choose prediction intervals for a single observation, or for the mean and standard deviation of the next randomly selected sample. See “Prediction Intervals” on page 60.

Tolerance Interval  Computes an interval to contain at least a specified proportion of the population. See “Tolerance Intervals” on page 60.

Process Capability  Measures the conformance of a process to given specification limits. See “Process Capability” on page 60.

Continuous Fit  Fits distributions to continuous variables. See “Fit Distributions” on page 63.

Discrete Fit  (Available when all data values are integers.) Fits distributions to discrete variables. See “Fit Distributions” on page 63.

Save  Saves information about continuous or categorical variables. See “Prediction Intervals” on page 60.

Remove  Permanently removes the variable and all its reports from the Distribution report.
Display Options for Continuous Variables

**Quantiles**  Shows or hides the Quantiles report. See “The Quantiles Report” on page 43.

**Set Quantile Increment**  Changes the quantile increment or revert to the default quantile increment.

**Custom Quantiles**  Sets custom quantiles by values or by increments. You can specify the confidence level and choose whether to compute smoothed empirical likelihood quantiles (for large data sets, this can take some time).

- For more information about how the weighted average quantiles are estimated, see “Statistical Details for Quantiles” on page 78.
- For more information about distribution-free confidence limits for the weighted average quantiles, see section 5.2 in Meeker et al. (2017).
- Smoothed empirical likelihood quantiles are based on a kernel density estimate. For more information about how these quantiles and their confidence limits are estimated, see Chen and Hall (1993).
- Confidence intervals and smoothed empirical likelihood quantiles are not available when fractional frequencies are used.

**Summary Statistics**  Shows or hides the Summary Statistics report. See “The Summary Statistics Report” on page 43.

**Horizontal Layout**  Changes the orientation of the histogram and the reports to vertical or horizontal.

**Axes on Left**  Moves the Count, Prob, Density, and Normal Quantile Plot axes to the left instead of the right.

This option is applicable only if Horizontal Layout is selected.

Histogram Options for Continuous Variables

**Histogram**  Shows or hides the histogram. See “Histograms” on page 39.

**Shadowgram**  Replaces the histogram with a shadowgram. To understand a shadowgram, consider that if the bin width of a histogram is changed, the appearance of the histogram changes. A shadowgram overlays histograms with different bin widths. Dominant features of a distribution are less transparent on the shadowgram.

Note that the following options are not available for shadowgrams:
Basic Analysis Options for Continuous Variables

- Std Error Bars
- Show Counts
- Show Percents

**Vertical** Changes the orientation of the histogram from a vertical to a horizontal orientation.

**Std Error Bars** Draws the standard error bar on each level of the histogram using the standard error. The standard error bar adjusts automatically when you adjust the number of bars with the hand tool. See “Resize Histogram Bars for Continuous Variables” on page 40 and “Standard Error Bars” on page 78.

**Set Bin Width** Changes the bin width of the histogram bars. See “Resize Histogram Bars for Continuous Variables” on page 40.

**Histogram Color** Changes the color of the histogram bars.

**Count Axis** Adds an axis that shows the frequency of column values represented by the histogram bars.

*Note:* If you resize the histogram bars, the count axis also resizes.

**Prob Axis** Adds an axis that shows the proportion of column values represented by histogram bars.

*Note:* If you resize the histogram bars, the probability axis also resizes.

**Density Axis** The density is the length of the bars in the histogram. Both the count and probability are based on the following calculations:

\[
\text{prob} = (\text{bar width}) \times \text{density} \\
\text{count} = (\text{bar width}) \times \text{density} \times (\text{total count})
\]

When looking at density curves that are added by the Fit Distribution option, the density axis shows the point estimates of the curves.

*Note:* If you resize the histogram bars, the density axis also resizes.

**Show Percents** Labels the proportion of column values represented by each histogram bar.

**Show Counts** Labels the frequency of column values represented by each histogram bar.
Normal Quantile Plot

Use the Normal Quantile Plot option to visualize the extent to which the variable is normally distributed. If a variable is normally distributed, the normal quantile plot approximates a diagonal straight line. This type of plot is also called a quantile-quantile plot, or Q-Q plot.

The normal quantile plot also shows Lilliefors confidence bounds (Conover 1980) and probability and normal quantile scales.

Figure 3.7 Normal Quantile Plot

Note the following information:

- The vertical axis shows the column values.
- The upper horizontal axis shows the normal quantile scale.
- The lower horizontal axis shows the empirical cumulative probability for each value.
- The dashed red line shows the Lilliefors confidence bounds.

For statistical details, see “Normal Quantile Plot” on page 80.

Outlier Box Plot

Use the outlier box plot (also called a Tukey outlier box plot) to see the distribution and identify possible outliers. Generally, box plots show selected quantiles of continuous distributions.
Note the following aspects about outlier box plots:

- The horizontal line within the box represents the median sample value.
- The confidence diamond contains the mean and the upper and lower 95% of the mean. If you drew a line through the middle of the diamond, you would have the mean. The top and bottom points of the diamond represent the upper and lower 95% of the mean.
- The ends of the box represent the 25th and 75th quantiles, also expressed as the 1st and 3rd quartile, respectively.
- The difference between the 1st and 3rd quartiles is called the interquartile range.
- The box has lines that extend from each end, sometimes called whiskers. The whiskers extend from the ends of the box to the outermost data point that falls within these distances:
  
  \[
  \begin{align*}
  \text{1st quartile} & - 1.5 \times (\text{interquartile range}) \\
  \text{3rd quartile} & + 1.5 \times (\text{interquartile range}) 
  \end{align*}
  \]

  If the data points do not reach the computed ranges, then the whiskers are determined by the upper and lower data point values (not including outliers).
- The bracket outside of the box identifies the shortest half, which is the most dense 50% of the observations (Rousseeuw and Leroy 1987).
- To remove objects from outlier box plots, see “Remove Objects from the Outlier or Quantile Box Plot” on page 54.

**Quantile Box Plot**

The Quantile Box Plot displays specific quantiles from the Quantiles report. If the distribution is symmetric, the quantiles in the box plot are approximately equidistant from each other. At a glance, you can see whether the distribution is symmetric. For example, if the quantile marks are grouped closely at one end, but have greater spacing at the other end, the distribution is skewed toward the end with more spacing.
Quantiles are values where the $p^\text{th}$ quantile is larger than $p\%$ of the values. For example, 10% of the data lies below the $10^\text{th}$ quantile, and 90% of the data lies below the $90^\text{th}$ quantile.

**Remove Objects from the Outlier or Quantile Box Plot**

You can remove the confidence diamond and the shortest half from outlier or quantile box plots. You can remove them for a single graph, or remove them for all future graphs.

**To remove them from an individual graph:**

1. Right-click the outlier box plot and select **Customize**.
2. Click **Box Plot**.
3. Deselect the check box next to **Confidence Diamond** or **Shortest Half**.

For more information about the Customize Graph window, see *Using JMP*.

**To remove them for all future graphs:**

1. Select **File > Preferences > Platforms > Distribution**.
2. Deselect these options:
   - **Show Box Plot Confidence Diamond**
   - **Show Outlier Box Plot Shortest Half**
3. Click **OK**.

Any box plots you now add in Distribution will not have the confidence diamond or shortest half.
**Stem and Leaf**

Each line of the plot has a Stem value that is the leading digit of a range of column values. The Leaf values are made from the next-in-line digits of the values. You can see the data point by joining the stem and leaf. In some cases, the numbers on the stem and leaf plot are rounded versions of the actual data in the table. The stem-and-leaf plot actively responds to clicking and the brush tool.

**Note:** The stem-and-leaf plot converts fractional frequencies to the smallest integer greater than or equal to the specified frequency.

**CDF Plot**

The CDF plot in Distribution creates a plot of the empirical cumulative distribution function. Use the CDF plot to determine the percent of data that is at or below a given value on the horizontal axis. When a distribution is fit to the data, the cumulative distribution function for the fitted distribution is overlaid on the CDF plot.
For example, in this CDF plot, approximately 34% of the data are less than a total fat value of 10 grams.

**Test Mean**

Use the **Test Mean** window to specify options for and perform a one-sample test for the mean. If you specify a value for the standard deviation, a $z$ test is performed. Otherwise, the sample standard deviation is used to perform a $t$ test. You can also request the nonparametric Wilcoxon Signed-Rank test.

Use the **Test Mean** option repeatedly to test different values. Each time you test the mean, a new Test Mean report appears.
**Description of the Test Mean Report**

**Statistics That Are Calculated for Test Mean**

- **t Test (or z Test)** Lists the value of the test statistic and the $p$-values for the two-sided and one-sided alternatives.

- **Signed-Rank** (Appears only if the Wilcoxon Signed-Rank test is selected.) Lists the value of the Wilcoxon signed-rank statistic followed by $p$-values for the two-sided and one-sided alternatives. The test uses the Pratt method to address zero values. This is a nonparametric test whose null hypothesis is that the median equals the postulated value. It assumes that the distribution is symmetric. See “Wilcoxon Signed Rank Test” on page 80.

**Probability Values**

- **Prob > |t|** The probability of obtaining an absolute $t$ value that is greater than the observed $t$ value when the population mean is equal to the hypothesized value. This is the $p$-value for observed significance of the two-tailed $t$ test.

- **Prob > t** The probability of obtaining a $t$ value greater than the computed sample $t$ ratio when the population mean is not different from the hypothesized value. This is the $p$-value for an upper-tailed test.

- **Prob < t** The probability of obtaining a $t$ value less than the computed sample $t$ ratio when the population mean is not different from the hypothesized value. This is the $p$-value for a lower-tailed test.

**Descriptions of the Test Mean Options**

- **PValue animation** Starts an interactive visual representation of the $p$-value. Enables you to change the hypothesized mean value while watching how the change affects the $p$-value.

- **Power animation** Starts an interactive visual representation of power and beta. You can change the hypothesized mean and sample mean while watching how the changes affect power and beta.

- **Remove Test** Removes the mean test.
Test Std Dev

Use the Test Std Dev option to perform a one-sample test for the standard deviation. Use the Test Std Dev option repeatedly to test different values. Each time you test the standard deviation, a new Test Standard Deviation report appears.

Test Statistic  Provides the value of the Chi-square test statistic. See “Standard Deviation Test” on page 82.

Min PValue  The probability of obtaining a more extreme Chi-square value when the population standard deviation does not differ from the hypothesized value. See “Standard Deviation Test” on page 82.

Prob>ChiSq  The probability of obtaining a Chi-square value greater than the computed sample Chi-square when the population standard deviation is not different from the hypothesized value. This is the \( p \)-value for observed significance of a one-tailed \( t \) test.

Prob<ChiSq  The probability of obtaining a Chi-square value less than the computed sample Chi-square when the population standard deviation is not different from the hypothesized value. This is the \( p \)-value for observed significance of a one-tailed \( t \) test.

Test Equivalence

Equivalence tests assess whether a population mean is equivalent to a hypothesized value. You must define a threshold difference that is considered equivalent to no difference. The Test Equivalence option uses the Two One-Sided Tests (TOST) approach. Two one-sided \( t \) tests are constructed for the null hypotheses that the difference between the true mean and the hypothesized value exceeds the threshold. If both null hypotheses are rejected, this implies that the true difference does not exceed the threshold. You conclude that the mean can be considered practically equivalent to the hypothesized value.

When you select the Test Equivalence option, you specify the Hypothesized Mean, the threshold difference (Difference Considered Practically Zero), and the Confidence Level. The Confidence Level is 1 - alpha, where alpha is the significance level for each one-sided test.

The Test Equivalence report in Figure 3.11 is for the variable BMI in the Diabetes.jmp sample data table. The Hypothesized Mean is 26.5 and the Difference Considered Practically Zero is specified as 0.5.
**Figure 3.11 Test Equivalence Report**

The report shows the following:

- A plot of your defined equivalence region that shows the Target and boundaries, defined by vertical lines labeled Lower and Upper.
- A confidence interval for the calculated mean. This confidence interval is a 1 - 2*alpha level interval.
- A table that shows the calculated mean, the specified lower and upper bounds, and a (1 - 2*alpha) level confidence interval for the mean.
- A table that shows the results of the two one-sided tests.
- A note that summarizes the results, and states whether the mean can be considered equivalent to the Target value.

**Confidence Intervals**

The **Confidence Interval** options for continuous variables display confidence intervals for the mean and standard deviation. The **0.90, 0.95, and 0.99** options compute two-sided confidence intervals for the mean and standard deviation. Use the **Confidence Interval > Other** option to select a confidence level, and select one-sided or two-sided confidence intervals. You can also enter a known sigma. If you use a known sigma, the confidence interval for the mean is based on z-values rather than t-values.

The Confidence Intervals report shows the mean and standard deviation parameter estimates with upper and lower confidence limits for 1 - $\alpha$. 

**Prediction Intervals**

Prediction intervals concern a single observation, or the mean and standard deviation of the next randomly selected sample. The calculations assume that the given sample is selected randomly from a normal distribution. Select one-sided or two-sided prediction intervals.

When you select the **Prediction Interval** option for a variable, the Prediction Intervals window appears. Use the window to specify the confidence level, the number of future samples, and either a one-sided or two-sided limit.

**Related Information**

- For statistical details, see “Prediction Intervals” on page 83.
- For an example, see “Example of Prediction Intervals” on page 74.

**Tolerance Intervals**

A tolerance interval contains at least a specified proportion of the population. It is a confidence interval for a specified proportion of the population, not the mean, or standard deviation. Complete discussions of tolerance intervals are found in Meeker et al. (2017) and in Tamhane and Dunlop (2000).

When you select the **Tolerance Interval** option for a variable, the Tolerance Intervals window appears. Use the window to specify the confidence level, the proportion to cover, a one-sided or two-sided limit, and the method. The two available methods are Assume Normal Distribution and Nonparametric. The Assume Normal Distribution option computes tolerance intervals that are based on the assumption that the sample was randomly selected from a normal distribution. The Nonparametric option computes distribution-free tolerance intervals.

**Related Information**

- For statistical details, see “Tolerance Intervals” on page 84.
- For an example, see “Example of Tolerance Intervals” on page 75.

**Process Capability**

Process capability analysis measures how well a process is performing compared to given specification limits. A good process is one that is stable and consistently produces product that is well within specification limits. A capability index is a measure that relates process performance, summarized by process centering and variability, to specification limits.
Specification Limits

If a column contains a Spec Limits column property and the Create Process Capability option on the launch window is selected, a Process Capability report is automatically created. This report is based on the normal distribution, unless the column also contains a Distribution column property. If the column contains a Distribution column property, the Process Capability report is based on the distribution specified in the column property.

**Tip:** To add specification limits to several columns at once, see *Quality and Process Methods*.

If a column does not contain specification limits, select **Process Capability** from the red triangle next to the name of the analysis variable and set specification limits in the Process Capability Analysis window.

To save specification limits from a report to the data table as a column property, select **Save Spec Limits as Column Properties** from the Process Capability red triangle. When you repeat the process capability analysis, the saved specification limits are automatically retrieved.

Process Capability Analysis Window

The Process Capability Analysis window appears when you select the Process Capability option from the red triangle next to the name of the analysis variable.

Use the Process Capability Analysis window to specify options for the capability analysis, including specification limits, the underlying distribution for the analysis, and the estimation method for sigma. Process capability requires you to choose how to estimate sigma, the within-group (short-term) variation. Different suboptions appear depending on which process capability option you choose.

**Figure 3.12** Process Capability Analysis Window
Enter Spec Limits  Specifies the Lower Spec Limit, the Target, and the Upper Spec Limit for the process capability analysis. At least one of these must be a nonmissing value. If you select the Show Limits option, the specification limits appear on the histogram in the Distribution platform report.

Process Capability Options  Depending on which option you choose, different additional options appear. Choose one of the following options:

Subgroup Size = 1  Sets the subgroup size to 1 and provides additional Moving Range options. See Quality and Process Methods.

Use Subgroup ID Column  Enables you to select a subgroup ID column and provides additional Subgrouping and Moving Range options. See Quality and Process Methods.

Use Constant Subgroup Size  Enables you to set a constant subgroup size and provides additional Subgrouping and Moving Range options. See Quality and Process Methods.

Use Historical Sigma  Assigns a historically accepted value for sigma. See Quality and Process Methods.

Use Nonnormal Distribution  Enables you to select a nonnormal distribution and provides additional Nonnormal Distribution Options. See Quality and Process Methods.

Show Within Capability  (Available only when Subgroup Size = 1 or Use Nonnormal Distribution is selected in Process Capability Options.) Specifies if estimates of within sigma are shown in the report.

Specify Alpha Level  Specifies the significance level for confidence limits.

Process Capability Analysis Report

After you click OK in the Process Capability Analysis window, a Process Capability report appears that contains a capability report for the selected variable. For more information about this report, see Quality and Process Methods.

- For statistical details, see Quality and Process Methods.
- For an example, see “Example of Process Capability” on page 76.
- For the Process Capability platform, see Quality and Process Methods.

Note: You can set preferences for many of the options in the Process Capability report in Distribution at File > Preferences > Platforms > Process Capability.
**Fit Distributions**

You can use the options in the Continuous Fit or Discrete Fit submenus to fit a distribution to a continuous variable. When you fit a distribution to a continuous variable, a curve is overlaid on the histogram and a Compare Distributions report and a Fitted Distribution report are added to the report window. A red triangle menu in the Fitted Distribution report contains additional options. See “Fit Distribution Options” on page 66. If a column contains a Distribution column property, the distribution in that column property is fit by default in the Distribution report.

**Note:** The Life Distribution platform also contains options for distribution fitting that might use different parameterizations and allow for censored observations. See *Reliability and Survival Methods*.

**Continuous Fit**

The Continuous Fit submenu contains options for fitting continuous distributions. For more information about the parameterization of these distributions, see “Continuous Fit Distributions” on page 86.

**Fit Normal**  Fits a normal distribution to the data. The normal distribution is often used to model symmetric data with most of the values falling in the middle of the curve.

**Fit Cauchy**  Fits a Cauchy distribution to the data. The Cauchy distribution has an undefined mean and standard deviation. Although most data do not inherently follow a Cauchy distribution, it can be useful for estimating a robust location and scale for data that contain a large proportion of outliers (up to 50%).

**Fit Student’s t**  Fits a Student’s t distribution to the data. The Student’s t distribution is a robust option that spans the space between a normal distribution and a Cauchy distribution. As the degrees of freedom in the Student’s t distribution approach infinity, the distribution is equivalent to the normal. When the degrees of freedom in the Student’s t distribution equals 1, the distribution is equivalent to the Cauchy. The Distribution platform estimates the degrees of freedom value.

**Fit SHASH**  Fits a sinh-arcsinh (SHASH) distribution to the data. The SHASH distribution is similar to Johnson distributions in that it is a transformation to normality, but the SHASH distribution includes the normal distribution as a special case. This distribution can be symmetric or asymmetric.

**Fit Exponential**  (Available only when all observations are nonnegative.) Fits an exponential distribution to the data. The exponential distribution is right-skewed and is often used to model lifetimes or the time between successive events.
Fit Gamma  (Available only when all observations are positive.) Fits a gamma distribution to the data. The gamma distribution is a flexible distribution for modeling positive values.

Fit Lognormal  (Available only when all observations are positive.) Fits a lognormal distribution to the data. The lognormal distribution is right-skewed and is often used to model lifetimes or the time until an event.

Fit Weibull  (Available only when all observations are positive.) Fits a Weibull distribution to the data. The Weibull distribution is a flexible distribution and is often used to model lifetimes or the time until an event.

Fit Normal 2 Mixture   Fits a mixture of two normal distributions. This flexible distribution is capable of fitting bimodal data.

Fit Normal 3 Mixture   Fits a mixture of three normal distributions. This flexible distribution is capable of fitting multi-modal data.

Fit Smooth Curve   Fits a smooth curve using nonparametric density estimation (kernel density estimation). Control the amount of smoothing by changing the bandwidth with the slider that appears in the Nonparametric Density report.

Fit Johnson   Fits a Johnson distribution to the data. The most appropriate of the three types of Johnson distribution (Su, Sb, and Sl) is fit and reported. The Johnson family of distributions is useful for its data-fitting capabilities because it supports every possible combination of skewness and kurtosis. Information about selection procedures and parameter estimation for the Johnson distributions can be found in Slifker and Shapiro (1980).

Fit Beta  (Available only when all observations are between 0 and 1.) Fits a beta distribution to the data. The beta distribution is useful for modeling data that are between 0 and 1 (not inclusive) and is often used to model proportions or rates.

Fit All   Fits all available continuous distributions to a variable. The Compare Distributions report contains statistics about each fitted distribution. By default, the best fit distribution is selected and displayed on the histogram. Use the check boxes to show or hide a fit report and overlay curve for the selected distribution. Initially, the Compare Distributions list is sorted by AICc in ascending order.

**Tip:** You can quickly remove distributions from the Compare Distributions list by double-clicking the name of the distribution in the Distribution column. This action also removes the corresponding Fitted Distribution report.

Enable Legacy Fitters   Shows or hides the Legacy Fitters submenu. Some features of distribution fitting have been updated in JMP 15. This option enables you to use the older features from previous JMP releases that have been retained for compatibility purposes. See “Details for the Legacy Distribution Fitters” on page 96.
Discrete Fit

The Discrete Fit submenu is available when all of the data values are integers. The Discrete Fit submenu contains options for fitting discrete distributions. For more information about the parameterization of these distributions, see “Discrete Fit Distributions” on page 93.

**Fit Poisson**  Fits a Poisson distribution to the data. The Poisson distribution is useful for modeling the number of events in a given interval and is often expressed as count data.

**Fit Negative Binomial**  Fits a negative binomial distribution to the data. The negative binomial distribution is useful for modeling the number of successes before a specified number of failures. The negative binomial distribution is also equivalent to the Gamma Poisson distribution.

**Fit ZI Poisson**  (Available only when there are values of zero in the data.) Fits a zero-inflated Poisson distribution to the data. The zero-inflated Poisson assumes a greater proportion of the data are zero values than would occur in a standard Poisson distribution.

**Fit ZI Negative Binomial**  (Available only when there are values of zero in the data.) Fits a zero-inflated negative binomial distribution to the data. The zero-inflated negative binomial assumes a greater proportion of the data are zero values than would occur in a standard negative binomial distribution.

**Fit Binomial**  Fits a binomial distribution to the data. The binomial distribution is useful for modeling the total number of successes in \( n \) independent trials that all have a fixed probability, \( p \), of success. The sample size can be specified as a fixed sample size for all observations, or it can be specified as another column in the data table that contains sample sizes for each row.

**Note:** When a non-constant sample size is specified, density curves, diagnostic plots, and profilers are not available.

**Fit Beta Binomial**  Fits a beta binomial distribution to the data. The beta binomial distribution is an overdispersed version of the binomial distribution. It requires a sample size greater than one for each observation. The sample size can be specified as a fixed sample size for all observations, or it can be specified as another column in the data table that contains sample sizes for each row.

**Note:** When a non-constant sample size is specified, density curves, diagnostic plots, and profilers are not available.
Fit Distribution Options

Each fitted distribution report has a red triangle menu that contains additional options.

**Density Curve**  Uses the estimated parameters of the distribution to overlay a density curve on the histogram.

**Diagnostic Plots**  Contains the following options:

- **QQ Plot**  Shows or hides a quantile-quantile (QQ) plot. This plot shows the relationship between the observations and the quantiles obtained using the estimated parameters.

- **PP Plot**  Shows or hides a percentile-percentile (PP) plot. This plot shows the relationship between the empirical cumulative distribution function (CDF) and the fitted CDF obtained using the estimated parameters.

**Profilers**  Contains the following options:

- **Distribution Profiler**  Shows or hides a prediction profiler of the cumulative distribution function (CDF).

- **Quantile Profiler**  Shows or hides a prediction profiler of the quantile function.

**Save Columns**  Contains the following options:

- **Save Density Formula**  Saves a column to the data table that contains the density formula computed using the estimated parameter values.

- **Save Distribution Formula**  Saves a column to the data table that contains the cumulative distribution function (CDF) formula computed using the estimated parameter values.

- **Save Simulation Formula**  Saves a column to the data table that contains a formula that generates simulated values using the estimated parameters. This column can be used in the Simulate utility as a Column to Switch In. See the “Simulate” chapter on page 331.

- **Save Transformed**  (Available only for Johnson and SHASH distribution fits.) Saves a column to the data table that contains a transform formula. The formula can be used to transform the analysis column to normality using the fitted distribution.

**Goodness of Fit**  (Not available for Johnson, Smooth Curve, Normal Mixture, Binomial, or Beta Binomial distributions.) Shows or hides a Goodness-of-Fit Test report that contains a goodness-of-fit test for the fitted distribution. For continuous fits, this is the Anderson-Darling test. The p-value for the test is simulated using a parametric bootstrap, similar to the procedure described in Section 4.1 of Stephens (1974). For discrete fits, this is a Pearson chi-squared test. For Normal distributions, the Shapiro-Wilk test for normality is also reported when the sample size is less than or equal to 2000 and there are no fixed parameters.
Fix Parameters  (Not available for Johnson distribution or smooth curve fits.) Enables you to fix parameters and re-estimate the non-fixed parameters. An Adequacy LR (likelihood ratio) Test report also appears, which tests your new parameters to determine whether they fit the data.

Process Capability  (Not available for Cauchy, Student’s t, or discrete distribution fits.) Enables you to create a Process Capability analysis using the fitted distribution, which is a measure of how well process performs with respect to the specification limits. When you select the Process Capability option from a Fitted Distribution red triangle menu, a window appears with the following options:

Enter Spec Limits  Enables you to manually enter specification limits. To use the fitted distribution to calculate specification limits, leave this section blank and use the options under Calculate Quantile Spec Limits Options.

Calculate Quantile Spec Limits Options  Enables you to calculate specification limits based on the fitted distribution. There are two methods available.

In the first method, you enter probabilities associated with the quantiles of the fitted distribution to calculate specification limits.

In the second method, you enter a K-Sigma Multiplier value that is used to calculate specification limits. This method has options for creating two-sided or one-sided limits.

After entering probabilities or a value for sigma multiplier, click Calculate Spec Limits to calculate the specification limits. These limits are entered into the Enter Spec Limits panel. Click OK to accept these limits and generate the Process Capability report.

Process Capability Options  Contains the following options:

The Moving Range Options outline contains options that enable you to select the type of moving range statistic. See Quality and Process Methods.

The Nonnormal Distribution Options outline contains options that enable you to select methods used for nonnormal process capability calculations. See Quality and Process Methods.

For more information about the Process Capability options and report, see Quality and Process Methods.

Note: You can set preferences for many of the options in the Process Capability report in Distribution at File > Preferences > Platforms > Process Capability.

Remove Fit  Removes the distribution fit from the report window.
Save Options for Continuous Variables

Use the Save menu options to save information about continuous variables. Each Save option generates a new column in the current data table. The new column is named by appending the variable name (denoted \texttt{<colname>} in the following definitions) to the Save command name (Table 3.1).

Select the Save options repeatedly to save the same information multiple times under different circumstances, such as before and after combining histogram bars. If you use a Save option multiple times, the column name is numbered (name1, name2, and so on) to ensure unique column names.

Table 3.1 Descriptions of Save Options

<table>

### Additional Examples of the Distribution Platform

- “Example of Selecting Data in Multiple Histograms”
- “Example Using a By Variable”
- “Examples of the Test Probabilities Option”
- “Example of Prediction Intervals”
- “Example of Tolerance Intervals”
- “Example of Process Capability”

**Example of Selecting Data in Multiple Histograms**

This example shows you how to select and highlight data in several histograms at once.
1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution.
3. Select Type and Size Co and click Y, Columns.
4. Click OK.
   You want to see the type distribution of companies that are small.
5. Click the bar next to small.
   You can see that there are more small computer companies than there are pharmaceutical companies. To broaden your selection, add medium companies.
6. Hold down the Shift key. In the Size Co histogram, click the bar next to medium.
   You can see the type distribution of small and medium sized companies. See Figure 3.13 at left. To narrow your selection, you want to see the small and medium pharmaceutical companies only.
7. Hold down the Ctrl and Shift keys (on Windows) or the Command and Shift keys (on macOS). In the Type histogram, click in the Computer bar to deselect it.
   You can see how many of the small and medium companies are pharmaceutical companies. See Figure 3.13 at right.

Figure 3.13  Selecting Data in Multiple Histograms

Example Using a By Variable

This example shows you how to use a By variable to create a separate analysis for each level of a categorical variable.
1. Select Help > Sample Data Library and open Lipid Data.jmp.
2. Select Analyze > Distribution.
3. Select Cholesterol and click **Y, Columns**.

4. Select Gender and click **By**.

   This results in a separate analysis for each level of Gender (female and male).

5. Click **OK**.

Change the orientation of the histograms and the reports.

6. Click the Distributions red triangle and select **Stack**.

Add a smooth curve to both histograms.

7. Hold down the Ctrl key. Click the Cholesterol red triangle and select **Continuous Fit > Fit Smooth Curve**.

Hide the Compare Distributions report.

8. Hold down the Ctrl key. Click the gray disclosure icon next to **Compare Distributions**.

**Figure 3.14** Separate Distributions by Gender

---

**Examples of the Test Probabilities Option**

These examples show you how to create a Test Probabilities report for variables with two levels or more.

Initiate a test probability report for a variable with more than two levels:
1. Select **Help > Sample Data Library** and open VA Lung Cancer.jmp.
2. Select **Analyze > Distribution**.
3. Select Cell Type and click **Y, Columns**.
4. Click **OK**.
5. Click the Cell Type red triangle and select **Test Probabilities**.
   See Figure 3.15 at left.

Initiate a test probability report for a variable with exactly two levels:

1. Select **Help > Sample Data Library** and open Penicillin.jmp.
2. Select **Analyze > Distribution**.
3. Select Response and click **Y, Columns**.
4. Click **OK**.
5. Click the Response red triangle and select **Test Probabilities**.
   See Figure 3.15 at right.

**Figure 3.15** Examples of Test Probabilities Options

![Test Probabilities Options](image)

---

**Example of Generating the Test Probabilities Report**

To generate a test probabilities report for a variable with more than two levels:

1. Refer to Figure 3.15 at left. Type 0.25 in all four Hypoth Prob fields.
2. Click the **Fix hypothesized values, rescale omitted** button.

3. Click **Done**.

Likelihood Ratio and Pearson Chi-square tests are calculated. See Figure 3.16 at left.

To generate a test probabilities report for a variable with exactly two levels:

1. Refer to Figure 3.15 at right. Type 0.5 in both Hypoth Prob fields.

2. Click the **probability less than hypothesized value** button.

3. Click **Done**.

Exact probabilities are calculated for the binomial test. See Figure 3.16 at right.

**Figure 3.16** Examples of Test Probabilities Reports
Example of Prediction Intervals

This example shows you how to add prediction intervals to your distribution report. Suppose you are interested in computing prediction intervals for the next 10 observations of ozone level.

1. Select Help > Sample Data Library and open Cities.jmp.
2. Select Analyze > Distribution.
4. Click OK.
5. Click the OZONE red triangle and select Prediction Interval.

**Figure 3.17 The Prediction Intervals Window**

6. In the Prediction Intervals window, type 10 next to Enter number of future samples.
7. Click OK.

**Figure 3.18 Example of a Prediction Interval Report**
In this example, you can be 95% confident about the following:

- Each of the next 10 observations will be between 0.013755 and 0.279995.
- The mean of the next 10 observations will be between 0.115596 and 0.178154.
- The standard deviation of the next 10 observations will be between 0.023975 and 0.069276.

**Example of Tolerance Intervals**

This example shows you how to add tolerance intervals to your distribution report. Suppose you want to estimate an interval that contains 90% of ozone level measurements.

1. Select **Help > Sample Data Library** and open Cities.jmp.
2. Select **Analyze > Distribution**.
3. Select **OZONE** and click **Y, Columns**.
4. Click **OK**.
5. Click the OZONE red triangle and select **Tolerance Interval**.

**Figure 3.19** The Tolerance Intervals Window

6. Keep the default selections, and click **OK**.
In this example, you can be 95% confident that at least 90% of the population lie between 0.057035 and 0.236715, based on the Lower TI (tolerance interval) and Upper TI values.

**Example of Process Capability**

This example shows you how to add process capability results to your distribution report. Suppose you want to characterize the acidity of pickles. The lower and upper specification limits are 8 and 17, respectively.

1. Select **Help > Sample Data Library** and open Quality Control/Pickles.jmp.
2. Select **Analyze > Distribution**.
3. Select Acid and click **Y, Columns**.
4. Click **OK**.
5. Click the Acid red triangle and select **Process Capability**.
6. Type 8 for the **LSL** (lower specification limit).
7. Type 17 for the **USL** (upper specification limit).
8. Click **OK**.
The Process Capability results are added to the report. The specification limits appear on the histogram in the Process Capability report so that the data can be visually compared to the limits. As you can see, some of the acidity levels are below the lower specification limit, and some are very close to the upper specification limit. The Ppk value is 0.510, indicating a process that is not capable, relative to the given specification limits.
Statistical Details for the Distribution Platform

• “Prediction Intervals”
• “Tolerance Intervals”
• “Continuous Fit Distributions”
• “Discrete Fit Distributions”

Standard Error Bars

Standard error bars are calculated using the standard error $\sqrt{np_i(1-p_i)}$ where $p_i=n_i/n$.

Statistical Details for Quantiles

This section describes how quantiles are computed.

To compute the $p$th quantile of $n$ nonmissing values in a column, arrange the $n$ values in ascending order and call these column values $y_1, y_2, ..., y_n$. Compute the rank number for the $p$th quantile as $p / 100(n + 1)$.

- If the result is an integer, the $p$th quantile is that rank’s corresponding value.
- If the result is not an integer, the $p$th quantile is found by interpolation. The $p$th quantile, denoted $q_p$, is defined as follows:

$$q_p = (1-f)y_i + (f)y_{i+1}$$

where:
- $n$ is the number of nonmissing values for a variable
- $y_1, y_2, ..., y_n$ represents the ordered values of the variable
- $y_{n+1}$ is taken to be $y_n$
- $i$ is the integer part and $f$ is the fractional part of $(n+1)p$. 

$np_i(1-p_i)$
Basic Analysis Statistical Details for the Distribution Platform

\[-(n + 1)p = i + f\]

For example, suppose a data table has 15 rows and you want to find the 75th and 90th quantile values of a continuous column. After the column is arranged in ascending order, the ranks that contain these quantiles are computed as follows:

\[
\frac{75}{100}(15 + 1) = 12 \quad \text{and} \quad \frac{90}{100}(15 + 1) = 14.4
\]

The value \(y_{12}\) is the 75th quantile. The 90th quantile is interpolated by computing a weighted average of the 14th and 15th ranked values as \(y_{90} = 0.6y_{14} + 0.4y_{15}\).

**Summary Statistics**

This section contains statistical details for specific statistics in the Distribution Summary Statistics report.

**Mean**

The mean is the sum of the nonmissing values divided by the number of nonmissing values. If you assigned a Weight or Freq variable, the mean is computed as follows:

1. Each column value is multiplied by its corresponding weight or frequency.
2. These values are added and divided by the sum of the weights or frequencies.

**Std Dev**

The standard deviation measures the spread of a distribution around the mean. It is often denoted as \(s\) and is the square root of the sample variance, denoted \(s^2\).

\[s = \sqrt{s^2}\]

where

\[
s^2 = \frac{\sum_{i=1}^{N} w_i(y_i - \bar{y}_w)^2}{N - 1}
\]

\(\bar{y}_w = \text{weighted mean}\)

**Std Err Mean**

The standard error mean is computed by dividing the sample standard deviation, \(s\), by the square root of \(N\). In the launch window, if you specified a column for Weight or Freq, then the denominator is the square root of the sum of the weights or frequencies.
Skewness

Skewness is based on the third moment about the mean and is computed as follows:

\[ \sum w_i^2 z_i^3 \frac{N}{(N-1)(N-2)} \]

where \( z_i = \frac{x_i - \bar{x}}{s} \)

and \( w_i \) is a weight term (= 1 for equally weighted items).

Kurtosis

Kurtosis is based on the fourth moment about the mean and is computed as follows:

\[ \frac{n(n+1)}{(n-1)(n-2)(n-3)} \sum_{i=1}^{n} w_i^2 \left( \frac{x_i - \bar{x}}{s} \right)^4 - \frac{3(n-1)^2}{(n-2)(n-3)} \]

where \( w_i \) is a weight term (= 1 for equally weighted items). Using this formula, the Normal distribution has a kurtosis of 0. This formula is often referred to as the excess kurtosis.

Normal Quantile Plot

The empirical cumulative probability for each value is computed as follows:

\[ \frac{r_i}{N+1} \]

where \( r_i \) is the rank of the \( i \)th observation, and \( N \) is the number of nonmissing (and nonexcluded) observations.

The normal quantile values are computed as follows:

\[ \Phi^{-1} \left( \frac{r_i}{N+1} \right) \]

where \( \Phi \) is the cumulative probability distribution function for the normal distribution.

These normal quantile values are Van Der Waerden approximations to the order statistics that are expected for the normal distribution.

Wilcoxon Signed Rank Test

The Wilcoxon signed-rank test can be used to test for the median of a single population or to test matched-pairs data for a common median. In the case of matched pairs, the test reduces to testing the single population of paired differences for a median of 0. The test assumes that the underlying population is symmetric.
The Wilcoxon test accommodates tied values. The test statistic is adjusted for differences of zero using a method suggested by Pratt. See Lehmann and D’Abrera (2006), Pratt (1959), and Cureton (1967).

Testing for the Median of a Single Population

- There are $N$ observations:
  \[ X_1, X_2, ..., X_N \]
- The null hypothesis is:
  \[ H_0: \text{distribution of } X \text{ is symmetric around } m \]
- The differences between observations and the hypothesized value $m$ are calculated as follows:
  \[ D_j = X_j - m \]

Testing for the Equality of Two Population Medians with Matched Pairs Data

A special case of the Wilcoxon signed-rank test is applied to matched-pairs data.

- There are $N$ pairs of observations from two populations:
  \[ X_1, X_2, ..., X_N \text{ and } Y_1, Y_2, ..., Y_N \]
- The null hypothesis is:
  \[ H_0: \text{distribution of } X - Y \text{ is symmetric around } 0 \]
- The differences between pairs of observations are calculated as follows:
  \[ D_j = X_j - Y_j \]

Wilcoxon Signed-Rank Test Statistic

The test statistic is based on the sum of the signed ranks. Signed ranks are defined as follows:

- The absolute values of the differences, $|D_j|$, are ranked from smallest to largest.
- The ranks start with the value 1, even if there are differences of zero.
- When there are tied absolute differences, they are assigned the average, or midrank, of the ranks of the observations.

Denote the rank or midrank for a difference $D_j$ by $R_j$. Define the signed rank for $D_j$ as follows:

- If the difference $D_j$ is positive, the signed rank is $R_j$.
- If the difference $D_j$ is zero, the signed rank is 0.
- If the difference $D_j$ is negative, the signed rank is $-R_j$. 
The signed-rank statistic is computed as follows:

\[ S = \frac{1}{2} \sum_{j=1}^{N} \text{signed ranks} \]

Define the following:

- \( d_0 \) is the number of signed ranks that equal zero
- \( R^+ \) is the sum of the positive signed ranks

Then the following holds:

\[ S = R^+ - \frac{1}{4}[N(N+1) - d_0(d_0 + 1)] \]

**Wilcoxon Signed-Rank Test P-Values**

For \( N \leq 20 \), exact p-values are calculated.

For \( N > 20 \), a Student’s \( t \) approximation to the statistic defined below is used. Note that a correction for ties is applied. See Iman (1974) and Lehmann and D’Abrera (2006).

Under the null hypothesis, the mean of \( S \) is zero. The variance of \( S \) is given by the following:

\[ \text{Var}(S) = \frac{1}{24} \left[ N(N+1)(2N+1) - d_0(d_0 + 1)(2d_0 + 1) - \frac{1}{2} \sum_{i > 0} d_i(d_i + 1)(d_i - 1) \right] \]

The last summation in the expression for \( \text{Var}(S) \) is a correction for ties. The notation \( d_i \) for \( i > 0 \) represents the number of values in the \( i \)th group of nonzero signed ranks. (If there are no ties for a given signed rank, then \( d_i = 1 \) and the summand is 0.)

The statistic \( t \) given by the following has an approximate \( t \) distribution with \( N - 1 \) degrees of freedom:

\[ t = \frac{S}{\sqrt{N \cdot \text{Var}(S) - S^2}} \]

**Standard Deviation Test**

Here is the formula for calculating the Test Statistic:

\[ \frac{(n-1)s^2}{\sigma^2} \]
The Test Statistic is distributed as a Chi-square variable with $n - 1$ degrees of freedom when the population is normal.

The Min PValue is the $p$-value of the two-tailed test, and is calculated as follows:

$$2 \times \text{min}(p1, p2)$$

where $p1$ is the lower one-tail $p$-value and $p2$ is the upper one-tail $p$-value.

**Normal Quantiles**

The normal quantile values are computed as follows:

$$\Phi^{-1}\left(\frac{r_i}{N + 1}\right)$$

where:

- $\Phi$ is the cumulative probability distribution function for the normal distribution.
- $r_i$ is the rank of the $i$th observation.
- $N$ is the number of nonmissing observations.

**Saving Standardized Data**

The standardized values are computed using the following formula:

$$\frac{X - \bar{X}}{S_X}$$

where:

- $X$ is the original column
- $\bar{X}$ is the mean of column $X$
- $S_X$ is the standard deviation of column $X$

**Prediction Intervals**

The prediction intervals are defined as follows:

- For $m$ future observations:

$$[\hat{y}_m, \tilde{y}_m] = \bar{X} \pm t_{(1 - \alpha/2m; n - 1)} \times \sqrt{\frac{1}{n} + \frac{1}{n} \times s}$$

for $m \geq 1$

- For the mean of $m$ future observations:
\[
[Y_L, Y_U] = \bar{x} \pm t_{(1 - \alpha/2, n - 1)} \times \frac{1 + \frac{1}{n}}{\sqrt{m}} \times s \quad \text{for} \quad m \geq 1.
\]

- For the standard deviation of \( m \) future observations:

\[
[s_L, s_U] = \left[ s \times \sqrt{\frac{1}{n} \left[ F_{1 - \alpha/2; (n - 1, m - 1)} - \Phi^{-1}(p) \right]}, s \times \sqrt{\frac{1}{n} \left[ 1 - F_{1 - \alpha/2; (m - 1, n - 1)} \right]} \right] \quad \text{for} \quad m \geq 2
\]

where \( m \) = number of future observations, and \( n \) = number of points in current analysis sample.

- The one-sided intervals are formed by using \( 1 - \alpha \) in the quantile functions.

See Meeker et al. (2017, ch. 4).

**Tolerance Intervals**

This section contains statistical details for one-sided and two-sided tolerance intervals.

**Normal Distribution-Based Intervals**

**One-Sided Interval**

The one-sided interval is computed as follows:

Lower Limit = \( \bar{x} - g's' \)

Upper Limit = \( \bar{x} + g's' \)

where

\[
g' = t(1 - \alpha, n - 1, \Phi^{-1}(p) \cdot \sqrt{n}) / \sqrt{n}
\]

- \( s \) is the standard deviation
- \( t \) is the quantile from the non-central t-distribution
- \( \Phi^{-1} \) is the standard normal quantile

**Two-Sided Interval**

The two-sided interval is computed as follows:

\[
[T_{pL}, T_{pU}] = [\bar{x} - g(1 - \alpha/2;p,n)s, \bar{x} + g(1 - \alpha/2;p,n)s]
\]

where \( s \) is the standard deviation and \( g(1-\alpha/2;p,n) \) is a constant.
To determine \( g \), consider the fraction of the population captured by the tolerance interval. Tamhane and Dunlop (2000) define this fraction as follows:

\[
\Phi\left( \frac{\bar{x} + gs - \mu}{\sigma} \right) - \Phi\left( \frac{\bar{x} - gs - \mu}{\sigma} \right)
\]

where \( \Phi \) denotes the standard normal cdf (cumulative distribution function).

Therefore, \( g \) solves the following equation:

\[
P\left\{ \Phi\left( \frac{\bar{x} + gs - \mu}{\sigma} \right) - \Phi\left( \frac{\bar{x} - gs - \mu}{\sigma} \right) \geq 1 - \gamma \right\} = 1 - \alpha
\]

where \( 1 - \gamma \) is the fraction of all future observations contained in the tolerance interval.

For more information about normal distribution-based tolerance intervals, see Tables J.1a, J.1b, J.6a, and J.6b of Meeker et al. (2017).

### Nonparametric Intervals

#### One-Sided Lower Limit

The lower 100(1 - \( \alpha \))% one-sided tolerance limit to contain at least a proportion \( \beta \) of the sampled distribution from a sample of size \( n \) is the order statistic \( x_{(l)} \). The index \( l \) is computed as follows:

\[
l = n - \Phi_{\text{bin}}^{-1}(1 - \alpha, n, \beta)
\]

where \( \Phi_{\text{bin}}^{-1}(1 - \alpha, n, \beta) \) is the \((1 - \alpha)^{th}\) quantile of the binomial distribution with \( n \) trials and probability of success \( \beta \).

The actual confidence level is computed as \( \Phi_{\text{bin}}(n - l, n, \beta) \), where \( \Phi_{\text{bin}}(x, n, \beta) \) is the probability of a binomially distributed random variable with \( n \) trials and probability of success \( \beta \) being less than or equal to \( x \).

Note that to compute a lower one-sided distribution-free tolerance interval, the sample size \( n \) must be at least as large as \((\log \alpha)/(\log \beta)\).

#### One-Sided Upper Limit

The upper 100(1 - \( \alpha \))% one-sided tolerance limit to contain at least a proportion \( \beta \) of the sampled distribution from a sample of size \( n \) is the order statistic \( x_{(u)} \). The index \( u \) is computed as follows:

\[
u = 1 + \Phi_{\text{bin}}^{-1}(1 - \alpha, n, \beta)
\]

where \( \Phi_{\text{bin}}^{-1}(1 - \alpha, n, \beta) \) is the \((1 - \alpha)^{th}\) quantile of the binomial distribution with \( n \) trials and probability of success \( \beta \).
probability of success $\beta$.

The actual confidence level is computed as $\Phi_{\text{bin}}(u-1, n, \beta)$, where $\Phi_{\text{bin}}(x, n, \beta)$ is the probability of a binomially distributed random variable with $n$ trials and probability of success $\beta$ being less than or equal to $x$.

Note that to compute an upper one-sided distribution-free tolerance interval, the sample size $n$ must be at least as large as $(\log \alpha)/(\log \beta)$.

**Two-Sided Interval**

The $100(1 - \alpha)\%$ two-sided tolerance interval to contain at least a proportion $\beta$ of the sampled distribution from a sample of size $n$ is computed as follows:

$$[\tilde{T}_{p_L}, \tilde{T}_{p_U}] = [x_{(l)}, x_{(u)}]$$

where $x_{(i)}$ is the $i$th order statistic and $l$ and $u$ are computed as follows:

Let $v = n - \Phi^{-1}_{\text{bin}}(1-\alpha, n, \beta)$, where $\Phi^{-1}_{\text{bin}}(1-\alpha, n, \beta)$ is the $(1 - \alpha)^{th}$ quantile of the binomial distribution with $n$ trials and probability of success $\beta$. If $v$ is less than 2, a two-sided distribution-free tolerance interval cannot be computed. If $v$ is greater than or equal to 2, $l = \text{floor}(v/2)$ and $u = \text{floor}(n + 1 - v/2)$.

The actual confidence level is computed as $\Phi_{\text{bin}}(u-l-1, n, \beta)$, where $\Phi_{\text{bin}}(x, n, \beta)$ is the probability of a binomially distributed random variable with $n$ trials and probability of success $\beta$ being less than or equal to $x$.

Note that to compute a two-sided distribution-free tolerance interval, the sample size $n$ must be at least as large as the $n$ in the following equation:

$$1 - \alpha = 1 - n \beta^{n-1} + (n - 1) \beta^n$$

For more information about distribution-free tolerance intervals, see Meeker et al. (2017, sec. 5.3).

**Continuous Fit Distributions**

This section contains statistical details for the options in the Continuous Fit menu.

**Fit Normal**

The Fit Normal option estimates the two parameters of the normal distribution:

- $\mu$ (the mean) defines the location of the distribution on the $x$-axis
- $\sigma$ (standard deviation) defines the dispersion or spread of the distribution
The standard normal distribution occurs when \( \mu = 0 \) and \( \sigma = 1 \).

\[
pdf: \quad \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left[ -\frac{(x-\mu)^2}{2\sigma^2} \right] \quad \text{for} \quad -\infty < x < \infty; \quad -\infty < \mu < \infty; \quad 0 < \sigma
\]

\[E(x) = \mu\]

\[\text{Var}(x) = \sigma^2\]

**Fit Cauchy**

The Fit Cauchy option fits a Cauchy distribution with location \( \mu \) and scale \( \sigma \).

\[
pdf: \quad \frac{\pi\sigma}{\pi\sigma^2 + (x-\mu)^2} \quad \text{for} \quad -\infty < x < \infty; \quad -\infty < \mu < \infty; \quad 0 < \sigma
\]

\[E(x) = \text{undefined}\]

\[\text{Var}(x) = \text{undefined}\]

**Fit Student’s t**

The Fit Student’s \( t \) option fits a Student’s \( t \) distribution with location \( \mu \), scale \( \sigma \), and degrees of freedom \( v \).

\[
pdf: \quad \frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)\sqrt{\pi\sigma^2}} \left[ 1 + \frac{(x-\mu)^2}{\nu\sigma^2} \right]^{-\frac{v+1}{2}} \quad \text{for} \quad -\infty < x < \infty; \quad -\infty < \mu < \infty; \quad 0 < \sigma; \quad 1 \leq \nu
\]

**Fit SHASH**

The Fit SHASH option fits a sinh-arcsinh (SHASH) distribution. The SHASH distribution is based on a transformation of the normal distribution and includes the normal distribution as a special case. It can be symmetric or asymmetric. The shape is determined by the two shape parameters, \( \gamma \) and \( \delta \). For more information about the SHASH distribution, see Jones and Pewsey (2009).

\[
pdf: \quad f(x) = \frac{\delta\cosh(w)}{\sqrt{\sigma^2 + (x-\theta)^2}} \phi[\sinh(w)] \quad \text{for} \quad -\infty < \gamma, \quad x, \quad 0 < \infty; \quad 0 < \delta, \quad \sigma
\]

where

\[\phi(\cdot) \text{ is the standard normal pdf}\]
• When \( \gamma = 0 \) and \( \delta = 1 \), the SHASH distribution is equivalent to the normal distribution with location \( \theta \) and scale \( \sigma \).
• The transformation \( \sinh(w) \) is normally distributed with \( \mu = 0 \) and \( \sigma = 1 \).

**Fit Exponential**

The exponential distribution is especially useful for describing events that randomly occur over time, such as survival data. The exponential distribution might also be useful for modeling elapsed time between the occurrence of non-overlapping events. Examples of non-overlapping events include the following: the time between a user’s computer query and response of the server, the arrival of customers at a service desk, or calls coming in at a switchboard.

The Exponential distribution is a special case of the two-parameter Weibull when \( \beta = 1 \) and \( \alpha = \sigma \), and also a special case of the Gamma distribution when \( \alpha = 1 \).

pdf: for \( 0 < x < \alpha, \sigma \),

\[
E(x) = \sigma \\
\text{Var}(x) = \sigma^2
\]

Devore (1995) notes that an exponential distribution is *memoryless*. Memoryless means that if you check a component after \( t \) hours and it is still working, the distribution of additional lifetime (the conditional probability of additional life given that the component has lived until \( t \)) is the same as the original distribution.

**Fit Gamma**

The Fit Gamma option estimates the gamma distribution parameters, \( \alpha > 0 \) and \( \sigma > 0 \). The parameter \( \alpha \), called alpha in the fitted gamma report, describes shape or curvature. The parameter \( \sigma \), called sigma, is the scale parameter of the distribution. The data must be greater than zero.

pdf: \( \frac{1}{\Gamma(\alpha)\sigma^\alpha} x^{\alpha-1} \exp(-x/\sigma) \) for \( 0 < x < \alpha, \sigma \),

\[
E(x) = \alpha \sigma \\
\text{Var}(x) = \alpha \sigma^2
\]

• The *standard* gamma distribution has \( \sigma = 1 \). Sigma is called the scale parameter because values other than 1 stretch or compress the distribution along the horizontal axis.
• The Chi-square \( \chi^2_{(v)} \) distribution occurs when \( \sigma = 2 \) and \( \alpha = v/2 \).
• The exponential distribution occurs when $\alpha = 1$.

  The standard gamma density function is strictly decreasing when $\alpha \leq 1$. When $\alpha > 1$, the density function begins at zero, increases to a maximum, and then decreases.

**Fit Lognormal**

The Fit Lognormal option estimates the parameters $\mu$ (scale) and $\sigma$ (shape) for the two-parameter lognormal distribution. A variable $Y$ is lognormal if and only if $X = \ln(Y)$ is normal. The data must be greater than zero.

\[
\text{pdf: } \frac{1}{\sigma \sqrt{2\pi}} \exp\left[\frac{-(\log(x) - \mu)^2}{2\sigma^2}\right] \quad \text{for } 0 \leq x; \quad -\infty < \mu < \infty; \quad 0 < \sigma
\]

\[
E(x) = \exp(\mu + \sigma^2/2)
\]

\[
\text{Var}(x) = \exp(2(\mu + \sigma^2)) - \exp(2\mu + \sigma^2)
\]

**Fit Weibull**

The Weibull distribution has different shapes depending on the values of $\alpha$ (scale) and $\beta$ (shape). It often provides a good model for estimating the length of life, especially for mechanical devices and in biology.

The pdf for the Weibull distribution is defined as follows:

\[
\text{pdf: } \frac{\beta (\frac{x}{\alpha})^{\beta-1}}{\alpha} \exp\left[-\left(\frac{x}{\alpha}\right)^\beta\right] \quad \text{for } \alpha, \beta > 0; \quad 0 < x
\]

\[
E(x) = \alpha \Gamma\left(1 + \frac{1}{\beta}\right)
\]

\[
\text{Var}(x) = \alpha^2 \left\{ \Gamma\left(1 + \frac{2}{\beta}\right) - \Gamma^2\left(1 + \frac{1}{\beta}\right) \right\}
\]

where $\Gamma(\cdot)$ is the Gamma function.
Fit Normal 2 Mixture and Fit Normal 3 Mixture

The Fit Normal 2 Mixture and Fit Normal 3 Mixture options fit a mixture of two or three normal distributions. These flexible distributions are capable of fitting bimodal or multi-modal data. A separate mean, standard deviation, and proportion of the whole is estimated for each group. In the following equations, \( k \) equals the number of normal distributions in the mixture.

pdf:

\[
\sum_{i=1}^{k} \frac{\pi_i}{\sigma_i} \phi \left( \frac{x - \mu_i}{\sigma_i} \right)
\]

\[
E(x) = \sum_{i=1}^{k} \pi_i \mu_i
\]

\[
Var(x) = \sum_{i=1}^{k} \pi_i (\mu_i^2 + \sigma_i^2) - \left( \sum_{i=1}^{k} \pi_i \mu_i \right)^2
\]

where \( \mu_i, \sigma_i, \) and \( \pi_i \) are the respective mean, standard deviation, and proportion for the \( i^{th} \) group, and \( \phi(\cdot) \) is the standard normal pdf.

Fit Johnson

The Fit Johnson option selects and fits the best-fitting distribution from the Johnson system of distributions, which contains three distributions that are all based on a transformed normal distribution. These three distributions are the following:

- Johnson Su, which is unbounded.
- Johnson Sb, which has bounds on both tails. The bounds are defined by parameters that can be estimated.
- Johnson Sl, which is bounded in one tail. The bound is defined by a parameter that can be estimated. The Johnson Sl family contains the family of lognormal distributions.

Only the fit for the selected distribution is reported. Information about selection procedures and parameter estimation for the Johnson distributions can be found in Slifker and Shapiro (1980). The parameter estimation does not use maximum likelihood.

Johnson distributions are popular because of their flexibility. In particular, the Johnson distribution system is noted for its data-fitting capabilities because it supports every possible combination of skewness and kurtosis. However, the SHASH distribution is also very flexible and is recommended over the Johnson distributions.
If $Z$ is a standard normal variate, then the system is defined as follows:

$$Z = \gamma + \delta f(Y)$$

where, for the Johnson Su:

$$f(Y) = \ln \left( Y + \sqrt{1 + Y^2} \right) = \sinh^{-1}Y$$

$$Y = \frac{X - \theta}{\sigma} \quad -\infty < X < \infty$$

where, for the Johnson Sb:

$$f(Y) = \ln \left( \frac{Y}{1-Y} \right)$$

$$Y = \frac{X - \theta}{\sigma} \quad 0 < X < \theta + \sigma$$

and for the Johnson Sl, where $\sigma = \pm 1$.

$$f(Y) = \ln(Y)$$

$$Y = \frac{X - \theta}{\sigma} \quad \begin{cases} 
0 < X < \infty & \text{if } \sigma = 1 \\
-\infty < X < \theta & \text{if } \sigma = -1 
\end{cases}$$

**Johnson Su**

pdf: \[ \frac{\delta}{\sigma} \left[ 1 + \left( \frac{x - \theta}{\sigma} \right)^2 \right]^{-1/2} \phi \left[ \gamma + \delta \sinh^{-1} \left( \frac{x - \theta}{\sigma} \right) \right] \]

for $-\infty < x, \theta, \gamma < \infty; \ 0 < \theta, \delta$

**Johnson Sb**

pdf: \[ \phi \left[ \gamma + \delta \ln \left( \frac{x - \theta}{\sigma - (x - \theta)} \right) \right] \left( \frac{\delta \sigma}{(x - \theta)(\sigma - (x - \theta))} \right) \]

for $0 < x < \theta + \sigma; \ 0 < \sigma$

**Johnson Sl**

pdf: \[ \frac{\delta}{|x - \theta|} \phi \left[ \gamma + \delta \ln \left( \frac{x - \theta}{\sigma} \right) \right] \]

for $0 < x$ if $\sigma = 1; \ \theta > x$ if $\sigma = -1$

where $\phi(\cdot)$ is the standard normal pdf.

**Fit Beta**

The beta distribution is useful for modeling the behavior of random variables that are constrained to fall in the interval $0,1$. For example, proportions always fall between 0 and 1. The Fit Beta option estimates two shape parameters, $\alpha > 0$ and $\beta > 0$. The beta distribution has values only in the interval $0,1$. 
pdf: \( \frac{1}{B(\alpha, \beta)\sigma^\alpha + \beta - 1} x^\alpha - 1 x^\beta - 1 \) for \( 0 < x < 1; \ 0 < \sigma, \alpha, \beta \)

\[ E(x) = \frac{\sigma - \alpha}{\alpha + \beta} \]

\[ \text{Var}(x) = \frac{\sigma^2 \alpha \beta}{(\alpha + \beta)^2 (\alpha + \beta + 1)} \]

where \( B(\cdot) \) is the Beta function.

**Fit All**

In the Compare Distributions report, the Distribution list is sorted by AICc in ascending order. Use the check boxes to show or hide a fit report and overlay curve for the selected distribution.

The formulas for AICc and BIC are defined as follows:

\[ \text{AICc} = -2\text{logL} + 2 k + \frac{2k(k + 1)}{n - (k + 1)} \]

\[ \text{BIC} = -2\text{logL} + k \ln(n) \]

where:

- \( \text{logL} \) is the log-likelihood.
- \( n \) is the sample size.
- \( k \) is the number of parameters.

The AICc Weight column shows normalized AICc values that sum to one. The AICc weight can be interpreted as the probability that a particular distribution is the true distribution given that one of the fitted distributions is the truth. Therefore, the distribution with the AICc weight closest to one is the better fit. The AICc weights are calculated using only nonmissing AICc values:

\[ \text{AICcWeight} = \exp[-0.5(AICc-min(AICc))] / \sum(\exp[-0.5(AICc-min(AICc))]) \]

where \( \text{min}(AICc) \) is the smallest AICc value among the fitted distributions.

For more information about the measures in the Compare Distributions report, see *Fitting Linear Models*. 
Discrete Fit Distributions

This section contains statistical details for the options in the Discrete Fit menu.

Fit Poisson

The Poisson distribution has a single scale parameter $\lambda > 0$.

$$\text{pmf: } \frac{e^{-\lambda} \lambda^x}{x!} \text{ for } 0 \leq \lambda < \infty; \quad x = 0, 1, 2, \ldots$$

$E(x) = \lambda$

$\text{Var}(x) = \lambda$

Since the Poisson distribution is a discrete distribution, the overlaid curve is a step function, with jumps that occur at every integer.

Fit Negative Binomial

The negative binomial distribution is useful for modeling the number of successes before a specified number of failures. The following parameterization contains mean parameter $\lambda$ and dispersion parameter $\sigma$.

$$\text{pmf: } \frac{\Gamma[x + (1/\sigma)]}{\Gamma[x + 1] \Gamma[1/\sigma]} \left( \frac{(\lambda \sigma)^x}{(1 + \lambda \sigma)^x + (1/\sigma)} \right), \quad x = 0, 1, 2, \ldots$$

$E(x) = \lambda$

$\text{Var}(x) = \lambda + \sigma \lambda^2$

where $\Gamma(\cdot)$ is the Gamma function.

Relationship between Negative Binomial and Gamma Poisson Distributions

The negative binomial distribution is equivalent to the Gamma Poisson distribution. The Gamma Poisson distribution is useful when the data are a combination of several Poisson($\mu$) distributions and each Poisson($\mu$) distribution has a different $\mu$.

The Gamma Poisson distribution results from assuming that $x | \mu$ follows a Poisson distribution and $\mu$ follows a Gamma($\alpha, \tau$). The Gamma Poisson has parameters $\lambda = \alpha \tau$ and $\sigma = \tau + 1$. The parameter $\sigma$ is a dispersion parameter. If $\sigma > 1$, there is over dispersion, meaning there is more variation in $x$ than explained by the Poisson alone. If $\sigma = 1$, $x$ reduces to Poisson($\lambda$).
Distributions
Chapter 3
Statistical Details for the Distribution Platform

pmf: for $0 < \lambda; 1 \leq \sigma; x = 0,1,2,...$

$$E(x) = \lambda$$
$$\text{Var}(x) = \lambda \sigma$$

where $\Gamma(\cdot)$ is the Gamma function.

The Gamma Poisson is equivalent to a Negative Binomial with $\sigma_{\text{negbin}} = (\sigma_{\text{gp}} - 1) / \lambda_{\text{gp}}$.

Run `demoGammaPoisson.jsl` in the JMP Samples/Scripts folder to compare a Gamma Poisson distribution with parameters $\lambda$ and $\sigma$ to a Poisson distribution with parameter $\lambda$.

**Fit ZI Poisson**

The zero-inflated (ZI) Poisson distribution has scale parameter $\lambda > 0$ and zero-inflation parameter $\pi$.

pmf:

$$\begin{cases} 
\pi + (1 - \pi) \exp[-\lambda], & \text{for } x = 0 \\
(1 - \pi) \frac{\lambda^x}{x!} \exp[-\lambda], & \text{for } x = 1, 2, ... 
\end{cases}$$

$$E(x) = (1 - \pi) \lambda$$
$$\text{Var}(x) = \lambda(1 - \pi)(1 + \lambda \pi)$$

**Fit ZI Negative Binomial**

The zero-inflated (ZI) negative binomial distribution has scale parameter $\lambda > 0$, dispersion parameter $\sigma > 0$, and zero-inflation parameter $\pi$.

pmf:

$$\begin{cases} 
\pi + (1 - \pi)(1 + \lambda \sigma)^{-1/(\sigma)}, & \text{for } x = 0 \\
(1 - \pi) \frac{\Gamma[x + (1/\sigma)]}{\Gamma[x + 1] \Gamma[1/\sigma]} \left[ \frac{(\lambda \sigma)^x}{(1 + \lambda \sigma)^x + (1/\sigma)} \right], & \text{for } x = 1, 2, ... 
\end{cases}$$

$$E(x) = (1 - \pi) \lambda$$
$$\text{Var}(x) = \lambda(1 - \pi)[1 + \lambda(\sigma + \pi)]$$
Fit Binomial

The Fit Binomial option accepts data in two formats: a constant sample size, or a column containing sample sizes.

\[
\text{pmf: } p(x) = \binom{n}{x} p^x (1-p)^{n-x} \quad \text{for } 0 \leq p \leq 1; \quad x = 0, 1, 2, \ldots, n
\]

\[E(x) = np\]

\[\text{Var}(x) = np(1-p)\]

where \(n\) is the number of independent trials.

**Note:** The confidence interval for the binomial parameter is a Score interval. See Agresti and Coull (1998).

Fit Beta Binomial

The beta binomial distribution is useful when the data are a combination of several Binomial(p) distributions and each Binomial(p) distribution has a different p. One example is the overall number of defects combined from multiple manufacturing lines, when the mean number of defects (p) varies between the lines.

The beta binomial distribution results from assuming that \(x|\pi\) follows a Binomial(n, \(\pi\)) distribution and \(\pi\) follows a Beta(\(\alpha\), \(\beta\)). The beta binomial has parameters \(p = \frac{\alpha}{\alpha+\beta}\) and \(\delta = \frac{1}{(\alpha+\beta+1)}\). The parameter \(\delta\) is a dispersion parameter. When \(\delta > 0\), there is over dispersion, meaning there is more variation in \(x\) than explained by the Binomial alone. When \(\delta < 0\), there is under dispersion. When \(\delta = 0\), \(x\) is distributed as Binomial(n, p).

The beta binomial exists only when \(n \geq 2\).

\[
\text{pmf: } p(x) = \frac{n!}{x!(n-x)!} \frac{\Gamma\left(\frac{1}{\delta} - 1\right) \Gamma\left[x + \frac{1}{\delta} - 1\right] \Gamma\left[n-x + (1-p)\left(\frac{1}{\delta} - 1\right)\right]}{\Gamma\left[p\left(\frac{1}{\delta} - 1\right)\right] \Gamma\left[(1-p)\left(\frac{1}{\delta} - 1\right)\right] \Gamma\left(n + \frac{1}{\delta} - 1\right)}
\]

for \(0 \leq p \leq 1; \quad \max\left(-\frac{p}{n-p-1} - \frac{1-p}{n-2+p}\right) \leq \delta \leq 1; \quad x = 0, 1, 2, \ldots, n\)

\[E(x) = np\]

\[\text{Var}(x) = np(1-p)[1+(n-1)\delta]\]

where \(\Gamma(\cdot)\) is the Gamma function.
Details for the Legacy Distribution Fitters

Remember that \( x \mid \pi \sim \text{Binomial}(n, \pi) \), while \( \pi \sim \text{Beta}(\alpha, \beta) \). The parameters \( p = \alpha / (\alpha + \beta) \) and \( \delta = 1 / (\alpha + \beta + 1) \) are estimated by the platform. To obtain estimates of \( \alpha \) and \( \beta \), use the following formulas:

\[
\hat{\alpha} = \hat{p} \left( \frac{1 - \hat{\delta}}{\delta} \right)
\]

\[
\hat{\beta} = (1 - \hat{p}) \left( \frac{1 - \hat{\delta}}{\delta} \right)
\]

If the estimate of \( \delta \) is 0, the formulas do not work. In that case, the beta binomial has reduced to the Binomial(n, p), and \( \hat{p} \) is the estimate of \( p \).

The confidence intervals for the beta binomial parameters are profile likelihood intervals.

Run `demoBetaBinomial.jsl` in the JMP Samples/Scripts folder to compare a beta binomial distribution with dispersion parameter \( \delta \) to a Binomial distribution with parameters \( p \) and \( n = 20 \).

**Details for the Legacy Distribution Fitters**

Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting **Continuous Fit > Enable Legacy Fitters** in the red triangle menu for a variable.

- “Fit Distributions Options (Legacy)”
- “Statistical Details for Continuous Fit Distributions (Legacy)”
- “Statistical Details for Discrete Fit Distributions (Legacy)”
- “Statistical Details for Fitted Quantiles (Legacy)”
- “Statistical Details for Fit Distribution Options (Legacy)”

**Fit Distributions Options (Legacy)**

Use the Continuous Fit or Discrete Fit options to fit a distribution to a continuous variable.

**Note:** Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting **Continuous Fit > Enable Legacy Fitters** in the red triangle menu for a variable.
A curve is overlaid on the histogram, and a Parameter Estimates report is added to the report window. A red triangle menu contains additional options. See “Fit Distribution Options (Legacy)” on page 98.

Note: The Life Distribution platform also contains options for distribution fitting that might use different parameterizations and allow for censoring. See Reliability and Survival Methods.

Continuous Fit (Legacy)

This section describes the distributions in the Legacy Fitters submenu that differ from the corresponding distributions in the updated Continuous Fit options.

- The Weibull distribution, Weibull with threshold distribution, and Extreme Value distribution often provide a good model for estimating the length of life, especially for mechanical devices and in biology.
- The Gamma distribution is bound by zero and has a flexible shape.
- The Beta distribution is useful for modeling the behavior of random variables that are constrained to fall in the interval 0,1. For example, proportions always fall between 0 and 1.
- The Smooth Curve distribution fits a smooth curve using nonparametric density estimation (kernel density estimation). The smooth curve is overlaid on the histogram and a slider appears beneath the plot. Control the amount of smoothing by changing the kernel standard deviation with the slider. The initial Kernel Std estimate is calculated from the standard deviation of the data.
- The Johnson Su, Johnson Sb, and Johnson Sl Distributions are useful for its data-fitting capabilities because it supports every possible combination of skewness and kurtosis.
- The Generalized Log (Glog) distribution is useful for fitting data that are rarely normally distributed and often have non-constant variance, like biological assay data.

Comparing All Distributions

The All option fits all applicable continuous distributions to a variable. The Compare Distributions report contains statistics about each fitted distribution. Use the check boxes to show or hide a fit report and overlay curve for the selected distribution. By default, the best fit distribution is selected.

The Show Distribution list is sorted by AICc in ascending order.

If your variable contains negative values, the Show Distribution list does not include those distributions that require data with positive values. Only continuous distributions are fitted by this command. Distributions with threshold parameters, like Beta and Johnson Sb, are not included in the list of possible distributions.
Related Information

For statistical details, see the following sections:

- “Statistical Details for Continuous Fit Distributions (Legacy)” on page 101
- “Statistical Details for Fitted Quantiles (Legacy)” on page 108
- “Fit Distribution Options (Legacy)” on page 98

Discrete Fit (Legacy)

The Discrete Fit option is available when all data values are integers. Use the Discrete Fit options to fit a distribution (such as Poisson or Binomial) to a discrete variable. The following distributions are available:

- Poisson
- Gamma Poisson
- Binomial
- Beta Binomial

Related Information

For statistical details, see the following sections:

- “Statistical Details for Discrete Fit Distributions (Legacy)” on page 106
- “Statistical Details for Fitted Quantiles (Legacy)” on page 108
- “Fit Distribution Options (Legacy)” on page 98

Fit Distribution Options (Legacy)

Each fitted distribution report has a red triangle menu that contains additional options.

Diagnostic Plot Creates a quantile or a probability plot. See “Diagnostic Plot” on page 99.

Density Curve Uses the estimated parameters of the distribution to overlay a density curve on the histogram.

Goodness of Fit Computes the goodness of fit test for the fitted distribution. See “Goodness of Fit” on page 100.

Fix Parameters Enables you to fix parameters and re-estimate the non-fixed parameters. An Adequacy LR (likelihood ratio) Test report also appears, which tests your new parameters to determine whether they fit the data.

Quantiles Returns the unscaled and uncentered quantiles for the specific lower probability values that you specify.
Set Spec Limits for K Sigma  Use this option when you do not know the specification limits for a process and you want to use its distribution as a guideline for setting specification limits.

Usually, specification limits are derived using engineering considerations. If there are no engineering considerations, and if the data are from a well behaved process, then quantiles from a fitted distribution are often used to help set specification limits. See “Set Spec Limits for K Sigma” on page 110.

Spec Limits  Computes generalizations of the standard capability indices, based on the specification limits and target you specify. See “Spec Limits” on page 101.

Save Fitted Quantiles  Saves the fitted quantile values as a new column in the current data table. See “Statistical Details for Fitted Quantiles (Legacy)” on page 108.

Save Density Formula  Creates a new column in the current data table that contains fitted values that have been computed by the density formula. The density formula uses the estimated parameter values.

Save Spec Limits  Saves the specification limits as a column property.

Save Transformed  Creates a new column and saves a formula. The formula can transform the column to normality using the fitted distribution. This option is available only when one of the Johnson distributions, the Glog distribution, or the SHASH distribution is fit.

Remove Fit  Removes the distribution fit from the report window.

Diagnostic Plot

The Diagnostic Plot option creates a quantile or a probability plot. Depending on the fitted distribution, the plot is in one of the following four formats.

The Fitted Quantiles versus the Data

- Weibull with threshold
- Gamma
- Beta
- Poisson
- GammaPoisson
- Binomial
- BetaBinomial

The Fitted Probability versus the Data

- Normal
• Normal Mixtures
• Exponential

The Fitted Probability versus the Data on Log Scale
• Weibull
• LogNormal
• Extreme Value

The Fitted Probability versus the Standard Normal Quantile
• SHAH
• Johnson Sl
• Johnson Sb
• Johnson Su
• Glog

The following options are available in the Diagnostic Plot red triangle menu:

Rotate  Reverses the x- and y-axes.

Confidence Limits  Draws Lilliefors 95% confidence limits for the Normal Quantile plot, and 95% equal precision bands with \( a = 0.001 \) and \( b = 0.99 \) for all other quantile plots (Meeker and Escobar 1998).

Line of Fit  Draws the straight diagonal reference line. If a variable fits the selected distribution, the values fall approximately on the reference line.

Median Reference Line  Draws a horizontal line at the median of the response.

Goodness of Fit
The Goodness of Fit option computes the goodness of fit test for the fitted distribution. The goodness of fit tests are not Chi-square tests, but are EDF (Empirical Distribution Function) tests. EDF tests offer advantages over the Chi-square tests, including improved power and invariance with respect to histogram midpoints.

• For Normal distributions, the Shapiro-Wilk test for normality is reported when the sample size is less than or equal to 2000. The KSL test is computed for samples that are greater than 2000.

• For discrete distributions that have sample sizes less than or equal to 30, the Goodness of Fit test is formed using two one-sided exact Kolmogorov tests combined to form a near-exact test. See Conover (1972). For sample sizes greater than 30, a Pearson Chi-squared goodness of fit test is performed.
Related Information

- For statistical details, see “Fit Distribution Options (Legacy)” on page 98.

Spec Limits

The Spec Limits option opens a window that enables you to enter specification limits and a target. Then generalizations of the standard capability indices are computed. Note that for the normal distribution, 3σ is both the distance from the lower 0.135 percentile to median (or mean) and the distance from the median (or mean) to the upper 99.865 percentile. These percentiles are estimated from the fitted distribution, and the appropriate percentile-to-median distances are substituted for 3σ in the standard formulas.

Related Information

- For statistical details, see “Fit Distribution Options (Legacy)” on page 98.

Statistical Details for Continuous Fit Distributions (Legacy)

This section contains statistical details for the options in the Continuous Fit menu.

Note: Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting Continuous Fit > Enable Legacy Fitters in the red triangle menu for a variable.

Normal

For more information about the normal distribution fit, see “Fit Normal” on page 86.

LogNormal

For more information about the lognormal distribution fit, see “Fit Lognormal” on page 89.

Weibull, Weibull with Threshold, and Extreme Value

The Weibull distribution has different shapes depending on the values of α (scale) and β (shape). It often provides a good model for estimating the length of life, especially for mechanical devices and in biology.

The pdf for the Weibull and Weibull with Threshold distributions is defined as follows:

\[
\text{pdf: } \frac{\beta}{\alpha} \left(\frac{x-\theta}{\alpha}\right)^{\beta-1} \exp\left[-\left(\frac{x-\theta}{\alpha}\right)^{\beta}\right] \quad \text{for } \alpha, \beta > 0; \quad \theta < x
\]
E(x) = 0 + αΓ\left(1 + \frac{1}{β}\right)

\text{Var}(x) = α^2\left\{Γ\left(1 + \frac{2}{β}\right) - Γ^2\left(1 + \frac{1}{β}\right)\right\}

where Γ(·) is the Gamma function.

The \textbf{Weibull} option sets the threshold parameter (θ) to zero. The \textbf{Weibull with Threshold} option, estimates the threshold parameter (θ) using the value of the minimum observation and estimates α and β using the rest of the observations. If you know what the threshold should be, set it by using the \textbf{Fix Parameters} option. See “Fit Distribution Options” on page 66.

\textbf{Note:} The Distribution platform uses a different estimation technique for the threshold parameter in the Weibull with Threshold distribution than does the Life Distribution platform. The Life Distribution estimation method is recommended for fitting this distribution. See Reliability and Survival Methods.

The Extreme Value distribution is equivalent to a two-parameter Weibull (α, β) distribution re-parameterized as δ = 1 / β and λ = ln(α).

\textbf{Exponential}

For more information about the exponential distribution fit, see “Fit Exponential” on page 88.

\textbf{Gamma}

The \textbf{Gamma} fitting option estimates the gamma distribution parameters, α > 0 and σ > 0. The parameter α, called alpha in the fitted gamma report, describes shape or curvature. The parameter σ, called sigma, is the scale parameter of the distribution. A third parameter, θ, called the Threshold, is the lower endpoint parameter. It is set to zero by default, unless there are negative values. You can also set its value by using the \textbf{Fix Parameters} option. See “Fit Distribution Options” on page 66.

\text{pdf:} \quad \frac{1}{\Gamma(α)σ^α}(x - θ)^{α - 1}\exp\left(-(x - θ)/σ\right) \quad \text{for} \quad 0 ≤ x; \quad 0 < α,σ

E(x) = ασ + θ

\text{Var}(x) = ασ^2

- The standard gamma distribution has σ = 1. Sigma is called the scale parameter because values other than 1 stretch or compress the distribution along the horizontal axis.
- The Chi-square \(\chi^2_ν\) distribution occurs when σ = 2, \(α = ν/2\), and \(θ = 0\).
• The exponential distribution is the family of gamma curves that occur when $\alpha = 1$ and $\theta = 0$.

The standard gamma density function is strictly decreasing when $\alpha \leq 1$. When $\alpha > 1$, the density function begins at zero, increases to a maximum, and then decreases.

**Beta**

The standard beta distribution is useful for modeling the behavior of random variables that are constrained to fall in the interval 0,1. For example, proportions always fall between 0 and 1. The Beta fitting option estimates two shape parameters, $\alpha > 0$ and $\beta > 0$, and two threshold parameters, $\theta$ and $\sigma$. The lower threshold is represented as $\theta$, and the upper threshold is represented as $\theta + \sigma$. The beta distribution has values only in the interval $\theta \leq x \leq (\theta + \sigma)$. The $\theta$ is estimated by the minimum value, and $\sigma$ is estimated by the range. The standard beta distribution occurs when $\theta = 0$ and $\sigma = 1$.

Set parameters to fixed values by using the Fix Parameters option. The upper threshold must be greater than or equal to the maximum data value, and the lower threshold must be less than or equal to the minimum data value. For more information about the Fix Parameters option, see “Fit Distribution Options” on page 66.

$$pdf: \frac{1}{B(\alpha, \beta)\sigma^{\alpha + \beta - 1}}(x - \theta)^{\alpha - 1}(\theta + \sigma - x)^{\beta - 1} \quad \text{for} \quad \theta \leq x \leq \theta + \sigma; \quad 0 < \sigma, \alpha, \beta$$

$$E(x) = \theta + \sigma \frac{\alpha}{\alpha + \beta}$$

$$Var(x) = \frac{\sigma^2\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)}$$

where $B(\cdot)$ is the Beta function.

**Normal Mixtures**

For more information about the normal mixtures distribution fits, see “Fit Normal 2 Mixture and Fit Normal 3 Mixture” on page 90.

**Smooth Curve**

The Smooth Curve option fits a smooth curve using nonparametric density estimation (kernel density estimation). The smooth curve is overlaid on the histogram and a slider appears beneath the plot. Control the amount of smoothing by changing the kernel standard deviation with the slider. The initial Kernel Std estimate is calculated from the standard deviation of the data.
SHASH

For more information about the SHASH distribution fit, see “Fit SHASH” on page 87.

Johnson Su, Johnson Sb, Johnson Sl

The Johnson system of distributions contains three distributions that are all based on a transformed normal distribution. These three distributions are the following:

- Johnson Su, which is unbounded.
- Johnson Sb, which has bounds on both tails. The bounds are defined by parameters that can be estimated.
- Johnson Sl, which is bounded in one tail. The bound is defined by a parameter that can be estimated. The Johnson Sl family contains the family of lognormal distributions.

The S refers to system, the subscript of the range. Although we implement a different method in the legacy fitters, information about selection criteria for a particular Johnson system can be found in Slifker and Shapiro (1980).

Johnson distributions are popular because of their flexibility. In particular, the Johnson distribution system is noted for its data-fitting capabilities because it supports every possible combination of skewness and kurtosis.

If Z is a standard normal variate, then the system is defined as follows:

\[ Z = \gamma + \delta f(Y) \]

where, for the Johnson Su:

\[ f(Y) = \ln\left(\sqrt{1 + Y^2}\right) = \sinh^{-1}Y \]

\[ Y = \frac{X - \theta}{\sigma} \quad -\infty < X < \infty \]

where, for the Johnson Sb:

\[ f(Y) = \ln\left(\frac{Y}{1 - Y}\right) \]

\[ Y = \frac{X - \theta}{\sigma} \quad 0 < X < \theta + \sigma \]

and for the Johnson Sl, where \( \sigma = \pm 1 \).

\[ f(Y) = \ln(Y) \]

\[ Y = \frac{X - \theta}{\sigma} \quad 0 < X < \infty \quad \text{if } \sigma = 1 \]

\[ -\infty < X < \theta \quad \text{if } \sigma = -1 \]
Johnson Su

pdf: \[ \frac{\delta}{\sigma}\left[1 + \left(\frac{x - \theta}{\sigma}\right)^2\right]^{-1/2} \phi\left[\gamma + \delta \sinh^{-1}\left(\frac{x - \theta}{\sigma}\right)\right] \] for \( -\infty < x, \theta, \gamma < \infty; 0 < \theta, \delta \)

Johnson Sb

pdf: \[ \phi\left[\gamma + \delta \ln\left(\frac{x - \theta}{\sigma - (x - \theta)}\right)\right] \left(\frac{\delta \sigma}{(x - \theta)(\sigma - (x - \theta))}\right) \] for \( \theta < x < \theta + \sigma; 0 < \sigma \)

Johnson Sl

pdf: \[ \frac{\delta}{|x - \theta|} \phi\left[\gamma + \delta \ln\left(\frac{x - \theta}{\sigma}\right)\right] \] for \( \theta < x \) if \( \sigma = 1; \theta > x \) if \( \sigma = -1 \)

where \( \phi(\cdot) \) is the standard normal pdf.

Note the following:

- Parameter estimates might be different between machines due to the order of operations and machine precision.
- The parameter confidence intervals are hidden in the default report. Parameter confidence intervals are not very meaningful for Johnson distributions, because they are transformations to normality. To show parameter confidence intervals, right-click in the report and select **Columns > Lower 95%** and **Upper 95%**.

**Generalized Log (Glog)**

This distribution is useful for fitting data that are rarely normally distributed and often have non-constant variance, like biological assay data. The Glog distribution is described with the parameters \( \mu \) (location), \( \sigma \) (scale), and \( \lambda \) (shape).

pdf: \[ \phi\left[\frac{1}{\sigma}\left[\log\left(\frac{x + \sqrt{x^2 + \lambda^2}}{2}\right) - \mu\right]\right] \frac{x + \sqrt{x^2 + \lambda^2}}{\sigma(x^2 + \lambda^2 + x\sqrt{x^2 + \lambda^2})} \]

for \( 0 \leq \lambda; 0 < \sigma; -\infty < \mu < \infty \)

The Glog distribution is a transformation to normality, and comes from the following relationship:

If \( z = \frac{1}{\sigma}\left[\log\left(\frac{x + \sqrt{x^2 + \lambda^2}}{2}\right) - \mu\right] \sim N(0,1) \), then \( x \sim \text{Glog}(\mu, \sigma, \lambda) \).

When \( \lambda = 0 \), the Glog reduces to the LogNormal \((\mu, \sigma)\).
**Note:** The parameter confidence intervals are hidden in the default report. Parameter confidence intervals are not very meaningful for the GLog distribution, because it is a transformation to normality. To show parameter confidence intervals, right-click in the report and select **Columns > Lower 95%** and **Upper 95%**.

---

**All**

In the Compare Distributions report, the Distribution list is sorted by AICc in ascending order. The AICc is defined as follows:

\[
\text{AICc} = -2 \log L + 2v + \frac{2v(v + 1)}{n - (v + 1)}
\]

where:

- \( \log L \) is the log-likelihood.
- \( n \) is the sample size.
- \( v \) is the number of parameters.

If the column contains negative values, the Distribution list does not include those distributions that require data with positive values. Only continuous distributions are listed. Distributions with threshold parameters, such as Beta and Johnson Sb, are not included in the list of possible distributions.

### Statistical Details for Discrete Fit Distributions (Legacy)

This section contains statistical details for the options in the Discrete Fit menu.

**Note:** Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting **Continuous Fit > Enable Legacy Fitters** in the red triangle menu for a variable.

**Poisson**

For more information about the Poisson distribution fit, see “Fit Poisson” on page 93.
Gamma Poisson

This distribution is useful when the data are a combination of several Poisson(\(\mu\)) distributions and each Poisson(\(\mu\)) distribution has a different \(\mu\). One example is the overall number of accidents combined from multiple intersections, when the mean number of accidents (\(\mu\)) varies between the intersections.

The Gamma Poisson distribution results from assuming that \(x \mid \mu\) follows a Poisson distribution and \(\mu\) follows a Gamma(\(\alpha, \tau\)). The Gamma Poisson has parameters \(\lambda = \alpha \tau\) and \(\sigma = \tau + 1\). The parameter \(\sigma\) is a dispersion parameter. If \(\sigma > 1\), there is over dispersion, meaning there is more variation in \(x\) than explained by the Poisson alone. If \(\sigma = 1\), \(x\) reduces to Poisson(\(\lambda\)).

The pmf is:

\[
\begin{align*}
\text{pmf: } & \frac{\Gamma\left(x + \frac{\lambda}{\sigma - 1}\right)}{\Gamma(x + 1)\Gamma\left(\frac{\lambda}{\sigma - 1}\right)}\left(\frac{\sigma - 1}{\sigma}\right)^x \frac{\lambda}{\sigma - 1} \quad \text{for } 0 < \lambda; \quad 1 \leq \sigma; \quad x = 0,1,2,\ldots \\
E(x) &= \lambda \\
\text{Var}(x) &= \lambda \sigma \\
\text{where } \Gamma(\cdot) &\text{ is the Gamma function.}
\end{align*}
\]

Remember that \(x \mid \mu \sim \text{Poisson}(\mu)\), while \(\mu \sim \text{Gamma}(\alpha, \tau)\). The platform estimates \(\lambda = \alpha \tau\) and \(\sigma = \tau + 1\). To obtain estimates for \(\alpha\) and \(\tau\), use the following formulas:

\[
\hat{\tau} = \frac{\hat{\sigma} - 1}{\hat{\alpha}} \\
\hat{\alpha} = \frac{\hat{\lambda}}{\hat{\tau}}
\]

If the estimate of \(\sigma\) is 1, the formulas do not work. In that case, the Gamma Poisson has reduced to the Poisson(\(\lambda\)), and \(\hat{\lambda}\) is the estimate of \(\lambda\).

If the estimate for \(\alpha\) is an integer, the Gamma Poisson is equivalent to a Negative Binomial with the following pmf:

\[
p(y) = \binom{y + r - 1}{y} p^r (1 - p)^y \quad \text{for } 0 \leq y
\]

with \(r = \alpha\) and \((1-p)/p = \tau\).

Run demoGammaPoisson.jsl in the JMP Samples/Scripts folder to compare a Gamma Poisson distribution with parameters \(\lambda\) and \(\sigma\) to a Poisson distribution with parameter \(\lambda\).

Binomial

For more information about the binomial distribution fit, see “Fit Binomial” on page 95.
Beta Binomial

For more information about the beta binomial distribution fit, see “Fit Beta Binomial” on page 95.

Statistical Details for Fitted Quantiles (Legacy)

**Note:** Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting **Continuous Fit > Enable Legacy Fitters** in the red triangle menu for a variable.

The fitted quantiles in the Diagnostic Plot and the fitted quantiles saved with the **Save Fitted Quantiles** command are formed using the following method:

1. The data are sorted and ranked. Ties are assigned different ranks.
2. Compute the \( p_{[i]} = \text{rank}_{[i]}/(n+1) \).
3. Compute the quantile \( q_{[i]} = \text{Quantile}_d(p_{[i]}) \) where \( \text{Quantile}_d \) is the quantile function for the specific fitted distribution, and \( i = 1,2,...,n \).

Statistical Details for Fit Distribution Options (Legacy)

This section describes Goodness of Fit tests for fitting distributions and statistical details for specification limits pertaining to fitted distributions.

**Note:** Some features of distribution fitting have been updated in JMP 15. This section contains details of the older features from previous JMP releases that have been retained for compatibility purposes. These features are available by selecting **Continuous Fit > Enable Legacy Fitters** in the red triangle menu for a variable.

<sup>a</sup> For the three Johnson distributions and the Glog distribution, the data are transformed to Normal, then the appropriate test of normality is performed.
Set Spec Limits for K Sigma

Type a K value and select one-sided or two-sided for your process capability analysis. Tail probabilities corresponding to K standard deviations are computed from the Normal distribution. The probabilities are converted to quantiles for the specific distribution that you have fitted. The resulting quantiles are used for specification limits in the process capability analysis. This option is similar to the Quantiles option, but you provide K instead of probabilities. K corresponds to the number of standard deviations that the specification limits are away from the mean.

For example, for a Normal distribution, where K = 3, the 3 standard deviations below and above the mean correspond to the 0.00135<sup>th</sup> quantile and 0.99865<sup>th</sup> quantile, respectively. The lower specification limit is set at the 0.00135<sup>th</sup> quantile, and the upper specification limit is set at the 0.99865<sup>th</sup> quantile of the fitted distribution. A process capability analysis is returned based on those specification limits.
Introduction to Fit Y by X
Examine Relationships between Two Variables

Use the Fit Y by X platform to analyze pairs of variables. You can do this using scatter plots, linear regression, ANOVA, multiple comparisons, logistic regression, contingency tables and much more. Specific analyses depend on the modeling types of the variables.

Fit Y-by-X launches one of four platforms:

- Use Bivariate to analyze a continuous Y and a continuous X
- Use One-way analysis, including ANOVA, to analyze a continuous Y and a categorical X
- Use Logistic regression to analyze a categorical Y and a continuous X
- Use Contingency to analyze a categorical Y and a categorical X

Figure 4.1 Examples of Four Types of Analyses
Contents

Overview of the Fit Y by X Platform .................................................. 115

Launch Specific Analyses from the JMP Starter Window ...................... 116
Overview of the Fit Y by X Platform

The Fit Y by X platform is a collection of four specific platforms (or types of analyses).

<table>
<thead>
<tr>
<th>Specific Platform</th>
<th>Modeling Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bivariate</td>
<td>Continuous Y by continuous X</td>
<td>Analyzes the relationship between two continuous variables. See Bivariate Analysis.</td>
</tr>
<tr>
<td>Oneway</td>
<td>Continuous Y by nominal or ordinal X</td>
<td>Analyzes how the distribution of a continuous Y variable differs across groups defined by a categorical X variable. See Oneway Analysis.</td>
</tr>
<tr>
<td>Logistic</td>
<td>Nominal or ordinal Y by continuous X</td>
<td>Fits the probabilities for response categories to a continuous X predictor. See Logistic Analysis.</td>
</tr>
<tr>
<td>Contingency</td>
<td>Nominal or ordinal Y by nominal or ordinal X</td>
<td>Analyzes the distribution of a categorical response variable Y as conditioned by the values of a categorical X factor. See Contingency Analysis.</td>
</tr>
</tbody>
</table>

Launch the Fit Y by X Platform

Launch the Fit Y by X platform by selecting Analyze > Fit Y by X.

Figure 4.2  The Fit Y by X Launch Window
For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Bivariate, Oneway, Logistic, Contingency**  This grid shows which analysis results from the different combinations of data types. Once you have assigned your columns, the applicable platform appears as a label above the grid.

**Block**  (Optional. Applicable only for Oneway and Contingency.):

- For the Oneway platform, specifying a Block variable identifies a second factor, which forms a two-way analysis without interaction. In the Oneway plot, the values of the Y variable are centered by the Block variable. If there are equal counts in each block by group cell, the available Oneway platform options are adapted to the two-way analysis setting. If there are unequal counts in the block by group cells, a Fit Model report is shown below the Oneway plot and the Oneway platform options are not available.

- For the Contingency platform, specifying a Block variable identifies a second factor and performs a Cochran-Mantel-Haenszel test.

For more information about launch windows, see *Using JMP*.

### Launch Specific Analyses from the JMP Starter Window

From the JMP Starter window, you can launch a specific analysis (*Bivariate, Oneway, Logistic, or Contingency*). If you select this option, specify the correct modeling types (Y and X variables) for the analysis (Table 4.1).

To launch a specific analysis from the JMP Starter Window, click the **Basic** category, and select a specific analysis.

Most of the platform launch options are the same. However, the naming for some of the Y and X platform buttons is customized for the specific analysis that you are performing.

Bivariate Analysis
Examine Relationships between Two Continuous Variables

Use the Bivariate platform to investigate the relationship between two continuous variables. Interactively add a simple linear regression line, polynomial regression curves, or smoothers to a scatter plot. Using the scatterplot, you can see at a glance the relationship between the two variables.

The Bivariate platform is the *continuous by continuous* personality of the Fit Y by X platform. The word bivariate simply means involving two variables instead of one (univariate) or many (multivariate).

Example of Bivariate Analysis

Learn how to construct a scatterplot for two continuous variables. This example uses the SAT.jmp sample data table. SAT test scores for students in the 50 U.S. states, plus the District of Columbia, are divided into two areas: verbal and math. You want to find out how the percentage of students taking the SAT tests is related to verbal test scores for 2004.

1. Select Help > Sample Data Library and open SAT.jmp.
2. Select Analyze > Fit Y by X.
4. Select % Taking (2004) and click X, Factor.
5. Click OK.

Figure 5.2 Example of SAT Scores by Percent Taking

You can see that the verbal scores were higher when a smaller percentage of the population took the test.

Launch the Bivariate Platform

To investigate the relationship between two continuous variables in a bivariate analysis, do the following:

1. Select Analyze > Fit Y by X.
2. Enter a continuous column for Y, Response.
3. Enter a continuous column for X, Factor.
The word Bivariate appears above the diagram, to indicate that you are performing a bivariate analysis.

**Note:** You can also launch a bivariate analysis from the JMP Starter window. Select View > JMP Starter > Basic > Bivariate.

For more information about this launch window, see the “Introduction to Fit Y by X” chapter on page 113. For more information about the options in the Select Columns red triangle menu, see Using JMP.

### The Bivariate Plot

The Bivariate report begins with a scatterplot for each pair of \( X \) and \( Y \) variables.

**Note:** To produce the plot shown in Figure 5.4, follow the instructions in “Example of Bivariate Analysis” on page 120.
Replace variables in the plot by dragging and dropping a variable, in one of two ways: swap existing variables by dragging and dropping a variable from one axis to the other axis; or, click a variable in the Columns panel of the associated data table and drag it onto an axis.

You can interact with this plot just as you can with other JMP plots (for example, resizing the plot, highlighting points with the arrow or brush tool, and labeling points). For more information about these features, see Using JMP.

You can fit curves on the plot and view statistical reports and additional menus using the fitting options that are located within the red triangle menu. See “Fitting Options” on page 122.

**Fitting Options**

The Bivariate Fit red triangle menu contains display options, fitting options, and control options.

**Note:** The Fit Group menu appears if you have specified multiple Y or multiple X variables. Menu options enable you to arrange reports or order them by RSquare. See Fitting Linear Models.

**Show Points**  Hides or shows the points in the scatterplot. A check mark indicates that points are shown.

**Histogram Borders**  Attaches histograms to the x- and y-axes of the scatterplot. A check mark indicates that histogram borders are turned on. See “Histogram Borders” on page 126.
Note: When you apply only the Hidden row state to rows in the data table, the corresponding points do not appear in the scatterplot. However, the histograms are constructed using the hidden rows. If you want to exclude rows from the construction of the histograms and from analysis results, apply the Exclude row state and select Redo > Redo Analysis from the Bivariate red triangle menu.

Summary Statistics  Shows the summary statistics for the plot, such as the correlation and confidence intervals, mean, and standard deviation.

Group By  Lets you select a classification (or grouping) variable. A separate analysis is computed for each level of the grouping variable, and regression curves or ellipses are overlaid on the scatterplot. See “Group By” on page 144.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Fitting Options

Each fitting option adds the following:

- a line, curve, or distribution to the scatterplot
- a red triangle menu to the report window
- a specific report to the report window
**Bivariate Analysis**

**Chapter 5**

**Fitting Options**

**Figures 5.5** Example of the Fit Mean Option

The following fitting options are available:

**Fit Mean**  Adds a horizontal line to the scatterplot that represents the mean of the Y response variable. See “Fit Mean” on page 127.

**Fit Line**  Adds straight line fits to your scatterplot using least squares regression. See “Fit Line and Fit Polynomial” on page 128.

**Fit Polynomial**  Fits polynomial curves of a certain degree using least squares regression. See “Fit Line and Fit Polynomial” on page 128.

**Fit Special**  Transforms Y and X. Transformations include: log, square root, square, reciprocal, and exponential. You can also turn off center polynomials, constrain the intercept and the slope, and fit polynomial models. See “Fit Special” on page 134.

**Flexible**  Provides options that enable you to control the smoothness of the estimated regression curve. See “Flexible” on page 136.

**Fit Orthogonal**  Provides options for orthogonal regression fits, which are useful when X is assumed to vary. This option provides sub options that reflect various assumptions about the variances of X and Y. See “Fit Orthogonal” on page 139.

**Robust**  Provides options that reduce the influence of outliers in your data set on the fitted model. See “Robust” on page 140.

**Density Ellipse**  Plots density ellipsoids for the bivariate normal distribution fit to the X and Y variables. See “Density Ellipse” on page 141.
Nonpar Density  Plots density contours based on a smoothed surface. The contours describe the density of data points. See “Nonpar Density” on page 143.

Note: You can remove a fit using the Remove Fit option. See “Fitting Menu Options” on page 145.

Fitting Option Categories

Fitting option categories include regression fits and density estimation.

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regression Fits</td>
<td>Regression methods fit a curve to the observed data points. The fitting methods include least squares fits as well as spline fits, kernel smoothing, orthogonal fits, and robust fits.</td>
</tr>
<tr>
<td>Density Estimation</td>
<td>Density estimation fits a bivariate distribution to the points. You can either select a bivariate normal density, characterized by elliptical contours, or a general nonparametric density.</td>
</tr>
</tbody>
</table>

Fit the Same Option Multiple Times

You can select the same fitting option multiple times, and each new fit is overlaid on the scatterplot. You can try fits, exclude points and refit, and you can compare them on the same scatterplot.

To apply a fitting option to multiple analyses in your report window, hold down the Ctrl key and select a fitting option.
Histogram Borders

The **Histogram Borders** option appends histograms to the x- and y-axes of the scatterplot. You can use the histograms to visualize the marginal distributions of the X and Y variables.

**Figure 5.6** Example of Histogram Borders
Fit Mean

Using the **Fit Mean** option, you can add a horizontal line to the scatterplot that represents the mean of the Y response variable. You can start by fitting the mean and then use the mean line as a reference for other fits (such as straight lines, confidence curves, polynomial curves, and so on).

**Figure 5.7** Example of Fit Mean

![Fit Mean example](image)

**Fit Mean Report**

The Fit Mean report shows summary statistics about the fit of the mean.

- **Mean**  Mean of the response variable. The predicted response when there are no specified effects in the model.

- **Std Dev [RMSE]**  Standard deviation of the response variable. Square root of the mean square error, also called the root mean square error (or RMSE).

- **Std Error**  Standard deviation of the response mean. Calculated by dividing the RMSE by the square root of the number of values.

- **SSE**  Error sum of squares for the simple mean model. Appears as the sum of squares for Error in the analysis of variance tables for each model fit.

For more information about the options in the Fit Mean menu, see “Fitting Menus” on page 144.
Fit Line and Fit Polynomial

Using the **Fit Line** option, you can add straight line fits to your scatterplot using least squares regression. Using the **Fit Polynomial** option, you can fit polynomial curves of a certain degree using least squares regression.

**Figure 5.8** Example of Fit Line and Fit Polynomial

Figure 5.8 shows an example that compares a linear fit to the mean line and to a degree 2 polynomial fit.

Note the following information:

- The **Fit Line** output is equivalent to a polynomial fit of degree 1.
- The **Fit Mean** output is equivalent to a polynomial fit of degree 0.

For more information about the options in the Linear Fit and Polynomial Fit Degree menus, see “Fitting Menus” on page 144. For statistical details about this fit, see “Fit Line” on page 159.

**Linear Fit and Polynomial Fit Reports**

The Linear Fit and Polynomial Fit reports begin with the equation of fit.
Figure 5.9 Example of Equations of Fit

Tip: You can edit the equation by clicking on it.

Each Linear and Polynomial Fit Degree report contains at least three reports. A fourth report, Lack of Fit, appears only if there are X replicates in your data.

Summary of Fit Report

The Summary of Fit reports in the Bivariate platform show the numeric summaries of the response for the linear fit and polynomial fit of degree 2 for the same data. You can compare multiple Summary of Fit reports to see the improvement of one model over another, indicated by a larger RSquare value and smaller Root Mean Square Error.

Figure 5.10 Summary of Fit Reports for Linear and Polynomial Fits

The Summary of Fit report contains the following columns:

**RSquare** Measures the proportion of the variation explained by the model. The remaining variation is not explained by the model and attributed to random error. The RSquare is 1 if the model fits perfectly.

Note: A low RSquare value suggests that there might be variables not in the model that account for the unexplained variation. However, if your data are subject to a large amount of inherent variation, even a useful regression model can have a low RSquare value. Read the literature in your research area to learn about typical RSquare values.

The RSquare values in Figure 5.10 indicate that the polynomial fit of degree 2 gives a small improvement over the linear fit. See “Summary of Fit Report” on page 160.
RSquare Adj  Adjusts the RSquare value to make it more comparable over models with different numbers of parameters by using the degrees of freedom in its computation. See “Summary of Fit Report” on page 160.

Root Mean Square Error  Estimates the standard deviation of the random error. It is the square root of the mean square for Error in the Analysis of Variance report (Figure 5.12).

Mean of Response  Provides the sample mean (arithmetic average) of the response variable. This is the predicted response when no model effects are specified.

Observations  Provides the number of observations used to estimate the fit. If there is a weight variable, this is the sum of the weights.

Lack of Fit Report

**Note:** The Lack of Fit report appears only if there are multiple rows that have the same x value.

Using the Lack of Fit report, you can estimate the error, regardless of whether you have the right form of the model. This occurs when multiple observations occur at the same x value. The error that you measure for these exact replicates is called pure error. This is the portion of the sample error that cannot be explained or predicted no matter what form of model is used. However, a lack of fit test might not be of much use if it has only a few degrees of freedom for it (few replicated x values).

**Figure 5.11** Examples of Lack of Fit Reports for Linear and Polynomial Fits

The difference between the residual error from the model and the pure error is called the lack of fit error. The lack of fit error can be significantly greater than the pure error if you have the wrong functional form of the regressor. In that case, you should try a different type of model fit. The Lack of Fit report tests whether the lack of fit error is zero.

The Lack of Fit report contains the following columns:

**Source**  The three sources of variation: Lack of Fit, Pure Error, and Total Error.

**DF**  The degrees of freedom (DF) for each source of error.
– The **Total Error** DF is the degrees of freedom found on the Error line of the Analysis of Variance table (shown under the “Analysis of Variance Report” on page 131). It is the difference between the **Total** DF and the **Model** DF found in that table. The **Error** DF is partitioned into degrees of freedom for lack of fit and for pure error.

– The **Pure Error** DF is pooled from each group where there are multiple rows with the same values for each effect. See “Lack of Fit Report” on page 161.

– The **Lack of Fit** DF is the difference between the **Total Error** and **Pure Error** DF.

**Sum of Squares** The sum of squares (SS for short) for each source of error.

– The **Total Error** SS is the sum of squares found on the Error line of the corresponding Analysis of Variance table, shown under “Analysis of Variance Report” on page 131.

– The **Pure Error** SS is pooled from each group where there are multiple rows with the same value for the x variable. This estimates the portion of the true random error that is not explained by model x effect. See “Lack of Fit Report” on page 161.

– The **Lack of Fit** SS is the difference between the **Total Error** and **Pure Error** sum of squares. If the lack of fit SS is large, the model might not be appropriate for the data. The F-ratio described below tests whether the variation due to lack of fit is small enough to be accepted as a negligible portion of the pure error.

**Mean Square** The sum of squares divided by its associated degrees of freedom. This computation converts the sum of squares to an average (mean square). F-ratios for statistical tests are the ratios of mean squares.

**F Ratio** The ratio of mean square for lack of fit to mean square for Pure Error. It tests the hypothesis that the lack of fit error is zero.

**Prob > F** The probability of obtaining a greater F-value if the variation due to lack of fit variance and the pure error variance are the same. A high p-value means that there is not a significant lack of fit.

**Max RSq** The maximum R² that can be achieved by a model using only the variables in the model. See “Lack of Fit Report” on page 161.

**Analysis of Variance Report**

Analysis of variance (ANOVA) for a regression partitions the total variation of a sample into components. These components are used to compute an F-ratio that evaluates the effectiveness of the model. If the probability associated with the F-ratio is small, then the model is considered a better statistical fit for the data than the response mean alone.

The Analysis of Variance reports in Figure 5.12 compare a linear fit (**Fit Line**) and a second degree (**Fit Polynomial**). Both fits are statistically better from a horizontal line at the mean.
Figure 5.12 Examples of Analysis of Variance Reports for Linear and Polynomial Fits

The Analysis of Variance Report contains the following columns:

**Source**  The three sources of variation: **Model**, **Error**, and **C. Total**.

**DF**  The degrees of freedom (DF) for each source of variation:

- A degree of freedom is subtracted from the total number of nonmissing values (N) for each parameter estimate used in the computation. The computation of the total sample variation uses an estimate of the mean. Therefore, one degree of freedom is subtracted from the total, leaving 50. The total corrected degrees of freedom are partitioned into the Model and Error terms.
- One degree of freedom from the total (shown on the Model line) is used to estimate a single regression parameter (the slope) for the linear fit. Two degrees of freedom are used to estimate the parameters ($\beta_1$ and $\beta_2$) for a polynomial fit of degree 2.
- The Error degrees of freedom is the difference between C. Total df and Model df.

**Sum of Squares**  The sum of squares (SS for short) for each source of variation:

- In this example, the total (C. Total) sum of squared distances of each response from the sample mean is 57,278.157, as shown in Figure 5.12. That is the sum of squares for the base model (or simple mean model) used for comparison with all other models.
- For the linear regression, the sum of squared distances from each point to the line of fit reduces from 12,012.733. This is the residual or unexplained (Error) SS after fitting the model. The residual SS for a second degree polynomial fit is 6,906.997, accounting for slightly more variation than the linear fit. That is, the model accounts for more variation because the model SS are higher for the second degree polynomial than the linear fit. The C. total SS less the Error SS gives the sum of squares attributed to the model.

**Mean Square**  The sum of squares divided by its associated degrees of freedom. The F-ratio for a statistical test is the ratio of the following mean squares:

- The **Model** mean square for the linear fit is 45,265.4. This value estimates the error variance, but only under the hypothesis that the model parameters are zero.
The Error mean square is 245.2. This value estimates the error variance.

**F Ratio**  The model mean square divided by the error mean square. The underlying hypothesis of the fit is that all the regression parameters (except the intercept) are zero. If this hypothesis is true, then both the mean square for error and the mean square for model estimate the error variance, and their ratio has an $F$-distribution.

**Prob > F**  The observed significance probability ($p$-value) of obtaining a greater $F$-value if the specified model fits no better than the overall response mean. Observed significance probabilities of 0.05 or less are often considered evidence of a regression effect.

### Parameter Estimates Report

The terms in the Parameter Estimates report for a linear fit are the intercept and the single $x$ variable.

For a polynomial fit of order $k$, there is an estimate for the model intercept and a parameter estimate for each of the $k$ powers of the $X$ variable.

#### Figure 5.13  Examples of Parameter Estimates Reports for Linear and Polynomial Fits

The Parameter Estimates report contains the following columns:

**Term**  Lists the name of each parameter in the requested model. The intercept is a constant term in all models.

**Estimate**  Lists the parameter estimates of the linear model. The prediction formula is the linear combination of these estimates with the values of their corresponding variables.

**Std Error**  Lists the estimates of the standard errors of the parameter estimates. They are used in constructing tests and confidence intervals.

**t Ratio**  Lists the test statistics for the hypothesis that each parameter is zero. It is the ratio of the parameter estimate to its standard error. If the hypothesis is true, then this statistic has a Student’s $t$-distribution.

**Prob>|t|**  Lists the observed significance probability calculated from each $t$-ratio. It is the probability of getting a $t$-ratio greater (in absolute value) than the computed value, given a
true null hypothesis. Often, a value below 0.05 (or sometimes 0.01) is interpreted as evidence that the parameter is significantly different from zero.

To reveal additional statistics, right-click in the report and select the **Columns** menu. The following statistics are not shown by default:

**Lower 95%**  The lower endpoint of the 95% confidence interval for the parameter estimate.

**Upper 95%**  The upper endpoint of the 95% confidence interval for the parameter estimate.

**Std Beta**  The standardized parameter estimate. It is useful for comparing the effect of $X$ variables that are measured on different scales. See “Parameter Estimates Report” on page 162.

**VIF**  The variance inflation factor.

**Design Std Error**  The design standard error for the parameter estimate. See “Parameter Estimates Report” on page 162.

---

**Fit Special**

Using the **Fit Special** option, you can transform Y and X. Although data can be transformed for various reasons, it is often done to render data more plausibly normal, so that the appropriate tests can then be conducted. You can also constrain the slope and intercept, fit a polynomial of specific degree, and center the polynomial.

**Note:** For an example of this option, see “Example of the Fit Special Option” on page 149.

The Specify Transformation or Constraint Window contains the following options:

**Y or X Transformation**  Use one of these options to transform the Y or X variable:

- Natural logarithm
- Square root
- Square
- Reciprocal
- Exponential

**Degree**  Use this option to fit a polynomial of the specified degree.

**Centered Polynomial**  To turn off polynomial centering, deselect the **Centered Polynomial** check box (Figure 5.19). Note that for transformations of the X variable, polynomial centering is not performed. Centering polynomials stabilizes the regression coefficients and reduces multicollinearity.
**Constrain Intercept to**  Select this check box to constrain the model intercept to be the specified value.

**Constrain Slope to**  Select this check box to constrain the model slope to be the specified value.

For more information about the red triangle options for this fit, see “Fitting Menus” on page 144.

---

**Fit Special Reports and Menus**

Depending on your selections in the Fit Special window, you see different reports and menus. The flowchart in Figure 5.14 shows you what reports and menus you see depending on your choices.

![Flowchart](image)

**Figure 5.14** Example of Fit Special Flowchart

---

**Transformed Fit Report**

The Transformed Fit report contains the reports described in “Linear Fit and Polynomial Fit Reports” on page 128. However, if you transformed Y, the Fit Measured on Original Scale report appears. This shows the measures of fit based on the original Y variables, and the fitted model transformed back to the original scale.
Flexible

Use the options in the Flexible menu to control the smoothness of the estimated regression curve.

- Fit Spline uses a penalized least squares approach. Adjust the degree of smoothness using the parameter lambda. See “Fit Spline” on page 136.
- Kernel Smoother is based on locally weighted fits. Control the influence of local behavior using the parameter alpha. See “Kernel Smoother” on page 137.
- Fit Each Value calculates the mean response at each X value. See “Fit Each Value” on page 138.

Fit Spline

Using the Fit Spline option, you can fit a smoothing spline that varies in smoothness (or flexibility) according to the lambda ($\lambda$) value. The lambda value is a tuning parameter in the spline formula. As the value of $\lambda$ decreases, the error term of the spline model has more weight and the fit becomes more flexible and curved. As the value of $\lambda$ increases, the fit becomes stiff (less curved), approaching a straight line.

Note the following information:

- The smoothing spline can help you see the expected value of the distribution of Y across X.
- The points closest to each piece of the fitted curve have the most influence on it. The influence increases as you lower the value of $\lambda$, producing a highly flexible curve.
- If you want to use a lambda value that is not listed on the menu, select Fit Spline > Other. If the scaling of the X variable changes, the fitted model also changes. To prevent this from happening, select the Standardize X option. Note that the fitted model remains the same for either the original X variable or the scaled X variable.
- You might find it helpful to try several $\lambda$ values. You can use the Lambda slider beneath the Smoothing Spline report to experiment with different $\lambda$ values. However, $\lambda$ is not invariant to the scaling of the data. For example, the $\lambda$ value for an X measured in inches, is not the same as the $\lambda$ value for an X measured in centimeters.

For more information about the options in the Smoothing Spline Fit menu, see “Fitting Menus” on page 144. For statistical details about this fit, see “Fit Spline” on page 159.
**Smoothing Spline Fit Report**

The Smoothing Spline Fit report contains the R-Square for the spline fit and the Sum of Squares Error. You can use these values to compare the spline fit to other fits, or to compare different spline fits to each other.

**R-Square**  Measures the proportion of variation accounted for by the smoothing spline model. See “Smoothing Fit Reports” on page 162.

**Sum of Squares Error**  Sum of squared distances from each point to the fitted spline. It is the unexplained error \((\text{residual})\) after fitting the spline model.

**Change Lambda**  Enables you to change the \(\lambda\) value, either by entering a number, or by moving the slider.

**Kernel Smoother**

The Kernel Smoother option produces a curve formed by repeatedly finding a locally weighted fit of a simple curve (a line or a quadratic) at sampled points in the domain. The many local fits (128 in total) are combined to produce the smooth curve over the entire domain. This method is also called Loess or Lowess, which was originally an acronym for Locally Weighted Scatterplot Smoother. The Kernel Smoother option implements the approach of Cleveland (1979) with a small adjustment for cases of near-perfect fits; the \(6 \times q50\) argument in Cleveland’s biweight function is replaced by \(\max(6 \times q50, 2 \times q90)\), where \(q50\) and \(q90\) are the 50\(^{\text{th}}\) and 90\(^{\text{th}}\) percentiles, respectively.

Use this method to quickly see the relationship between variables and to help you determine the type of analysis or fit to perform.

For more information about the options in the Local Smoother menu, see “Fitting Menus” on page 144.

**Local Smoother Report**

The Local Smoother report contains the R-Square for the smoother fit and the Sum of Squares Error. You can use these values to compare the smoother fit to other fits, or to compare different smoother fits to each other.

**R-Square**  Measures the proportion of variation accounted for by the smoother model. See “Smoothing Fit Reports” on page 162.

**Sum of Squares Error**  Sum of squared distances from each point to the fitted smoother. It is the unexplained error \((\text{residual})\) after fitting the smoother model.
Local Fit (lambda) Select the polynomial degree for each local fit. Quadratic polynomials can track local bumpiness more smoothly. Lambda is the degree of certain polynomials that are fitted by the method. Lambda can be 0, 1 or 2.

Weight Function Specify how to weight the data in the neighborhood of each local fit. Loess uses tri-cube. The weight function determines the influence that each \( x_i \) and \( y_i \) has on the fitting of the line. The influence decreases as \( x_i \) increases in distance from \( x \) and finally becomes zero.

Smoothness (alpha) Controls how many points are part of each local fit. Use the slider or type in a value directly. Alpha is a smoothing parameter. It can be any positive number, but typical values are 1/4 to 1. As alpha increases, the curve becomes smoother.

Sampling Delta Controls the amount of sampling that is used in the fitting process. By default, the sampling delta is zero, which means that none of the points are skipped. As the sampling delta increases, points within delta of the last sample point are skipped in the fitting process. You can use this option to reduce the number of points used when the data are dense.

Robustness Re-weights the points to de-emphasize points that are farther from the fitted curve. Specify the number of times to repeat the process (number of passes). The goal is to converge the curve and automatically filter out outliers by giving them small weights.

Fit Each Value

The Fit Each Value option fits a value to each unique X value. The fitted values are the means of the response for each unique X value.

For more information about the options in the Fit Each Value menu, see “Fitting Menus” on page 144.

Fit Each Value Report

The Fit Each Value report shows summary statistics about the model fit.

- **Number of Observations** The total number of observations.
- **Number of Unique Values** The number of unique X values.
- **Degrees of Freedom** The pure error degrees of freedom.
- **Sum of Squares** The pure error sum of squares.
- **Mean Square** The pure error mean square.
Fit Orthogonal

The **Fit Orthogonal** option fits linear models that account for variability in \(X\) as well as \(Y\). This is also known as Deming regression.

**Note:** For an example of this option, see “Example of the Fit Orthogonal Option” on page 152.

**Fit Orthogonal Options**

Select one of the following options to specify a variance ratio.

**Univariate Variances, Prin Comp**  Uses the univariate variance estimates computed from the samples of \(X\) and \(Y\). This turns out to be the standardized first principal component. This option is not a good choice in a measurement systems application since the error variances are not likely to be proportional to the population variances.

**Equal Variances**  Uses 1 as the variance ratio, which assumes that the error variances are the same. Using equal variances is equivalent to the non-standardized first principal component line. Suppose that the scatterplot is scaled the same in the \(X\) and \(Y\) directions. When you show a normal density ellipse, you see that this line is the longest axis of the ellipse.

**Fit X to Y**  Uses a variance ratio of zero, which indicates that \(Y\) effectively has no variance.

**Specified Variance Ratio**  Lets you enter any ratio that you want, giving you the ability to use known information about the measurement error in \(X\) and response error in \(Y\).

For more information about the options in the Orthogonal Fit Ratio menu, see “Fitting Menus” on page 144. For statistical details about this fit, see “Fit Orthogonal” on page 159.

**Orthogonal Fit Ratio Report**

The Orthogonal Fit Ratio report shows summary statistics about the orthogonal regression model.

**Variable**  The names of the variables used to fit the line.

**Mean**  The mean of each variable.

**Std Dev**  The standard deviation of each variable.

**Variance Ratio**  The variance ratio used to fit the line.

**Correlation**  The correlation between the two variables.

**Intercept**  The intercept of the fitted line.
Slope  The slope of the fitted line.

LowerCL  The lower confidence limit for the slope.

UpperCL  The upper confidence limit for the slope.

Alpha  Enter the alpha level used in computing the confidence interval.

Robust

The Robust option provides two methods to reduce the influence of outliers in your data set. Outliers can lead to incorrect estimates and decisions.

Note: For an example of this option, see “Example of the Fit Robust Command“ on page 153.

For more information about the options in the Robust Fit and Cauchy Fit menus, see “Fitting Menus“ on page 144.

Fit Robust

The Fit Robust option reduces the influence of outliers in the response variable. The Huber M-estimation method is used. Huber M-estimation finds parameter estimates that minimize the Huber loss function:

\[ l(e) = \sum_i \rho(e_i) \]

where

\[ \rho(e) = \begin{cases} 
\frac{1}{2}e^2 & \text{if } |e| < k \\
ke - \frac{1}{2}k^2 & \text{if } |e| \geq k 
\end{cases} \]

\(e_i\) refers to the residuals

The Huber loss function penalizes outliers and increases as a quadratic for small errors and linearly for large errors. In the JMP implementation, \(k = 2\). For more information about robust fitting, see Huber (1973) and Huber and Ronchetti (2009).
Fit Cauchy

The Cauchy option estimates parameters using maximum likelihood and a Cauchy link function. This method assumes that the errors have a Cauchy distribution. A Cauchy distribution has fatter tails than the normal distribution, resulting in a reduced emphasis on outliers. This option can be useful if you have a large proportion of outliers in your data. However, if your data are close to normal with only a few outliers, this option can lead to incorrect inferences.

Density Ellipse

Using the **Density Ellipse** option, you can draw an ellipse (or ellipses) that contains the specified mass of points. The number of points is determined by the probability that you select from the **Density Ellipse** menu.

**Note:** For an example of this option, see “Example of Group By Using Density Ellipses” on page 155.

For more information about the options in the Bivariate Normal Ellipse menu, see “Fitting Menus” on page 144.

**Figure 5.15  Example of Density Ellipses**

The density ellipsoid is computed from the bivariate normal distribution fit to the X and Y variables. The bivariate normal density is a function of the means and standard deviations of the X and Y variables and the correlation between them. The **Other** selection lets you specify any probability greater than zero and less than or equal to one.
These ellipses are both density contours and confidence curves. As confidence curves, they show where a given percentage of the data is expected to lie, assuming the bivariate normal distribution.

The density ellipsoid is a good graphical indicator of the correlation between two variables. The ellipsoid collapses diagonally as the correlation between the two variables approaches either 1 or –1. The ellipsoid is more circular (less diagonally oriented) if the two variables are less correlated.

**Correlation Report**

The Correlation report that accompanies each **Density Ellipse** fit shows the correlation coefficient for the X and Y variables.

<table>

Nonpar Density

When a plot shows thousands of points, the mass of points can be too dark to show patterns in density. Using the Nonpar Density (nonparametric density) option makes it easier to see the patterns.

Nonpar Density estimates a smooth nonparametric bivariate surface that describes the density of data points. The plot adds a set of contour lines showing the density (Figure 5.16). The contour lines are quantile contours in 5% intervals. This means that about 5% of the points generated from the estimated nonparametric distribution are below the lowest contour, 10% are below the next contour, and so on. The highest contour has about 95% of the points below it.

Figure 5.16  Example of Nonpar Density

To change the size of a nonparametric density contour grid, press Shift and select **Nonpar Density** from the Bivariate red triangle menu. Enter a larger value than the default 102 points.

For more information about the options in the Quantile Density Contours menu, see “Fitting Menus” on page 144.

Quantile Density Contours Report

The Quantile Density Contours report shows the standard deviations used in creating the nonparametric density.
Group By

Using the Group By option, you can select a classification (grouping) variable. When a grouping variable is in effect, the Bivariate platform computes a separate analysis for each level of the grouping variable. The scatterplot shows the fitted models (lines, curves, contours, or ellipses) for each grouping variable. The fit for each level of the grouping variable is identified beneath the scatterplot, with individual pop-up menus.

When a grouping variable is in effect, the Group By option is checked in the Bivariate Fit red triangle menu. You can change the grouping variable by first selecting the Group By option to remove (uncheck) the existing variable. Then, select the Group By option again and respond to its window as before.

The Group By option enables you to generate separate analyses by a grouping variable while plotting the fits on the same scatterplot. This enables you to visually compare the fits across groups.

Note: For examples of this option, see “Example of Group By Using Density Ellipses” on page 155 and “Example of Group By Using Regression Lines” on page 156.

Fitting Menus

In addition to a report, each fitting option adds a fitting menu to the report window. The following table shows the fitting menus that correspond to each fitting option.

<table>
<thead>

Fitting Menu Options

The Fitting menu options depend on the selected fit.

- “Options That Apply to Most Fits” on page 145
- “Options That Apply to Multiple Fits” on page 146
- “Options That Apply to Bivariate Normal Ellipse” on page 147
- “Options That Apply to Quantile Density Contours” on page 147

Options That Apply to Most Fits

**Line of Fit**  Displays or hides the line or curve describing the model fit. For the Bivariate Normal Ellipse report, this option shows or hides the ellipse representing the contour border. Not applicable for Quantile Density Contours.

**Line Color**  Lets you select from a palette of colors for assigning a color to each fit. Not applicable for Quantile Density Contours.

**Line Style**  Lets you select from the palette of line styles for each fit. Not applicable for Quantile Density Contours.

**Line Width**  Lets you change the line widths for the line of fit. The default line width is the thinnest line. Not applicable for Quantile Density Contours.

**Report**  Turns the fit’s report on and off. Does not modify the Bivariate plot.

**Remove Fit**  Removes the fit from the graph and removes its report.
Options That Apply to Multiple Fits

Confid Curves Fit  Displays or hides the confidence limits for the expected value (mean). This option is not available for the Fit Spline, Density Ellipse, Fit Each Value, and Fit Orthogonal fits and is dimmed on those menus.

Confid Curves Indiv  Displays or hides the confidence limits for an individual predicted value. The confidence limits reflect variation in the error and variation in the parameter estimates. This option is not available for the Fit Mean, Fit Spline, Density Ellipse, Fit Each Value, and Fit Orthogonal fits and is dimmed on those menus.

Save Predicteds  Creates a new column in the current data table called Predicted colname where colname is the name of the Y variable. This column includes the prediction formula and the computed sample predicted values. The prediction formula computes values automatically for rows that you add to the table. This option is not available for the Fit Each Value and Density Ellipse fits and is dimmed on those menus.

You can use the Save Predicteds and Save Residuals options for each fit. If you use these options multiple times or with a grouping variable, it is best to rename the resulting columns in the data table to reflect each fit.

Save Residuals  Creates a new column in the current data table called Residuals colname where colname is the name of the Y variable. Each value is the difference between the actual (observed) value and its predicted value. Unlike the Save Predicteds option, this option does not create a formula in the new column. This option is not available for the Fit Each Value and Density Ellipse fits and is dimmed on those menus.

You can use the Save Predicteds and Save Residuals options for each fit. If you use these options multiple times or with a grouping variable, it is best to rename the resulting columns in the data table to reflect each fit.

Save Studentized Residuals  Creates a new column in the data table containing the result of dividing the residual by the standard error of the residual.

Mean Confidence Limit Formula  Creates a new column in the data table containing a formula for the mean confidence intervals.

Indiv Confidence Limit Formula  Creates a new column in the data table containing a formula for the individual confidence intervals.

Plot Residuals (Linear, Polynomial, and Fit Special Only)  Produces five diagnostic plots: residual by predicted, actual by predicted, residual by row, residual by X, and a normal quantile plot of the residuals. See “Diagnostics Plots” on page 148.

Set α Level  Enables you to set the alpha level used in computing confidence bands for various fits.
**Confid Shaded Fit**  Draws the same curves as the **Confid Curves Fit** option and shades the area between the curves.

**Confid Shaded Indiv**  Draws the same curves as the **Confid Curves Indiv** option and shades the area between the curves.

**Save Coefficients**  Saves the spline coefficients as a new data table that contains columns named X, A, B, C, and D. The X column contains the knot points. A, B, C, and D are the intercept, linear, quadratic, and cubic coefficients of the third-degree polynomial. These coefficients span from the corresponding value in the X column to the next highest value.

**Options That Apply to Bivariate Normal Ellipse**

- **Shaded Contour**  Shades the area inside the density ellipse.
- **Select Points Inside**  Selects the points inside the ellipse.
- **Select Points Outside**  Selects the points outside the ellipse.

**Options That Apply to Quantile Density Contours**

- **Kernel Control**  Displays a slider for each variable, where you can change the standard deviation that defines the range of X and Y values for determining the density of contour lines.
- **5% Contours**  Shows or hides the 5% contour lines.
- **Contour Lines**  Shows or hides the 10% contour lines.
- **Contour Fill**  Fills the areas between the contour lines.
- **Color Theme**  Changes the color theme of the contour lines.
- **Select Points by Density**  Selects points that fall in a user-specified quantile range.
- **Color by Density Quantile**  Colors the points according to density.
- **Save Density Quantile**  Creates a new column containing the density quantile each point is in.

**Mesh Plot**  A three-dimensional plot of the density over a grid of the two analysis variables.
Figure 5.17  Example of a Mesh Plot

Modal Clustering  Creates a new column in the current data table and fills it with cluster values.

Note: If you save the modal clustering values first and then save the density grid, the grid table also contains the cluster values. The cluster values are useful for coloring and marking points in plots.

Save Density Grid  Saves the density estimates and the quantiles associated with them in a new data table. The grid data can be used to visualize the density in other ways, such as with the Scatterplot 3D or the Contour Plot platforms.

Diagnostics Plots

The Plot Residuals option creates residual plots and other plots to diagnose the model fit. The following plots are available:

Residual by Predicted Plot  A plot of the residuals versus the predicted values. A histogram of the residuals is also created.

Actual by Predicted Plot  A plot of the actual values versus the predicted values.

Residual by Row Plot  A plot of the residual values versus the row number.

Residual by X Plot  A plot of the residual values versus the X variable.

Residual Normal Quantile Plot  A Normal quantile plot of the residuals.
Additional Examples of the Bivariate Platform

These sections provide examples of different bivariate fits.

- "Example of the Fit Special Option"
- "Example of the Fit Orthogonal Option"
- "Example of the Fit Robust Command"
- "Example of Group By Using Density Ellipses"
- "Example of Group By Using Regression Lines"
- "Example of Grouping Using a By Variable"

Example of the Fit Special Option

This example shows you how to add transformations to your data. Start by transforming Y as log and X as square root:

1. Select Help > Sample Data Library and open SAT.jmp.
2. Select Analyze > Fit Y by X.
4. Select % Taking (2004) and click X, Factor.
5. Click OK.

Figure 5.18  Example of SAT Scores by Percent Taking

6. Click the Bivariate Fit red triangle and select Fit Special. The Specify Transformation or Constraint window appears. For a description of this window, see “Fit Special” on page 134.
Figure 5.19  The Specify Transformation or Constraint Window

7. Within Y Transformation, select **Natural Logarithm: log(y)**.
8. Within X Transformation, select **Square Root: sqrt(x)**.
9. Click **OK**.
Figure 5.20 Example of Fit Special Report

Figure 5.20 shows the fitted line plotted on the original scale. The model appears to fit the data well, as the plotted line goes through the cloud of points.
Example of the Fit Orthogonal Option

This example shows you how to standardize variables using the Distribution platform and then use the standardized variables to fit the orthogonal model.

Standardize the Variables

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Distribution.
4. Click OK.
5. Hold down the Ctrl key. Click the height red triangle and select Save > Standardized.
   Holding down the Ctrl key broadcasts the operation to all variables in the report window. Notice that in the Big Class.jmp sample data table, two new columns have been added.

Use the Standardized Variables to Fit the Orthogonal Model

1. From the Big Class.jmp sample data table, select Analyze > Fit Y by X.
2. Select Std weight and click Y, Response.
3. Select Std height and click X, Factor.
4. Click OK.
5. Click the red triangle next to Bivariate Fit of Std weight By Std height and select Fit Line.
6. Click the red triangle next to Bivariate Fit of Std weight By Std height and select Fit Orthogonal. Then select each of the following:
   - Equal Variances
   - Fit X to Y
   - Specified Variance Ratio and type 0.2.
   - Specified Variance Ratio and type 5.
The scatterplot in Figure 5.21 shows the standardized height and weight values with various line fits that illustrate the behavior of the orthogonal variance ratio selections. The standard linear regression (Fit Line) occurs when the variance of the \( X \) variable is considered to be very small. **Fit X to Y** is the opposite extreme, when the variation of the \( Y \) variable is ignored. All other lines fall between these two extremes and shift as the variance ratio changes. As the variance ratio increases, the variation in the \( Y \) response dominates and the slope of the fitted line shifts closer to the \( Y \) by \( X \) fit. Likewise, when you decrease the ratio, the slope of the line shifts closer to the \( X \) by \( Y \) fit.

**Example of the Fit Robust Command**

This example shows you how to fit a robust model using the Huber M-estimation method. The data in the Weight Measurements.jmp sample data table shows the height and weight measurements taken by 40 students.

1. Select **Help > Sample Data Library** and open Weight Measurements.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select weight and click **Y, Response**.
4. Select height and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Bivariate Fit of weight By height and select **Fit Line**.
7. Click the red triangle next to Bivariate Fit of weight By height and select **Robust > Fit Robust**.
If you look at the standard Analysis of Variance report, you might wrongly conclude that height and weight do not have a linear relationship, since the $p$-value is 0.1203. However, when you look at the Robust Fit report, you would probably conclude that they do have a linear relationship, because the $p$-value there is 0.0489. It appears that some of the measurements are unusually low, perhaps due to incorrect user input. These measurements were unduly influencing the analysis.
Example of Group By Using Density Ellipses

This example shows you how to use a grouping (By) variable and add density ellipses to your data. In the Hot Dogs.jmp sample data table, the Type column identifies three different types of hot dogs: beef, meat, or poultry. You want to group the three types of hot dogs according to their cost variables.

1. Select Help > Sample Data Library and open Hot Dogs.jmp.
2. Select Analyze > Fit Y by X.
3. Select $/oz and click Y, Response.
4. Select $/lb Protein and click X, Factor.
5. Click OK.
6. Click the red triangle next to Bivariate Fit of $/oz By $/lb Protein and select Group By.
7. From the list, select Type.
8. Click OK.
9. Click the red triangle next to Bivariate Fit of $/oz By $/lb Protein and select Density Ellipse > 0.90.

Color the points according to Type:
10. Right-click the scatterplot and select Row Legend.
11. Select Type in the column list and click OK.

Figure 5.23 Example of Group By

The ellipses in Figure 5.23 show clearly how the different types of hot dogs cluster with respect to the cost variables.
Example of Group By Using Regression Lines

This example shows you how to use a grouping variable to overlay regression lines to compare slopes of the different groups.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select height and click X, Factor.
5. Click OK.

To create the example on the left in Figure 5.24:
6. Click the red triangle next to Bivariate Fit of weight By height and select Fit Line.

To create the example on the right in Figure 5.24:
7. From the Linear Fit menu, select Remove Fit.
8. Click the red triangle next to Bivariate Fit of weight By height and select Group By.
9. From the list, select sex.
10. Click OK.
11. Click the red triangle next to Bivariate Fit of weight By height and select Fit Line.

**Figure 5.24**  Example of Regression Analysis for Whole Sample and Grouped Sample

The scatterplot to the left in Figure 5.24 has a single regression line that relates weight to height. The scatterplot to the right shows separate regression lines for males and females.
Example of Grouping Using a By Variable

This example shows another method of grouping by specifying a By variable in the launch window. This results in separate reports and graphics for each level of the By variable (or combinations of By variables).

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select weight and click **Y, Response**.
4. Select height and click **X, Factor**.
5. Select sex and click **By**.
6. Click **OK**.
7. Press Ctrl, click the red triangle menu next to Bivariate Fit of weight By height sex =F, and select **Fit Line** from the red triangle menu.
There are separate analyses for each level of the By variable (sex). So you see a scatterplot for the females and a scatterplot for the males.
Statistical Details for the Bivariate Platform

- “Fit Line”
- “Fit Spline”
- “Fit Orthogonal”
- “Summary of Fit Report”
- “Lack of Fit Report”
- “Parameter Estimates Report”
- “Smoothing Fit Reports”
- “Correlation Report”

Fit Line

The **Fit Line** option finds the parameters $\beta_0$ and $\beta_1$ for the straight line that fits the points to minimize the residual sum of squares. The model for the $i^{th}$ row is written $y_i = \beta_0 + \beta_1 x_i + \epsilon_i$.

A polynomial of degree 2 is a parabola; a polynomial of degree 3 is a cubic curve. For degree $k$, the model for the $i^{th}$ observation is defined as follows:

$$y_i = \sum_{j=0}^{k} \beta_j x_i^j + \epsilon_i$$

Fit Spline

The cubic spline method uses a set of third-degree polynomials spliced together such that the resulting curve is continuous and smooth at the splices (knot points). The estimation is done by minimizing an objective function that is a combination of the sum of squared errors and a penalty for curvature integrated over the curve extent. See the paper by Reinsch (1967) or the text by Eubank (1999) for a description of this method.

Fit Orthogonal

Standard least square fitting assumes that the $X$ variable is fixed and the $Y$ variable is a function of $X$ plus error. If there is random variation in the measurement of $X$, you should fit a line that minimizes the sum of the squared perpendicular differences (Figure 5.26). However, the perpendicular distance depends on how $X$ and $Y$ are scaled, and the scaling for the perpendicular is reserved as a statistical issue, not a graphical one.
The fit requires that you specify the ratio of the variance of the error in $Y$ to the error in $X$. This is the variance of the error, not the variance of the sample points, so you must choose carefully. The ratio $(\sigma_y^2)/(\sigma_x^2)$ is infinite in standard least squares because $\sigma_x^2$ is zero. If you do an orthogonal fit with a large error ratio, the fitted line approaches the standard least squares line of fit. If you specify a ratio of zero, the fit is equivalent to the regression of $X$ on $Y$, instead of $Y$ on $X$.

The most common use of this technique is in comparing two measurement systems that both have errors in measuring the same value. Thus, the $Y$ response error and the $X$ measurement error are both the same type of measurement error. Where do you get the measurement error variances? You cannot get them from bivariate data because you cannot tell which measurement system produces what proportion of the error. So, you either must blindly assume some ratio like 1, or you must rely on separate repeated measurements of the same unit by the two measurement systems.

An advantage to this approach is that the computations give you predicted values for both $Y$ and $X$; the predicted values are the point on the line that is closest to the data point, where closeness is relative to the variance ratio.

Confidence limits are calculated as described in Tan and Iglewicz (1999).

**Summary of Fit Report**

**RSquare**

Using quantities from the corresponding analysis of variance table, the RSquare for any continuous response fit is calculated as follows:

\[
\begin{align*}
\text{RSquare} & = \frac{\text{Sum of Squares for Model}}{\text{Sum of Squares for C. Total}}
\end{align*}
\]
RSquare Adj

The RSquare Adj is a ratio of mean squares instead of sums of squares and is calculated as follows:

\[
1 - \frac{\text{Mean Square for Error}}{\text{Mean Square for C. Total}}
\]

The mean square for Error is in the Analysis of Variance report (Figure 5.12). You can compute the mean square for C. Total as the Sum of Squares for C. Total divided by its respective degrees of freedom.

Lack of Fit Report

Pure Error DF

For the Pure Error DF, consider the cases where more than one observation has the same value for height. In general, if there are \( g \) groups having multiple rows with identical values for each effect, the pooled DF, denoted \( \text{DF}_p \), is defined as follows:

\[
\text{DF}_p = \sum_{i=1}^{g} (n_i - 1)
\]

where \( n_i \) is the number of observations in the \( i \)th group.

Pure Error SS

For the Pure Error SS, in general, if there are \( g \) groups having multiple rows with the same \( x \) value, the pooled SS, denoted \( \text{SS}_p \), is defined as follows:

\[
\text{SS}_p = \sum_{i=1}^{g} \text{SS}_i
\]

where \( \text{SS}_i \) is the sum of squares for the \( i \)th group corrected for its mean.

Max RSq

Because Pure Error is invariant to the form of the model and is the minimum possible variance, Max RSq is calculated as follows:

\[
1 - \frac{\text{SS(Pure error)}}{\text{SS(Total for whole model)}}
\]
Parameter Estimates Report

Std Beta

Std Beta is calculated as follows:

\[ \hat{\beta}(s_x/s_y) \]

where \( \hat{\beta} \) is the estimated parameter, \( s_x \) and \( s_y \) are the standard deviations of the X and Y variables.

Design Std Error

Design Std Error is calculated as the standard error of the parameter estimate divided by the RMSE.

Smoothing Fit Reports

R-Square is equal to 1-(SSE/C.Total SS), where C.Total SS is available in the Fit Line ANOVA report.

Correlation Report

The Pearson correlation coefficient is denoted \( r \), and is computed as follows:

\[ r_{xy} = \frac{s_{xy}}{\sqrt{s_x^2 s_y^2}} \quad \text{where} \quad s_{xy} = \frac{\sum w_i(x_i - \bar{x})(y_i - \bar{y})}{df} \]

Where \( w_i \) is either the weight of the \( i \)th observation if a weight column is specified, or 1 if no weight column is assigned.
Use the Oneway platform to explore how the distribution of a continuous Y variable differs across groups defined by a categorical X variable. You can use ANOVA, nonparametric tests, or multiple comparisons to evaluate differences in means across groups. Density and CDF plots enable you to visualize the distribution of your response by the X categories. For example, you might want to find out how different categories of the same type of drug (X) affect patient pain levels on a numerical scale (Y).

The Oneway platform is the *continuous by nominal or ordinal* personality of the Fit Y by X platform. The analysis results appear in a plot, and you can interactively add additional analyses, such as the following:

- a one-way analysis of variance to fit means and to test that they are equal
- nonparametric tests
- a test for homogeneity of variance
- multiple-comparison tests on means, with means comparison circles
- outlier box plots overlaid on each group
- power details for the one-way layout

Overview of Oneway Analysis

A one-way analysis of variance tests for differences between group means. The total variability in the response is partitioned into two parts: within-group variability and between-group variability. If the between-group variability is large relative to the within-group variability, then the differences between the group means are considered to be significant.

Example of Oneway Analysis

Learn how to perform a one-way analysis of variance in JMP to test if the differences in group means are significant. In this data, thirty-three participants were administered three different types of analgesics (A, B, and C). The participants were asked to rate their pain levels on a sliding scale. You want to find out if the means for A, B, and C are significantly different.

1. Select Help > Sample Data Library and open Analgesics.jmp.
2. Select Analyze > Fit Y by X.
4. Select drug and click X, Factor.
5. Click OK.

You notice that one drug (A) has consistently lower scores than the other drugs. You also notice that the x-axis ticks are unequally spaced. The length between the ticks is proportional to the number of scores (observations) for each drug.
Perform an analysis of variance on the data.

6. Click the red triangle next to Oneway Analysis of pain By drug and select **Means/Anova**.

**Note:** If the X factor has only two levels, the **Means/Anova** option appears as **Means/Anova/Pooled t**, and adds a Pooled t test report to the report window.

**Figure 6.3** Example of the Means/Anova Option

Note the following observations:

- Mean diamonds representing confidence intervals appear.
  - The line near the center of each diamond represents the group mean. At a glance, you can see that the mean for each drug looks significantly different.
  - The vertical span of each diamond represents the 95% confidence interval for the mean of each group.

See “Mean Diamonds and X-Axis Proportional” on page 180.

- The Summary of Fit table provides overall summary information about the analysis.
• The Analysis of Variance report shows the standard ANOVA information. You notice that the Prob > F (the p-value) is 0.0053, which supports your visual conclusion that there are significant differences between the drugs.

• The Means for Oneway Anova report shows the mean, sample size, and standard error for each level of the categorical factor.

Launch the Oneway Platform

To perform a one-way analysis of variance, do the following:

1. Select Analyze > Fit Y by X.
2. Enter a continuous column for Y, Response.
3. Enter a nominal or ordinal column for X, Factor.

Figure 6.4 The Fit Y by X Launch Window

The word Oneway appears above the diagram, to indicate that you are performing a one-way analysis.

Note: You can also launch a one-way analysis from the JMP Starter window. Select View > JMP Starter > Basic > Oneway.

For more information about this launch window, see the “Introduction to Fit Y by X” chapter on page 113. For more information about the options in the Select Columns red triangle menu, see Using JMP.
Specifying a Block variable identifies a second factor, which forms a two-way analysis without interaction. In the Oneway plot, the values of the Y variable are centered by the Block variable. If there are equal counts in each block by group cell, the available Oneway platform options are adapted to the two-way analysis setting. If there are unequal counts in the block by group cells, a Fit Model report is shown below the Oneway plot and the Oneway platform options are not available.

**Data Format**

The Oneway platform requires that each row contain information for one or more observations with the same level of the X variable. If a row represents more than one observation, you must use a Weight or Freq variable to indicate how many observations the row represents.

When one-way data are in a format other than a JMP data table, sometimes they are arranged so that a row contains information for multiple observations. To analyze the data in JMP, you must import the data and restructure it so that each row of the JMP data table contains information for a single observation. See “Example of Stacking Data for a Oneway Analysis” on page 232.

**The Oneway Plot**

The Oneway plot shows the response points for each X factor value. You can compare the distribution of the response across the levels of the X factor. The distinct values of X are sometimes called levels. If a Block variable is specified in the launch window, the values of the Y variable in the Oneway plot are centered by the Block variable.

Replace variables in the plot in one of two ways: swap existing variables by dragging and dropping a variable from one axis to the other axis; or, click a variable in the Columns panel of the associated data table and drag it onto an axis.

You can add reports, additional plots, and tests to the report window using the options in the red triangle menu for Oneway Analysis. See “Oneway Platform Options” on page 170.

To produce the plot shown in Figure 6.5, follow the instructions in “Example of Oneway Analysis” on page 166.
Figure 6.5 The Oneway Plot

Note: Any rows that are excluded in the data table are also hidden in the Oneway plot.

Oneway Platform Options

The Oneway platform red triangle menu contains graph and analyses options. These include ANOVA, nonparametric tests, and multiple comparisons methods to evaluate differences in means across groups. Density and CDF plots enable you to visualize the distribution of your response by the X categories. Many of these options are not available if a Block variable is specified in the launch window.

Note: The Fit Group menu appears if you have specified multiple Y or X variables. Menu options enable you to arrange reports or order them by RSquare. See Fitting Linear Models.

</tbody>
</table>
The red triangle menu for Oneway Analysis provides the following options. Some options might not appear unless specific conditions are met.

**Quantiles** Lists the following quantiles for each group:
- 0% (Minimum)
- 10%
- 25%
- 50% (Median)
- 75%
- 90%
- 100% (Maximum)

Activates **Box Plots** from the **Display Options** menu. See “Quantiles” on page 175.

**Means/Anova** Fits means for each group and performs a one-way analysis of variance to test if there are differences among the means. See “Means/Anova and Means/Anova/Pooled t” on page 176.

**Note:** If the X factor has two levels, the menu option changes to **Means/Anova/Pooled t** and produces a Pooled t test report assuming equal variances.

**Means and Std Dev** Gives summary statistics for each group. The standard errors for the means use individual group standard deviations rather than the pooled estimate of the standard deviation.

The plot now contains mean lines, error bars, and standard deviation lines. For a brief description of these elements, see “Display Options” on page 174. For more information about these elements, see “Mean Lines, Error Bars, and Standard Deviation Lines” on page 181.

**t test** (Available only if the X factor has two levels.) Produces a t test report assuming that the variances are not equal. See “The t Test Report” on page 177.

**Analysis of Means Methods** Provides five commands for performing Analysis of Means (ANOM) procedures. There are commands for comparing means, variances, and ranges. See “Analysis of Means Methods” on page 181.

**Compare Means** Provides multiple-comparison methods for comparing sets of group means. See “Compare Means” on page 185.

**Nonparametric** Provides nonparametric comparisons of group locations. See “Nonparametric Tests” on page 192.
Unequal Variances Perform four tests for equality of group variances. Also gives the Welch test, which is an ANOVA test for comparing means when the variances within groups are not equal. See “Unequal Variances” on page 199.

Equivalence Tests Tests that a difference is less than a specified threshold value. You can specify using a pooled variance or unequal variances for the variance assumption in the test. See “Equivalence Tests” on page 201.

Robust Provides two methods for reducing the influence of outliers on your data. See “Robust” on page 203.

Power Provides calculations of statistical power and other details about a given hypothesis test. See “Power” on page 204.

The Power Details window and reports also appear within the Fit Model platform. For further discussion and examples of power calculations, see Fitting Linear Models.

Set a Level You can select an option from the most common alpha levels or specify any level with the Other selection. Changing the alpha level results in the following actions:

– recalculates confidence limits
– adjusts the mean diamonds on the plot (if they are showing)
– modifies the upper and lower confidence level values in reports
– changes the critical number and comparison circles for all Compare Means reports
– changes the critical number for all Nonparametric Multiple Comparison reports

Normal Quantile Plot Provides the following options for plotting the quantiles of the data in each group:

Plot Actual by Quantile Appends a quantile plot to the Oneway Analysis plot. The quantile plot shares the Oneway Analysis vertical axis for the response variable. The cumulative probabilities for each group are on the horizontal axis. The plot shows quantiles computed within each level of the categorical X factor.

Plot Quantile by Actual Generates a quantile plot with the response variable on the horizontal axis and cumulative probabilities on the vertical axis. The plot shows quantiles computed within each level of the categorical X factor.

Line of Fit Shows or hides a reference line fit to the data for each level of the X variable.

Normal Quantile Label Shows or hides labels inside the right vertical axis of the Normal Quantile Plot and inside the top axis of the Actual by Quantile plot. The labels represent the normal quantile scale.

CDF Plot Plots the cumulative distribution function for all of the groups in the Oneway report. See “CDF Plot” on page 206.
Densities  Compares densities across groups. See “Densities” on page 206.

Matching Column  Specify a matching variable to perform a matching model analysis. Use this option when the data in your Oneway analysis comes from matched (paired) data, such as when observations in different groups come from the same participant.

The plot now contains matching lines that connect the matching points. See “Matching Column” on page 207.

Save  Saves the following quantities as new columns in the current data table:

Save Residuals  Saves values computed as the response variable minus the mean of the response variable within each level of the factor variable.

Save Standardized  Saves standardized values of the response variable computed within each level of the factor variable. This is the centered response divided by the standard deviation within each level.

Save Normal Quantiles  Saves normal quantile values computed within each level of the categorical factor variable.

Save Predicted  Saves the predicted mean of the response variable for each level of the factor variable.

Display Options  Adds or removes elements from the plot. See “Display Options” on page 174.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Display Options

Using Display Options, you can add or remove elements from the Oneway data plot. Some options might not appear unless they are relevant.

**All Graphs**  Shows or hides all graphs.

**Points**  Shows or hides data points on the plot.

**Box Plots**  Shows or hides outlier box plots for each group. For an example, see “Conduct the Oneway Analysis” on page 236.

**Mean Diamonds**  Draws a horizontal line through the mean of each group proportional to its horizontal axis. The top and bottom points of the mean diamond show the upper and lower 95% confidence points for each group. See “Mean Diamonds and X-Axis Proportional” on page 180.

**Mean Lines**  Draws a line at the mean of each group. See “Mean Lines, Error Bars, and Standard Deviation Lines” on page 181.

**Mean CI Lines**  Draws lines at the upper and lower 95% confidence levels for each group.

**Mean Error Bars**  Identifies the mean of each group and shows error bars one standard error above and below the mean. See “Mean Lines, Error Bars, and Standard Deviation Lines” on page 181.

**Grand Mean**  Draws the overall mean of the Y variable on the plot.

**Std Dev Lines**  Shows lines one standard deviation above and below the mean of each group. See “Mean Lines, Error Bars, and Standard Deviation Lines” on page 181.

**Comparison Circles**  Shows or hides comparison circles. This option is available only when one of the **Compare Means** options is selected. See “Comparison Circles” on page 238. For an example, see “Conduct the Oneway Analysis” on page 236.

**Connect Means**  Connects the group means with a straight line.

**Mean of Means**  Draws a line at the mean of the group means.

**X-Axis proportional**  Makes the spacing on the x-axis proportional to the sample size of each level. See “Mean Diamonds and X-Axis Proportional” on page 180.

**Points Spread**  Spreads points over the width of the interval

**Points Jittered**  Adds small spaces between points that overlay on the same y value. The horizontal adjustment of points varies from 0.375 to 0.625 with a $4 \times \text{Uniform}(0,1)-0.5$ distribution.
Matching Lines  (Appears only when the Matching Column option is selected.) Connects matching points.

Matching Dotted Lines  (Appears only when the Matching Column option is selected.)
Draws dotted lines to connect cell means from missing cells in the table. The values used as the endpoints of the lines are obtained using a two-way ANOVA model.

Histograms  Draws side-by-side histograms to the right of the original plot.

Robust Mean Lines  (Appears only when a Robust option is selected.) Draws a line at the robust mean of each group.

Legend  Displays a legend for the Normal Quantile Plot, CDF Plot, and Densities options.

Quantiles

The Quantiles report lists selected percentiles for each level of the X factor variable. The median is the 50th percentile, and the 25th and 75th percentiles are called the quartiles.

The Quantiles option adds the following elements to the plot:

• the grand mean representing the overall mean of the Y variable
• outlier box plots summarizing the distribution of points at each factor level

Figure 6.6 Outlier Box Plot and Grand Mean

Note: To hide these elements, click the red triangle next to Oneway Analysis and select Display Options > Box Plots or Grand Mean.

Outlier Box Plots

The outlier box plot is a graphical summary of the distribution of data. Note the following aspects about outlier box plots (Figure 6.7):

• The horizontal line within the box represents the median sample value.
• The ends of the box represent the 75th and 25th quantiles, also expressed as the 3rd and 1st quartile, respectively.
• The difference between the 1st and 3rd quartiles is called the interquartile range.
• Each box has lines, sometimes called whiskers, that extend from each end. The whiskers extend from the ends of the box to the outermost data point that falls within these distances:
  \[
  3\text{rd quartile} + 1.5*(\text{interquartile range})
  \]
  \[
  1\text{st quartile} - 1.5*(\text{interquartile range})
  \]

If the data points do not reach the computed ranges, then the whiskers are determined by the upper and lower data point values (not including outliers).

Figure 6.7 Examples of Outlier Box Plots

Means/Anova and Means/Anova/Pooled t

The Means/Anova option performs an analysis of variance. If the X factor contains exactly two levels, this option appears as Means/Anova/Pooled t. In addition to the other reports, a Pooled t test report assuming pooled (or equal) variances appears.

Mean diamonds are added to the Oneway plot  See “Display Options” on page 174 and “Mean Diamonds and X-Axis Proportional” on page 180.

The $t$ Test Report

There are two types of $t$ tests: equal variances and unequal variances.

- If you select the \texttt{Means/Anova/Pooled t} option, a Pooled $t$ Test report appears. This $t$ test assumes equal variances.
- If you select the \texttt{t Test} option from the red triangle menu, a $t$ test report appears. This $t$ test assumes unequal variances.
The t Test report contains the following columns:

**t Test plot**  Shows the sampling distribution of the difference in the means, assuming that the null hypothesis is true. The vertical red line is the actual difference in the means. The shaded areas correspond to the p-values.

**Difference**  Shows the estimated difference between the two X levels. In the plots, the Difference value appears as a red line that compares the two levels.

**Std Err Dif**  Shows the standard error of the difference.

**Upper CL Dif**  Shows the upper confidence limit for the difference.

**Lower CL Dif**  Shows the lower confidence limit for the difference.

**Confidence**  Shows the level of confidence (1-alpha). To change the level of confidence, select a new alpha level from the **Set α Level** command from the platform red triangle menu.

**t Ratio**  Value of the t-statistic.

**DF**  The degrees of freedom used in the t test.

**Prob > |t|**  The p-value associated with a two-tailed test.

**Prob > t**  The p-value associated with an upper-tailed test.

**Prob < t**  The p-value associated with a lower-tailed test.

The Analysis of Variance Report

The Analysis of Variance report partitions the total variation of a sample into two components. The ratio of the two mean squares forms the F ratio. If the probability associated with the F ratio is small, then the model is a better fit statistically than the overall response mean.

Note: If you specified a **Block** column, then the Analysis of Variance report includes the **Block** variable.

**Source**  Lists the three sources of variation. These sources are the model source, **Error**, and **C. Total** (corrected total).

**DF**  Records an associated degrees of freedom (DF for short) for each source of variation:

- The degrees of freedom for **C. Total** are N - 1, where N is the total number of observations used in the analysis.
- If the X factor has k levels, then the model has k - 1 degrees of freedom.

The **Error** degrees of freedom is the difference between the **C. Total** degrees of freedom and the **Model** degrees of freedom (in other words, N - k).
**Sum of Squares** Records a sum of squares (SS for short) for each source of variation:

- The total (C. Total) sum of squares of each response from the overall response mean. The C. Total sum of squares is the base model used for comparison with all other models.

- The sum of squared distances from each point to its respective group mean. This is the remaining unexplained Error (residual) SS after fitting the analysis of variance model. The total SS minus the error SS gives the sum of squares attributed to the model. This tells you how much of the total variation is explained by the model.

**Mean Square** Is a sum of squares divided by its associated degrees of freedom:

- The Model mean square estimates the variance of the error, but only under the hypothesis that the group means are equal.

- The Error mean square estimates the variance of the error term independently of the model mean square and is unconditioned by any model hypothesis.

**F Ratio** The model mean square divided by the error mean square. If the hypothesis that the group means are equal (there is no real difference between them) is true, then both the mean square for error and the mean square for model estimate the error variance. Their ratio has an \( F \) distribution. If the analysis of variance model results in a significant reduction of variation from the total, the \( F \) ratio is higher than expected.

**Prob>F** Probability of obtaining an \( F \) value greater than the one calculated if there is no difference in the population group means. Observed significance probabilities of 0.05 or less are often considered evidence that there are differences in the group means.

### The Means for Oneway Anova Report

The Means for Oneway Anova report summarizes response information for each level of the nominal or ordinal factor.

**Level** Lists the levels of the X variable.

**Number** Lists the number of observations in each group.

**Mean** Lists the mean of each group.

**Std Error** Lists the estimates of the standard deviations for the group means. This standard error is estimated assuming that the variance of the response is the same in each level. It is the root mean square error found in the Summary of Fit report divided by the square root of the number of values used to compute the group mean.

**Lower 95% and Upper 95%** Lists the lower and upper 95% confidence interval for the group means.
The Block Means Report

If you have specified a Block variable on the launch window, the **Means/Anova** and **Means/Anova/Pooled t** commands produce a Block Means report. This report shows the means for each block and the number of observations in each block.

Mean Diamonds and X-Axis Proportional

A mean diamond illustrates a sample mean and confidence interval.

**Figure 6.8 Examples of Mean Diamonds and X-Axis Proportional Options**

Note the following observations:

- The top and bottom of each diamond represent the (1-alpha)x100 confidence interval for each group. The confidence interval computation assumes that the variances are equal across observations. Therefore, the height of the diamond is proportional to the reciprocal of the square root of the number of observations in the group.

- If the **X-Axis proportional** option is selected, the horizontal extent of each group along the horizontal axis (the horizontal size of the diamond) is proportional to the sample size for each level of the X variable. Therefore, the narrower diamonds are usually taller, because fewer data points results in a wider confidence interval.

- The mean line across the middle of each diamond represents the group mean.

- Overlap marks appear as lines above and below the group mean. For groups with equal sample sizes, overlapping marks indicate that the two group means are not significantly different at the given confidence level. Overlap marks are computed as group mean $\pm \frac{(\sqrt{2})}{2} \times CI/2$. Overlap marks in one diamond that are closer to the mean of another diamond than that diamond’s overlap marks indicate that those two groups are not different at the given confidence level.
The mean diamonds automatically appear when you select the **Means/Anova/Pooled t** or **Means/Anova** option from the platform menu. However, you can show or hide them at any time by selecting **Display Options > Mean Diamonds** from the red triangle menu.

**Mean Lines, Error Bars, and Standard Deviation Lines**

Show mean lines by selecting **Display Options > Mean Lines**. Mean lines indicate the mean of the response for each level of the X variable.

Mean error bars and standard deviation lines appear when you select the **Means and Std Dev** option from the red triangle menu. To turn each option on or off singly, select **Display Options > Mean Error Bars** or **Std Dev Lines**.

**Analysis of Means Methods**

Analysis of means (ANOM) is a multiple comparison method for means, proportions, or variances. You might want to use these ANOM under these circumstances:

- to test whether any of the group means are statistically different from the overall (sample) mean
- to test whether any of the group standard deviations are statistically different from the root mean square error (RMSE)
- to test whether any of the group ranges are statistically different from the overall mean of the ranges

**Note:** Within the Contingency platform, you can use the **Analysis of Means for Proportions** when the response has two categories. See the “Contingency Analysis” chapter on page 247.

For a description of ANOM methods and to see how JMP implements ANOM, see the book by Nelson et al. (2005).
Note: If you specify a Block variable in the launch window and there are equal counts for each combination of Block and X variable level, the ANOM chart is the only Analysis of Means chart available. If you specify a Block variable in the launch window and there are unequal counts, none of the Analysis of Means options are available.

Analysis of Means for Location

You can test whether groups have a common mean or center value using the following options:

- ANOM
- ANOM with Transformed Ranks

ANOM

Use ANOM to compare group means to the overall mean. This method assumes that your data are approximately normally distributed. See “Example of an Analysis of Means Chart” on page 208.

ANOM with Transformed Ranks

This is the nonparametric version of the ANOM analysis. Use this method if your data is clearly non-normal and cannot be transformed to normality. ANOM with Transformed Ranks compares each group’s mean transformed rank to the overall mean transformed rank. The ANOM test involves applying the usual ANOM procedure and critical values to the transformed observations.

Transformed Ranks

Suppose that there are \( n \) observations. The transformed observations are computed as follows:

- Rank all observations from smallest to largest, accounting for ties. For tied observations, assign each one the average of the block of ranks that they share.
- Denote the ranks by \( R_1, R_2, ..., R_n \).
- The transformed rank corresponding to the \( i \)th observations is:

\[
\text{Transformed } R_i = \text{Normal Quantile} \left[ \frac{R_i}{2n + 1} + 0.5 \right]
\]

The ANOM procedure is applied to the values Transformed \( R_i \). Since the ranks have a uniform distribution, the transformed ranks have a folded normal distribution. See Nelson et al. (2005).
Analysis of Means for Scale

You can test for homogeneity of variation within groups using the following options:

- ANOM for Variances
- ANOM for Variances with Levene (ADM)
- ANOM for Ranges

ANOM for Variances

Use this method to compare group standard deviations (or variances) to the root mean square error (or mean square error). This method assumes that your data is approximately normally distributed. To use this method, each group must have at least four observations. For more information about the ANOM for Variances test, see Wludyka and Nelson (1997) and Nelson et al. (2005). For an example, see “Example of an Analysis of Means for Variances Chart” on page 209.

ANOM for Variances with Levene (ADM)

This method provides a robust test that compares the group means of the absolute deviations from the median (ADM) to the overall mean ADM. Use ANOM for Variances with Levene (ADM) if you suspect that your data is non-normal and cannot be transformed to normality. ANOM for Variances with Levene (ADM) is a nonparametric analog of the ANOM for Variances analysis. For more information about the ANOM for Variances with Levene (ADM) test, see Levene (1960) or Brown and Forsythe (1974).

ANOM for Ranges

Use this test to compare group ranges to the mean of the group ranges. This is a test for scale differences based on the range as the measure of spread. See Wheeler (2003).

Note: ANOM for Ranges is available only for balanced designs and specific group sizes. See “Restrictions for ANOM for Ranges Test” on page 183.

Restrictions for ANOM for Ranges Test

Unlike the other ANOM decision limits, the decision limits for the ANOM for Ranges chart uses only tabled critical values. For this reason, ANOM for Ranges is available only for the following:

- groups of equal sizes
- groups specifically of the following sizes: 2–10, 12, 15, and 20
- number of groups between 2 and 30
• alpha levels of 0.10, 0.05, and 0.01

**Analysis of Means Charts**

Each Analysis of Means Methods option adds a decision chart to the report window that shows the following:

- an upper decision limit (UDL)
- a lower decision limit (LDL)
- a horizontal (center) line that falls between the decision limits; the center line position is determined by the chart type:
  - ANOM: the overall mean
  - ANOM with Transformed Ranks: the overall mean of the transformed ranks
  - ANOM for Variances: the root mean square error (or MSE when in variance scale)
  - ANOM for Variances with Levene (ADM): the overall absolute deviation from the mean
  - ANOM for Ranges: the mean of the group ranges

If a group’s plotted statistic falls outside of the decision limits, then the test indicates that there is a statistical difference between that group’s statistic and the overall average of the statistic for all the groups.

**Analysis of Means Options**

Each Analysis of Means Methods option adds an Analysis of Means red triangle menu to the report window.

**Set Alpha Level**  Select an option from the most common alpha levels or specify any level with the *Other* selection. Changing the alpha level modifies the upper and lower decision limits.

**Note:** For ANOM for Ranges, only the selections 0.10, 0.05, and 0.01 are available.

**Show Summary Report**  The reports are based on the Analysis of Means method:

- For ANOM, creates a report showing group means and decision limits.
- For ANOM with Transformed Ranks, creates a report showing group mean transformed ranks and decision limits.
- For ANOM for Variances, creates a report showing group standard deviations (or variances) and decision limits.
– For ANOM for Variances with Levene (ADM), creates a report showing group mean ADMs and decision limits.
– For ANOM for Ranges, creates a report showing group ranges and decision limits.

**Graph in Variance Scale**  (Available only for ANOM for Variances.) Changes the scale of the vertical axis from standard deviations to variances.

**Display Options**  Contains the following options to customize the display:

- **Show Decision Limits**  Shows or hides decision limit lines.
- **Show Decision Limit Shading**  Shows or hides decision limit shading.
- **Show Center Line**  Shows or hides the center line statistic.
- **Point Options: Show Needles**  Shows the needles. This is the default option. **Show Connected Points**  shows a line connecting the means for each group. **Show Only Points**  shows only the points representing the means for each group.

## Compare Means

Use the Compare Means options to perform multiple comparisons of group means. Methods include the Tukey-Kramer all pairs test and the Dunnett’s multiple comparison test with a control. All of these methods use pooled variance estimates for the means. Each Compare Means option, except for the Each Pair Stepwise, Newman-Keuls method, adds comparison circles next to the plot and specific reports to the report window. For more information about comparison circles, see “Using Comparison Circles” on page 187.

**Note:**  Another method for comparing means is ANOM. See “Analysis of Means Methods” on page 181.

<td>Tests whether there are differences between the means using the Studentized range test in a stepwise procedure. This is the Newman-Keuls or Student-Newman-Keuls method (<a href="https://en.wikipedia.org/wiki/F.J._Keuls">Keuls</a> 1952). This test is less conservative than a Tukey HSD test. See “Each Pair Stepwise, Newman-Keuls” on page 190.</td>
<td>none</td>
</tr>
</tbody>
</table>

**Note:** If you have specified a **Block** column, then the multiple comparison methods are performed on data that has been adjusted for the Block means.

For an example showing all of these tests, see “Example Contrasting Four Compare Means Tests” on page 217.
Using Comparison Circles

Each multiple comparison test, except for the Each Pair Stepwise, Newman-Keuls method, begins with a comparison circles plot, which is a visual representation of group mean comparisons. Figure 6.10 shows the comparison circles for the All Pairs, Tukey HSD method. Other comparison tests lengthen or shorten the radii of the circles.

**Note:** To permanently hide the comparison circles plot, select File > Preferences > Platforms > Oneway and deselect the Comparison Circles option.

**Figure 6.10** Visual Comparison of Group Means

Compare each pair of group means visually by examining the intersection of the comparison circles. The outside angle of intersection tells you whether the group means are significantly different (Figure 6.11).

- Circles for means that are significantly different either do not intersect, or intersect slightly, so that the outside angle of intersection is less than 90 degrees.
- If the circles intersect by an angle of more than 90 degrees, or if they are nested, the means are not significantly different.

**Figure 6.11** Angles of Intersection and Significance
If the intersection angle is close to 90 degrees, you can verify whether the means are significantly different by clicking on the comparison circle to select it (Figure 6.12). To deselect circles, click in the white space outside the circles.

**Figure 6.12** Highlighting Comparison Circles

Groups that are different from the selected group appear as thick gray circles.

Groups that are not different from the selected group appear as thin red circles.

The selected group appears as a thick red circle.

Related Information

- “Comparison Circles” on page 238

**Each Pair, Student’s t**

The Each Pair, Student’s t test shows the Student’s t test for each pair of group levels and tests only individual comparisons. For an example of this test, see “Example of the Each Pair, Student’s t Test” on page 210.

**All Pairs, Tukey HSD**

The All Pairs, Tukey HSD test (also called Tukey-Kramer) protects the significance tests of all combinations of pairs, and the HSD intervals become greater than the Student’s t pairwise LSDs. Graphically, the comparison circles become larger and differences are less significant.

The q statistic is calculated as $q^* = (1/\sqrt{2}) \times q$ where $q$ is the required percentile of the studentized range distribution. For an example of this test, see “Example of the All Pairs, Tukey HSD Test” on page 212.

**With Best, Hsu MCB**

The With Best, Hsu MCB test determines whether the mean for a given level exceeds the maximum mean of the remaining levels, or is smaller than the minimum mean of the remaining levels. See Hsu (1996). For an example of this test, see “Example of the With Best, Hsu MCB Test” on page 214.
The quantiles for the Hsu MCB test vary by the level of the categorical variable. Unless the sample sizes are equal across levels, the comparison circle technique is not exact. The radius of a comparison circle is given by the standard error of the level multiplied by the largest quantile value. Use the \( p \)-values of the tests to obtain precise assessments of significant differences. See “Comparison with Max and Min” on page 189.

**Note:** Means that are not regarded as the maximum or the minimum by MCB are also the means that are not contained in the selected subset of Gupta (1965) of potential maximums or minimum means.

### Confidence Quantile

This report gives the quantiles for each level of the categorical variable. These correspond to the specified value of Alpha.

### Comparison with Max and Min

The report shows \( p \)-values for one-sided Dunnett tests. For each level other than the best, the \( p \)-value given is for a test that compares the mean of the sample best level to the mean of each remaining level treated as a control (potentially best) level. The \( p \)-value for the sample best level is obtained by comparing the mean of the second sample best level to the mean of the sample best level treated as a control.

The report shows three columns.

**Level**  The level of the categorical variable.

**with Max p-Value**  For each level of the categorical variable, this column gives a \( p \)-value for a test that the mean of that level exceeds the maximum mean of the remaining levels. Use the tests in this column to screen out levels whose means are significantly smaller than or equal to the (unknown) largest true mean.

**with Min p-Value**  For each level of the categorical variable, this column gives a \( p \)-value for a test that the mean of that level is smaller than the minimum mean of the remaining levels. Use the tests in this column to screen out levels whose means are significantly greater than or equal to the (unknown) smallest true mean.

### LSD Threshold Matrix

The first report shown is for the maximum and the second is for the minimum.

For the maximum report, a column shows the row mean minus the column mean minus the LSD. If a value is positive, the row mean is significantly higher than the mean for the column, and the mean for the column is not the maximum.
For the *minimum* report, a column shows the row mean minus the column mean plus the LSD. If a value is negative, the row mean is significantly less than the mean for the column, and the mean for the column is not the minimum.

**With Control, Dunnett’s**

The *With Control, Dunnett’s* test compares a set of means against the mean of a control group. The LSDs that it produces are between the Student’s t and Tukey-Kramer LSDs, because they are sized to refrain from an intermediate number of comparisons. For an example of this test, see “Example of the With Control, Dunnett’s Test” on page 215.

In the Dunnett’s report, the $|d|$ quantile appears, and can be used in a manner similar to a Student’s t-statistic. The LSD threshold matrix shows the absolute value of the difference minus the LSD. If a value is positive, its mean is more than the LSD apart from the control group mean and is therefore significantly different.

**Each Pair Stepwise, Newman-Keuls**

The *Each Pair Stepwise, Newman-Keuls* test compares the sample means using an iterative, stepwise procedure. At each iteration, Tukey’s HSD test is used to test the difference between two group means. For an example of this test, see “Example of the Each Pair Stepwise, Newman-Keuls Test” on page 217.

**Caution:** The Newman-Keuls test does not control the family-wise error rate. Use caution when interpreting the results of this procedure.

The following procedure is used for testing $J$ group means:

Define the following:

- $J =$ number of groups (sorted in ascending order of group means)
- $N =$ number of observations
- $d =$ degrees of freedom, calculated as $N - J$
- $i =$ index of smallest group mean involved in a comparison
- $j =$ index of largest group mean involved in a comparison
- $k =$ minimum value of $j$ in any comparison during the procedure

At the beginning of the procedure, set $i = 1$, $j = J$, and $k = 2$.

1. Perform Tukey’s HSD test for groups $i$ and $j$, where the number of groups for finding the appropriate quantile equals $j - i + 1$.
   - If the test is significant, groups $i$ and $j$ are determined to be significantly different. Decrease $j$ by 1.
If this causes $j$ to be less than $k$, then increase $i$ by 1, set $k = \max(i, j) + 1$, set $j = J$, and continue to step 2.

If this causes $j$ to be greater than or equal to $k$, then continue to step 2.

- If the test is not significant, groups $i$ and $j$ are not determined to be significantly different. Increase $i$ by 1, set $k = j + 1$, set $j = J$, and continue to step 2.

2. Determine whether the procedure continues or stops based on the value of $k$.

- If $k$ is greater than $i$ and $k$ is less than or equal to $J$, repeat step 1.
- If $k$ is less than or equal to $i$ or $k$ is greater than $J$, stop the procedure. Any remaining untested ranges are deemed not to be significantly different.

The quantile used for Tukey’s HSD is different for each test and is based on the number of group means between the sorted means being tested. In the Newman-Keuls report, the Smallest Quantile Considered (labeled Smallest $q^*$) is the smallest studentized range quantile used in the above procedure divided by the square root of 2.

The test results are reported in the Connecting Letters Report.

For more information about the Newman-Keuls test, see Howell (2013).

\textbf{Note:} There are no mean circles added to the Comparison Circles graph when you use the Each Pair Stepwise, Newman-Keuls test. This is because each comparison has a different cut-off depending on the number of means between the two means being tested. Therefore, each circle would be a different size.

\section*{Compare Means Options}

The Means Comparisons reports contain a red triangle menu with the following options:

\begin{itemize}
  \item \textbf{Difference Matrix} \quad Shows or hides a table of all differences of means.
  \item \textbf{Confidence Quantile} \quad Shows or hides the critical value(s) and significance level ($\alpha$) used for the means comparison procedure.
  \item \textbf{LSD Threshold Matrix} \quad (Not available for the Newman-Keuls test.) Shows or hides a matrix of pairwise differences of means minus the least significant difference for those means. A positive value indicates a pair of means that are significantly different.
  \item \textbf{Connecting Letters Report} \quad (Available only for the Student’s $t$, Tukey’s HSD, and the Newman-Keuls tests.) Shows or hides the traditional letter-coded report where means that do not share a letter are significantly different.
  \item \textbf{Ordered Differences Report} \quad (Available only for the Student’s $t$ and Tukey’s HSD tests.) Shows or hides all pairwise positive-side differences, standard error of the difference, confidence intervals, $p$-values, and a plot of the magnitude of the difference with overlaid
confidence intervals. Confidence intervals that do not fully contain their corresponding difference bar indicate means that are significantly different from each other.

**Detailed Comparisons Report** (Available only for the Student’s t test.) Shows or hides a detailed report for each comparison. Each section shows the difference between the levels, standard error and confidence intervals, t-ratios, p-values, and degrees of freedom. A plot illustrating the comparison appears on the right of each report.

## Nonparametric Tests

Nonparametric tests are useful when the usual analysis of variance assumption of normality is not viable. The Nonparametric options provide several methods for testing the hypothesis of equal means or medians across groups. Nonparametric multiple comparison procedures are also available to control the overall error rate for pairwise comparisons. Nonparametric tests use functions of the response ranks, called rank scores. See Hajek (1969) and SAS Institute Inc. (2020a).

**Note:** If you specify a Block variable in the launch window and there are equal counts for each combination of Block and X variable level, the Friedman Rank Test is the only Nonparametric option available. If you specify a Block variable in the launch window and there are unequal counts, none of the Nonparametric options are available.

Note the following:

- For the Wilcoxon, Median, Van der Waerden, and Friedman Rank tests, if the X factor has more than two levels, a chi-square approximation to the one-way test is performed.
- If you specify a Block column, the nonparametric tests (except for the Friedman Rank Test) are conducted on data values that are centered using the block means.

**Wilcoxon Test** Performs a test based on Wilcoxon rank scores. The Wilcoxon rank scores are the simple ranks of the data. The Wilcoxon test is the most powerful rank test for errors with logistic distributions. If the factor has more than two levels, the Kruskal-Wallis test is performed. For information about the report, see “The Wilcoxon, Median, Van der Waerden, and Friedman Rank Test Reports” on page 193. For an example, see “Example of the Nonparametric Wilcoxon Test” on page 218.

The Wilcoxon test is also called the Mann-Whitney test.

**Median Test** Performs a test based on Median rank scores. The Median rank scores are either 1 or 0, depending on whether a rank is above or below the median rank. The Median test is the most powerful rank test for errors with double-exponential distributions. For information about the report, see “The Wilcoxon, Median, Van der Waerden, and Friedman Rank Test Reports” on page 193.
The Wilcoxon, Median, Van der Waerden, and Friedman Rank Test Reports

For each test, the report shows the descriptive statistics followed by the test results. Test results appear in the 1-Way Test, ChiSquare Approximation report and, if the X variable has exactly two levels, a 2-Sample Test, Normal Approximation report also appears. The descriptive statistics are the following:

- **Level**: The levels of X.
- **Count**: The frequencies of each level.
- **Score Sum**: The sum of the rank score for each level.
- **Expected Score**: The expected score under the null hypothesis that there is no difference among class levels.
Score Mean  The mean rank score for each level.

(Mean-Mean0)/Std0  The standardized score. Mean0 is the mean score expected under the null hypothesis. Std0 is the standard deviation of the score sum expected under the null hypothesis. The null hypothesis is that the group means or medians are in the same location across groups.

2-Sample Test, Normal Approximation

When you have exactly two levels of X, a 2-Sample Test, Normal Approximation report appears. This report gives the following:

S  Gives the sum of the rank scores for the level with the smaller number of observations.

Z  Gives the test statistic for the normal approximation test. See “Two-Sample Normal Approximations” on page 243.

Prob>|Z|  Gives the p-value, based on a standard normal distribution, for the normal approximation test.

1-Way Test, ChiSquare Approximation

This report gives results for a chi-square test for location. See Conover (1999).

ChiSquare  Gives the values of the chi-square test statistic. See “One-Way ChiSquare Approximations” on page 244.

DF  Gives the degrees of freedom for the test.

Prob>ChiSq  Gives the p-value for the test. The p-value is based on a ChiSquare distribution with degrees of freedom equal to the number of levels of X minus 1.

2-Sample, Exact Test

If your data are sparse, skewed, or heavily tied, exact tests might be more suitable than approximations based on asymptotic behavior. When you have exactly two levels of X, JMP Pro computes test statistics for exact tests. Select Nonparametric > Exact Test and select the test of your choice. A 2-Sample: Exact Test report appears. This report gives the following:

S  Gives the sum of the rank scores for the observations in the smaller group. If the two levels of X have the same numbers of observations, then the value of S corresponds to the last level of X in the value ordering.

Prob ≤ S  Gives a one-sided p-value for the test.

Prob ≥ |S-Mean|  Gives a two-sided p-value for the test.
Kolmogorov-Smirnov Two-Sample Test Report

The Kolmogorov-Smirnov test is available only when X has exactly two levels. The report shows descriptive statistics followed by test results. The descriptive statistics are the following:

**Level**  The two levels of X.

**Count**  The frequencies of each level.

**EDF at Maximum**  For a level of X, gives the value of the empirical cumulative distribution function (EDF) for that level at the value of X for which the difference between the two EDFs is a maximum. For the row named Total, gives the value of the pooled EDF (the EDF for the entire data set) at the value of X for which the difference between the two EDFs is a maximum.

**Deviation from Mean at Maximum**  For each level, gives the value obtained by the following steps:
- Compute the difference between the EDF at Maximum for the given level and the EDF at maximum for the pooled data set (Total).
- Multiply this difference by the square root of the number of observations in that level, given as Count.

Kolmogorov-Smirnov Asymptotic Test

This report gives the details for the test.

**KS**  A Kolmogorov-Smirnov statistic computed as follows:

\[
KS = \max_j \left( \frac{1}{n} \sum_i n_i (F_i(x_j) - F(x_j))^2 \right)
\]

The formula uses the following notation:
- \(x_j, j = 1, ..., n\) are the observations
- \(n_i\) is the number of observations in the \(i\)th level of X
- \(F\) is the pooled cumulative empirical distribution function
- \(F_i\) is the cumulative empirical distribution function for the \(i\)th level of X

This version of the Kolmogorov-Smirnov statistic applies even when there are more than two levels of X. Note, however, that JMP performs the Kolmogorov-Smirnov analysis only when X has only two levels of X.

**KSa**  An asymptotic Kolmogorov-Smirnov statistic computed as \(KS \sqrt{n}\), where \(n\) is the total number of observations.
D = max|F1 - F2|  The maximum absolute deviation between the EDFs for the two levels. This is the version of the Kolmogorov-Smirnov statistic typically used to compare two samples.

Prob > D  The p-value for the test. This is the probability that D exceeds the computed value under the null hypothesis of no difference between the levels.

D+ = max(F1 - F2)  A one-sided test statistic for the alternative hypothesis that the level of the first group exceeds the level of the second group.

Prob > D+  The p-value for the test of D+.

D- = max(F2 - F1)  A one-sided test statistic for the alternative hypothesis that the level of the second group exceeds the level of the first group.

Prob > D-  The p-value for the test of D-.

**Kolmogorov-Smirnov Exact Test**

For the Kolmogorov-Smirnov exact test, the report gives the same statistics as does the asymptotic test, but the p-values are computed to be exact.

**Nonparametric Multiple Comparisons**

This option provides several methods for performing nonparametric multiple comparisons. These tests are based on ranks and, except for the Wilcoxon Each Pair test, control for the overall experimentwise error rate. For more information about these tests, see See Dunn (1964) and Hsu (1996). For information about the reports, see “Nonparametric Multiple Comparisons Procedures” on page 196.

**Nonparametric Multiple Comparisons Procedures**

**Wilcoxon Each Pair**  Performs the Wilcoxon test on each pair. This procedure does not control for the overall alpha level. This is the nonparametric version of the Each Pair, Student’s t option found on the Compare Means menu. See “Wilcoxon Each Pair, Steel-Dwass All Pairs, and Steel with Control” on page 197.

**Steel-Dwass All Pairs**  Performs the Steel-Dwass test on each pair. This is the nonparametric version of the All Pairs, Tukey HSD option found on the Compare Means menu. See “Wilcoxon Each Pair, Steel-Dwass All Pairs, and Steel with Control” on page 197.

**Steel With Control**  Compares each level to a control level. This is the nonparametric version of the With Control, Dunnett’s option found on the Compare Means menu. See “Wilcoxon Each Pair, Steel-Dwass All Pairs, and Steel with Control” on page 197.
**Dunn All Pairs for Joint Ranks**  Performs a comparison of each pair, similar to the Steel-Dwass All Pairs option. The Dunn method computes ranks for all the data, not just the pair being compared. The reported \( p \)-value reflects a Bonferroni adjustment. It is the unadjusted \( p \)-value multiplied by the number of comparisons. If the adjusted \( p \)-value exceeds 1, it is reported as 1. See “Dunn All Pairs for Joint Ranks and Dunn with Control for Joint Ranks” on page 198.

**Dunn With Control for Joint Ranks**  Compares each level to a control level, similar to the Steel With Control option. The Dunn method computes ranks for all the data, not just the pair being compared. The reported \( p \)-value reflects a Bonferroni adjustment. It is the unadjusted \( p \)-value multiplied by the number of comparisons. If the adjusted \( p \)-value exceeds 1, it is reported as 1. See “Dunn All Pairs for Joint Ranks and Dunn with Control for Joint Ranks” on page 198.

**Wilcoxon Each Pair, Steel-Dwass All Pairs, and Steel with Control**

The reports for these multiple comparison procedures give test results and confidence intervals. For these tests, observations are ranked within the sample obtained by combining only the two levels used in a given comparison.

- **q**\(^*\)**  The quantile used in computing the confidence intervals.
- **Alpha**  The alpha level used in computing the confidence interval. You can change the confidence level by selecting the Set \( \alpha \) Level option from the Oneway menu.
- **Level**  The first level of the X variable used in the pairwise comparison.
- **- Level**  The second level of the X variable used in the pairwise comparison.

**Score Mean Difference**  The mean of the rank score of the observations in the first level (Level) minus the mean of the rank scores of the observations in the second level (-Level), where a continuity correction is applied.

Denote the number of observations in the first level by \( n_1 \) and the number in the second level by \( n_2 \). The observations are ranked within the sample consisting of these two levels. Tied ranks are averaged. Denote the sum of the ranks for the first level by ScoreSum\(_1\) and for the second level by ScoreSum\(_2\).

If the difference in mean scores is positive, then the Score Mean Difference is defined as follows:

\[
\text{Score Mean Difference} = \frac{(\text{ScoreSum}_1 - 0.5)}{n_1} - \frac{\text{(ScoreSum}_2 + 0.5)}{n_2}
\]

If the difference in mean scores is negative, then the Score Mean Difference is defined as follows:

\[
\text{Score Mean Difference} = \frac{(\text{ScoreSum}_1 + 0.5)}{n_1} - \frac{\text{(ScoreSum}_2 -0.5)}{n_2}
\]
**Std Error Dif**  The standard error of the Score Mean Difference.

**Z**  The standardized test statistic, which has an asymptotic standard normal distribution under the null hypothesis of no difference in means.

**p-Value**  The p-value for the asymptotic test based on Z.

**Hodges-Lehmann**  The Hodges-Lehmann estimator of the location shift. All paired differences consisting of observations in the first level minus observations in the second level are constructed. The Hodges-Lehmann estimator is the median of these differences. The Difference Plot bar chart shows the size of the Hodges-Lehmann estimate.

**Lower CL**  The lower confidence limit for the Hodges-Lehmann statistic.

**Upper CL**  The upper confidence limit for the Hodges-Lehmann statistic.

**Note:** Not computed if group sample sizes are large enough to cause memory issues.

**Dunn All Pairs for Joint Ranks and Dunn with Control for Joint Ranks**

These comparison procedures are based on the rank of an observation in the entire data set. For the Dunn with Control for Joint Ranks tests, you must select a control level.

**Level**  The first level of the X variable used in the pairwise comparison.

**- Level**  The second level of the X variable used in the pairwise comparison.

**Score Mean Difference**  The mean of the rank score of the observations in the first level (Level) minus the mean of the rank scores of the observations in the second level (-Level), where a continuity correction is applied. The ranks are obtained by ranking the observations within the entire sample. Tied ranks are averaged. The continuity correction is described in “Score Mean Difference” on page 197.

**Std Error Dif**  The standard error of the Score Mean Difference.

**Z**  The standardized test statistic, which has an asymptotic standard normal distribution under the null hypothesis of no difference in means.

**p-Value**  The p-value for the asymptotic test based on Z.
Unequal Variances

JMP provides four tests for equality of group variances. When the variances across groups are not equal, the usual assumptions for analysis of variance are not satisfied. For example, the ANOVA \( F \) test is not valid and an analysis that does not assume equal group variances should be used. The concept behind the first three tests of equal variances is to perform an analysis of variance on a new response variable constructed to measure the spread in each group. The fourth test is Bartlett’s test, which is similar to the likelihood ratio test under normal distributions. The Unequal Variances option is not available when a Block variable is specified in the launch window.

**Note:** Another method to test for unequal variances is ANOMV. See “Analysis of Means Methods” on page 181.

The following Tests for Equal Variances are available:

**O'Brien** Constructs a dependent variable so that the group means of the new variable equal the group sample variances of the original response. An ANOVA on the O'Brien variable is actually an ANOVA on the group sample variances (O'Brien 1979; Olejnik and Algina 1987).

**Brown-Forsythe** Shows the \( F \) test from an ANOVA where the response is the absolute value of the difference of each observation and the group median (Brown and Forsythe 1974).

**Levene** Shows the \( F \) test from an ANOVA where the response is the absolute value of the difference of each observation and the group mean (Levene 1960). The spread is measured as \( z_{ij} = |y_{ij} - \bar{y}_i| \) (as opposed to the SAS default \( z_{ij}^2 = (y_{ij} - \bar{y}_i)^2 \)).

**Bartlett** Compares the weighted arithmetic average of the sample variances to the weighted geometric average of the sample variances. The geometric average is always less than or equal to the arithmetic average with equality holding only when all sample variances are equal. The more variation there is among the group variances, the more these two averages differ. A function of these two averages is created, which approximates a \( \chi^2 \)-distribution (or, in fact, an \( F \) distribution under a certain formulation). Large values correspond to large values of the arithmetic or geometric ratio, and therefore to widely varying group variances. Dividing the Bartlett Chi-square test statistic by the degrees of freedom gives the \( F \) value shown in the table. Bartlett’s test is not very robust to violations of the normality assumption (Bartlett and Kendall 1946).

**F Test 2-sided** (Available only if there are two levels of the X variable.) If there are only two groups tested, then a standard \( F \) test for unequal variances is also performed. The \( F \) test is the ratio of the larger to the smaller variance estimate. The \( p \)-value from the \( F \) distribution is doubled to make it a two-sided test.
Note: If you have specified a Block column, then the variance tests are performed on data after it has been adjusted for the Block means.

See “Example of the Unequal Variances Option” on page 221.

Tests That the Variances Are Equal Report

The Tests That the Variances Are Equal report shows the differences between group means to the grand mean and to the median, and gives a summary of testing procedures.

If the equal variances test reveals that the group variances are significantly different, use Welch’s test instead of the regular ANOVA test. The Welch statistic is based on the usual ANOVA $F$ test. However, the means are weighted by the reciprocal of the group mean variances (Welch 1951; Brown and Forsythe 1974; Asiribo and Gurland 1990). If there are only two levels, the Welch ANOVA is equivalent to an unequal variance $t$ test.

Description of the Tests That the Variances Are Equal Report

**Level**  Lists the factor levels occurring in the data.

**Count**  Records the frequencies of each level.

**Std Dev**  Records the standard deviations of the response for each factor level. The standard deviations are equal to the means of the O’Brien variable. If a level occurs only once in the data, no standard deviation is calculated.

**MeanAbsDif to Mean**  Records the mean absolute difference of the response and group mean. The mean absolute differences are equal to the group means of the Levene variable.

**MeanAbsDif to Median**  Records the absolute difference of the response and group median. The mean absolute differences are equal to the group means of the Brown-Forsythe variable.

**Test**  Lists the names of the tests performed.

**F Ratio**  Records a calculated $F$ statistic for each test. See “Tests That the Variances Are Equal” on page 241.

**DFNum**  Records the degrees of freedom in the numerator for each test. If a factor has $k$ levels, the numerator has $k - 1$ degrees of freedom. Levels occurring only once in the data are not used in calculating test statistics for O’Brien, Brown-Forsythe, or Levene. The numerator degrees of freedom in this situation is the number of levels used in calculations minus one.

**DFDen**  Records the degrees of freedom used in the denominator for each test. For O’Brien, Brown-Forsythe, and Levene, a degree of freedom is subtracted for each factor level used.
in calculating the test statistic. If a factor has k levels, the denominator degrees of freedom is $n - k$.

**p-Value**  Probability of obtaining an $F$-ratio value larger than the one calculated if the variances are equal across all levels.

**Note:** A warning appears if any level of the X variable contains fewer than 5 observations. For more information about the performance of the above tests with small sample sizes, see Brown and Forsythe (1974) and Miller (1972).

### Description of the Welch's Test Report

**F Ratio**  Shows the $F$ test statistic for the equal means test.

**DFNum**  Records the degrees of freedom in the numerator of the test. If a factor has $k$ levels, the numerator has $k - 1$ degrees of freedom. Levels occurring only once in the data are not used in calculating the Welch ANOVA. The numerator degrees of freedom in this situation is the number of levels used in calculations minus one.

**DFDen**  Records the degrees of freedom in the denominator of the test. See “Tests That the Variances Are Equal” on page 241.

**Prob>F**  Probability of obtaining an $F$ value larger than the one calculated if the means are equal across all levels. Observed significance probabilities of 0.05 or less are considered evidence of unequal means across the levels.

**t Test**  Shows the relationship between the $F$ ratio and the $t$ Test. Calculated as the square root of the $F$ ratio. Appears only if the X factor has two levels.

### Equivalence Tests

Equivalence tests are useful when you want to detect differences in means that are of *practical* interest. You must specify a threshold difference for which smaller differences are considered practically equivalent. In other words, if two group means differ by this amount or less, you are willing to consider them equivalent.

See “Example of an Equivalence Test” on page 222.
Equivalence Tests Report

Once you have specified the threshold value and variance assumption, the Equivalence Tests report appears. The full title of the report is Equivalence Tests with Pooled Variance or the Equivalence Tests with Unequal Variances, depending on the specified variance assumption. The specified threshold value implies upper and lower bounds, which are shown at the top of the report. The top of the report also contains the $\alpha$ level of the equivalence tests. The report consists of a table that contains the equivalence tests and a scatterplot that displays them. The equivalence tests and confidence intervals are based on Student’s $t$ critical values.

**Tip:** To change the $\alpha$ level of the equivalence tests, use the Set $\alpha$ Level option in the Oneway Analysis red triangle menu before you select the Equivalence Tests option.

The red triangle menu next to Equivalence Tests with Pooled Variance or Equivalence Tests with Unequal Variances contains the following options:

**Equivalence TOST Tests**  Shows or hides the Equivalence TOST Tests report.

**Equivalence Tests Scatterplot**  Shows or hides the Equivalence Tests Scatterplot report.

**Equivalence Tests Pairwise Comparisons**  Shows or hides the Practical Equivalence reports for all pairwise comparisons.

**Remove**  Removes the Equivalence Tests report from the Oneway Analysis report window.

**Equivalence TOST Tests**

The Two One-Sided Tests (TOST) method is used to test for a practical difference between the means (Schuirmann 1987). Two one-sided $t$ tests using the specified variance assumption are constructed for the null hypotheses that the true difference exceeds the threshold values. If both tests reject, the difference in the means does not statistically exceed either threshold value. Therefore, the groups are considered practically equivalent. If only one or neither test rejects, then the groups might not be practically equivalent.

For each comparison, the Equivalence TOST Tests report gives the following information:

**Difference**  Estimated difference in the means.

**Lower Bound t Ratio, Upper Bound t Ratio**  Lower and upper bound $t$ ratios for the two one-sided pooled-variance significance tests.

**Lower Bound p-Value, Upper Bound p-Value**  $p$-values corresponding to the lower and upper bound $t$ ratios.

**Maximum p-Value**  Maximum of the lower and upper bound $p$-values.

**Lower and Upper**  Limits for a $1-2\alpha$ confidence interval for the difference in the means.
**Equivalence Tests Scatterplot**

Using colors, this scatterplot indicates which means are practically equivalent and which are not practically equivalent as determined by the equivalence test. This plot is sometimes called a *diffogram* or a mean-mean scatterplot.

The plot shows a solid reference line on the diagonal as well as a shaded reference band. The width of the band is twice the practical difference. The coordinates of the point on the line segment are the means for the corresponding groups. There is an implied third axis on the diagonal where each line segment corresponds to a $1 - 2\alpha$ confidence interval for a pairwise comparison. Hover over one of these points to show a tooltip that indicates the groups being compared and the estimated difference. When a line segment is entirely contained within the diagonal band, it follows that the means are practically equivalent.

The Equivalence Tests Scatterplot has the following option:

**Show Reference Lines**  Displays reference lines for the points on the scatterplot. This is not recommended if there are many points in the scatterplot. If there are many points, it is better to hover over the points to view the labels.

**Robust**

The Robust option provides two methods to reduce the influence of outliers or extreme data points in your data set: Robust Fit and Cauchy Fit. The Robust options are not available when a Block variable is specified in the launch window.

**Robust Fit**

The Robust Fit option reduces the influence of outliers in the response variable. The Huber M-estimation method is used. Huber M-estimation finds parameter estimates that minimize the Huber loss function:

$$l(\varepsilon) = \sum_{i} \rho(e_i)$$

where

$$\rho(e) = \begin{cases} 
\frac{1}{2}e^2 & \text{if } |e| < k \\
ke - \frac{1}{2}k^2 & \text{if } |e| \geq k 
\end{cases}$$
$e_i$ refers to the residuals

The Huber loss function penalizes outliers and increases as a quadratic for small errors and linearly for large errors. For more information about robust fitting, see Huber (1973) and Huber and Ronchetti (2009). See “Example of the Robust Fit Option” on page 224.

**Cauchy Fit**

The Cauchy fit option assumes that the errors have a Cauchy distribution. A Cauchy distribution has fatter tails than the normal distribution, resulting in a reduced emphasis on outliers. This option can be useful if you have a large proportion of outliers in your data. However, if your data are close to normal with only a few outliers, this option can lead to incorrect inferences. The Cauchy option estimates parameters using maximum likelihood and a Cauchy link function.

**Power**

The **Power** option calculates statistical power and other details about a given hypothesis test. See “Example of the Power Option” on page 225. For statistical details, see “Power” on page 240.

- **LSV** (the Least Significant Value) is the value of some parameter or function of parameters that would produce a certain $p$-value alpha. Said another way, you want to know how small an effect would be declared significant at some $p$-value alpha. The LSV provides a measuring stick for significance on the scale of the parameter, rather than on a probability scale. It shows how sensitive the design and data are.

- **LSN** (the Least Significant Number) is the total number of observations that would produce a specified $p$-value alpha given that the data has the same form. The LSN is defined as the number of observations needed to reduce the variance of the estimates enough to achieve a significant result with the given values of alpha, sigma, and delta (the significance level, the standard deviation of the error, and the effect size). If you need more data to achieve significance, the LSN helps tell you how many more. The LSN is the total number of observations that yields approximately 50% power.

- **Power** is the probability of getting significance ($p$-value < alpha) when a real difference exists between groups. It is a function of the sample size, the effect size, the standard deviation of the error, and the significance level. The power tells you how likely your experiment is to detect a difference (effect size), at a given alpha level.

**Note:** When there are only two groups in a one-way layout, the LSV computed by the power facility is the same as the least significant difference (LSD) shown in the multiple-comparison tables.
Power Details Window and Reports

The Power Details window and reports are the same as those in the general fitting platform launched by the Fit Model platform. For more information about power calculation, see Fitting Linear Models.

For each of four columns Alpha, Sigma, Delta, and Number, fill in a single value, two values, or the start, stop, and increment for a sequence of values (Figure 6.32). Power calculations are performed on all possible combinations of the values that you specify.

**Alpha (α)** Significance level, between 0 and 1 (usually 0.05, 0.01, or 0.10). Initially, a value of 0.05 shows.

**Sigma (σ)** Standard error of the residual error in the model. Initially, RMSE, the estimate from the square root of the mean square error is supplied here.

**Delta (δ)** Raw effect size. For more information about effect size computations, see Fitting Linear Models. The first position is initially set to the square root of the sums of squares for the hypothesis divided by $n$ (that is, $\delta = \sqrt{\text{SS}/n}$).

**Number (n)** Total sample size across all groups. Initially, the actual sample size is put in the first position.

**Solve for Power** Solves for the power (the probability of a significant result) as a function of all four values: $\alpha$, $\sigma$, $\delta$, and $n$.

**Solve for Least Significant Number** Solves for the number of observations needed to achieve approximately 50% power given $\alpha$, $\sigma$, and $\delta$.

**Solve for Least Significant Value** Solves for the value of the parameter or linear test that produces a $p$-value of $\alpha$. This is a function of $\alpha$, $\sigma$, $n$, and the standard error of the estimate. This feature is available only when the X factor has two levels and is usually used for individual parameters.

**Adjusted Power and Confidence Interval** When you look at power retrospectively, you use estimates of the standard error and the test parameters.

- Adjusted power is the power calculated from a more unbiased estimate of the non-centrality parameter.
- The confidence interval for the adjusted power is based on the confidence interval for the non-centrality estimate.

Adjusted power and confidence limits are computed only for the original Delta, because that is where the random variation is.
Normal Quantile Plot

You can create two types of normal quantile plots:

- **Plot Actual by Quantile** creates a plot of the response values versus the normal quantile values. The quantiles are computed and plotted separately for each level of the X variable.
- **Plot Quantile by Actual** creates a plot of the normal quantile values versus the response values. The quantiles are computed and plotted separately for each level of the X variable.

The **Line of Fit** option shows or hides the lines of fit on the quantile plots. The **Normal Quantile Label** option shows or hides labels inside the right vertical axis of the Normal Quantile Plot and inside the top axis of the Actual by Quantile plot. The labels represent the normal quantile scale.

The Normal Quantile Plot options are not available when a Block variable is specified in the launch window.

See “Example of a Normal Quantile Plot” on page 227.

CDF Plot

The CDF plot shows the cumulative distribution function for all of the groups in the Oneway report. CDF plots are useful if you want to compare the distributions of the response across levels of the X factor. The CDF Plot option is not available when a Block variable is specified in the launch window. See “Example of a CDF Plot” on page 228.

Densities

The **Densities** options provide several ways to visually compare the distribution and composition of the response across the levels of the X factor. There are three density options:

- **Compare Densities** shows a smooth curve estimating the density of each group. The smooth curve is the density estimate for each group.
- **Composition of Densities** shows the summed densities, weighted by each group’s counts. At each X value, the Composition of Densities plot shows how each group contributes to the total.
- **Proportion of Densities** shows the contribution of the group as a proportion of the total at each X level.

The Densities options are not available when a Block variable is specified in the launch window.
See “Example of the Densities Options” on page 229.

Matching Column

Use the Matching Column option to specify a matching (ID) variable for a matching model analysis. The Matching Column option addresses the case when the data in a one-way analysis come from matched (paired) data. Matched data can occur when observations in different groups come from the same participant. The Matching Column option is not available when a Block variable is specified in the launch window. See “Example of the Matching Column Option” on page 230.

Note: A special case of matching leads to the paired t test. The Matched Pairs platform handles this type of data, but the data must be organized with the pairs in different columns, not in different rows.

The Matching Column option performs two primary actions:

- It fits an additive model (using an iterative proportional fitting algorithm) that includes both the grouping variable (the X variable in the Fit Y by X analysis) and the matching variable that you select. The iterative proportional fitting algorithm makes a difference if there are hundreds of participants, because the equivalent linear model would be very slow and would require huge memory resources.

- It draws lines between the points that match across the groups. If there are multiple observations with the same matching ID value, lines are drawn from the mean of the group of observations.

The Matching Column option automatically activates the Matching Lines option connecting the matching points. To turn the lines off, select Display Options > Matching Lines.

The Matching Fit report shows the effects with F tests. These are equivalent to the tests that you get with the Fit Model platform if you run two models, one with the interaction term and one without. If there are only two levels, then the F test is equivalent to the paired t test.

Note: For more information about the Fit Model platform, see Fitting Linear Models.

Example of an Analysis of Means Chart

1. Select Help > Sample Data Library and open Analgesics.jmp.
2. Select Analyze > Fit Y by X.
4. Select drug and click X, Factor.
5. Click OK.
6. Click the Analysis of Means red triangle and select Analysis of Means Methods > ANOM.
For the example, the means for drug A and C are statistically different from the overall mean. The drug A mean is lower and the drug C mean is higher. Note the decision limits for the drug types are not the same, due to different sample sizes.

**Example of an Analysis of Means for Variances Chart**

Use ANOMV to test if the variability is significantly different between brands of springs. Four different brands of springs were tested to see what weight is required to extend a spring 0.10 inches. Six springs of each brand were tested. The data was checked for normality, since the ANOMV test is not robust to non-normality. Examine the brands to determine whether the variability is significantly different between brands.

1. Select Help > Sample Data Library and open Spring Data.jmp.
2. Select Analyze > Fit Y by X.
3. Select Weight and click Y, Response.
4. Select Brand and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of Weight By Brand and select Analysis of Means Methods > ANOM for Variances.
7. Click the red triangle next to Analysis of Means for Variances and select Show Summary Report.
Figure 6.14  Example of Analysis of Means for Variances Chart

Note that the standard deviation for Brand 2 exceeds the lower decision limit. Therefore, Brand 2 has significantly lower variance than the other brands.

Example of the Each Pair, Student’s t Test

This example illustrates the use of all possible \( t \) tests.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select age and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of weight By age and select Compare Means > Each Pair, Student’s t.
The means comparison method can be thought of as seeing if the actual difference in the means is greater than the difference that would be significant. This difference is called the LSD (least significant difference). The LSD term is used for Student’s $t$ intervals and in context with intervals for other tests. In the comparison circles graph, the distance between the circles’ centers represent the actual difference. The LSD is what the distance would be if the circles intersected at right angles.
In Figure 6.16, the LSD threshold table shows the difference between the absolute difference in the means and the LSD (least significant difference). If the values are positive, the difference in the two means is larger than the LSD, and the two groups are significantly different.

**Example of the All Pairs, Tukey HSD Test**

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select age and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of weight By age and select Compare Means > All Pairs, Tukey HSD.
Figure 6.17  Example of All Pairs, Tukey HSD Comparison Circles

Figure 6.18  Example of Means Comparisons Report for All Pairs, Tukey HSD
In Figure 6.18, the Tukey-Kramer HSD Threshold matrix shows the actual absolute difference in the means minus the HSD. This value represents the difference that would be significant. Pairs with a positive value are significantly different. The \( q^* \) (appearing above the HSD Threshold Matrix table) is the quantile that is used to scale the HSDs. It has a computational role comparable to a Student’s \( t \).

**Example of the With Best, Hsu MCB Test**

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select *weight* and click **Y, Response**.
4. Select *age* and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of weight By age and select **Compare Means > With Best, Hsu MCB**.

**Figure 6.19** Examples of With Best, Hsu MCB Comparison Circles
The Comparison with Max and Min report compares the mean of each level to the maximum and the minimum of the means of the remaining levels. For example, the mean for age 15 differs significantly from the maximum of the means of the remaining levels. The mean for age 17 differs significantly from the minimum of the means of the remaining levels. The maximum mean could occur for age 16 or age 17, because neither mean differs significantly from the maximum mean. By the same reasoning, the minimum mean could correspond to any of the ages other than age 17.

**Example of the With Control, Dunnett’s Test**

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select weight and click **Y, Response**.
4. Select age and click **X, Factor**.

5. Click **OK**.

6. Click the red triangle next to Oneway Analysis of weight By age and select **Compare Means > With Control, Dunnett’s**.

7. Select the group to use as the control group. In this example, select age 12.

   Alternatively, click a row to highlight it in the scatterplot before selecting the **Compare Means > With Control, Dunnett’s** option. The test uses the selected row as the control group.

8. Click **OK**.

**Figure 6.21** Example of With Control, Dunnett’s Comparison Circles

Using the comparison circles, you can conclude that level 17 is the only level that is significantly different from the control level of 12.
Example of the Each Pair Stepwise, Newman-Keuls Test

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select age and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of weight By age and select Compare Means > Each Pair Stepwise, Newman-Keuls.

Figure 6.22 Example of Means Comparisons Report for Each Pair Stepwise, Newman-Keuls

The Connecting Letters Report shows that Level 17 is significantly different from all other levels except 16 and 15.

Example Contrasting Four Compare Means Tests

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Select weight and click Y, Response.
4. Select age and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of weight By age and select each one of the Compare Means options. For the With Control, Dunnett’s option, select age 17 as the control group.
The four methods all test differences between group means. Each test is used for a specific hypothesis and different findings can occur.

**Figure 6.23** Comparison Circles for Four Multiple Comparison Tests

In Figure 6.23, age group 17 is highlighted. The other control circles are colored in relation to age group 17. Notice that for the Student’s t and Hsu methods, age group 15 (the third circle from the top) is gray. This indicates that it is significantly different from age group 17. However, for the Tukey and Dunnett methods, age group 15 is red, which indicates that it is not significantly different from age group 17.

**Example of the Nonparametric Wilcoxon Test**

Use a Wilcoxon test to determine if the mean profit earned by companies differs by type of company. In Companies.jmp, the data consist of various metrics on two types of companies, Pharmaceutical (12 companies) and Computer (20 companies).

1. Select **Help > Sample Data Library** and open Companies.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select Profits ($M) and click **Y, Response**.
4. Select Type and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of Profits ($M) By Type and select **Display Options > Box Plots**.
The box plots suggest that the distributions are not normal or even symmetric. There is a very large value for the company in row 32 that might affect parametric tests.

7. Click the red triangle next to Oneway Analysis of Profits ($M) By Type and select Means/ANOVA/Pooled t.

The $F$ test shows no significance because the $p$-value is large ($p = 0.1163$). This might be due to the large value in row 32 and the possible violation of the normality assumption.
8. Click the red triangle next to Oneway Analysis of Profits ($M) By Type and select **t Test**.

**Figure 6.26**  t Test Results

![t Test Results](image)

The Prob > |t| for a two-sided test is 0.0671. The t test does not assume equal variances, but the unequal variances t test is also a parametric test.

9. Click the red triangle next to Oneway Analysis of Profits ($M) By Type and select **Nonparametric > Wilcoxon Test**.

**Figure 6.27**  Wilcoxon Test Results

![Wilcoxon Test Results](image)

The Wilcoxon test is a nonparametric test. It is based on ranks, so it is resistant to outliers. Also, it does not require normality.

Both the normal and the chi-square approximations for the Wilcoxon test statistic indicate significance at a *p*-value of 0.0010. You conclude that there is a significant difference in the location of the distributions, and conclude that mean profit differs based on company type.

The normal and chi-square tests are based on the asymptotic distributions of the test statistics. If you have JMP Pro, you can conduct an exact test.

10. Click the red triangle next to Oneway Analysis of Profits ($M) By Type and select **Nonparametric > Exact Test > Wilcoxon Exact Test**.
The observed value of the test statistic is $S = 283$. This is the sum of the ranks for the level of Type with the smaller sample size (pharmaceuticals). The probability of observing an absolute difference from the mean midrank that exceeds the absolute value of $S$ minus the mean of the midranks is 0.0005. This is a two-sided test for a difference in location and supports rejecting the hypothesis that profits do not differ by type of company.

In this example, the nonparametric tests are more appropriate than the normality-based ANOVA test and the unequal variances $t$ test. The nonparametric tests are resistant to the large value in row 32 and do not require the assumption of normality.

**Example of the Unequal Variances Option**

In this example, suppose you want to test whether two groups (males and females) have equal variance.

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select **height** and click **Y, Response**.
4. Select **sex** and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of height By sex and select **Unequal Variances**.
Since the $p$-value from the 2-sided $F$ Test is large, you cannot conclude that the variances are unequal.

**Example of an Equivalence Test**

In this example, you investigate whether the difference in height between males and females is less than 6 inches.

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select height and click **Y, Response.**
4. Select sex and click X, **Factor**.
5. Click OK.
6. Click the red triangle Oneway Analysis of height By sex and select **Equivalence Tests**.
7. Type 6 as the difference considered practically zero.
8. Click OK.

**Figure 6.30** Example of an Equivalence Test

Using two one-sided tests, you can see that the *p*-value is small for both. Therefore, you can conclude that the difference in population means is located somewhere between -6 and 6. For your purposes, you can declare the means to be practically equivalent.
Example of the Robust Fit Option

Use a Robust fit in this example where one of three groups contains outliers. The data in the Drug Toxicity.jmp sample data table shows the toxicity levels for three different formulations of a drug.

1. Select Help > Sample Data Library and open Drug Toxicity.jmp.
2. Select Analyze > Fit Y by X.
4. Select Formulation and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of Toxicity By Formulation and select Means/Anova.
7. Click the red triangle next to Oneway Analysis of Toxicity By Formulation and select Robust > Robust Fit.
If you look at the standard Analysis of Variance report, you might wrongly conclude that there is a difference between the three formulations, since the \( p \)-value is 0.0319. However, when you look at the Robust Fit report, you would not conclude that the three formulations are significantly different, because the \( p \)-value there is 0.21755. It appears that the toxicity for a few of the observations is unusually high, creating the undue influence on the data.

**Example of the Power Option**

1. Select **Help > Sample Data Library** and open Typing Data.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select speed and click **Y, Response**.
4. Select brand and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of speed By brand and select **Power**.
7. Within the From row, type 2 for Delta (the third box) and type 11 for Number.
8. Within the To row, type 6 for Delta, and type 17 in the Number box.
9. Within the By row, type 2 for both Delta and Number.
10. Select the **Solve for Power** check box.

**Figure 6.32** Example of the Power Details Window

11. Click **Done**.

**Note:** The **Done** button remains dimmed until all of the necessary options are applied.

Power is computed for each combination of Delta and Number, and appears in the Power report.

To plot the Power values:

12. Click the Power Details red triangle and select **Power Plot**.
13. You might need to click and drag vertically on the Power axis to see all of the data in the plot.

Power is plotted for each combination of Delta and Number. As you might expect, the power rises for larger Number (sample sizes) values and for larger Delta values (difference in means).

**Example of a Normal Quantile Plot**

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select height and click **Y, Response**.
4. Select sex and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of height By sex and select **Normal Quantile Plot > Plot Actual by Quantile**.
Figure 6.34 Example of a Normal Quantile Plot

![Normal Quantile Plot](image)

Note the following:

- The Line of Fit appears by default.
- The data points track very closely to the line of fit, indicating a normal distribution.

Example of a CDF Plot

1. Select Help > Sample Data Library and open Analgesics.jmp.
2. Select Analyze > Fit Y by X.
4. Select drug and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of pain By drug and select CDF Plot.
The levels of the X variables in the initial Oneway analysis appear in the CDF plot as different curves. The horizontal axis of the CDF plot uses the $y$ value in the initial Oneway analysis.

**Example of the Densities Options**

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
4. Select sex and click X, Factor.
5. Click OK.
6. Click the red triangle next to Oneway Analysis of height By sex and select all three options: Densities > Compare Densities, Densities > Composition of Densities, and Densities > Proportion of Densities.
**Figure 6.36** Example of the Densities Options

This example uses the Matching.jmp sample data table, which contains data on six animals and the miles that they travel during different seasons.

1. Select **Help > Sample Data Library** and open Matching.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select miles and click **Y, Response**.
4. Select season and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of miles By season and select **Matching Column**.
7. Select subject as the matching column.
8. Click OK.

**Figure 6.37** Example of the Matching Column Report

The plot graphs the miles traveled by season, with subject as the matching variable. The labels next to the first measurement for each subject on the graph are determined by the species and subject variables.

The Matching Fit report shows the season and subject effects with F tests. These are equivalent to the tests that you get with the Fit Model platform if you run two models, one with the interaction term and one without. If there are only two levels, then the F test is equivalent to the paired t test.

**Note:** For more information about the Fit Model platform, see *Fitting Linear Models.*
Example of Stacking Data for a Oneway Analysis

When your data are in a format other than a JMP data table, sometimes they are arranged so that a row contains information for multiple observations. To analyze the data in JMP, you must import the data and restructure it so that each row of the JMP data table contains information for a single observation. For example, suppose that your data are in a spreadsheet. The data for parts produced on three production lines are arranged in three sets of columns. In your JMP data table, you need to stack the data from the three production lines into a single set of columns so that each row represents the data for a single part.

Description and Goals

This example uses the file Fill Weights.xlsx, which contains the weights of cereal boxes randomly sampled from three different production lines. Figure 6.38 shows the format of the data.

- The ID columns contain an identifier for each cereal box that was measured.
- The Line columns contain the weights (in ounces) for boxes sampled from the corresponding production line.

Figure 6.38 Data Format

<table>
<thead>
<tr>
<th>Weights</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>215</td>
</tr>
<tr>
<td>287</td>
</tr>
<tr>
<td>381</td>
</tr>
<tr>
<td>683</td>
</tr>
<tr>
<td>514</td>
</tr>
<tr>
<td>517</td>
</tr>
<tr>
<td>946</td>
</tr>
</tbody>
</table>

The target fill weight for the boxes is 12.5 ounces. Although you are interested in whether the three production lines are meeting the target, initially you want to see whether the three lines are achieving the same mean fill rate. You can use Oneway to test for differences among the mean fill weights.

To use the Oneway platform, you need to do the following:

1. Import the data into JMP. See “Import the Data” on page 233.
2. Reshape the data so that each row in the JMP data table reflects only a single observation. Reshaping the data requires that you stack the cereal box IDs, the line identifiers, and the weights into columns. See “Stack the Data” on page 234.
Import the Data

This example illustrates two ways to import data from Microsoft Excel into JMP. Select one method or explore both:

- Use the File > Open option to import data from a Microsoft Excel file using the Excel Import Wizard. See “Import the Data Using the Excel Import Wizard” on page 233. This method is convenient for any Excel file.
- Copy and paste data from Microsoft Excel into a new JMP data table. See “Copy and Paste the Data from Excel” on page 234. You can use this method with small data files.

For more information about how to import data from Microsoft Excel, see Using JMP.

Import the Data Using the Excel Import Wizard

1. Select Help > Sample Data Library and open Fill Weights.xlsx located in the Samples/Import Data folder.
   
   The file opens in the Excel Import Wizard.

2. Type 3 next to Column headers start on row.
   
   In the Excel file, row 1 contains information about the table and row 2 is blank. The column header information starts on row 3.

3. Type 2 for Number of rows with column headers.
   
   In the Excel file, rows 3 and 4 both contain column header information.

4. Click Import.

Figure 6.39 JMP Table Created Using Excel Import Wizard

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>Weight</td>
<td>ID</td>
<td>Weight</td>
<td>ID</td>
<td>Weight</td>
</tr>
<tr>
<td>1</td>
<td>215</td>
<td>2</td>
<td>287</td>
<td>3</td>
<td>381</td>
</tr>
<tr>
<td>2</td>
<td>12.42</td>
<td>3</td>
<td>12.49</td>
<td>4</td>
<td>12.80</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>4</td>
<td>683</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>5</td>
<td>514</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
<td>6</td>
<td>517</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
<td>7</td>
<td>946</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The data are placed in seven rows and multiple IDs appear in each row. For each of the three lines, there are an ID and Weight column, giving a total of six columns.

Notice that the “Weights” part of the ID column name is unnecessary and misleading. You could rename the columns now, but it will be more efficient to rename the columns after you stack the data.

5. Proceed to “Stack the Data” on page 234.
Copy and Paste the Data from Excel

1. Open Fill Weights.xlsx in Microsoft Excel.
2. Select the data inside the table but exclude the unnecessary “Weights” heading.
3. Right-click and select Copy.
4. In JMP, select File > New > Data Table.
5. Select Edit > Paste with Column Names.

   The Edit > Paste with Column Names option is used when your column names are included in the selection on the clipboard.

Figure 6.40 JMP Table Created Using Paste with Column Names

6. Proceed to “Stack the Data” on page 234.

Stack the Data

Use the Stack option to place one observation in each row of a new data table. For more information about the Stack option, see Using JMP.

1. In the JMP data table, select Tables > Stack.
2. Select all six columns and click Stack Columns.
3. Select Multiple Series Stack.

   You are stacking two series, ID and Line, so you do not change the Number of Series, which is set to 2 by default. The columns that contain the series are not contiguous. They alternate (ID, Line A, ID, Line B, ID, Line C). For this reason, you do not check Contiguous.
4. Deselect Stack By Row.
5. Select Eliminate Missing Rows.
6. Enter Stacked next to Output table name.
7. Click OK.

   In the new data table, Data and Data 2 are columns containing the ID and Weight data.
8. Right-click the Label column heading and select Delete Columns.
The entries in the Label column were the column headings for the box IDs in the imported data table. These entries are not needed.

9. Rename each column by double-clicking on the column header:
   - Data to ID
   - Label 2 to Line
   - Data 2 to Weight

10. In the Columns panel, click the icon to the left of ID and select **Nominal**.
    Although ID is given as a number, it is an identifier and should be treated as nominal when modeling. This is not an issue in this example, but it is good practice to assign the appropriate modeling type to a column.

11. (Applies only if you imported the data from Excel using **File > Open.**) Do the following:
    1. Click the Line column header to select the column and select **Cols > Recode**.
    2. Click **New Column** and select **In Place**.
    3. Change the values in the **New Values** column to match those in Figure 6.41 below.

**Figure 6.41** Recode Column Values

4. Click **Recode**.

Your new data table is now properly structured for JMP analysis. Each row contains data for a single cereal box. The first column gives the box ID, the second gives the production line, and the third gives the weight of the box (Figure 6.42).
Conduct the Oneway Analysis

This part of the example contains the following tasks:

- Conduct a Oneway Analysis of Variance to test for differences in the mean fill weights among the three production lines.
- Obtain Comparison Circles to explore which lines might differ.
- Label points by ID in case you want to reweigh or further examine their boxes.

Before beginning, verify that you are using the Stacked data table.

1. Select **Analyze > Fit Y by X**.
2. Select **Weight** and click **Y, Response**.
3. Select **Line** and click **X, Factor**.
4. Click **OK**.
5. Click the red triangle next to Oneway Analysis of Weight By Line and select **Means/Anova**.

   The mean diamonds in the plot show 95% confidence intervals for the production line means. The points that fall outside the mean diamonds might seem like outliers. However, they are not. To see this, add box plots to the plot.

6. Click the red triangle next to Oneway Analysis of Weight By Line and select **Display Options > Box Plots**.

   All points fall within the box plots boundaries. Therefore, they are not outliers.

7. From the data table, in the Columns panel, right-click **ID** and select **Label/Unlabel**.
8. In the plot, hover over the points to see their ID values, as well as their Line and Weight data (Figure 6.43).

9. Click the red triangle next to Oneway Analysis of Weight By Line and select Compare Means > All Pairs, Tukey HSD.

   Comparison circles appear in a panel to the right of the plot.

10. Click the bottom comparison circle.

**Figure 6.43** Oneway Analysis of Weight by Line

In the Analysis of Variance report, the $p$-value of 0.0102 provides evidence that the means are not all equal. In the plot, the comparison circle for Line C is selected and appears red. Since the circle for Line B appears as thick gray, the mean for Line C differs from the mean for Line B at the 0.05 significance level. The means for Lines A and B do not show a statistically significant difference.
The mean diamonds shown in the plot span 95% confidence intervals for the means. The numeric bounds for the 95% confidence intervals are given in the Means for Oneway ANOVA report. Both of these indicate that the confidence intervals for Lines B and C do not contain the target fill weight of 12.5: Line B seems to overfill and Line C seems to underfill. For these two production lines, the underlying causes that result in off-target fill weights must be addressed.

---

**Statistical Details for the Oneway Platform**

- “Comparison Circles”
- “Power”
- “Summary of Fit Report”
- “Tests That the Variances Are Equal”
- “Nonparametric Test Statistics”

**Comparison Circles**

Comparison circles are a graphical representation of the least significant difference (LSD) in a multiple comparison test. This least significant difference is a Student’s $t$-statistic multiplied by the standard error of the difference of the two means and is defined as follows:

$$\text{LSD} = t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1 - \hat{\mu}_2)$$

The standard error of the difference of two independent means is calculated from the following relationship:

$$[\text{std}(\hat{\mu}_1 - \hat{\mu}_2)]^2 = [\text{std}(\hat{\mu}_1)]^2 + [\text{std}(\hat{\mu}_2)]^2$$

When the means are uncorrelated, these quantities have the following relationship:

$$\text{LSD}^2 = [t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1 - \hat{\mu}_2)]^2 = [t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1)]^2 + [t_{\alpha/2} \cdot \text{std}(\hat{\mu}_2)]^2$$

These squared values form a Pythagorean relationship, illustrated graphically by the right triangle shown in Figure 6.44.
**Figure 6.44** Relationship of the Difference between Two Means

![Diagram of a triangle with legs labeled \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1 - \hat{\mu}_2) \) and hypotenuse labeled \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1) \) and \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_2) \), and right angle labeled \( t_{\alpha} \cdot \text{std}(\hat{\mu}_1) \) and \( t_{\alpha} \cdot \text{std}(\hat{\mu}_2) \).]

The hypotenuse of this triangle is a measuring stick for comparing means. The means are significantly different if and only if the actual difference is greater than the hypotenuse (LSD).

Suppose that you have two means that are exactly on the borderline, where the actual difference is the same as the least significant difference. Draw the triangle with vertices at the means measured on a vertical scale. Also, draw circles around each mean so that the diameter of each is equal to the confidence interval for that mean.

**Figure 6.45** Geometric Relationship of \( t \) Test Statistics

![Diagram with circles around \( \hat{\mu}_1 \) and \( \hat{\mu}_2 \) and legs labeled \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1 - \hat{\mu}_2) \), hypotenuses labeled \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_1) \) and \( t_{\alpha/2} \cdot \text{std}(\hat{\mu}_2) \), and right angles labeled \( t_{\alpha} \cdot \text{std}(\hat{\mu}_1) \) and \( t_{\alpha} \cdot \text{std}(\hat{\mu}_2) \).]

The radius of each circle is the length of the corresponding leg of the triangle, which is \( t_{\alpha/2} \text{std}(\hat{\mu}_i) \).

The circles must intersect at the same right angle as the triangle legs, giving the following relationship:

- If the means differ exactly by their least significant difference, then the confidence interval circles around each mean intersect at a right angle. That is, the angle of the tangents is a right angle.

Now, consider how these circles must intersect if the means are different by greater than or less than the least significant difference:

- If the circles intersect so that the outside angle is greater than a right angle, then the means are not significantly different. If the circles intersect so that the outside angle is less than a right angle, then the means are significantly different. An outside angle of less than 90 degrees indicates that the means are farther apart than the least significant difference.
• If the circles do not intersect, then they are significantly different. If they nest, they are not significantly different (Figure 6.11).

The same graphical technique works for many multiple-comparison tests, substituting a different probability quantile value for the Student’s $t$.

**Power**

To compute power, you use the noncentral $F$ distribution. The formula (O’Brien and Lohr 1984) is defined as follows:

$$\text{Power} = \text{Prob}(F > F_{crit}, v_1, v_2, nc)$$

where:

- $F$ is distributed as the noncentral $F(nc, v_1, v_2)$ and $F_{crit} = F(1-\alpha, v_1, v_2)$ is the $1 - \alpha$ quantile of the $F$ distribution with $v_1$ and $v_2$ degrees of freedom.
- $v_1 = r - 1$ is the numerator df.
- $v_2 = r(n - 1)$ is the denominator df.
- $n$ is the number per group.
- $r$ is the number of groups.
- $nc = n(CSS)/\sigma^2$ is the non-centrality parameter.

$$CSS = \sum_{g=1}^{r} (\mu_g - \mu)^2$$ is the corrected sum of squares.

- $\mu_g$ is the mean of the $g^{th}$ group.
- $\mu$ is the overall mean.
- $\sigma^2$ is estimated by the mean squared error (MSE).

**Summary of Fit Report**

**Rsquare**

Using quantities from the Analysis of Variance report for the model, the $R^2$ for any continuous response fit is calculated as follows:

- Sum of Squares (Model)
- Sum of Squares (C Total)
Adj Rsquare

Adj Rsquare is a ratio of mean squares instead of sums of squares and is calculated as follows:

\[
1 - \frac{\text{Mean Square (Error)}}{\text{Mean Square (C Total)}}
\]

The mean square for Error is found in the Analysis of Variance report and the mean square for C. Total can be computed as the C. Total Sum of Squares divided by its respective degrees of freedom. See “The Analysis of Variance Report” on page 178.

Tests That the Variances Are Equal

F Ratio

O’Brien’s test constructs a dependent variable so that the group means of the new variable equal the group sample variances of the original response. The O’Brien variable is computed as follows:

\[
\frac{(n_{ij} - 1.5)n_{ij}(y_{ijk} - \bar{y}_{ij})^2 - 0.5s_{ij}^2(n_{ij} - 1)}{(n_{ij} - 1)(n_{ij} - 2)}
\]

where \(n\) represents the number of \(y_{ijk}\) observations.

Brown-Forsythe is the model \(F\) statistic from an ANOVA on \(z_{ij} = |y_{ij} - \bar{y}_i|\) where \(\bar{y}_i\) is the median response for the \(i\)th level.

The Levene \(F\) is the model \(F\) statistic from an ANOVA on \(z_{ij} = |y_{ij} - \bar{y}_i|\) where \(\bar{y}_i\) is the mean response for the \(i\)th level.

Bartlett’s test is calculated as follows:

\[
T = \frac{v\log\left(\sum_i\frac{v_i}{s_i^2}\right) - \sum_i v_i\log(s_i^2)}{1 + \frac{\sum_i \frac{1}{v_i} - \frac{1}{v}}{3(k-1)}}
\]

where \(v_i = n_i - 1\) and \(v = \sum v_i\)

and \(n_i\) is the count on the \(i\)th level and \(s_i^2\) is the response sample variance on the \(i\)th level. The Bartlett statistic has a \(\chi^2\)-distribution. Dividing the Chi-square test statistic by the degrees of freedom results in the reported \(F\) value.
Welch’s Test F Ratio

The Welch’s Test F Ratio is computed as follows:

\[
F = \frac{\left\{ \sum_{i} w_i (\bar{y}_i - \bar{y}_{..})^2 \right\}}{k - 1} \left\{ 1 + \frac{2(k-2)}{k^2 - 1} \left[ \sum_{i} \frac{1 - \frac{w_i}{u}}{n_i - 1} \right] \right\}
\]

where \( w_i = \frac{n_i}{2} \), \( u = \sum_i w_i \bar{y}_i \bar{y}_{..} = \sum_i \frac{w_i \bar{y}_i}{u} \), and \( n_i \) is the count on the \( i \)th level, \( \bar{y}_i \) is the mean response for the \( i \)th level, and \( s_i^2 \) is the response sample variance for the \( i \)th level.

Welch’s Test DF Den

The Welch approximation for the denominator degrees of freedom is defined as follows:

\[
df = \frac{1}{\left( \frac{3}{k^2 - 1} \right) \left[ \sum_i \frac{1 - \frac{w_i}{u}}{n_i - 1} \right]}
\]

where \( w_i \), \( n_i \) and \( u \) are defined as in the F ratio formula.

Nonparametric Test Statistics

This section provides formulas for the test statistics used in the Wilcoxon, Median, van der Waerden, and Friedman Rank tests.

Notation

The tests are based on scores and use the following notation.

\( j = 1, \ldots, n \) The observations in the entire sample.

\( i = 1, \ldots, k \) The levels of \( X \), where \( k \) is the total number of levels.

\( n_1, n_2, \ldots, n_k \) The number of observations in each of the \( k \) levels of \( X \).

\( R_j \) The midrank of the \( j \)th observation. The midrank is the observation’s rank if it is not tied and its average rank if it is tied.

\( \alpha \) A function of the midranks used to define scores for the various tests.
The following notation is used when a Block variable is specified in the launch window.

\[ b = 1, \ldots, B \]  

The levels of the blocking variable, where \( B \) is the total number of blocks.

\[ R_{bi} \]  

The midrank of the \( i^{th} \) level of \( X \) within block \( b \).

The function \( \alpha \) defines scores as follows:

**Wilcoxon Scores**

\[ \alpha(R_j) = R_j \]

**Median Scores**

\[ \alpha(R_j) = \begin{cases} 
1 & \text{if } R_j > \text{median} \\
0 & \text{if } R_j < \text{median} \\
t & \text{if } R_j = \text{median} 
\end{cases} \]

Let \( n_t \) denote the number of observations tied at the median and let \( n_u \) denote the number of observations greater than the median. Then \( t \) is given by the following:

\[ t = \frac{\text{floor}(n/2) - n_u}{n_t} \]

**van der Waerden Scores**

\[ \alpha(R_j) = \text{Standard Normal Quantile}(R_j/(n + 1)) \]

**Friedman Rank Scores**

\[ \alpha(R_{bi}) = R_{bi} \]

**Two-Sample Normal Approximations**

Tests based on the normal approximation are given only when \( X \) has exactly two levels. The notation used in this section is defined in “Notation” on page 242. The statistics that appear in the Two-Sample Normal Approximation report are defined below.

\[ S \]  

The statistic \( S \) is the sum of the values \( \alpha(R_j) \) for the observations in the smaller group. If the two levels of \( X \) have the same numbers of observations, then the value of \( S \) corresponds to the last level of \( X \) in the value ordering.

\[ Z \]  

The value of \( Z \) is defined as follows:

\[ Z = (S - E(S))/\sqrt{\text{Var}(S)} \]
**Note:** The Wilcoxon test adds a continuity correction. If $(S - E(S))$ is greater than zero, then 0.5 is subtracted from the numerator. If $(S - E(S))$ is less than zero, then 0.5 is added to the numerator.

$E(S)$ The expected value of $S$ under the null hypothesis. Denote the number of observations in the smaller level, or in the last level in the value ordering if the two groups have the same number of observations, by $n_l$:

$$E(S) = \frac{n_l}{n} \sum_{j=1}^{n} \alpha(R_j)$$

$Var(S)$ Define $ave$ to be the average score across all observations. Then the variance of $S$ is defined as follows:

$$Var(S) = \frac{n_1 n_2}{n(n-1)} \sum_{j=1}^{n} (\alpha(R_j) - ave)^2$$

**Two-Sample Normal Approximations for Friedman Rank Test**

When you use the Friedman Rank test, the calculations for the two-sample normal approximation is the same as above, except that the variance of $S$ is different. The variance of $S$ is computed as follows:

$$Var(S) = \frac{B}{(n-1)} \sum_{j=1}^{n} (\alpha(R_j) - ave)^2$$

**One-Way ChiSquare Approximations**

**Note:** The ChiSquare test based on the Wilcoxon scores is known as the Kruskal-Wallis test.

The notation used in this section is defined in “Notation” on page 242. The following quantities are used in calculating the ChiSquare statistic:

$T_i$ The total of the scores for the $i^{th}$ level of $X$.

$E(T_i)$ The expected value of the total score for level $i$ under the null hypothesis of no difference in levels, defined as follows:

$$E(T_i) = \frac{n_i}{n} \sum_{j=1}^{n} \alpha(R_j)$$
Define \( \text{ave} \) to be the average score across all observations. Then the variance of \( T \) is defined as follows:

\[
\text{Var}(T) = \frac{1}{(n-1)} \sum_{j=1}^{n} (\alpha(R_j) - \text{ave})^2
\]

The value of the test statistic is given below. This statistic is asymptotically ChiSquare on \( k - 1 \) degrees of freedom.

\[
C = \left( \frac{1}{n} \sum_{i=1}^{k} \left( T_i - E(T_i) \right)^2 / n_i \right) / \text{Var}(T)
\]

**One-Way ChiSquare Approximations for Friedman Rank Test**

The ChiSquare test statistic for the Friedman Rank Test is calculated as follows:

\[
C = \left( \frac{1}{n} \sum_{i=1}^{k} \left( T_i - E(T_i) \right)^2 / n_i \right) /
\left( \frac{1}{(k-1)} \sum_{j=1}^{n} (\alpha(R_j) - \text{ave})^2 / n_i \right)
\]
Chapter 7

Contingency Analysis
Examine Relationships between Two Categorical Variables

Use the Contingency platform to investigate the relationship between two categorical variables. The categorical variables can be nominal or ordinal. The analysis results include a mosaic plot, a contingency table of frequency counts and proportions, and Chi-squared tests of significance. You can interactively perform additional analyses and tests on your data, such as Analysis of Means for Proportions, correspondence analysis and association analyses. The Contingency platform is the *categorical by categorical* personality of the Fit Y by X platform.

Example of Contingency Analysis

Learn how to examine the relationship between two categorical variables in JMP. This example uses data collected from car polls. The data include respondent attributes: sex, marital status, and age. The data also include attributes of the respondent’s car: country of origin, the size, and the type. Examine the relationship between car sizes (small, medium, and large) and the cars’ country of origin.

1. Select Help > Sample Data Library and open Car Poll.jmp.
2. Select Analyze > Fit Y by X.
3. Select size and click Y, Response.
4. Select country and click X, Factor.
5. Click OK.
Launch the Contingency Platform

To perform a contingency analysis, do the following:

1. Select **Analyze > Fit Y by X**.
2. Enter a nominal or ordinal column for **Y, Response**.
3. Enter a nominal or ordinal column for **X, Factor**.

**Figure 7.3** The Fit Y by X Launch Window

The word Contingency appears above the diagram, to indicate that you are performing a contingency analysis.

**Note:** You can also launch a contingency analysis from the JMP Starter window. Select View > JMP Starter > Basic > Contingency.

For more information about this launch window, see the “Introduction to Fit Y by X” chapter on page 113. For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Data Format**

Categorical data are often presented in summary form, where there is only one row in the data table for each combination of levels of the Y and X variables. In this situation, use the Freq or Weight variable to indicate the number of observations that each row represents. For an example of summarized categorical data, see “Example of Analysis of Means for Proportions” on page 267.
The Contingency Report

The Contingency report initially shows a Mosaic Plot, a Contingency Table, and a Tests report. You can run additional analyses and tests using the red triangle menu options. For more information about all of these reports and options, see “Contingency Platform Options” on page 253.

To produce the plot shown in Figure 7.4, follow the instructions in “Example of Contingency Analysis” on page 249.

Figure 7.4 Example of a Contingency Report

Note: Any rows that are excluded in the data table are also hidden in the Mosaic Plot.
Contingency Platform Options

Use the options within the Contingency Analysis red triangle menu to perform additional analyses.

**Note:** The Fit Group menu appears if you have specified multiple Y variables. Menu options enable you to arrange reports or order them by RSquare. See *Fitting Linear Models*.

**Mosaic Plot**  A graphical representation of the data in the Contingency Table. See “Mosaic Plot” on page 255.

**Contingency Table**  A two-way frequency table. There is a row for each factor level and a column for each response level. See “Contingency Table” on page 257.

**Tests**  Analogous to the Analysis of Variance table for continuous data. The tests show that the response level rates are the same across X levels. See “Tests” on page 259.

**Set \( \alpha \) level**  Changes the alpha level used in confidence intervals. Select one of the common values (0.10, 0.05, 0.01) or select a specific value using the *Other* option.

**Analysis of Means for Proportions**  (Appears only if the response has exactly two levels.) Compares response proportions for the X levels to the overall response proportion. See “Analysis of Means for Proportions” on page 260.

**Correspondence Analysis**  Shows which rows or columns of a frequency table have similar patterns of counts. In the correspondence analysis plot, there is a point for each row and for each column of the contingency table. See “Correspondence Analysis” on page 261.

**Cochran Mantel Haenszel**  Tests if there is a relationship between two categorical variables after blocking across a third classification. See “Cochran-Mantel-Haenszel Test” on page 262.

**Agreement Statistic**  (Appears only when the X and Y variables have the same levels.) Displays the Kappa statistic (Agresti 1990), its standard error, confidence interval, hypothesis test, and Bowker’s test of symmetry, also known as McNemar's test. See “Agreement Statistic” on page 263.

**Relative Risk**  (Appears only when the X and Y variables have two levels.) Calculates risk ratios. See “Relative Risk” on page 263.

**Odds Ratio**  (Appears only when the X and Y variables have two levels.) Produces a report of the odds ratio. See “Odds Ratio Option” on page 277.

The report also gives a confidence interval for this ratio. You can change the alpha level using the *Set \( \alpha \) Level* option.
Two Sample Test for Proportions  (Appears only when the X and Y variables have two levels.) Performs a two-sample test for proportions. This test compares the proportions of the Y variable between the two levels of the X variable. See “Two Sample Test for Proportions” on page 264.

Measures of Association  Describes the association between the variables in the contingency table. See “Measures of Association” on page 264.

Cochran Armitage Trend Test  (Appears only when one variable has two levels and the other variable is ordinal.) Tests for trends in binomial proportions across levels of a single variable. See “Cochran Armitage Trend Test” on page 266.

Exact Test  Provides exact versions of the following tests:

- Fisher’s Test
- Cochran Armitage Trend Test
- Agreement Statistic

See “Exact Test” on page 266.

Display Options > Horizontal Mosaic  Rotates the mosaic plot horizontally or vertically.

Make Into Data Table  Creates a JMP data table from the report table.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Mosaic Plot

The mosaic plot is a graphical representation of the two-way frequency table or Contingency Table. A mosaic plot is divided into rectangles; the vertical length of each rectangle is proportional to the proportions of the Y variable in each level of the X variable. The mosaic plot was introduced by Hartigan and Kleiner (1981) and refined by Friendly (1994).

To produce the plot shown in Figure 7.5, follow the instructions in “Example of Contingency Analysis” on page 249.

Figure 7.5  Example of a Mosaic Plot

Note the following about the mosaic plot:

- The proportions on the horizontal axis represent the number of observations for each level of the X variable, which is country.
- The proportions on the vertical axis at right represent the overall proportions of Small, Medium, and Large cars for the combined levels (American, European, and Japanese).
- The scale of the vertical axis at left shows the response probability. The whole axis is equivalent to a probability of one (representing the total sample).

Clicking on a rectangle in the mosaic plot highlights the selection and highlights the corresponding data in the associated data table.

Replace variables in the mosaic plot by dragging and dropping a variable, in one of two ways: swap existing variables by dragging and dropping a variable from one axis to the other axis; or, click a variable in the Columns panel of the associated data table and drag it onto an axis.
Pop-Up Menu

Right-click the mosaic plot to change colors and label the cells.

**Set Colors**  Shows the current assignment of colors to levels. See “Set Colors” on page 256.

**Cell Labeling**  Specify a label to be drawn in the mosaic plot. Select one of the following options:

- **No Labels**  Shows no labels, and removes any of the other options.
- **Label by Count**  Shows the number of observations in each cell.
- **Label by Percent**  Shows the percent of observations in each cell.
- **Label by Value**  Shows the levels of the Y variable corresponding to each cell.
- **Label by Row**  Shows the row labels for all of the rows represented by the cell.

**Note:** For descriptions of the remainder of the right-click options, see *Using JMP*.

**Set Colors**

When you select the **Set Colors** option, the Select Colors for Values window appears.

![Select Colors for Values Window](image)

The default mosaic colors depend on whether the response column is ordinal or nominal, and whether there is an existing Value Colors column property. To change the color for any level, click the oval in the second column of colors and select a new color.

**Description of the Select Colors for Values Window**

**Macros**  Computes a color gradient between any two levels:

- **Gradient Between Ends**  Applies a gradient to all levels of the variable.
- **Gradient Between Selected Points**  Applies a color gradient to the levels that you have selected. You can select a range of levels by dragging the cursor over the levels that you want to select, or by pressing the Shift key and clicking the first and last level.
Reverse Colors  Reverses the color order.

Revert to Old Colors  Reverts any of your changes.

Color Theme  Changes the colors for each value based on a color theme.

Save Colors to Column  If you change the default color theme, then select this check box, a new column property (Value Colors) is added to the column in the associated data table. To edit this property from the data table, select Cols > Column Info.

Contingency Table

The Contingency Table is a two-way frequency table. There is a row for each factor level and a column for each response level.

To produce the plot shown in Figure 7.7, follow the instructions in “Example of Contingency Analysis” on page 249.

Figure 7.7  Example of a Contingency Table

Note the following about Contingency tables:

- The Count, Total%, Col%, and Row% correspond to the data within each cell that has row and column headings (such as the cell under American and Large).
- The last column contains the total counts for each row and percentages for each row.
- The bottom row contains total counts for each column and percentages for each column.

In Figure 7.7, focus on the cars that are large and come from America. The following table explains the conclusions that you can make about these cars using the Contingency Table.
Table 7.1 Conclusions Based on Example of a Contingency Table

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
<th>Label in Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
<td>Number of cars that are both large and come from America</td>
<td>Count</td>
</tr>
<tr>
<td>11.88%</td>
<td>Percentage of all cars that are both large and come from America ((36/303)^{a})</td>
<td>Total%</td>
</tr>
<tr>
<td>85.71%</td>
<td>Percentage of large cars that come from America ((36/42)^{b})</td>
<td>Col%</td>
</tr>
<tr>
<td>31.30%</td>
<td>Percentage of American cars that are large ((36/115)^{c})</td>
<td>Row%</td>
</tr>
<tr>
<td>37.95%</td>
<td>Percentage of all cars that come from America ((115/303))</td>
<td>(none)</td>
</tr>
<tr>
<td>13.86%</td>
<td>Percentage of all cars that are large ((42/303))</td>
<td>(none)</td>
</tr>
</tbody>
</table>

\(a\). 303 is the total number of cars in the poll.
\(b\). 42 is the total number of large cars in the poll.
\(c\). 115 is the total number of American cars in the poll.

Tip: To show or hide data in the Contingency Table, from the red triangle menu next to Contingency Table, select the option that you want to show or hide.

Description of the Contingency Table

**Count**  Cell frequency, margin total frequencies, and grand total (total sample size).

**Total%**  Percent of cell counts and margin totals to the grand total.

**Row%**  Percent of each cell count to its row total.

**Col%**  Percent of each cell count to its column total.

**Expected**  Expected frequency \((E)\) of each cell under the assumption of independence.
    Computed as the product of the corresponding row total and column total divided by the grand total.

**Deviation**  Observed cell frequency \((O)\) minus the expected cell frequency \((E)\).

**Cell Chi Square**  Chi-square values computed for each cell as \(\frac{(O - E)^2}{E}\).

**Col Cum**  Cumulative column total.

### Tests

The Tests report shows the results for two tests to determine whether the response level rates are the same across X levels.

To produce the report shown in Figure 7.8, follow the instructions in “Example of Contingency Analysis” on page 249.

**Figure 7.8  Example of a Tests Report**

Note the following about the Chi-square statistics:

- When both categorical variables are responses (Y variables), the Chi-square statistics test that they are independent.
- You might have a Y variable with a fixed X variable. In this case, the Chi-square statistics test that the distribution of the Y variable is the same across each X level.

### Description of the Tests Report

- **N**  Total number of observations.
- **DF**  Records the degrees of freedom associated with the test. The degrees of freedom are equal to \((c - 1)(r - 1)\), where \(c\) is the number of columns and \(r\) is the number of rows.
- **-LogLike**  Negative log-likelihood, which measures fit and uncertainty (much like sums of squares in continuous response situations). See *Fitting Linear Models*.
- **Rsquare (U)**  Portion of the total uncertainty attributed to the model fit.
  - An \(R^2\) of 1 means that the factors completely predict the categorical response.
  - An \(R^2\) of 0 means that there is no gain from using the model instead of fixed background response rates.
See “Tests Report” on page 278.

**Test**  Lists two Chi-square statistical tests of the hypothesis that the response rates are the same in each sample category. See “Tests Report” on page 278.

**Prob>ChiSq**  Lists the probability of obtaining a Chi-square value greater than the one computed if no relationship exists between the response and factor. If both variables have only two levels, Fisher’s exact probabilities for the one-tailed tests and the two-tailed test also appear.

### Fisher’s Exact Test

This report gives the results of Fisher’s exact test for a 2x2 table. The results appear automatically for 2x2 tables. For more information about Fisher’s exact test and the test for $r \times c$ tables, see “Exact Test” on page 266.

### Analysis of Means for Proportions

The analysis of means for proportions (ANOMP) is a multiple comparison method for testing if individual group proportions differ from the overall proportion.

**Note:** For a description of Analysis of Means methods, see the document by Nelson et al. (2005). See also “Example of Analysis of Means for Proportions” on page 267.

If the response has two levels, you can use this option to compare response proportions for the X levels to the overall response proportion. This method uses the normal approximation to the binomial. Therefore, if the sample sizes are too small, a warning appears in the results.

The following options appear in the red triangle menu:

**Set Alpha Level**  Selects the alpha level used in the analysis.

**Show Summary Report**  Produces a report that shows the response proportions with decision limits for each level of the X variable. The report indicates whether a limit has been exceeded.

**Switch Response Level for Proportion**  Changes the response category used in the analysis.

**Display Options**  Shows or hides the decision limits, decision limit shading, center line, and point options.
Correspondence Analysis

The Correspondence Analysis option in the Contingency platform provides a graphical technique to show which rows or columns of a frequency table have similar patterns of counts. In the correspondence analysis plot, there is a point for each row and for each column. Use Correspondence Analysis when you have many levels, making it difficult to derive useful information from the mosaic plot.

Note: See also “Example of Correspondence Analysis” on page 268.

Understanding Correspondence Analysis Plots

The row profile can be defined as the set of row-wise rates, or in other words, the counts in a row divided by the total count for that row. If two rows have very similar row profiles, their points in the correspondence analysis plot are close together. Squared distances between row points are approximately proportional to Chi-square distances that test the homogeneity between the pair of rows.

Column and row profiles are alike because the problem is defined symmetrically. The distance between a row point and a column point has no meaning. However, the directions of columns and rows from the origin are meaningful, and the relationships help interpret the plot.

Correspondence Analysis Options

Use the options in the Correspondence Analysis red triangle menu to add a 3-D scatterplot to the Contingency report and to add column properties to the data table.

3D Correspondence Analysis  Produces a 3-D scatterplot.

Save Value Order  Takes the order of the levels sorted by the first correspondence score coefficient and makes a column property for both the X and Y columns.

The Details Report

The Details report contains statistical information about the correspondence analysis and shows the values used in the plot.

Singular Value  Provides the singular value decomposition of the contingency table. For the formula, see “Details Report in Correspondence Analysis” on page 279.

Inertia  Lists the square of the singular values, reflecting the relative variation accounted for in the canonical dimensions.
Portion  Portion of inertia with respect to the total inertia.

Cumulative  Shows the cumulative portion of inertia. If the first two singular values capture the bulk of the inertia, then the 2-D correspondence analysis plot is sufficient to show the relationships in the table.

X variable c1, c2, c3  The values plotted on the Correspondence Analysis plot (Figure 7.11).

Y variable c1, c2, c3  The values plotted on the Correspondence Analysis plot (Figure 7.11).

**Cochran-Mantel-Haenszel Test**

The Cochran-Mantel-Haenszel test evaluates the relationship between two categorical variables after blocking across a third classification.

**Note:** See also “Example of a Cochran Mantel Haenszel Test” on page 271.

Correlation of Scores  Applicable when both Y or X are ordinal or interval. The alternative hypothesis is that there is a linear association between Y and X in at least one level of the blocking variable.

Row Score by Col Categories  Applicable when Y is ordinal or interval. The alternative hypothesis is that, for at least one level of the blocking variable, the mean scores of the $r$ rows are unequal.

Col Score by Row Categories  Applicable when X is ordinal or interval. The alternative hypothesis is that, for at least one level of the blocking variable, the mean scores of the $c$ columns are unequal.

General Assoc. of Categories  Tests that for at least one level of the blocking variable, there is some type of association between X and Y.
Agreement Statistic

When the two variables have the same levels, the Agreement Statistic option is available. This option shows the Kappa statistic (Agresti 1990), its standard error, confidence interval, hypothesis test, and Bowker's test of symmetry.

The Kappa statistic and associated $p$-value given in this section are approximate. An exact version of the agreement statistic is available. See “Exact Test” on page 266.

**Note:** For statistical details, see “Agreement Statistic Option” on page 277. See also “Example of the Agreement Statistic Option” on page 272.

- **Kappa** Shows the Kappa statistic.
- **Std Err** Shows the standard error of the Kappa statistic.
- **Lower 95%** Shows the lower endpoint of the confidence interval for Kappa.
- **Upper 95%** Shows the upper endpoint of the confidence interval for Kappa.
- **Prob>Z** Shows the $p$-value for a one-sided test for Kappa. The null hypothesis tests if Kappa equals zero.
- **Prob>|Z|** Shows the $p$-value for a two-sided test for Kappa.
- **ChiSquare** Shows the test statistic for Bowker’s test. For Bowker’s test of symmetry, the null hypothesis is that the probabilities in the square table satisfy symmetry, or that $p_{ij}=p_{ji}$ for all pairs of table cells. When both X and Y have two levels, this test is equal to McNemar’s test.
- **Prob>ChiSq** Shows the $p$-value for the Bowker’s test.

Relative Risk

**Note:** See also “Example of the Relative Risk Option” on page 273.

Calculate risk ratios for 2x2 contingency tables using the Relative Risk option. Confidence intervals also appear in the report. You can find more information about this method in Agresti (1990, sect. 3.4.2).

The Choose Relative Risk Categories window appears when you select the Relative Risk option. You can select a single response and factor combination, or you can calculate the risk ratios for all combinations of response and factor levels.
Two Sample Test for Proportions

When both the X and Y variables have two levels, you can construct a confidence interval for the difference between the two proportions. It also computes the test corresponding to the confidence interval.

**Note:** See also “Example of a Two Sample Test for Proportions” on page 274.

**Description**  Shows the test being performed.

**Proportion Difference**  Shows the difference in the proportions between the levels of the X variable.

**Lower 95%**  Shows the lower endpoint of the confidence interval for the difference. Based on the adjusted Wald confidence interval.

**Upper 95%**  Shows the upper endpoint of the confidence interval for the difference. Based on the adjusted Wald confidence interval.

**Adjusted Wald Test**  Shows two-tailed and one-tailed tests.

**Prob**  Shows the \( p \)-values for the tests.

**Response <variable> category of interest**  Select which response level to use in the test.

---

Measures of Association

The **Measures of Association** option provides association statistics.

**Note:** See also “Example of the Measures of Association Option” on page 275.

**Gamma**  Based on the number of concordant and discordant pairs and ignores tied pairs. Takes values in the range -1 to 1.

**Kendall’s Tau-b**  Similar to Gamma and uses a correction for ties. Takes values in the range -1 to 1.

**Stuart’s Tau-c**  Similar to Gamma and uses an adjustment for table size and a correction for ties. Takes values in the range -1 to 1.

**Somers’ D**  An asymmetric modification of Tau-b.

– The C|R denotes that the row variable X is regarded as an independent variable and the column variable Y is regarded as dependent.
Similarly, the R|C denotes that the column variable Y is regarded as an independent variable and the row variable X is dependent.

Somers’ D differs from Tau-b in that it uses a correction for ties only when the pair is tied on the independent variable. It takes values in the range -1 to 1.

**Lambda Asymmetric** Diffs for C|R and R|C.
- For C|R, is interpreted as the probable improvement in predicting the column variable Y given knowledge of the row variable X.
- For R|C, is interpreted as the probable improvement in predicting the row variable X given knowledge about the column variable Y.

Takes values in the range 0 to 1.

**Lambda Symmetric** Loosely interpreted as the average of the two Lambda Asymmetric measures. Takes values in the range 0 to 1.

**Uncertainty Coef**
- For C|R, is the proportion of uncertainty in the column variable Y that is explained by the row variable X.
- For R|C, is interpreted as the proportion of uncertainty in the row variable X that is explained by the column variable Y.

Takes values in the range 0 to 1.

**Uncertainty Coef Symmetric** Symmetric version of the two Uncertainty Coef measures. Takes values in the range 0 to 1.

**Notes:**
- Each statistic appears with its standard error and confidence interval.
- Gamma, Kendall’s Tau-b, Stuart’s Tau-c, and Somers’ D are measures of ordinal association that consider whether the variable Y tends to increase as X increases. They classify pairs of observations as concordant or discordant. A pair is concordant if an observation with a larger value of X also has a larger value of Y. A pair is discordant if an observation with a larger value of X has a smaller value of Y. These measures are appropriate only when both variables are ordinal.
- The Lambda and Uncertainty measures are appropriate for ordinal and nominal variables.

For computational details about the measures of association statistics, see the FREQ Procedure chapter in SAS Institute Inc. (2020b). The following references also contain additional information:
- Brown and Benedetti (1977)
- Goodman and Kruskal (1979)
- Kendall and Stuart (1979)
Contingency Analysis
Chapter 7
Cochran Armitage Trend Test

- Snedecor and Cochran (1980)
- Somers (1962)

Cochran Armitage Trend Test

Note: See also “Example of the Cochran Armitage Trend Test” on page 276.

This Cochran Armitage Trend tests for trends in binomial proportions across the levels of a single variable. This test is appropriate only when one variable has two levels and the other variable is ordinal. The two-level variable represents the response, and the other represents an explanatory variable with ordered levels. The null hypothesis is the hypothesis of no trend, which means that the binomial proportion is the same for all levels of the explanatory variable.

The test statistic and p-values given in this test are approximate. An exact version of the trend test is available. See “Exact Test” on page 266.

Exact Test

The following Exact tests are available in the Contingency platform:

**Fisher’s Exact Test**  Performs Fisher’s Exact test for an r x c table. This is a test for association between two variables. Fisher’s exact test assumes that the row and column totals are fixed, and uses the hypergeometric distribution to compute probabilities.

This test does not depend on any large-sample distribution assumptions. This means it is appropriate for situations where the Likelihood Ratio and Pearson tests become less reliable, like for small sample sizes or sparse tables.

The report includes the following information:

- **Table Probability (P)**  Gives the probability for the observed table. This is not the p-value for the test.
- **Two-sided Prob \( \leq P \)**  Gives the p-value for the two-sided test.

For 2x2 tables, the Fisher’s Exact test is automatically performed, unless one row or column contains all zeros (in this case, the test cannot be calculated). See “Tests” on page 259.

**Exact Cochran Armitage Trend Test**  Performs the exact version of the Cochran Armitage Trend Test. This test is available only when one of the variables has two levels. For more information about the trend test, see “Cochran Armitage Trend Test” on page 266.
**Exact Agreement Statistic**  Performs an exact test for testing agreement between variables. This is an exact test for the Kappa statistic. This is available only when the two variables have the same levels. For more information about agreement testing, see “Agreement Statistic” on page 263.

**Note:** If the overall sample size is larger than 32767 and the contingency table is larger than 2x2, the exact test options are not available.

---

**Additional Examples of the Contingency Platform**

- “Example of Analysis of Means for Proportions”
- “Example of Correspondence Analysis”
- “Example of a Cochran Mantel Haenszel Test”
- “Example of the Agreement Statistic Option”
- “Example of the Relative Risk Option”
- “Example of a Two Sample Test for Proportions”
- “Example of the Measures of Association Option”
- “Example of the Cochran Armitage Trend Test”

**Example of Analysis of Means for Proportions**

This example shows you how to examine the proportion of patients that arrived on-time to their appointments. The Office Visits.jmp sample data table records late and on-time appointments for six clinics in a geographic region. 60 random appointments were selected from 1 week of records for each of the six clinics. To be considered on-time, the patient must be taken to an exam room within five minutes of their scheduled appointment time.

1. Select **Help > Sample Data Library** and open Office Visits.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select **On Time** and click **Y, Response**.
4. Select **Clinic** and click **X, Factor**.
5. Select **Frequency** and click **Freq**.
6. Click **OK**.
7. Click the red triangle next to Contingency Analysis of On Time By Clinic and select **Analysis of Means for Proportions**.
8. Click the red triangle next to Analysis of Means for Proportions and select **Show Summary Report** and **Switch Response Level for Proportion**.
Figure 7.9  Example of Analysis of Means for Proportions

Figure 7.9 shows the proportion of patients who were on-time from each clinic. From Figure 7.9, notice the following:

- The proportion of on-time arrivals is the highest for clinic F, followed by clinic B.
- Clinic D has the lowest proportion of on-time arrivals, followed by clinic A.
- Clinic E and clinic C are close to the average, and do not exceed the decision limits.

Example of Correspondence Analysis

This example uses the Cheese.jmp sample data table. This table contains data from the Newell cheese tasting experiment; the data were reported in McCullagh and Nelder (1989). The experiment records counts more than nine different response levels across four different cheese additives.

1. Select Help > Sample Data Library and open Cheese.jmp.
2. Select Analyze > Fit Y by X.
   The Response values range from one to nine, where one is the least liked, and nine is the best liked.
4. Select Cheese and click X, Factor.
   A, B, C, and D represent four different cheese additives.
5. Select Count and click **Freq**.

6. Click **OK**.

**Figure 7.10**  Mosaic Plot for the Cheese Data

From the mosaic plot, you notice that the distributions do not appear alike. However, it is challenging to make sense of the mosaic plot across nine levels. A correspondence analysis can help define relationships in this type of situation.

7. To see the correspondence analysis plot, click the red triangle next to Contingency Analysis of Response By Cheese and select **Correspondence Analysis**.

**Figure 7.11**  Example of a Correspondence Analysis Plot
Figure 7.11 shows the correspondence analysis graphically, where the plot axes are labeled c1 and c2. Notice the following:

- c1 seems to correspond to a general satisfaction level. The cheeses on the c1 axis go from least liked at the top to most liked at the bottom.
- Cheese D is the most liked cheese, with responses of 8 and 9.
- Cheese B is the least liked cheese, with responses of 1, 2, and 3.
- Cheeses C and A are in the middle, with responses of 4, 5, 6, and 7.

8. Click the red triangle next to Correspondence Analysis and select 3D Correspondence Analysis.

Figure 7.12 Example of a 3-D Scatterplot

Notice the following:

- Looking at the c1 axis, responses 1 through 5 appear to the right of 0 (positive). Responses 6 through 9 appear to the left of 0 (negative).
- Looking at the c2 axis, A and C appear to the right of 0 (positive). B and D appear to the left of 0 (negative).
- You can conclude that c1 corresponds to the general satisfaction (from least to most liked).
Example of a Cochran Mantel Haenszel Test

This example examines the relationship between hot dog type and taste.

1. Select Help > Sample Data Library and open Hot Dogs.jmp.
2. Select Analyze > Fit Y by X.
3. Select Type and click Y, Response.
4. Select Taste and click X, Factor.
5. Click OK.
6. Click the red triangle next to Contingency Analysis of Type By Taste and select Cochran Mantel Haenszel.
7. Select Protein/Fat as the grouping variable and click OK.

Figure 7.13 Example of a Cochran-Mantel-Haenszel Test

Notice the following:

- The Tests report shows a marginally significant Chi-square probability of about 0.0799, indicating some significance in the relationship between hot dog taste and type.
The Cochran Mantel Haenszel report shows that the \( p \)-value for the general association of categories is 0.2816, which is much larger than 5%.

**Example of the Agreement Statistic Option**

This example examines the relationship between two raters. The data gives results from three people (raters) rating fifty parts three times each. Examine the relationship between raters A and B.

1. Select **Help > Sample Data Library** and open **Attribute Gauge.jmp**.
2. Select **Analyze > Fit Y by X**.
3. Select A and click **Y, Response**.
4. Select B and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Contingency Analysis of A By B and select **Agreement Statistic**.

**Figure 7.14  Example of the Agreement Statistic Report**
You notice that the agreement statistic of 0.86 is high (close to 1) and the p-value of <.0001 is small. This reinforces the high agreement seen by looking at the diagonal of the contingency table. Agreement between the raters occurs when both raters give a rating of 0 or both give a rating of 1.

Example of the Relative Risk Option

This example examines the relative probabilities of being married and single for the participants in a poll.

1. Select Help > Sample Data Library and open Car Poll.jmp.
2. Select Analyze > Fit Y by X.
3. Select marital status and click Y, Response.
4. Select sex and click X, Factor.
5. Click OK.
6. Click the red triangle next to Contingency Analysis of marital status By sex and select Relative Risk.
   The Choose Relative Risk Categories window appears.

Figure 7.15  The Choose Relative Risk Categories Window

Note the following about the Choose Relative Risk Categories window:

- If you are interested in only a single response and factor combination, you can select that here. For example, if you clicked OK in the window in Figure 7.15, this is the calculation:

\[
\frac{P(Y = \text{Married} \mid X = \text{Female})}{P(Y = \text{Married} \mid X = \text{Male})}
\]

- If you would like to calculate the risk ratios for all \(2 \times 2 = 4\) combinations of response and factor levels, select the Calculate All Combinations check box (Figure 7.16).

7. Ask for all combinations by selecting the Calculate All Combinations check box. Leave all other default selections as is.
**Figure 7.16** Example of the Risk Ratio Report

![Contingency Analysis Table](image)

The relative risk is calculated as follows:

1. Examine the first entry in the Relative Risk report, which is $P(\text{Married} | \text{Female})/P(\text{Married} | \text{Male})$.

2. You can find these probabilities in the Contingency Table. Since the probabilities are computed based on two levels of sex, which differs across the rows of the table, use the Row% to read the probabilities:

   
   \[
   \begin{align*}
   P(\text{Married} | \text{Female}) &= 0.6884 \\
   P(\text{Married} | \text{Male}) &= 0.6121
   \end{align*}
   \]

   Therefore, the relative risk is calculated as follows:

   \[
   P(\text{Married} | \text{Female})/P(\text{Married} | \text{Male}) = \frac{0.6884}{0.6121} = 1.1247
   \]

**Example of a Two Sample Test for Proportions**

This example examines the probability of being married for males and females.

1. Select Help > Sample Data Library and open Car Poll.jmp.

2. Select Analyze > Fit Y by X.

3. Select marital status and click Y, Response.

4. Select sex and click X, Factor.

5. Click OK.

6. Click the red triangle next to Contingency Analysis of marital status By sex and select Two Sample Test for Proportions.
In this example, you are comparing the probability of being married between females and males. See the Row% in the Contingency Table to obtain the following:

\[
P(\text{Married} \mid \text{Female}) = 0.6884 \\
P(\text{Married} \mid \text{Male}) = 0.6121
\]

The difference between these two numbers, 0.0763, is the Proportion Difference shown in the report. The two-sided confidence interval is \([-0.03175, 0.181621]\). The \(p\)-value by the adjusted Wald method corresponding to the confidence interval is 0.1686, which is close to the \(p\)-value (0.1665) by Pearson’s Chi-square test. Generally, Pearson’s Chi-square test is more popular than the modified Wald’s test for testing the difference of two proportions.

**Example of the Measures of Association Option**

This example examines the association of being married with gender.

1. Select Help > Sample Data Library and open Car Poll.jmp.
2. Select Analyze > Fit Y by X.
3. Select marital status and click Y, Response.
4. Select sex and click X, Factor.
5. Click OK.
6. Click the red triangle next to Contingency Analysis of marital status By sex and select Measures of Association.
Since the variables that you want to examine (sex and marital status) are nominal, use the Lambda and Uncertainty measures. All of them are small, so it seems that there is a weak association between sex and marital status.

**Example of the Cochran Armitage Trend Test**

This example investigates whether there is a relationship between the proportion of males and females that buy different sizes of cars.

1. Select Help > Sample Data Library and open Car Poll.jmp.

For the purposes of this test, change size to an ordinal variable:

2. In the Columns panel, right-click the icon next to size and select Ordinal.

3. Select Analyze > Fit Y by X.

4. Select sex and click Y, Response.

5. Select size and click X, Factor.

6. Click OK.

7. Click the red triangle next to Contingency Analysis of sex By size and select Cochran Armitage Trend Test.

**Figure 7.19  Example of the Cochran Armitage Trend Test Report**

The two-sided \( p \)-value (0.7094) is large. From this, you cannot conclude that there is a relationship in the proportion of male and females that purchase different sizes of cars.
Statistical Details for the Contingency Platform

- “Agreement Statistic Option”
- “Odds Ratio Option”
- “Tests Report”
- “Details Report in Correspondence Analysis”

**Agreement Statistic Option**

Viewing the two response variables as two independent ratings of the \( n \) subjects, the Kappa coefficient equals +1 when there is complete agreement of the raters. When the observed agreement exceeds chance agreement, the Kappa coefficient is positive and its magnitude reflects the strength of agreement. Although unusual in practice, Kappa is negative when the observed agreement is less than chance agreement. The minimum value of Kappa is between -1 and 0, depending on the marginal proportions.

The Kappa coefficient is computed as follows:

\[
\hat{\kappa} = \frac{P_0 - P_c}{1 - P_c} \quad \text{where} \quad P_0 = \sum_{i} p_{ii} \quad \text{and} \quad P_c = \sum_{i} p_{i+} p_{+i}
\]

Note that \( p_{ij} \) is the proportion of subjects in the \((i, j)^{th}\) cell, such that \( \sum_{i,j} p_{ij} = 1 \).

The asymptotic variance of the simple kappa coefficient is estimated by the following:

\[
\text{var} = \frac{A + B - C}{(1 - P_c)^2 n} \quad \text{where} \quad A = \sum_{i} p_{ii}[1 - (p_{i+} + p_{+i})(1 - \hat{\kappa})]^2, \quad B = (1 - \hat{\kappa})^2 \sum_{i \neq j} p_{ij}(p_{i+} + p_{+j})^2 \quad \text{and} \quad C = [\hat{\kappa} - P_c (1 - \hat{\kappa})]^2
\]

For Bowker’s test of symmetry, the null hypothesis is that the probabilities in the two-by-two table satisfy symmetry \((p_{ij} = p_{ji})\).

**Odds Ratio Option**

The Odds Ratio is calculated as follows:

\[
\frac{p_{11} \times p_{22}}{p_{12} \times p_{21}}
\]
where $p_{ij}$ is the count in the $i^{th}$ row and $j^{th}$ column of the 2x2 table.

**Tests Report**

**Rsquare (U)**

Rsquare (U) is computed as follows:

\[
\text{Rsquare (U)} = \frac{-\text{log likelihood for Model}}{-\text{log likelihood for Corrected Total}}
\]

The total negative log-likelihood is found by fitting fixed response rates across the total sample.

**Test**

The two Chi-square tests are computed as follows:

The Likelihood Ratio Chi-square test statistic is computed as twice the negative log-likelihood for Model in the Tests table. Some books use the notation $G^2$ for this statistic. The difference of two negative log-likelihoods, one with whole-population response probabilities and one with each-population response rates, is defined as follows:

\[
G^2 = 2 \left[ \sum_{ij} (-n_{ij}) \ln(p_{ij}) - \sum_{ij} n_{ij} \ln(p_{ij}) \right] \text{ where } p_{ij} = \frac{n_{ij}}{N} \text{ and } p_j = \frac{N_j}{N}
\]

This formula can be more compactly written as follows:

\[
G^2 = 2 \sum_i \sum_j n_{ij} \ln \left( \frac{n_{ij}}{e_{ij}} \right)
\]

The Pearson Chi-square test statistic is calculated by summing the squares of the differences between the observed and expected cell counts. The Pearson Chi-square test exploits the property that frequency counts tend to a normal distribution in very large samples. The familiar form of this Chi-square statistic is defined as follows:

\[
\chi^2 = \sum \frac{(O - E)^2}{E}
\]

where $O$ is the observed cell counts and $E$ is the expected cell counts. The summation is over all cells. There is no continuity correction done here, as is sometimes done in 2-by-2 tables.
Details Report in Correspondence Analysis

Lists values from the following singular value decomposition (SVD):

\[ \mathbf{D}^{-0.5}_r (\mathbf{P} - re') \mathbf{D}^{-0.5}_c = \mathbf{U} \text{Diag}(\Lambda) \mathbf{V}' \]

where:

- \( \mathbf{P} \) is the matrix of counts divided by the total frequency
- \( r \) and \( c \) are row and column sums of \( \mathbf{P} \)
- the \( \mathbf{D} \) matrices are diagonal matrices of the values of \( r \) and \( c \)
- \( \Lambda \) is the column vector of the singular values reported in the details report

For more information about singular value decomposition, see *Multivariate Methods*.

The row coordinates \((rc)\) and column coordinates \((cc)\) in the details report are computed as follows:

\[ rc = \mathbf{D}^{-0.5}_r \mathbf{U} \text{Diag}(\Lambda) \]

\[ cc = \mathbf{D}^{-0.5}_c \mathbf{V} \text{Diag}(\Lambda) \]
Chapter 8

Logistic Analysis

Examine Relationships between a Categorical Y and a Continuous X Variable

Use the Logistic platform to fit a logistic regression model to a categorical response with a continuous X predictor. Options include a ROC curve, lift curve, and odds ratio estimates. The fitted model estimates probabilities for each X value. The Logistic platform is the nominal or ordinal by continuous personality of the Fit Y by X platform. There is a distinction between nominal and ordinal responses on this platform:

- Nominal logistic regression estimates a set of curves to partition the probability among the responses.
- Ordinal logistic regression models the probability of being less than or equal to a given response. This has the effect of estimating a single logistic curve, which is shifted horizontally to produce probabilities for the ordered categories. This model is less complex and is recommended for ordered responses.

Overview of Logistic Regression

Logistic regression has a long tradition with widely varying applications such as modeling dose-response data and purchase-choice data. Unfortunately, many introductory statistics courses do not cover this fairly simple method. Many texts in categorical statistics cover it (Agresti 1990), in addition to texts on logistic regression (Hosmer and Lemeshow 1989). Some analysts use the method with a different distribution function, the normal. In that case, it is called probit analysis. Some analysts use discriminant analysis instead of logistic regression because they prefer to think of the continuous variables as Ys and the categories as Xs and work backward. However, discriminant analysis assumes that the continuous data are normally distributed random responses, rather than fixed regressors.

Simple logistic regression is a more graphical and simplified version of the general facility for categorical responses in the Fit Model platform. For examples of more complex logistic regression models, see Fitting Linear Models.

Nominal Logistic Regression

Nominal logistic regression estimates the probability of choosing one of the response levels as a smooth function of the x factor. The fitted probabilities must be between 0 and 1, and must sum to 1 across the response levels for a given factor value.

In a logistic probability plot, the vertical axis represents probability. For k response levels, k - 1 smooth curves partition the total probability (which equals 1) among the response levels. The fitting principle for a logistic regression minimizes the sum of the negative natural logarithms of the probabilities fitted to the response events that occur (that is, maximum likelihood).

Ordinal Logistic Regression

When Y is ordinal, a modified version of logistic regression is used for fitting. The cumulative probability of being at or below each response level is modeled by a curve. The curves are the same for each level except that they are shifted to the right or left.

The ordinal logistic model fits a different intercept, but the same slope, for each of r - 1 cumulative logistic comparisons, where r is the number of response levels. Each parameter estimate can be examined and tested individually, although this is seldom of much interest.

The ordinal model is preferred to the nominal model when it is appropriate because it has fewer parameters to estimate. In fact, it is practical to fit ordinal responses with hundreds of response levels.
Example of Nominal Logistic Regression

Learn how to examine the relationship between a nominal Y response and a continuous X factor. The data in this example comes from an experiment where 5 groups, each containing 12 rabbits, were injected with streptococcus bacteria. Once the rabbits were confirmed to have the bacteria in their system, they were given different doses of penicillin. You want to find out whether the natural log (\(\ln(dose)\)) of dosage amounts has any effect on whether the rabbits are cured.

1. Select Help > Sample Data Library and open Penicillin.jmp.
2. Select Analyze > Fit Y by X.
4. Select ln(dose) and click X, Factor.
   Notice that JMP automatically fills in Count for Freq. Count was previously assigned the role of Freq.
5. From the Target Level list, select Cured.
6. Click OK.
Figure 8.2 Example of Nominal Logistic Report

The plot shows the fitted model as a function of ln(dose). The fitted model is the predicted probability of being cured. The p-value is significant, indicating that the dosage amounts have a significant effect on whether the rabbits are cured.

Tip: To change the response level that is analyzed, specify a Target Level in the launch window or use the Value Order column property.

Launch the Logistic Platform

To perform a logistic analysis, do the following:

1. Select Analyze > Fit Y by X.
2. Enter a nominal or ordinal column for Y, Response.
3. Enter a continuous column for **X, Factor**.

**Figure 8.3 Fit Y by X Launch Window**

The word Logistic appears above the image, to indicate that you are performing a logistic analysis.

**Note:** You can also launch a logistic analysis from the JMP Starter window. Select **View > JMP Starter > Basic > Logistic**.

When the response is binary and has a nominal modeling type, a Target Level menu appears in the launch window. Use this menu to specify the level of the response whose probability you want to model.

**Tip:** The default value is the higher of the two levels based on the order of the levels. Check that the default value is the level that you want to model.

For more information about the Fit Y by X launch window, see the “Introduction to Fit Y by X” chapter on page 113. For more information about the options in the Select Columns red triangle menu, see Using JMP.

**Data Structure**

Your data can consist of unsummarized or summarized data:

**Unsummarized data** There is one row for each observation containing its X value and its Y value.

**Summarized data** Each row represents a set of observations with common X and Y values. The data table must contain a column that gives the counts for each row. Enter this column as Freq in the launch window.
The Logistic Report

The Logistic report window contains the Logistic plot, the Iterations report, the Whole Model Test report, the Fit Details report, and the Parameter Estimates report.

To produce the plot shown in Figure 8.4, follow the instructions in “Example of Nominal Logistic Regression” on page 284.

Figure 8.4 Example of a Logistic Report

Note: The red triangle menu provides more options that can add to the initial report window. See “Logistic Platform Options” on page 291.
Logistic Plot

The logistic probability plot illustrates the logistic fit. At each value on the horizontal axis, the probability scale in the vertical direction is partitioned into probabilities for each response category. The probabilities are measured as the vertical distance between the curves, with the total across all response category probabilities summing to 1.

The points in the logistic plot represent the observations from the data table. The horizontal position of each point is determined by its value of continuous factor. The vertical position of each point is randomly chosen to be between curves that correspond to the value of its response category. This jittering of the points makes it easier to see where the points are most dense, but the vertical position does not correspond to the values on the vertical axis. Because a fixed random seed is used, the vertical positions do not differ across multiple fits of the same model.

You can replace variables in the plot by clicking on a variable in the Columns panel of the associated data table and dragging it onto an axis.

Note: See also “Additional Example of a Logistic Plot” on page 296.

Iterations

The Iterations report shows each iteration and the evaluated criteria that determine whether the logistic model has converged. Iterations appear only for nominal logistic regression.

Whole Model Test

The Whole Model Test report shows if the model fits better than constant response probabilities. This report is analogous to the Analysis of Variance report for a continuous response model. It is a specific likelihood ratio Chi-square test that evaluates how well the categorical model fits the data.

The negative sum of natural logs of the observed probabilities is called the negative log-likelihood (–LogLikelihood). The negative log-likelihood for categorical data plays the same role as sums of squares in continuous data: twice the difference in the negative log-likelihood from the model fitted by the data and the model with equal probabilities is a Chi-square statistic. This test statistic examines the hypothesis that the x variable has no effect on the responses.

Values of the RSquare (U) (sometimes denoted as $R^2$) range from 0 to 1. High $R^2$ values are indicative of a good model fit, and are rare in categorical models.
The Whole Model Test report contains the following columns:

**Model**  Sometimes called Source.
- The **Reduced** model contains only an intercept.
- The **Full** model contains all of the effects as well as the intercept.
- The **Difference** is the difference of the log-likelihoods of the full and reduced models.

**DF**  Records the degrees of freedom associated with the model.

**–LogLikelihood**  Measures variation, sometimes called *uncertainty*, in the sample.

- **Full** (the full model) is the negative log-likelihood (or uncertainty) calculated after fitting the model. The fitting process involves predicting response rates with a linear model and a logistic response function. This value is minimized by the fitting process.
- **Reduced** (the reduced model) is the negative log-likelihood (or uncertainty) for the case when the probabilities are estimated by fixed background rates. This is the background uncertainty when the model has no effects.

The difference of these two negative log-likelihoods is the reduction due to fitting the model. Two times this value is the likelihood ratio Chi-square test statistic.

See *Fitting Linear Models*.

**Chi-Square**  The likelihood ratio Chi-square test of the hypothesis that the model fits no better than fixed response rates across the whole sample. It is twice the –LogLikelihood for the Difference Model. It is two times the difference of two negative log-likelihoods, one with whole-population response probabilities and one with each-population response rates. See “Statistical Details for the Logistic Platform” on page 302.

**Prob>ChiSq**  The observed significance probability, often called the *p*-value, for the Chi-square test. It is the probability of getting a Chi-square value greater than the one computed. Models are often judged significant if this probability is below 0.05.

**RSquare (U)**  The proportion of the total uncertainty that is attributed to the model fit, defined as the **Difference** negative log-likelihood value divided by the **Reduced** negative log-likelihood value. An RSquare (U) value of 1 indicates that the predicted probabilities for events that occur are equal to one: There is no uncertainty in predicted probabilities. Because certainty in the predicted probabilities is rare for logistic models, RSquare (U) tends to be small. See “Statistical Details for the Logistic Platform” on page 302.

**Note:** RSquare (U) is also known as McFadden’s *pseudo R-square*.

**AICc**  The corrected Akaike Information Criterion. See *Fitting Linear Models*.

**BIC**  The Bayesian Information Criterion. See *Fitting Linear Models*.
Observations  Sometimes called Sum Wgts. The total sample size used in computations. If you specified a Weight variable, this is the sum of the weights.

Fit Details

The Fit Details report in the Logistic Platform contains the following statistics:

Measure  Contains the following measures of fit:

   Entropy RSquare  Compares the log-likelihoods from the fitted model and the constant probability model. This is the same as Rsquare (U). See “Statistical Details for the Logistic Platform” on page 302.

   Generalized RSquare  A measure that can be applied to general regression models. It is based on the likelihood function L and is scaled to have a maximum value of 1. The Generalized RSquare measure simplifies to the traditional RSquare for continuous normal responses in the standard least squares setting. Generalized RSquare is also known as the Nagelkerke or Craig and Uhler $R^2$, which is a normalized version of Cox and Snell’s pseudo $R^2$. See Nagelkerke (1991).

   Mean -Log p  The average of -log($p$), where $p$ is the fitted probability associated with the event that occurred.

   RASE  The root average square error, where the differences are between the response and $p$ (the fitted probability for the event that actually occurred).

   Mean Abs Dev  The average of the absolute values of the differences between the response and $p$ (the fitted probability for the event that actually occurred).

   Misclassification Rate  The rate for which the response category with the highest fitted probability is not the observed category.

   N  The number of observations.

For Entropy RSquare and Generalized RSquare, values closer to 1 indicate a better fit. For Mean -Log p, RASE, Mean Abs Dev, and Misclassification Rate, smaller values indicate a better fit.

Training  The value of the measure of fit.

Definition  The algebraic definition of the measure of fit.
Parameter Estimates

The nominal logistic model fits a parameter for the intercept and slope for each of \( k - 1 \) logistic comparisons, where \( k \) is the number of response levels. The Parameter Estimates report lists these estimates. Each parameter estimate can be examined and tested individually, although this is seldom of much interest.

**Term**  Lists each parameter in the logistic model. There is an intercept and a slope term for the factor at each level of the response variable, except the last level.

**Estimate**  Lists the parameter estimates given by the logistic model.

**Std Error**  Lists the standard error of each parameter estimate. They are used to compute the statistical tests that compare each term to zero.

**Chi-Square**  Lists the Wald tests for the hypotheses that each of the parameters is zero. The Wald Chi-square is computed as \((\text{Estimate} / \text{Std Error})^2\).

**Prob>ChiSq**  Lists the observed significance probabilities for the Chi-square tests.

Covariance of Estimates

Reports the estimated variances of the parameter estimates, and the estimated covariances between the parameter estimates. The square root of the variance estimates is the same as those given in the **Std Error** section.

---

Logistic Platform Options

The Logistic Fit red triangle menu contains options that affect the Logistic plot. If you have specified multiple Y response variables, the Fit Group red triangle menu appears instead. See *Fitting Linear Models*.

**Odds Ratios**  Adds odds ratios to the Parameter Estimates report. See *Fitting Linear Models*.

This option is available only for a response with two levels.

**Inverse Prediction**  Prediction of \( x \) values from given \( y \) values. See “Inverse Prediction” on page 294.

This option is available only for two-level nominal responses.

**Logistic Plot**  Shows or hides the logistic plot.

**Plot Options**  Contains the following options:

**Show Points**  Shows or hides the points in the logistic plot.
Show Rate Curve  Is useful only if you have several points for each x-value. In these cases, you get reasonable estimates of the rate at each value, and compare this rate with the fitted logistic curve. To prevent too many degenerate points, usually at zero or one, JMP shows only the rate value if there are at least three points at the x-value.

Line Color  Enables you to select the color of the plot curves.

ROC Curve  Produces a Receiver Operating Characteristic (ROC) curve. The ROC curve is a plot of sensitivity versus (1 - specificity) for each value of x. See “ROC Curves” on page 292.

Lift Curve  Produces a lift curve for the model. A lift curve shows the same information as a ROC curve, but in a way to dramatize the richness of the ordering at the beginning. The vertical axis shows the ratio of how rich that portion of the population is in the chosen response level compared to the rate of that response level as a whole. See Fitting Linear Models for more information about lift curves.

Save Probability Formula  Creates new data table columns that contain formulas. See “Save Probability Formula” on page 293.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

ROC Curves

When you do a simple logistic regression with a binary outcome, there is a platform option for a ROC curve for that analysis. After selecting the ROC Curve option, you must specify which level to use as the positive response.

Note: See also “Example of ROC Curves” on page 298.
Suppose you have an $x$ value that is a diagnostic measurement and you want to determine a threshold value of $x$ that indicates the following:

- A condition exists if the $x$ value is greater than the threshold.
- A condition does not exist if the $x$ value is less than the threshold.

For example, you could measure a blood component level as a diagnostic test to predict a type of cancer. Now consider the diagnostic test as you vary the threshold and thus cause more or fewer false positives and false negatives. You then plot those rates. The ideal is to have a very narrow range of $x$ criterion values that best divides true negatives and true positives. The Receiver Operating Characteristic (ROC) curve shows how rapidly this transition happens. The goal of the ROC curve is to have diagnostics that maximize the area under the curve.

Two standard definitions are used in medicine:

- **Sensitivity**, the probability that a given $x$ value (a test or measure) correctly predicts an existing condition. For a given $x$, the probability of incorrectly predicting the existence of a condition is $1 - \text{sensitivity}$.
- **Specificity**, the probability that a test correctly predicts that a condition does not exist.

A ROC curve is a plot of sensitivity by $(1 - \text{specificity})$ for each value of $x$. The area under the ROC curve is a common index used to summarize the information contained in the curve.

If a test predicted perfectly, it would have a value above which the entire abnormal population would fall and below which all normal values would fall. It would be perfectly sensitive and then pass through the point (0,1) on the grid. The closer the ROC curve comes to this ideal point, the better its discriminating ability. A test with no predictive ability produces a curve that follows the diagonal of the grid (DeLong et al. 1988).

The ROC curve is a graphical representation of the relationship between false-positive and true-positive rates. A standard way to evaluate the relationship is with the area under the curve, shown below the plot in the report. In the plot, a yellow line is drawn at a 45-degree angle tangent to the ROC Curve. This marks a good cutoff point under the assumption that false negatives and false positives have similar costs.

### Save Probability Formula

The **Save Probability Formula** option creates new data table columns. These data table columns save the following:

- formulas for linear combinations (typically called logits) of the $x$ factor
- prediction formulas for the response level probabilities
- a prediction formula that gives the most likely response
Inverse Prediction

Inverse prediction is the opposite of prediction. It is the prediction of $x$ values from given $y$ values. But in logistic regression, instead of a $y$ value, you have the probability attributed to one of the $Y$ levels. This feature works only for two-level nominal responses.

The Fit Model platform also has an option that gives an inverse prediction with confidence limits. See Fitting Linear Models for more information about inverse prediction.

Note: See also “Example of Inverse Prediction Using the Crosshair Tool” on page 299 and “Example of Inverse Prediction Using the Inverse Prediction Option” on page 300.

Additional Examples of Logistic Regression

This section contains additional examples using logistic regression in the Logistic platform.

- “Example of Ordinal Logistic Regression”
- “Additional Example of a Logistic Plot”
- “Example of ROC Curves”
- “Example of Inverse Prediction Using the Crosshair Tool”
- “Example of Inverse Prediction Using the Inverse Prediction Option”

Example of Ordinal Logistic Regression

This example shows you how to examine the relationship between an ordinal $Y$ response and a continuous $X$ factor. In this example, suppose you want to model the severity of an adverse event as a function of treatment duration value.

1. Select Help > Sample Data Library and open AdverseR.jmp.
2. Right-click the icon to the left of ADR SEVERITY and change the modeling type to ordinal.
3. Select Analyze > Fit Y by X.
4. Select ADR SEVERITY and click Y, Response.
5. Select ADR DURATION and click X, Factor.
6. Click OK.
You interpret this report the same way as the nominal report. See “The Logistic Report” on page 287.

In the plot, markers for the data are drawn at their $x$-coordinate. When several data points appear at the same $y$ position, the points are jittered. That is, small spaces appear between the data points so that you can see each point more clearly.

Where there are many points, the curves are pushed apart. Where there are few to no points, the curves are close together. The data pushes the curves in that way because the criterion that is maximized is the product of the probabilities fitted by the model. The fit tries to avoid points attributed to have a small probability, which are points crowded by the curves of fit. See Fitting Linear Models for more information about computational details.

For more information about the Whole Model Test report and the Parameter Estimates report, see “The Logistic Report” on page 287. In the Parameter Estimates report, an intercept parameter is estimated for every response level except the last, but there is only one slope parameter. The intercept parameters show the spacing of the response levels. They always increase monotonically.
Additional Example of a Logistic Plot

In this example, suppose you want to use car weight to predict car size (Type) for 116 cars. Car size can be one of the following, from smallest to largest: Sporty, Small, Compact, Medium, or Large.

1. Select Help > Sample Data Library and open Car Physical Data.jmp.
2. In the Columns panel, right-click the icon to the left of Type, and select Ordinal.
3. Right-click Type and select Column Info.
4. From the Column Properties menu, select Value Order.
5. Verify that the data are in the following top-down order: Sporty, Small, Compact, Medium, Large.
6. Click OK.
7. Select Analyze > Fit Y by X.
8. Select Type and click Y, Response.
9. Select Weight and click X, Factor.
10. Click OK.

The report window appears.

Figure 8.6 Example of Type by Weight Logistic Plot

Note the following observations:

- The first (bottom) curve represents the probability that a car at a given weight is Sporty.
- The second curve represents the probability that a car is Small or Sporty. Looking only at the distance between the first and second curves corresponds to the probability of being Small.
• As you might expect, heavier cars are more likely to be Large.
• Markers for the data are drawn at their x-coordinate. The y position is jittered randomly within the range corresponding to the response category for that row.

If the x-variable has no effect on the response, then the fitted lines are horizontal and the probabilities are constant for each response across the continuous factor range. Figure 8.7 shows a logistic plot where Weight is not useful for predicting Type.

**Figure 8.7** Examples of Sample Data Table and Logistic Plot Showing No y by x Relationship

<table>
<thead>
<tr>
<th>Type</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Large</td>
<td>2500</td>
</tr>
<tr>
<td>Medium</td>
<td>2500</td>
</tr>
<tr>
<td>Compact</td>
<td>2500</td>
</tr>
<tr>
<td>Small</td>
<td>2500</td>
</tr>
<tr>
<td>Sporty</td>
<td>2500</td>
</tr>
<tr>
<td>Large</td>
<td>3500</td>
</tr>
<tr>
<td>Medium</td>
<td>3500</td>
</tr>
<tr>
<td>Compact</td>
<td>3500</td>
</tr>
<tr>
<td>Small</td>
<td>3500</td>
</tr>
<tr>
<td>Sporty</td>
<td>3500</td>
</tr>
</tbody>
</table>

**Note:** To re-create the plots in Figure 8.7 and Figure 8.8, you must first create the data tables shown here, and then perform steps 7-10 at the beginning of this section.

If the response is completely predicted by the value of the factor, then the logistic curves are effectively vertical. The prediction of a response is near certain (the probability is almost 1) at each of the factor levels. Figure 8.8 shows a logistic plot where Weight almost perfectly predicts Type.
Figure 8.8 Examples of Sample Data Table and Logistic Plot Showing an Almost Perfect \( y \) by \( x \) Relationship

In this case, the parameter estimates become very large and are labeled *unstable* in the regression report. In these cases, you might consider using the Generalized Linear Model personality with Firth bias-adjusted estimates. See *Fitting Linear Models*.

**Example of ROC Curves**

1. Select **Help > Sample Data Library** and open Penicillin.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select Response and click **Y, Response**.
4. Select \( \ln(\text{dose}) \) and click **X, Factor**.
   
   Notice that JMP automatically fills in Count for **Freq**. Count was previously assigned the role of Freq.
5. From the Target Level list, select Cured.
6. Click **OK**.
7. Click the red triangle next to Logistic Fit of Response By \( \ln(\text{dose}) \) and select **ROC Curve**.

**Note:** This example shows a ROC Curve for a nominal response. For more information about ordinal ROC curves, see *Predictive and Specialized Modeling*.

The results for the response by \( \ln(\text{dose}) \) example are shown here. The ROC curve plots the probabilities described above, for predicting response. Note that in the ROC Table, the row with the highest Sens-(1-Spec) is marked with an asterisk.
Since the ROC curve is well above a diagonal line, you conclude that the model has good predictive ability.

**Example of Inverse Prediction Using the Crosshair Tool**

This example shows you how to use the crosshair tool in JMP to visually approximate an inverse prediction. In a study of rabbits who were given penicillin, you want to know what dose of penicillin results in a 0.5 probability of curing a rabbit. In this case, the inverse prediction for 0.5 is called the \( ED_{50} \), the effective dose corresponding to a 50% survival rate.

Determine which dose is equally likely either to cure or to be lethal.

1. Select **Help > Sample Data Library** and open Penicillin.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select **Response** and click **Y, Response**.
4. Select \( \ln(\text{dose}) \) and click **X, Factor**.
Notice that JMP automatically fills in Count for Freq. Count was previously assigned the role of Freq.

5. From the Target Level list, select Cured.

6. Click OK.

7. Click the crosshairs tool.

8. Place the horizontal crosshair line at about 0.5 on the vertical (Response) probability axis.

9. Move the cross-hair intersection to the prediction line, and read the ln(dose) value that shows on the horizontal axis.

In this example, a rabbit with a ln(dose) of approximately -0.9 is equally likely to be cured as it is to die.

Figure 8.10 Example of Crosshair Tool on Logistic Plot

Example of Inverse Prediction Using the Inverse Prediction Option

If your response has exactly two levels, the Inverse Prediction option enables you to request an exact inverse prediction. You are given the x value corresponding to a given probability of the lower response category, as well as a confidence interval for that x value.

1. Select Help > Sample Data Library and open Penicillin.jmp.

2. Select Analyze > Fit Y by X.

4. Select ln(dose) and click X, Factor.

   Notice that JMP automatically fills in Count for Freq. Count was previously assigned the role of Freq.

5. From the Target Level list, select Cured.
6. Click **OK**.
7. Click the red triangle next to Logistic Fit of Response By ln(dose) and select **Inverse Prediction** (Figure 8.11).
8. Type 0.95 for the **Confidence Level**.
9. Select **Two sided** for the confidence interval.
10. Request the response probability of interest. Type 0.5 and 0.9 for this example, which indicates you are requesting the values for ln(dose) that correspond to a 0.5 and 0.9 probability of being cured.
11. Click **OK**.

   The Inverse Prediction plot appears.

**Figure 8.11** Inverse Prediction Window

![Inverse Prediction Window](image)

**Figure 8.12** Example of Inverse Prediction Plot

![Inverse Prediction Plot](image)
Statistical Details for the Logistic Platform

This section contains statistical details for the Whole Model Test report.

Chi-Square

The Chi-Square statistic is sometimes denoted \( G^2 \) and is defined as follows:

\[
G^2 = 2(\sum -\ln p(\text{background}) - \sum -\ln p(\text{model}))
\]

where the summations are over all observations instead of all cells.

RSquare (U)

The ratio of this test statistic to the background log-likelihood is subtracted from 1 to calculate \( R^2 \). More simply, RSquare (U) is computed as follows:

\[
\frac{\text{negative log-likelihood for Difference}}{\text{negative log-likelihood for Reduced}}
\]

using quantities from the Whole Model Test report.

Note: RSquare (U) is also known as McFadden’s pseudo R-square.
Chapter 9

Tabulate
Create Summary Tables Interactively

Use the Tabulate platform to interactively construct summary tables, or pivot tables, of descriptive statistics. The Tabulate platform is an easy and flexible way to present summary data in tabular form. Tables are built from assigning data table columns as rows or columns in the tabulation and then assigning the desired summary statistics.

Figure 9.1  Tabulate Examples
## Contents

Example of the Tabulate Platform

Learn how to summarize data in a tabular format using the Tabulate platform. In this example, you have data containing height measurements for male and female students. You want to create a table that shows the mean height for males and females and the aggregate mean for both sexes.

**Figure 9.2** Table Showing Mean Height

<table>
<thead>
<tr>
<th>sex</th>
<th>Mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>60.9</td>
</tr>
<tr>
<td>M</td>
<td>63.9</td>
</tr>
<tr>
<td>All</td>
<td>62.6</td>
</tr>
</tbody>
</table>

1. Select *Help > Sample Data Library* and open *Big Class.jmp*.
2. Select *Analyze > Tabulate*.
   
   Since height is the variable that you are examining, you want it to appear at the top of the table.
3. Click height and drag it into the Drop zone for columns.
You want the statistics by sex, and you want sex to appear on the side.

4. Click **sex** and drag it into the blank cell next to the number 2502.
Instead of the sum, you want it to show the mean.

5. Click Mean and drag it on top of Sum.
Figure 9.5  Mean Statistic Added

You also want to see the combined mean for males and females.

6. Click All and drag it on top of sex. Or, you can simply select the **Add Aggregate Statistics** check box.
7. (Optional) Click **Done**.

The completed table shows the mean height for females, males, and the combined mean height for both.
Launch the Tabulate Platform

To launch the Tabulate platform, select **Analyze > Tabulate**.

**Figure 9.7** The Tabulate Interactive Table

![Tabulate Interactive Table](image)

**Note:** For more information about red triangle options, see “Tabulate Platform Options” on page 320. For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Tabulate window contains the following options:

**Interactive table/Dialog**  Switch between the two modes. Use the interactive table mode to drag and drop items, creating a custom table. Use the dialog mode to create a simple table using a fixed format. See “Use the Dialog” on page 312.

**Statistics options**  Lists standard statistics. Drag any statistic from the list to the table to incorporate it. See “Add Statistics” on page 313.

**Drop zone for columns**  Drag and drop columns or statistics here to create columns.
**Note:** If the data table contains columns with names equal to those in the Statistics options, be sure to drag and drop the column name from the column list. Otherwise, JMP might substitute the statistic of the same name in the table.

**Drop zone for rows**  Drag and drop columns or statistics here to create rows.

**Tip:** You can also select one or more columns in the columns list, select one or more of the statistics, and then Alt-click (Option-click on macOS) on a drop zone to create rows or columns in the table.

**Resulting cells**  Shows the resulting cells based on the columns or statistics that you drag and drop.

**Freq**  Identifies the data table column whose values assign a frequency to each row. This option is useful when a frequency is assigned to each row in summarized data.

**Weight**  Identifies the data table column whose variables assign weight (such as importance or influence) to the data.

**Page Column**  Generates separate tables for each category of a nominal or ordinal column. See “Example Using a Page Column” on page 328.

**Include missing for grouping columns**  Creates a separate group for missing values in grouping columns. When unchecked, missing values are not included in the table. Note that any missing value codes that you have defined as column properties are taken into account.

**Order by count of grouping columns**  Changes the order of the table to be in descending order of the values of the grouping columns.

**Add Aggregate Statistics**  Adds aggregate statistics for all rows and columns.

**Default Statistics**  Enables you to change the default statistics that appear when you drag and drop analysis or non-analysis (for example, grouping) columns.

**Change Format**  Enables you to change the numeric format for displaying specific statistics. See “Change Numeric Formats” on page 315.

**Change Plot Scale**  (Appears only if Show Chart is selected from the red triangle menu.) Enables you to specify a uniform custom scale.

**Uniform plot scale**  (Appears only if Show Chart is selected from the red triangle menu.) Deselect this box for each column of bars to use the scale determined separately from the data in each displayed column.
Use the Dialog

If you prefer not to drag and drop and build a table interactively, you can create a simple table using the Dialog interface in the Tabulate platform. After selecting **Analyze > Tabulate**, select **Dialog** from the menu, as shown in Figure 9.8. You can make changes to the table by selecting **Show Control Panel** from the red triangle menu, and then drag and drop new items into the table.

**Figure 9.8** Using the Dialog

The dialog contains the following options:

- **Include marginal statistics**  
  Aggregates summary information for categories of a grouping column.

- **For quantile statistics, enter value (%)**  
  Enter the value at which the specific percentage of the argument is less than or equal to. For example, 75% of the data is less than the 75th quantile. This applies to all grouping columns.

- **Statistics**  
  Once you have selected a column, select a standard statistic to apply to that column. See “Add Statistics” on page 313.

- **Grouping (row labels)**  
  Select the column to use as the row label.

- **Grouping (column labels)**  
  Select the column to use as the column label.
Add Statistics

Tabulate supports a list of standard statistics that appear in the control panel. You can drag any keyword from that list to the table, just like you do with the columns. Note the following:

**Tip:** You can select both a column and a statistic at the same time and drag them into the table.

- The statistics associated with each cell are calculated on values of the analysis columns from all observations in that category, as defined by the grouping columns.
- All of the requested statistics have to reside in the same dimension, either in the row table or in the column table.
- If you drag a continuous column into a data area, it is treated as an analysis column.

**Note:** Analysis columns are numeric, continuous columns for which you want to compute statistics. See “Analysis Columns” on page 317.

Tabulate uses the following keywords:

- **N** Provides the number of nonmissing values in the column. This is the default statistic when there is no analysis column.
- **Mean** Provides the arithmetic mean of a column’s values. It is the sum of nonmissing values (and if defined, multiplied by the weight variable) divided by the **Sum Wgt**.
- **Std Dev** Provides the sample standard deviation, computed for the nonmissing values. It is the square root of the sample variance.
- **Min** Provides the smallest nonmissing value in a column.
- **Max** Provides the largest nonmissing value in a column.
- **Range** Provides the difference between Max and Min.
- **% of Total** Computes the percentage of total of the whole population. The denominator used in the computation is the total of all the included observations, and the numerator is the total for the category. If there is no analysis column, the % of Total is the percentage of total of counts. If there is an analysis column, the % of Total is the percentage of the total of the sum of the analysis column. Thus, the denominator is the sum of the analysis column over all the included observations, and the numerator is the sum of the analysis column for that category. You can request different percentages by dragging the keyword into the table.
  - Dropping one or more grouping columns from the table to the % of Total heading changes the denominator definition. For this, Tabulate uses the sum of these grouping columns for the denominator.
To get the percentage of the column total, drag all the grouping columns on the row table and drop them onto the % of Total heading (same as Column %). Similarly, to get the percentage of the row total, drag all grouping columns on the column table and drop them onto the % of Total heading (same as Row %).

N Missing  Provides the number of missing values.

N Categories  Provides the number of distinct categories in the analysis column.

Sum  Provides the sum of all values in the column. This is the default statistic for analysis columns when there are no other statistics for the table.

Sum Wgt  Provides the sum of all weight values in a column. Or, if no column is assigned the weight role, Sum Wgt is the total number of nonmissing values.

Variance  Provides the sample variance, computed for the nonmissing values. It is the sum of squared deviations from the mean, divided by the number of nonmissing values minus one.

Std Err  Provides the standard error of the mean. It is the standard deviation divided by the square root of N. If a column is assigned the role of weight, then the denominator is the square root of the sum of the weights.

CV  (Coefficient of Variation) Provides the measure of dispersion, which is the standard deviation divided by the mean multiplied by one hundred.

Median  Provides the 50th percentile, which is the value where half the data are below and half are above or equal to the 50th quantile (median).

Geometric Mean  The n\textsuperscript{th} root of the product of the data. For example, geometric means are often used to calculate interest rates. The statistic is also helpful when the data contains a large value in a skewed distribution.

Note: Negative values result in missing numbers, and zero values (with no negative values) result in zero.

Interquartile Range  Provides the difference between the 3rd quartile and 1st quartile.

Quantiles  Provides the value at which the specific percentage of the argument is less than or equal to. For example, 75\% of the data is less than the 75th quantile. You can request different quantiles by clicking and dragging the Quantiles keyword into the table, and then entering the quantile into the box that appears.

Column %  Provides the percent of each cell count to its column total if there is no analysis column. If there is an analysis column, the Column % is the percent of the column total of the sum of the analysis column. For tables with statistics on the top, you can add Column % to tables with multiple row tables (stacked vertically).
**Row %**  Provides the percent of each cell count to its row total if there is no analysis column. If there is an analysis column, the Row % is the percent of the row total of the sum of the analysis column. For tables with statistics on the side, you can add Row % to tables with multiple column tables (side by side tables).

**All**  Aggregates summary information for categories of a grouping column.

### Change Numeric Formats

The formats of each cell depend on the analysis column and the statistics. For counts, the default format has no decimal digits. For each cell defined by some statistics, JMP tries to determine a reasonable format using the format of the analysis column and the statistics requested. To override the default format:

1. Click the **Change Format** button at the bottom of the Tabulate window.
2. In the panel that appears, enter the field width, a comma, and then the number of decimal places that you want displayed in the table (Figure 9.9).
3. To exhibit the cell value in Percent format, add a comma after the number of decimal places and type the word **Percent**.
4. (Optional) If you would like JMP to determine the best format for you to use, type the word **Best** in the text box.
   - JMP now considers the precision of each cell value and selects the best way to show it.
5. Click **OK** to implement the changes and close the Format section, or click **Set Format** to see the changes implemented without closing the Format section.

![Figure 9.9 Changing Numeric Formats](image)
The Tabulate Output

The Tabulate output consists of one or more column tables concatenated side by side, and one or more row tables concatenated top to bottom. The output might have only a column table or a row table.

Figure 9.10 Tabulate Output

Creating a table interactively is an iterative process:

- Click the items (columns or statistics) from the appropriate list, and drag them into the drop zone (for rows or columns). See “Edit Tables” on page 319, and “Column and Row Tables” on page 318.

- Add to the table by repeating the drag and drop process. The table updates to reflect the latest addition. If there are already column headings or row labels, you can decide where the addition goes relative to the existing items.

Note the following about clicking and dragging:

- JMP uses the modeling type to determine a column’s role. Continuous columns are assumed to be analysis columns. See “Analysis Columns” on page 317. Ordinal or nominal columns are assumed to be grouping columns. See “Grouping Columns” on page 317.

- When you drag and drop multiple columns into the initial table:
If the columns share a set of common values, they are combined into a single table. A crosstabulation of the column names and the categories gathered from these columns is generated. Each cell is defined by one of the columns and one of the categories.

If the columns do not share common values, they are put into separate tables.

You can always change the default action by right-clicking on a column and selecting **Combine Tables** or **Separate Tables**. See “Right-Click Menu for Columns” on page 321.

- To nest columns, create a table with the first column, and then drag the additional columns into the first column.
- In a properly created table, all grouping columns are together, all analysis columns are together, and all statistics are together. Therefore, JMP does not intersperse a statistics keyword within a list of analysis columns. JMP also does not insert an analysis column within a list of grouping columns.
- You can drag columns from the Table panel in the data table onto a Tabulate table instead of using the Tabulate Control Panel.

**Note:** The Tabulate table is updated when you add data to the open data table, delete rows, and recode the data.

### Analysis Columns

Analysis columns in the Tabulate platform are any numeric (continuous) columns for which you want to compute statistics. Tabulate computes statistics on the analysis columns for each category formed from the grouping columns.

**Note:** All the analysis columns must reside in the same dimension, either in the row table or in the column table.

### Grouping Columns

Grouping columns in the Tabulate platform are columns (nominal or ordinal) that you want to use to classify your data into categories of information. They can have character, integer, or even decimal values, but the number of unique values should be limited.

Note the following:

- If grouping columns are nested, Tabulate constructs distinct categories from the hierarchical nesting of the values of the columns. For example, from the grouping columns Sex with values F and M, and the grouping column Marital Status with values Married and Single, Tabulate constructs four distinct categories: F and Married, F and Single, M and Married, M and Single.
• You can specify grouping columns for column tables as well as row tables. Together they generate the categories that define each table cell.

• Tabulate does not include observations with a missing value for one or more grouping columns by default. You can include them by checking the **Include missing for grouping columns** option.

• To specify codes or values that should be treated as missing, use the Missing Value Codes column property. You can include these by checking the **Include missing for grouping columns** option. For more information about Missing Value Codes, see *Using JMP*.

### Column and Row Tables

In the Tabulate platform, a table is defined by its column headings and row labels. These sub-tables are referred to as **row tables** and **column tables** (Figure 9.11).

**Example of Row and Column Tables in the Tabulate Platform**

1. Select **Help > Sample Data Library** and open Car Poll.jmp.
2. Select **Analyze > Tabulate**.
3. Drag size into the Drop zone for rows.
4. Drag country to the left of the size heading.
5. Drag Mean over the N heading.
6. Drag Std Dev below the Mean heading.
7. Drag age above the Mean heading.
8. Drag type to the far right of the table.
9. Drag sex under the table.
Figure 9.11  Row and Column Tables

For multiple column tables, the labels on the side are shared across the column tables. In this instance, country and sex are shared across the tables. Similarly, for multiple row tables, the headings on the top are shared among the row tables. In this instance, both age and type are shared among the tables.

Edit Tables

There are several ways to edit items that you add to a table. You can delete items, remove column labels, or edit statistical key words or labels.

Delete Items

After you add items to the table, you can remove them in any one of the following ways:

- Drag the item away from the table.
- To remove the last item, click **Undo**.
- Right-click an item and select **Delete**.

Remove Column Labels

Grouping columns display the column name on top of the categories associated with that column. For some columns, the column name might seem redundant. Remove the column name from the column table by right-clicking on the column name and selecting **Remove Column Label**. To re-insert the column label, right-click one of its associated categories and select **Restore Column Label**.
Edit Statistical Key Words and Labels

You can edit a statistical key word or a statistical label. For example, instead of Mean, you might want to use the word Average. Right-click the word that you want to edit and select **Change Item Label**. In the box that appears, enter the new label. Alternatively, you can type directly into the edit box.

If you change one statistics keyword to another statistics keyword, JMP assumes that you actually want to change the statistics, not just the label. It would be as if you have deleted the statistics from the table and added the latter.

Tabulate Platform Options

The following options are available from the red triangle menu next to Tabulate:

**Show Control Panel**  Displays the control panel for further interaction.

**Show Table**  Displays the summarized data in tabular form.

**Show Chart**  Displays the summarized data in bar charts that mirrors the table of summary statistics. The simple bar chart enables visual comparison of the relative magnitude of the summary statistics. By default, all columns of bars share the same scale. You can have each column of bars use the scale determined separately from the data in each displayed column, by clearing the **Uniform plot scale** check box. You can specify a uniform custom scale using the **Change Plot Scale** button. The charts are either 0-based or centered on 0. If the data are all nonnegative, or all non-positive, the charts baseline is at 0. Otherwise, the charts are centered on 0.

**Show Shading**  Displays gray shading boxes in the table when there are multiple rows.

**Show Tooltip**  Displays tips that appear when you hover over areas of the table.

**Show Test Build Panel**  Displays the control area that lets you create a test build using a random sample from the original table. This is particularly useful when you have large amounts of data. See “Show Test Build Panel” on page 321.

**Make Into Data Table**  Makes a data table from the report. There is one data table for each row table, because labels of different row tables might not be mapped to the same structure.

**Full Path Column Name**  Uses the fully qualified column names of grouping columns for the column name in the created data table.

See *Using JMP* for more information about the following options:
Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

For a description of the options in the Select Columns red triangle menu, see Using JMP.

Show Test Build Panel

If you have a very large data table, you might want to use a small subset of the data table to try out different table layouts to find one that best shows the summary information. In this case, JMP generates a random subset of the size as specified and uses that subset when it builds the table. To use the test build feature:

1. Click the Tabulate red triangle and select Show Test Build Panel.
2. Enter the size of the sample that you want in the box under Sample Size (>1) or Sampling Rate (<1), as shown in Figure 9.12. The size of the sample can be either the proportion of the active table that you enter or the number of rows from the active table.

Figure 9.12  The Test Build Panel

3. Click Resample.
4. To see the sampled data in a JMP data table, click the Test Data View button. When you dismiss the test build panel, Tabulate uses the full data table to regenerate the tables as designed.

Right-Click Menu for Columns

Right-click a column in a table to see the following options:

Delete  Deletes the selected column.

Use as Grouping column  Changes the analysis column to a grouping column.

Use as Analysis column  Changes the grouping column to an analysis column.
Change Item Label  (Appears only for separate or nested columns.) Enter a new label.

Combine Tables (Columns by Categories)  (Appears only for separate or nested columns.) Combines separate or nested columns. See “Example of Combining Columns into a Single Table” on page 326.

Nest Grouping Columns  Nests grouping columns vertically or horizontally.

Separate Tables  (Appears only for combined tables.) Creates a separate table for each column.

Remove Column Label  Removes the column name from the column table.

Restore Column Label  Restores a hidden column name to the column table.

Order By Count  Orders the levels of a grouping column by the count of each level, from most to least. This option can also be used to override the setting of the Order by count of grouping columns option for a particular grouping column.

Additional Examples of the Tabulate Platform

- “Example of Creating Different Tables and Rearranging Contents”
- “Example of Combining Columns into a Single Table”
- “Example Using a Page Column”

Example of Creating Different Tables and Rearranging Contents

This example contains the following steps:

1. Create a Table of Counts
2. Create a Table Showing Statistics
3. Rearrange the Table Contents

Create a Table of Counts

Suppose that you would like to create a table that contains counts for how many people in a survey own Japanese, European, and American cars. You also want the counts broken down by the size of the car.
Figure 9.13  Table Showing Counts of Car Ownership

<table>
<thead>
<tr>
<th>country</th>
<th>size</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>American</td>
<td>Large</td>
<td>36</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>53</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>26</td>
</tr>
<tr>
<td>European</td>
<td>Large</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>17</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>19</td>
</tr>
<tr>
<td>Japanese</td>
<td>Large</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>54</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>92</td>
</tr>
</tbody>
</table>

1. Select **Help > Sample Data Library** and open Car Poll.jmp.
2. Select **Analyze > Tabulate**.
3. Click **country** and drag it into the Drop zone for rows.
4. Click **size** and drag it to the right of the **country** heading.

Figure 9.14  Country and Size Added to the Table
Create a Table Showing Statistics

Suppose that you would like to see the mean (average) and the standard deviation of the age of people who own each size of car.

**Figure 9.15** Table Showing Mean and Standard Deviation by Age

<table>
<thead>
<tr>
<th>country</th>
<th>size</th>
<th>age</th>
<th>Mean</th>
<th>Std Dev</th>
</tr>
</thead>
<tbody>
<tr>
<td>American</td>
<td>Large</td>
<td>age</td>
<td>Mean 31.8</td>
<td>Std Dev 6.2</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>age</td>
<td>Mean 31.1</td>
<td>Std Dev 7.0</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>age</td>
<td>Mean 30.4</td>
<td>Std Dev 5.8</td>
</tr>
<tr>
<td>European</td>
<td>Large</td>
<td>age</td>
<td>Mean 30.5</td>
<td>Std Dev 5.8</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>age</td>
<td>Mean 30.9</td>
<td>Std Dev 6.2</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>age</td>
<td>Mean 30.8</td>
<td>Std Dev 5.4</td>
</tr>
<tr>
<td>Japanese</td>
<td>Large</td>
<td>age</td>
<td>Mean 28.5</td>
<td>Std Dev 4.9</td>
</tr>
<tr>
<td></td>
<td>Medium</td>
<td>age</td>
<td>Mean 30.2</td>
<td>Std Dev 4.7</td>
</tr>
<tr>
<td></td>
<td>Small</td>
<td>age</td>
<td>Mean 28.7</td>
<td>Std Dev 5.9</td>
</tr>
</tbody>
</table>

1. Start from Figure 9.14. Click *age* and drag it to the right of the *size* heading.
2. Click *Mean* and drag it over *Sum*.
3. Click *Std Dev* and drag it below *Mean*.

Std Dev is placed below Mean in the table. Dropping Std Dev above Mean places Std Dev above Mean in the table.
Rearrange the Table Contents

Suppose that you would prefer size to be on top, showing a crosstab layout.

1. Start from Figure 9.16. Click the size heading and drag it to the right of the table headings.
Figure 9.18 Moving size

2. Click age and drag it under the Large Medium Small heading.
3. Select both Mean and Std Dev, and then drag them under the Large heading.

Now your table clearly presents the data. It is easier to see the mean and standard deviation of the car owner age broken down by car size and country.

Example of Combining Columns into a Single Table

In this example, you have data from students indicating the importance of self-reported factors in children’s popularity (grades, sports, looks, money). Suppose that you want to see all of these factors in a single, combined table with additional statistics and factors.

Figure 9.19 Adding Demographic Data

1. Select Help > Sample Data Library and open Children's Popularity.jmp.
2. Select Analyze > Tabulate.
3. Select Grades, Sports, Looks, and Money and drag them into the Drop zone for rows.

**Figure 9.20** Columns by Categories

Notice that a single, combined table appears. Tabulate the percentage of the one to four ratings of each category.

4. Drag Gender into the empty heading at left.

5. Drag % of Total above the numbered headings.

6. Drag All beside the number 4.

**Figure 9.21** Gender, % of Total, and All Added to the Table
Break down the tabulation further by adding demographic data.

7. Drag Urban/Rural below the % of Total heading.

**Figure 9.22** Urban/Rural Added to the Table

<table>
<thead>
<tr>
<th></th>
<th>% of Total</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Urban</td>
<td>Rural</td>
<td>Suburban</td>
</tr>
<tr>
<td>Gender</td>
<td></td>
<td>1 2 3 4</td>
<td>1 2 3 4</td>
</tr>
<tr>
<td>boy</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Grades</td>
<td>2.30%</td>
<td>2.93%</td>
<td>3.66%</td>
</tr>
<tr>
<td>Sports</td>
<td>8.49%</td>
<td>3.97%</td>
<td>2.72%</td>
</tr>
<tr>
<td>Looks</td>
<td>3.14%</td>
<td>4.80%</td>
<td>2.72%</td>
</tr>
<tr>
<td>Money</td>
<td>1.88%</td>
<td>2.30%</td>
<td>4.81%</td>
</tr>
<tr>
<td>girl</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Grades</td>
<td>4.39%</td>
<td>4.29%</td>
<td>4.09%</td>
</tr>
<tr>
<td>Sports</td>
<td>2.30%</td>
<td>6.68%</td>
<td>5.44%</td>
</tr>
<tr>
<td>Looks</td>
<td>5.62%</td>
<td>3.55%</td>
<td>3.35%</td>
</tr>
<tr>
<td>Money</td>
<td>1.05%</td>
<td>2.93%</td>
<td>4.10%</td>
</tr>
</tbody>
</table>

You can see that for boys in rural, suburban, and urban areas, sports are the most important factor for popularity. For girls in rural, suburban, and urban areas, looks are the most important factor for popularity.

**Example Using a Page Column**

In this example, you have data containing height measurements for male and female students. You want to create a table that shows the mean of the heights by the age of the students. Then you want to stratify your data by sex in different tables. To do so, add the stratification column as a page column, which builds the pages for each group.

**Figure 9.23** Mean Height of Students by Sex

Females | Males

1. Select **Help > Sample Data Library** and open Big Class.jmp.
2. Select **Analyze > Tabulate**.
   
   Since height is the variable that you are examining, you want it to appear at the top of the table.
3. Click height and drag it into the Drop zone for columns.
You want the statistics by age, and you want age to appear on the side.

4. Click age and drag it into the blank cell next to the number 2502.

5. Click Mean and drag it into the cell that says Sum.

6. Click sex and drag it into Page Column.

7. Select F from the Page Column list to show the mean of the heights for only females.

8. Select M from the Page Column list to show the mean of the heights for only males. You can also select None Selected to show all values.

**Figure 9.24** Using a Page Column
The Simulate platform is available only in JMP Pro.

The Simulate feature provides powerful parametric and nonparametric simulation capability. Use Simulate to do the following:

- Expand on the bootstrap to provide parametric bootstrapping.
- Obtain power calculations in nonstandard situations.
- Approximate the distribution of statistics, such as predicted values, and confidence intervals, in nonstandard situations.
- Conduct permutation tests.
- Explore the effect of assumptions about predictors on models.
- Explore various “what if” scenarios relative to your models.
- Evaluate new or existing statistical methods.

The Simulate option is available in many reports, including all of those that support Bootstrap. To access the Simulate option, right-click in a report.

Overview of the Simulate Platform

The Simulate platform provides simulated results for a column of statistics in a report. Right-click a column of statistics in a report and select Simulate. In the Simulate window, specify a column in your data table that forms the basis for your simulation. This is the column that you switch out. This column can have any role in the analysis. In particular, it can be a response or a predictor in a model. You then specify a column in your data table that contains a formula that you want to use for the simulation. This is the column that you switch in. It functions as a surrogate for the column that you switched out.

**Note:** Your data table must contain a column that has a random component.

The method works as follows. A column of simulated values is generated based on the formula in the formula column that you switch in. The entire analysis that generated the report containing the statistics of interest is rerun using this new column of simulated values to replace the column that you switched out. This process is repeated $N$ times, where $N$ is the total number of samples that you specify.

The Simulate analysis produces an output data table showing a summary of the analysis.

- Each row of the data table represents the results of the analysis for one column of simulated values.
- There is a column for each row of the report table involved in the simulation.
- There are scripts to facilitate your analysis.

**Tip:** The Simulate platform reruns the entire analysis that appears in the platform report from which Simulate is invoked. As a result, Simulate might run slowly for your selected column because of extraneous analyses in the report. If Simulate is taking a long time, remove extraneous options from the platform report before running Simulate.

Simulate is available in all statistical platforms except the following: Association Analysis, Diagram, Multidimensional Scaling, Multiple Factor Analysis, Reliability Block Diagram, Reliability Forecast, Repairable Systems Simulation, Response Screening, and Text Explorer.
Examples That Use Simulate

Learn how to get simulated results for your data in different scenarios.

- “Construct Semiparametric Confidence Intervals for Variance Components”
- “Conduct a Permutation Test”
- “Explore Retaining a Factor in Generalized Regression”
- “Conduct Prospective Power Analysis for a Nonlinear Model”
- For an example that shows how to simulate a confidence interval for Ppk and the percent nonconforming for a non-normal variable, see Quality and Process Methods.

Construct Semiparametric Confidence Intervals for Variance Components

In this example, your goal is to obtain semiparametric confidence intervals for the variance components of hard-to-change variables. For this data, you are interested in the effects of temperature, time, and the amount of catalyst on a reaction. Temperature is a very-hard-to-change variable (whole plot factor), time is hard-to-change (subplot factor), and the amount of catalyst is easy-to-change. For information about whole plot and subplot factors, see the Design of Experiments Guide.

Previous studies have suggested that the whole-plot standard deviation is about twice the error standard deviation, and the sub-plot error is about 1.5 times the error standard deviation. The Wald intervals given in the REML report, which assume that the variance components are asymptotically normal, have poor coverage properties. You obtain confidence intervals using percentiles of the simulated distributions of the variance components.

Construct the Design

In this section, you construct a custom design for your split-split-plot experiment.

**Tip:** If you prefer to skip the steps in this section, select Help > Sample Data Library and open Design Experiment/Catalyst Design.jmp. In the Catalyst Design.jmp data table, click the green triangle next to the DOE Simulate script. Then go to “Fit the Model” on page 337.

1. Select DOE > Custom Design.
2. In the Factors outline, type 3 next to Add N Factors.
3. Click Add Factor > Continuous.
4. Double-click to rename these factors Temperature, Time, and Catalyst.
Keep the default Values of –1 and 1 for these factors.

5. For Temperature, click Easy and select Very Hard.
This defines Temperature to be a whole plot factor.

6. For Time, click Easy and select Hard for Time.
This defines Time to be a subplot factor.

7. Click Continue.

8. In the Model outline, select Interactions > 2nd.
This adds all two-way interactions to the model.

9. Click the Custom Design red triangle and select Simulate Responses.
This opens the Simulate Responses window after you select Make Table to construct the design table.

**Note:** Setting the Random Seed in step 10 and Number of Starts in step 11 reproduces the same design shown in this example. In constructing a design on your own, these steps are not necessary.

10. (Optional) Click the Custom Design red triangle and select Set Random Seed. Type 12345 and click OK.

11. (Optional) Click the Custom Design red triangle and select Number of Starts. Type 1000 and click OK.

12. Click Make Design.

13. Click Make Table.

**Note:** The entries in your Y and Y Simulated columns might differ from those that appear in Figure 10.2.
The design table and a Simulate Responses window appear. Notice that the design table contains a **DOE Simulate** script. At any time, you can run this script to specify different parameter values.
Continue to the next section, where you specify standard deviations for the whole plot and subplot errors, and fit a REML model to the first set of simulated values.

**Fit the Model**

In this section, you fit a model using the REML method. Assume that the whole plot and subplot errors are normal. Based on your estimates of their standard deviations, if the error standard deviation is about 1 unit, the whole plot standard deviation is about 2 units and the subplot standard deviation is about 1.5 units. Since you are interested only in the whole- and sub-plot variation, you do not need to change the values assigned to Effects in the Simulate Responses outline.

1. In the Distribution panel (Figure 10.3), next to **Whole Plots** $\sigma$, type 2.
   Notice that the Normal distribution is selected by default. As a result, normal error is added to the formula.
2. Next to **Subplots** $\sigma$, type 1.5.
3. Click **Apply**.
   In the data table, the formula for $Y$ Simulated updates to reflect your specifications. To view the formula, click the plus sign to the right of the column name in the Columns panel.
4. In the data table, click the green triangle next to the **Model** script.
5. Click the $Y$ variable next to the $Y$ button and click **Remove**.
6. Click $Y$ Simulated and click the $Y$ button.
   This action replaces $Y$ with a column that contains a simulation formula.
7. Click **Run**.
   The model that is fit is based on a single set of simulated responses.

**Note:** Because the values in $Y$ Simulated are randomly generated, the entries in your report might differ from those that appear in Figure 10.4.

---

**Figure 10.4** REML Report Showing Wald Confidence Intervals

<table>
<thead>
<tr>
<th>REML Variance Component Estimates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Random Effect</strong></td>
</tr>
<tr>
<td>Whole Plots</td>
</tr>
<tr>
<td>Subplots</td>
</tr>
<tr>
<td>Residual</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

-2 LogLikelihood = 63.800021519

*Note: Total is the sum of the positive variance components. Total including negative estimates = 2.2738839*
Generate Confidence Intervals

In this section, you simulate variance component estimates and use these to construct simulated percentile confidence intervals.

1. In the REML Variance Components Estimates outline, right-click in the Var Component column and select Simulate.

Figure 10.5 Simulate Window

In your simulations, you replace the column Y Simulated, which you used to run your model, with a new instance of the column Y Simulated, which generates a new column of simulated values for each simulation. The column on which you right-clicked and that appears as selected, Var Component, is simulated for each effect listed in the Parameter Estimates table.

2. Next to Number of Samples, enter 200.

3. (Optional) Next to Random Seed, enter 456.
   This reproduces the values shown in Figure 10.6, except for the values in row 1.

4. Click OK.
   The entries in your row 1 might differ from those that appear in Figure 10.6.
The first row of the Fit Least Squares Simulate Results (Var Component) data table contains the initial values of **Var Component** and is excluded. The remaining rows contain simulated values.

5. Run the **Distribution** script.

**Figure 10.7** Distribution Plots for Variance Components (Partial View)
For each variance component, confidence intervals at various confidence levels are shown in the Simulation Results report. Compare the 95% intervals in the Alpha=0.05 row of each table to the intervals given in the REML report (Figure 10.4):

- The simulated 95% confidence interval for the whole-plot variance component is -3.296 to 22.863. The Wald interval given in the REML report is -1.973 to 5.086.
- The simulated 95% confidence interval for the sub-plot variance component is -0.332 to 10.459. The Wald interval given in the REML report is -0.605 to 1.223.

The intervals that you obtain using simulation are considerably wider than the REML interval calculated from your single set of values. For more precise intervals, consider running a larger number of simulations.

**Conduct a Permutation Test**

In this example, you use Simulate to conduct a randomization or permutation test. You are studying the effects of three drugs on pain, and are interested in whether they differ in their effects. Because you have a very small sample size and are somewhat concerned about violations of the usual ANOVA assumptions, you can use Simulate to conduct a permutation test.

First, you construct a formula that randomly shuffles the pain measurements among the three drugs. Under the null hypothesis of no effect, any of these allocations is as likely as any other. It follows that the $F$ ratios obtained in this manner approximate the distribution of $F$ ratios under the null hypothesis. Finally, you compare the observed value of the $F$ ratio to the null distribution obtained by simulation.

**Define the Simulation Formula**

1. Select Help > Sample Data Library and open Analgesics.jmp.
2. Select Cols > New Columns.
3. Type Pain Shuffled for Column Name.
4. From the Column Properties list, select Formula.
5. In the function list, select Row > Col Stored Value.
6. In the Columns list, double-click pain.
7. Click the insert key (^) in the list of symbols above the editor panel.
8. From the list of functions, select Random > Col Shuffle.

Figure 10.8 Completed Formula

$$\text{Col Stored Value (pain, Col Shuffle ( ))}$$
This formula randomly shuffles the entries in the pain column.

9. Click OK in the Formula Editor window.

10. Click OK in the Column Info window.

Perform the Permutation Test

1. Select Analyze > Fit Y by X.
2. Select pain and click Y, Response.
4. Click OK.
5. Click the Oneway Analysis red triangle and select Means/Anova.

Figure 10.9 Analysis of Variance Report

Notice that the F ratio is 6.2780.

6. In the Analysis of Variance outline, right-click the F Ratio column and select Simulate.
7. In the Column to Switch Out list, click pain.
8. In the Column to Switch In list, click Pain Shuffled.
9. Next to Number of Samples, enter 1000.
10. (Optional) Next to Random Seed, enter 456.
   This reproduces the values in this example.

Figure 10.10 Completed Simulate Window

11. Click OK.

   In the table of simulated results, the C. Total and Error columns are empty, since the F Ratio value in the Analysis of Variance table applies only to drug.

12. In the table of simulated values, run the Distribution script.
The observed $F$ ratio value of 6.2780 is represented with a red line in the histogram. This value falls in the upper 0.5% of the simulated null distribution of $F$ ratios. This presents strong evidence that the three drugs differ in their effects on pain.

**Explore Retaining a Factor in Generalized Regression**

In this example, you construct a generalized regression model and use the active parameters to fit a reduced model. Based on this reduced model, you use simulation to explore the likelihood that one of the factors is included in the model.

A pharmaceutical manufacturer has historical information about the dissolution of a tablet inside the body and various factors that can affect the dissolution rate. A tablet with a dissolution rate below 70 is considered defective. You want to understand which factors affect dissolution rate.

**Fit the Model**

In this section, you fit a model using generalized regression.

*Tip:* If you prefer not to work through the steps in this section, click the green triangle next to the **Generalized Regression** script in the Tablet Production.jmp data table to obtain the model.
1. Select Help > Sample Data Library and open Tablet Production.jmp.
2. Select Analyze > Fit Model.
3. Click Dissolution and click Y.
4. Select Mill Time through Atomizer Pressure and click Add.
5. From the Personality list, select Generalized Regression.
6. Click Run.
7. In the Model Launch panel, select the Adaptive box.
8. In the Model Launch panel, click Go.

Figure 10.12 Model Based on Adaptive Lasso

You are interested in the parameter estimates shown in the Normal Adaptive Lasso with AICc Validation report. Based on the nonzero parameter estimates, the model suggests that Mill Time, Screen Size, Blend Time, Blend Speed, Compressor, Coating Viscosity, and Spray Rate are related to Dissolution.

Reduce the Model

Before reducing the model, ensure that no columns are selected in the Tablet Production.jmp data table. Selected columns are not deselected in the first step below. Ensuring that no columns are selected prevents the inadvertent inclusion of columns with zeroed terms.
If you prefer not to work through the steps in this section, click the green triangle next to the **Generalized Regression Reduced Model** script in the Tablet Production.jmp data table to obtain the reduced model.

1. Click the red triangle next to Normal Adaptive Lasso with AICc Validation and select **Relaunch Active Set > Relaunch with Active Effects**.

   This opens a Fit Model window that places the terms with nonzero coefficient estimates in the Parameter Estimates reports into the Construct Model Effects list. The response is entered as Y. The Generalized Regression personality is selected.

2. Click **Run**.

3. In the Model Launch panel, select the **Adaptive** box.

4. In the Model Launch panel, click **Go**.

**Figure 10.13 Reduced Model Using Adaptive Lasso**

<table>
<thead>
<tr>
<th>Parameter Estimates for Original Predictors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Term</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>Intercept</td>
</tr>
<tr>
<td>Mill Time</td>
</tr>
<tr>
<td>Screen Size [3-5]</td>
</tr>
<tr>
<td>Screen Size [4-5]</td>
</tr>
<tr>
<td>Blend Time</td>
</tr>
<tr>
<td>Blend Speed</td>
</tr>
<tr>
<td>Compressor [Compress1-Compress2]</td>
</tr>
<tr>
<td>Coating Viscosity</td>
</tr>
<tr>
<td>Spray Rate</td>
</tr>
</tbody>
</table>

Notice that the estimate for **Blend Speed** has a confidence interval (Lower 95%) that comes very close to including zero. Next, perform a simulation study to see how often **Blend Speed** would be included in the model if other data values from the dissolution distribution have been observed.

**Explore the Inclusion of Blend Speed in the Model**

Use the report for the reduced model (Figure 10.13) in the steps below.

1. Click the red triangle next to Normal Adaptive Lasso with AICc Validation and select **Save Columns > Save Simulation Formula**.

   This adds a new column called **Dissolution Simulation Formula** to the Tablet Production.jmp data table.

2. (Optional) In the data table Columns panel, click the plus sign to the right of **Dissolution Simulation Formula**.
Figure 10.14 Simulation Formula

For each row, this formula simulates a value that could be obtained given the model and the distribution of Dissolution, which is estimated to be Normal with standard deviation about 1.998.

3. Click Cancel.

4. Go back to the reduced model report window. In the Parameter Estimates for Original Predictors report, right-click in the Estimate column and select Simulate. Make sure that Dissolution is selected in the Column to Switch Out list.

5. Next to Number of Samples, enter 300.

For the simulation, you ask JMP to replace the Dissolution column in each of 300 analyses with values simulated using the Dissolution Simulation Formula column.

6. (Optional) Set the Random Seed to 123.

This reproduces the values in this example.
Simulate Chapter 10
Examples That Use Simulate

**Figure 10.15** Completed Simulation Window

7. Click **OK**.
   
The first row of the table contains the initial values of the Estimates and is excluded. The remaining rows contain simulated values.

8. Run the **Distribution** script.

9. Press Ctrl, click the **Blend Speed** red triangle and select **Display Options > Customize Summary Statistics**.

10. Select **N Zero**.

11. Click **OK**.

12. Scroll to the Distribution report for **Blend Speed**.
Figure 10.16 Histogram of Simulated Blend Speed Coefficient Estimates

The Summary Statistics report shows that for $103/300 = 34.3\%$ of the simulations, the Blend Speed estimates are zero.

**Conduct Prospective Power Analysis for a Nonlinear Model**

In this example, you are interested in the main effects of six continuous factors on whether a part passes or fails inspection. The response is binomial and you can afford a total of 60 runs.

**Plan for the Example**

You model the probability of a success using a generalized linear model with the logit as a link function. The logit link function fits a logistic model:

$$
\pi(X) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 X_1 + \ldots + \beta_6 X_6)}}
$$
where \( \pi(X) \) denotes the probability that a part passes at the given design settings \( X = (X_1, X_2, ..., X_6) \).

Denote the linear predictor by \( L(X) \):

\[
L(X) = \beta_0 + \beta_1 X_1 + \ldots + \beta_6 X_6
\]

Next, you explore power for the following values of the coefficients of the linear predictor:

<table>
<thead>
<tr>
<th>Coefficient</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \beta_0 )</td>
<td>0</td>
</tr>
<tr>
<td>( \beta_1 )</td>
<td>1</td>
</tr>
<tr>
<td>( \beta_2 )</td>
<td>0.9</td>
</tr>
<tr>
<td>( \beta_3 )</td>
<td>0.8</td>
</tr>
<tr>
<td>( \beta_4 )</td>
<td>0.7</td>
</tr>
<tr>
<td>( \beta_5 )</td>
<td>0.6</td>
</tr>
<tr>
<td>( \beta_6 )</td>
<td>0.5</td>
</tr>
</tbody>
</table>

Because the intercept in the linear predictor is 0, when all factors are set to 0, the probability of a passing part equals 50%. The probabilities associated with the levels of the \( i^{th} \) factor, when all other factors are set to 0, are given below.

<table>
<thead>
<tr>
<th>Factor</th>
<th>Percent Passing at ( X_i = 1 )</th>
<th>Percent Passing at ( X_i = -1 )</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>( X_1 )</td>
<td>73.11%</td>
<td>26.89%</td>
<td>46.2%</td>
</tr>
<tr>
<td>( X_2 )</td>
<td>71.09%</td>
<td>28.91%</td>
<td>42.2%</td>
</tr>
<tr>
<td>( X_3 )</td>
<td>69.00%</td>
<td>31.00%</td>
<td>38.0%</td>
</tr>
<tr>
<td>( X_4 )</td>
<td>66.82%</td>
<td>33.18%</td>
<td>33.6%</td>
</tr>
<tr>
<td>( X_5 )</td>
<td>64.56%</td>
<td>35.43%</td>
<td>29.1%</td>
</tr>
<tr>
<td>( X_6 )</td>
<td>62.25%</td>
<td>37.75%</td>
<td>24.5%</td>
</tr>
</tbody>
</table>

For example, when all factors other than \( X_1 \) are set to 0, the difference in pass rates that you want to detect is 46.2%. The smallest difference in pass rates that you want to detect occurs when all factors other than \( X_6 \) are set to zero and that difference is 24.5%.
Construct the Design

In this section, you construct a custom design for your experiment.

**Note:** If you prefer to skip the steps in this section, select Help > Sample Data Library and open Design Experiment/Binomial Experiment.jmp. Click the green triangle next to the DOE Simulate script and then go to “Define Simulated Responses” on page 351.

1. Select DOE > Custom Design.

   **Note:** Although a custom design is not optimal for a non-linear situation, in this example, for simplicity, you can use the Custom Design platform rather than the Nonlinear Design platform. For an example illustrating why a design constructed using the Nonlinear Design platform is better than an orthogonal design, see the Design of Experiments Guide.

2. In the Factors outline, type 6 next to Add N Factors.
3. Click Add Factor > Continuous.
4. Click Continue.
   
   You are constructing a main effects design, so do not make any changes to the Model outline.
5. Under Number of Runs, type 60 next to User Specified.
6. Click the Custom Design red triangle and select Simulate Responses.
   
   This opens the Simulate Responses window after you select Make Table to construct the design table.

   **Note:** Setting the Random Seed in step 7 and Number of Starts in step 8 reproduces the same design shown in this example. In constructing a design on your own, these steps are not necessary.

7. (Optional) Click the Custom Design red triangle and select Set Random Seed. Type 12345 and click OK.
8. (Optional) Click the Custom Design red triangle and select Number of Starts. Type 1 and click OK.
9. Click Make Design.
10. Click Make Table.

   **Note:** The entries in your Y and Y Simulated columns might differ from those that appear in Figure 10.17.
The design table and a Simulate Responses window appear. Two columns are added to the design table:

- Y contains a set of values simulated according to the specifications in the Simulate Responses window.
- Y Simulated contains a formula that calculates its values using the formula for the model that is specified in the Simulate Responses window. To view the formula, click the plus sign to the right of the column name in the Columns panel.

Continue to the next section, where you simulate binomial responses and fit a generalized linear model to these simulated responses.
Define Simulated Responses

Your plan is to simulate binomial response data where the probability of success is given by a logistic model. For more information about Simulate Response, see the Design of Experiments Guide.

Note: If you prefer to skip the steps in this section, click the green triangle next to the Simulate Model Responses script. Then go to “Fit the Generalized Linear Model” on page 352.

1. In the Simulate Responses window (Figure 10.18), enter the following values under Y:
   - Next to Intercept, type 0.
   - Next to X1, 1 is entered by default. Keep that value.
   - Next to X2, type 0.9.
   - Next to X3, type 0.8.
   - Next to X4, type 0.7.
   - Next to X5, type 0.6.
   - Next to X6, type 0.5.

2. In the Distribution outline, select Binomial.
   Leave the value for N set to 1, indicating that there is only one unit per trial.

Figure 10.19 Complete Simulate Responses Window

3. Click Apply.
   In the design data table, the Y Simulated column is replaced with a formula column that generates binomial values. A column called Y N Trials indicates the number of trials for each run.

4. (Optional) Click the plus sign to the right of Y Simulated in the Columns panel.
5. Click Cancel.

**Fit the Generalized Linear Model**

In this section, you fit a logistic model using the Generalized Linear Model personality.

1. In the data table, click the green triangle next to the Model script.
2. Click the Y variable next to the Y button and click Remove.
3. Click Y Simulated and click the Y button.
   
   You are replacing Y with a column that contains randomly generated binomial values.
4. From the Personality list, select Generalized Linear Model.
5. From the Distribution list, select Binomial.
   
   Notice that the Logit function appears in the Link Function menu.
6. Click Run.
   
   The model that is fit is based on a single set of simulated binomial responses.

**Explore Power**

In this section, you simulate likelihood ratio test $p$-values to explore the power of detecting a difference over a range of probability values that is determined by the linear predictor with the coefficient values given in “Plan for the Example” on page 347.

1. In the Effect Tests outline, right-click in the Prob>ChiSq column and select Simulate.

**Figure 10.21 Simulate Window**
Make sure the Y Simulated column is selected in the Column to Switch Out list. This column contains the values that were used to fit the model. When you select the column Y Simulated under Column to Switch In, for each simulation, you are telling JMP to replace the values in Y Simulated with a new column of values that are simulated using the formula in the column Y Simulated.

The column that you have selected in the report, Prob>ChiSq, is the p-value for a likelihood ratio test of whether the associated main effect is 0. The Prob>ChiSq value is simulated for each effect listed in the Effect Tests table.

2. Next to **Number of Samples**, type **500**.
3. Click **OK**.

A Generalized Linear Model Simulate Results data table appears.

**Note:** Because response values are simulated, your simulated p-values might differ from those shown in Figure 10.22.

---

**Figure 10.22** Table of Simulated Results, Partial View

The first row of the table contains the initial values of Prob>ChiSq and is excluded. The remaining 500 rows contain simulated values.

4. Run the **Power Analysis** script.

**Note:** Because response values are simulated, your simulated power results might differ from those shown in Figure 10.23.
**Figure 10.23** Distribution Plots for the First Two Effects

The histograms plot the 500 simulated Prob>ChiSq values for each main effect. The Simulated Power outline shows the simulated Rejection Rate in the 500 simulations.

For easier viewing, stack the reports and de-select the plots.

5. Click the Distributions red triangle and select **Stack**.
6. Press Ctrl and click the X1 red triangle, and de-select **Outlier Box Plot**.
7. Press Ctrl and click the X1 red triangle, select **Histogram Options**, and de-select **Histogram**.

**Note:** Because response values are simulated, your simulated power results might differ from those shown in Figure 10.24.
In the Simulated Power outlines, the Rejection Rate for each row gives the proportion of \( p \)-values that are smaller than the corresponding \( \alpha \). For example, for \( X_3 \), which corresponds to a coefficient value of 0.8 and a probability difference of 38%, the simulated power for a 0.05 significance level is \( \frac{379}{500} = 0.758 \). Table 10.1 summarizes the estimated power at the 0.05 significance level for all effects. Notice how power decreases as the Difference to Detect decreases. Also notice that the power to detect an effect as large as 24.5% (\( X_6 \)) is only approximately 0.37.

**Note:** Because response values are simulated, your simulated power results might differ from those shown in Table 10.1.

### Table 10.1 Simulated Power at Significance Level 0.05

<table>
<thead>

Launch the Simulate Window

To launch the Simulate platform, right-click a column of calculated values in a report window and select Simulate. The Simulate platform is available in many reports, including all reports that support bootstrapping. To use the Simulate platform, the data table must contain a formula with a random component that simulates data.

**Note:** The Simulate platform is not available in reports that use a By variable.

The Simulate Window

When you click OK to run the simulation, a window that contains a progress bar and a Stop Early button appears. The number of the sample being simulated is shown above the progress bar. If you click Stop Early, the simulated values that have been computed up to that point are presented in a Simulate Results table. The window also shows you which analyses are being run at any given time.
The Simulate window contains these panels and options:

**Column to Switch Out**  The column that is replaced by the Column to Switch In.

**Column to Switch In**  The column that replaces the Column to Switch Out. The analysis is repeated with values simulated according to the formula in the Column to Switch In. Only columns with formulas are listed in the Column to Switch In panel.

**Number of Samples**  Number of times that the report is re-run for a set of simulated data. The default value is 2500.

**Random Seed**  A value that controls the simulated results. The random seed makes the results reproducible.

---

**The Simulate Results Table**

Simulate results appear in a table. Note the following:

- The first row of the table contains the values for the table items that appear in the report. For this reason, the first row is always excluded.

- The remaining rows give the simulation results. The number of remaining rows is equal to the Number of Samples that you specified in the Simulate launch window.

- The rows in the report are identified by the first column in the report table that contains the selected column of calculated values. A column appears in the simulated results table for each item in this first column.

- The table contains a **Distribution** script that constructs a Distribution report. This report contains histograms, quantiles, summary statistics, and simulation results for each column in the simulated results data table. In addition to the standard Distribution report, the report contains the following items:
  - A red line that denotes the original estimate appears on the histogram.
  - A Simulation Results report containing the original estimate, as well as confidence intervals and empirical $p$-values for the simulation. See “*Simulation Results Report*” on page 358.
  - If the values in the simulated results data table have a PValue format, a Simulated Power report is also provided. See “*Simulated Power Report*” on page 358.

- The table contains a **Power Analysis** script only if you have simulated a column of $p$-values. This script constructs a Distribution report showing histograms of $p$-values and provides a Simulated Power report. See “*Simulated Power Report*” on page 358.
**Simulation Results Report**

**Original Estimate**  The value of the original estimate, also shown in the first row of the Simulate Results data table. This estimate is labeled $Y_0$.

**Confidence Intervals**  Lower and upper limits for quantile-based confidence intervals at the following significance levels: 0.05, 0.10, 0.20, and 0.50.

**Empirical p-Values**  The empirical $p$-values for a two-sided test and both one-sided tests that compare the simulated values to the original estimate. These $p$-values are computed as the proportions of the simulated values that fall in the ranges that are specified in the Test column of the report.

**Simulated Power Report**

**Alpha**  The significance level: 0.01, 0.05, 0.10, and 0.20.

**Rejection Count**  The number of simulations where the test rejects at the corresponding significance level.

**Rejection Rate**  The proportion of simulations where the test rejects at the corresponding significance level.

**Lower 95% and Upper 95%**  Lower and upper limits for a 95% confidence interval for the simulated rejection rate. The interval is computed using the Wilson score method. See Wilson (1927).

**Tip:** Increase the Number of Samples for a narrower confidence interval.
Bootstrapping is available only in JMP Pro.

Bootstrapping is a resampling method for approximating the sampling distribution of a statistic. You can use bootstrapping to estimate the distribution of a statistic and its properties, such as its mean, bias, standard error, and confidence intervals. Bootstrapping is especially useful in the following situations:

- The theoretical distribution of the statistic is complicated or unknown.
- Inference using parametric methods is not possible because of violations of assumptions.

**Note:** Bootstrap is available only from a right-click in a report. It is not a platform command.

Overview of Bootstrapping

Bootstrapping repeatedly resamples the observations that are used in your report to construct an estimate of the distribution of a statistic or statistics. The observations are assumed to be independent.

In the simple bootstrap, the \( n \) observations are resampled with replacement to produce a bootstrap sample of size \( n \). Note that some observations might not appear in the bootstrap sample, and others might appear multiple times. The number of times that an observation occurs in the bootstrap sample is called its bootstrap weight. For each bootstrap iteration, the entire analysis that produced the statistic of interest is rerun with these changes:

- the bootstrap sample of \( n \) observations is the data set
- the bootstrap weight is a frequency variable in the analysis platform

This process is repeated to produce a distribution of values for the statistic or statistics of interest.

However, the simple bootstrap can sometimes be inadequate. For example, suppose your data set is small or you have a logistic regression setting where you can encounter separation issues. In such cases, JMP enables you to conduct Bayesian bootstrapping using fractional weights. When fractional weights are used, a fractional weight is associated with each observation. The fractional weights sum to \( n \). The statistic of interest is computed by treating the fractional weights as a frequency variable in the analysis platform. For information about fractional weights, see “Fractional Weights” on page 366 and “Calculation of Fractional Weights” on page 375.

To run a bootstrap analysis in a report, right-click in a table column that contains the statistic that you want to bootstrap and select Bootstrap.

**Note:** Bootstrap is available only from a right-click in a report. It is not a platform command.

JMP provides bootstrapping in many statistical platforms. See “Platforms that Support Bootstrapping” on page 362 for a complete list. The observations that comprise the sample are all observations that are used in the calculations for the statistics of interest. If the report uses a frequency column, the observations in that column are treated as if they were repeated the number of times indicated by the Freq variable. If the report uses a Weight variable, Bootstrap treats it as it was treated in the calculations for the report.

**Tip:** Bootstrap reruns the entire analysis that appears in the platform report from which Bootstrap is invoked. As a result, Bootstrap might run slowly for your selected column because of extraneous analyses in the report. If Bootstrap is running slowly, remove extraneous options from the platform report before running Bootstrap.
Platforms that Support Bootstrapping

Bootstrapping is available in the following statistical platforms:

- Boosted Tree
- Bootstrap Forest
- Categorical
- Destructive Degradation
- Discriminant
- Distribution
- Fit Curve
- Fit Life by X
- Fit Parametric Survival
- Fit Proportional Hazards
- Fit Y by X
- Generalized Linear Model
- Generalized Regression
- Life Distribution
- Logistic
- Loglinear Variance
- Multiple Correspondence Analysis
- Multivariate
- Neural
- Nonlinear
- Parametric Survival
- Partial Least Squares
- Partition
- Principal Components
- Proportional Hazard
- Standard Least Squares
- Survival
- Uplift
Example of Bootstrapping

This example uses the Car Physical Data.jmp sample data table. A tire manufacturer wants to predict an engine’s horsepower from the engine’s displacement (in³). The company is most interested in estimating the slope of the relationship between the variables. The slope values help the company predict the corresponding change in horsepower when the displacement changes.

In this example, the regression assumption of homogeneity of variance is violated, so the confidence limits from the regression analysis for the slope might be misleading. For this reason, the company uses a bootstrap estimate of the confidence interval for the slope.

1. Select Help > Sample Data Library and open Car Physical Data.jmp.
2. Select Analyze > Fit Y by X.
4. Select Displacement and click X, Factor.
5. Click OK.
6. Click the red triangle next to Bivariate Fit of Horsepower By Displacement and select Fit Line.
   The slope estimate is 0.503787, approximately 0.504.
7. (Optional) Right-click in the Parameter Estimates report and select Columns > Lower 95%.
8. (Optional) Right-click in the Parameter Estimates report and select Columns > Upper 95%.
   The confidence limits from the regression analysis for the slope are 0.4249038 and 0.5826711.
**Figure 11.2 The Bootstrap Option**

The column that you right-click is relevant when the **Split Selected Column** option is selected. See “Bootstrapping Window Options” on page 365.

10. Type 1000 for the **Number of Bootstrap Samples**.

11. (Optional) To match the results in Figure 11.3, type 12345 for the **Random Seed**.

12. Click **OK**.

    The bootstrap process runs and produces a Bootstrap Results data table with unstacked results for the slope and intercept.

    Next, analyze the bootstrapped slope.

13. In the Bootstrap Results table, run the **Distribution script**.

    The Distribution report includes the Bootstrap Confidence Limits report.
The estimate of the slope (step 6) is 0.504. Based on the bootstrap results for 95% coverage, the company can estimate the slope to be between 0.40028 and 0.61892. When the displacement is changed by one unit, with 95% confidence, the horsepower changes by some amount between 0.40028 and 0.61892. The bootstrap confidence interval for the slope (0.400 to 0.619) is slightly wider than the confidence interval (0.425 to 0.583) obtained using the usual regression assumptions in step 7 and step 8.

**Note:** The BC Lower and BC Upper columns in the Bootstrap Confidence Limits report refer to *bias-corrected intervals*. See “Bias-Corrected Percentile Intervals” on page 375.

### Bootstrapping Window Options

To perform a bootstrap analysis, right-click a numeric column of sample statistics in a table in a report window and select **Bootstrap**. The selected column is highlighted, and the Bootstrapping window appears. After you select options and click **OK** in the Bootstrapping window, bootstrap results for every statistic in the column appear in the default results table.

**Note:** The Bootstrap option is not available in reports that use a By variable.

The Bootstrapping window contains the following options:

**Number of Bootstrap Samples**  Sets the number of times that you want to resample the data and compute the statistics. A larger number results in more precise estimates of the statistics’ properties. By default, the number of bootstrap samples is set to 2500.
**Random Seed**  Sets a random seed that you can re-enter in subsequent runs of the bootstrap analysis to duplicate your current results. By default, no seed is set.

**Fractional Weights**  Performs a Bayesian bootstrap analysis. In each bootstrap iteration, each observation is assigned a weight that is calculated as described in “Calculation of Fractional Weights” on page 375. The weighted observations are used in computing the statistics of interest. By default, the Fractional Weights option is not selected and a simple bootstrap analysis is conducted.

**Tip:** Use the Fractional Weights option if the number of observations that are used in your analysis is small or if you are concerned about separation in a logistic regression setting.

Suppose that the Fractional Weights option is selected. For each bootstrap iteration, each observation that is used in the report is assigned a nonzero weight. These weights sum to \( n \), the number of observations used in the calculations of the statistics of interest. For more information about how the weights are calculated and used, see “Calculation of Fractional Weights” on page 375.

**Split Selected Column**  Places bootstrap results for each statistic in the column that you selected for bootstrapping into a separate column in the Bootstrap Results table. Each row of the Bootstrap Results table (other than the first) corresponds to a single bootstrap sample.

If you deselect this option, a Stacked Bootstrap Results table appears. For each bootstrap iteration, this table contains results for the entire report table that contains the column that you selected for bootstrapping. Results for each row of the report table appear as rows in the Stacked Bootstrap Results table. Each column in the report table defines a column in the Stacked Bootstrap Results table. For an example, see “Stacked Bootstrap Results Table” on page 367.

**Discard Stacked Table if Split Works**  (Applicable only if the Split Selected Column option is selected.) Determines the number of results tables produced by Bootstrap.

If the Discard Stacked Table if Split Works option is not selected, then two Bootstrap tables are shown:

- The Stacked Bootstrap Results table, which contains bootstrap results for each row of the table containing the column that you selected for bootstrapping. This table gives bootstrap results for every statistic in the report, where each column is defined by a statistic.

- The unstacked Bootstrap Results table, which is obtained by splitting the stacked table. This table provides results only for the column that is selected in the original report.

If the Discard Stacked Table if Split Works option is selected and if the Split Selected Column operation is successful, the Stacked Bootstrap Results table is not shown.
The initial results of a bootstrap analysis appear in a stacked results table (Figure 11.4). This table might not appear if you have selected the Discard Stacked Table if Split Works option. Figure 11.4 shows a bootstrap table that is based on the Parameter Estimates report obtained by fitting a Bivariate model in Fit Y by X to Car Physical Data.jmp. See “Overview of Bootstrapping” on page 361.

Figure 11.4 Stacked Bootstrap Results Table

| X | Y          | Term        | ~Bias   | Estimate | Std Error | t Ratio | Prob>|t| | BootID• |
|---|------------|-------------|---------|----------|-----------|---------|-------|-------|--------|
| 1 | Displacement | Horsepower  | Intercept | 50.443509471 | 6.7462099999 | 7.48 | <.0001 | 0 |
| 2 | Displacement | Horsepower  | Displacement | 0.5037874592 | 0.0398202111 | 12.65 | <.0001 | 0 |
| 3 | Displacement | Horsepower  | Intercept | 45.385604758 | 5.4724273046 | 8.29 | <.0001 | 1 |
| 4 | Displacement | Horsepower  | Displacement | 0.5451674092 | 0.0306151772 | 17.81 | <.0001 | 1 |
| 5 | Displacement | Horsepower  | Intercept | 40.843862813 | 7.0508187236 | 5.79 | <.0001 | 2 |
| 6 | Displacement | Horsepower  | Displacement | 0.5854988173 | 0.0457041828 | 12.81 | <.0001 | 2 |
| 7 | Displacement | Horsepower  | Intercept | 47.765642104 | 5.4677610087 | 8.74 | <.0001 | 3 |
| 8 | Displacement | Horsepower  | Displacement | 0.4943459579 | 0.0305765677 | 16.17 | <.0001 | 3 |
| 9 | Displacement | Horsepower  | Intercept | 59.75806908 | 7.0436720036 | 8.48 | <.0001 | 4 |
| 10 | Displacement | Horsepower  | Displacement | 0.4385540785 | 0.042053201 | 10.43 | <.0001 | 4 |
| 12 | Displacement | Horsepower  | Displacement | 0.3969640071 | 0.0393100058 | 10.10 | <.0001 | 5 |
| 13 | Displacement | Horsepower  | Intercept | 41.234989734 | 5.8543901826 | 7.04 | <.0001 | 6 |
| 14 | Displacement | Horsepower  | Displacement | 0.5723548142 | 0.024172131 | 16.75 | <.0001 | 6 |
| 15 | Displacement | Horsepower  | Intercept | 43.876867815 | 7.808596052 | 5.62 | <.0001 | 7 |
| 16 | Displacement | Horsepower  | Displacement | 0.5731377467 | 0.0439823115 | 13.03 | <.0001 | 7 |

Note the following about the stacked results table:

- For each bootstrap sample, there is a row for each value given in the first column of the report table. These values are shown in a column whose name is the name of the first column in the report table. In this example, for each bootstrap sample there is a row containing results for each Term: Intercept and Displacement, which appear in the Term column.

- The data table columns that are used in the analysis appear in the table. In this example, X is Displacement, and Y is Horsepower.

- There is a column for every column in the report table that you are bootstrapping. In this example, the columns are ~Bias, Estimate, Std Error, t Ratio, and Prob>|t|. Note that ~Bias is a column in the Fit Y by X report that is hidden unless one of the parameter estimates is biased.

- The BootID• column identifies the bootstrap sample. The rows where BootID• = 0 correspond to the original estimates. Those rows are marked with an X and have the excluded row state. In this example, each bootstrap sample is used to calculate results for two rows: the results for Intercept and the results for Displacement.
• The data table name begins with “Stacked Bootstrap Results”.

If you selected the **Split Selected Column** option, an unstacked results table might also appear. See “Unstacked Bootstrap Results Table” on page 368.

---

**Unstacked Bootstrap Results Table**

Select **Split Selected Column** to create a bootstrap table that contains separate columns for the report column that you selected. Each column corresponds to a Term in the report table. For example, in Figure 11.5, the **Estimate** column from Figure 11.4 is split into two columns (Displacement and Intercept), one for each level of Term.

**Figure 11.5  Unstacked Bootstrap Results Table**

</table>

Note the following about the unstacked results table:

• There is a single row for each bootstrap sample.

• The data table columns used in the analysis appear in the table. In this example, X is Displacement, and Y is Horsepower.

• There is a column for each row of the report that was bootstrapped.

• If you specified a Random Seed in the Bootstrapping window, the bootstrap results table contains a table variable called Random Seed that gives its value.

• The unstacked bootstrap results table contains a Source table script and a Distribution table script. The Distribution table script enables you to quickly obtain statistics based on the bootstrap samples, including bootstrap confidence intervals.

• The **BootID** column identifies the bootstrap sample. The row where **BootID** = 0 corresponds to the original estimates. That row is marked with an X and has the excluded row state. In the unstacked bootstrap table, each row is calculated from a single bootstrap sample.
The data table name ends with “Bootstrap Results (<colname>)”, where <colname> identifies the column in the report that was bootstrapped.

Analysis of Bootstrap Results

Analyze your bootstrap results using the Distribution platform:

- If your analysis produced an unstacked bootstrap results table, run the Distribution script in the table.
- If your analysis produced a stacked bootstrap results table, select Analyze > Distribution and assign the columns of interest to the appropriate roles. In most cases, it is appropriate to assign the column that corresponds to the first column in the report table to the By role.

The Distribution platform provides summary statistics for your bootstrap results. It also produces a Bootstrap Confidence Limits report for any table that contains a BootID column (Figure 11.6).

You can use the Distribution report to obtain two types of bootstrap confidence intervals:

- The Quantiles report provides percentile intervals. For example, to construct a 95% confidence interval using the percentile method, use the 2.5% and 97.5% quantiles as the interval bounds.
- The Bootstrap Confidence Limits report provides bias-corrected percentile intervals. The report shows intervals with 95%, 90%, 80%, and 50% coverage levels. The BC Lower and BC Upper columns show the lower and upper endpoints, respectively. For more information about the computation of the bias-corrected percentile intervals, see “Bias-Corrected Percentile Intervals” on page 375.

The **Original Estimate** at the bottom of the Bootstrap Confidence Limits report is the estimate of the statistic using the original data.

For more information about interpreting the Bootstrap Confidence Limits report, see “Overview of Bootstrapping” on page 361. Efron (1981) describes the methods for both the percentile interval and the bias-corrected percentile interval.

### Additional Example of Bootstrapping

This example illustrates the benefits of the Fractional Weights (Bayesian Bootstrap) option for a small data table. The data consist of a response, \( Y \), measured on three samples of each of seven different soil types. A scientist is interested in finding a confidence interval for the mean response for the *wabash* soil type.

Because each soil type has only three observations, the simple bootstrap has the potential to exclude all three of the observations for *wabash* from a bootstrap sample. The Fractional Weights option ensures that all observations for every soil type are represented in all bootstrap samples.

The scientist examines the distribution of *wabash* sample means from both bootstrap methods:
- “Simple Bootstrap Analysis” on page 371
- “Bayesian Bootstrap Analysis” on page 373
Simple Bootstrap Analysis

1. Select **Help > Sample Data Library** and open Snapdragon.jmp.
2. Select **Analyze > Fit Y by X**.
3. Select Y and click **Y, Response**.
4. Select Soil and click **X, Factor**.
5. Click **OK**.
6. Click the red triangle next to Oneway Analysis of Y By Soil and select **Means/Anova**.
7. In the Means for Oneway Anova report, right-click the Mean column and select **Bootstrap**.
8. Type 1000 for the **Number of Bootstrap Samples**.
9. (Optional) To match the results in Figure 11.7, type 12345 for the **Random Seed**.
10. Click **OK**.

**Figure 11.7** Bootstrap Results for a Simple Bootstrap

The missing values in Figure 11.7 represent bootstrap iterations in which none of the observations for a given soil type were selected for the bootstrap sample.

11. Select **Analyze > Distribution**.
12. Select wabash and click **Y, Columns**.
13. Click **OK**.

**Figure 11.8** Distribution of *wabash* Means from a Simple Bootstrap

![Distribution of wabash Means from a Simple Bootstrap](image)

Figure 11.8 shows the distribution of *wabash* means from the simple bootstrap analysis. Notice the following:

- The Summary Statistics report indicates that the number of rows containing bootstrap means for *wabash* is \( N = 961 \). Although you conducted 1,000 iterations, 39 bootstrap samples did not contain any of the three observations for *wabash*.

- The histogram of sample means is not smooth, with peaks at the two extremes. The three values for *wabash* are 38.2, 37.8, and 31.9. The peak at the low end of the distribution results from bootstrap samples that contain only the value 31.9. The peak
at the high end results from bootstrap samples that contain one or both of the values 38.2 and 37.8.

Next, use the Fractional Weights (Bayesian Bootstrap) option to avoid obtaining missing values from the bootstrap samples and to smooth the distribution of bootstrapped means.

**Bayesian Bootstrap Analysis**

1. In the Oneway Analysis report, right-click the **Mean** column in the **Means for Oneway Anova** report and select **Bootstrap**.
2. Type 1000 for the **Number of Bootstrap Samples**.
3. (Optional) To match the results in Figure 11.9, type 12345 for the **Random Seed**.
4. Select the **Fractional Weights** option.
5. Click **OK**.

</tbody>
</table>

There are no missing values in the Bayesian Bootstrap results table. All 21 rows in the Snapdragon.jmp data table are included, with varying bootstrap weights, in each bootstrap sample.

6. Select **Analyze > Distribution**.
7. Select **wabash** and click **Y, Columns**.
8. Click **OK**.

**Figure 11.10** Distribution of wabash Means from a Bayesian Bootstrap

The Bayesian Bootstrap produces a much smoother distribution for the *wabash* sample means. All 1,000 bootstrap samples include the three observations for *wabash*. For each iteration, the *wabash* sample mean is calculated using different fractional weights.

The Bootstrap Confidence Limits report shows that a 95% confidence interval for the mean is 32.6396 to 37.8168.
Calculation of Fractional Weights

The Fractional Weights option is based on the Bayesian bootstrap (Rubin 1981). The number of times that an observation occurs in a given bootstrap sample is called its bootstrap weight. In the simple bootstrap, the bootstrap weights for each bootstrap sample are determined using simple random sampling with replacement.

In the Bayesian approach, sampling probabilities are treated as unknown parameters and their posterior distribution is obtained using a non-informative prior. Estimates of the probabilities are obtained by sampling from this posterior distribution. These estimates are used to construct the bootstrap weights:

- Randomly generate a vector of $n$ values from a gamma distribution with shape parameter equal to $(n-1)/n$ and scale parameter equal to 1.

  **Note:** Rubin (1981) uses 1 as the gamma shape parameter. The shape parameter that is used in JMP Pro ensures that the mean and variance of the fractional weights are equal to the mean and variance of the simple bootstrap weights.

- Compute $S$ as the sum of the $n$ values.

- Compute the fractional weights by multiplying the vector of $n$ values by $N / S$, where $N$ equals the number of rows or the sum of the frequencies if a Freq variable is specified.

  **Note:** If a Freq variable is specified for the analysis, multiply the shape parameter for the gamma distribution by the Freq values on a row-by-row basis. The sum of the values of the Freq variable must be greater than 1. Then the shape parameters are equal to $f_i(N - 1)/N$, where $f_i$ is the Freq value for the $i^{th}$ row and $N$ equals the sum of the Freq values.

This procedure scales the fractional weights for each row to have mean and variance over bootstrap sampling equal to those of the simple bootstrap weights. The fractional bootstrap weights in each bootstrap sample are positive, sum to $N$, and have a mean of 1.

Bias-Corrected Percentile Intervals

This section describes the calculation of the bias-corrected (BC) confidence intervals that appear in the Bootstrap Confidence Limits report when you run the Distribution script in the Bootstrap Results table. Bias-corrected percentile intervals improve on the ability of percentile intervals in accounting for asymmetry in the bootstrap distribution. See Efron (1981).
Notation

- $p^*$ is the proportion of bootstrap samples with an estimate of the statistic of interest that is less than or equal to the original estimate.
- $z_0$ is the $p^*$ quantile of a standard normal distribution.
- $z_\alpha$ is the $\alpha$ quantile of a standard normal distribution.

Bias-Corrected Confidence Interval Endpoints

The endpoints of a $(1 - \alpha)$ bias-corrected confidence intervals are given by quantiles of the bootstrap distribution:

- The lower endpoint is the following quantile:
  \[
  \Phi\left(2z_0 + \frac{z_\alpha}{2}\right)
  \]

- The upper endpoint is the following quantile:
  \[
  \Phi\left(2z_0 + \frac{z_{1 - \frac{\alpha}{2}}}{2}\right)
  \]
Many features in this platform are available only in JMP Pro and noted with this icon.

The Text Explorer platform enables you to analyze unstructured text, such as comment fields in surveys or incident reports. Interact with the text data by using tools to combine similar terms, recode misspecified terms, and understand the underlying patterns in your textual data.

The JMP Pro version of the platform contains analysis tools that use singular value decomposition (SVD) to group similar documents into topics. You can cluster text documents or cluster terms that are in a collection of documents. You can also cluster documents using latent class analysis.

The JMP Pro version of the platform also contains tools for identifying important terms and sentiments in your documents. Term selection enables you to identify the terms that best explain different responses. Sentiment analysis enables you to identify sentiment terms in document using lexical analysis and scores documents for positive, negative, and overall sentiment. The Sentiment Analysis feature includes basic natural language processing (NLP) support.

Overview of the Text Explorer Platform

The Text Explorer platform enables you to explore unstructured text in order to better understand its meaning. Unstructured text data are common. For example, unstructured text data could result from a free response field in a survey, product review comments, or incident reports.

Text analysis is often an iterative process, so you might alternate between curating and analyzing the list of terms.

Curating the List of Terms

Text analysis uses some unique terminology. A term or token is the smallest piece of text, similar to a word in a sentence. However, you can define terms in many ways, including through the use of regular expressions; the process of breaking the text into terms is called tokenization.

- A phrase is a short collection of terms; the platform has options to manage phrases that are specified as terms in and of themselves.
- A document refers to a collection of words; in a JMP data table, the unstructured text in each row of the text column corresponds to a document.
- A corpus refers to a collection of documents.

It is often desirable to exclude some common words from the analysis. These excluded words are called stop words. The platform has a default list of stop words, but you can also add specific words as stop words. Although stop words are not eligible to be terms, they can be used in phrases.

You can also recode terms; this is useful for combining synonyms into one common term.

Stemming is the process of combining words with identical beginnings (stems) by removing the endings that differ. This results in “jump”, “jumped”, and “jumping” all being treated as the term “jump·”. The stemming procedure is similar to the procedure used in the Snowball string processing language. When a phrase is stemmed, each word in the phrase is stemmed as it would be stemmed as a stand-alone term.
Analyzing the List of Terms

Text analysis in the Text Explorer platform uses a *bag of words* approach. Other than in the formation of phrases, the order of terms is ignored. The analysis is based on the term counts.

After you curate the list of terms through the use of regular expressions, stop words, recoding, and stemming, you can perform analyses on the curated list of terms. The analysis options in the platform are based on the *document term matrix* (DTM). Each row in the DTM corresponds to a document (a cell in a text column of a JMP data table). Each column in the DTM corresponds to a term from the curated term list. This approach implements the bag of words approach since it ignores word ordering. In its simplest form, each cell of the DTM contains the frequency (number of occurrences) of the column’s term in the row’s document. There are various other weighting schemes for the DTM; these are described in “Save Options” on page 406.

The analysis options that are available in the platform first perform a singular value decomposition (SVD) on the document term matrix. This can greatly reduce the number of columns needed to represent the term information in the data. For more information about singular value decomposition, see *Multivariate Methods*. Hierarchical clustering options are available for clustering the terms and for clustering the documents. These options enable you to group similar terms or documents together.

Text Explorer Platform Workflow

These are the expected steps for using the Text Explorer platform:

1. Specify the method for tokenizing (either built-in or customized regular expression).
2. Use the report to specify additional stop words, add phrases to the term list, perform recodes of terms, and specify exceptions to stemming rules.
3. Specify the preference for stemming.
4. Use word and phrase counts, SVD, and clustering approaches to identify important terms and phrases.

*Note: JMP Pro* The SVD and clustering options are available only in JMP Pro.

5. Save results for use in further analysis: the term table, the DTM, the singular vectors, or other results.

*Note: JMP Pro* The option to save the singular vectors is available only in JMP Pro.

Text Processing Steps

In the JMP Text Explorer platform, text is processed in three stages: tokenizing, phrasing, and terming.

Tokenizing Stage

The Tokenizing stage performs the following operations:

1. Convert text to lowercase.
2. Apply Tokenizing method (either Basic Words or Regex) to group characters into tokens.
3. Recode tokens based on specified recode definitions. Note that recoding occurs before stemming.

   **Note:** Recode operations are processed internally in one pass regardless of the order that they are specified in the report window.

Phrasing Stage

The Phrasing stage collects phrases that occur in the corpus (collection of documents) and enables you to specify that individual phrases be treated as terms. Phrases cannot start or end with a stop word, but they can contain a stop word.

Terming Stage

The Terming stage creates the Term List from the tokens and phrases that result from the previous stages.

For each token, the Terming stage performs the following operations:

1. Check that the minimum and maximum length requirements specified in the launch window are met. Tokens that contain only numbers are excluded from this operation.
2. Check that the token is qualified to become a term; tokens parsed by the Basic Words tokenization method must contain at least one alphabetical or Unicode character. Tokens that contain only numbers are excluded from this operation. The Regex tokenization method uses regular expressions to determine what characters are part of a token.
3. Check that the token is not a stop word.
4. Apply stemming and stem exceptions.

For each phrase that you add, the Terming stage performs the following operations:

1. Add the phrase to the Term List. Phrases should apply stemming to each word in the phrase that is stemmed in the Term List. Phrases that have different raw tokens but the same stems are combined in the Term List.
2. Remove token term occurrences that appear in the phrase.
Example of the Text Explorer Platform

Learn how to explore text responses in JMP. In this example, you want to explore the text responses from a survey about pets.

1. Select **Help > Sample Data Library** and open **Pet Survey.jmp**.
2. Select **Analyze > Text Explorer**.
3. Select **Survey Response** and click **Text Columns**.
4. From the Language list, select **English**.
5. Click **OK**.

**Figure 12.2** Example of Initial Text Explorer Report

At a glance, you can see that there are 372 unique terms in 194 documents. In all, there are 2075 tokenized terms. The most common term is “cat”, and it occurs 55 times.

6. Click the red triangle next to Text Explorer for Survey Response and select **Term Options > Stemming > Stem All Terms**.
7. In the Phrase List table, select **cat food** and **dog food**, right-click the selection, and select **Add Phrase**.
The terms cat food and dog food are included in the Term List.

8. Scroll down in the Term List and find the cat and dog food entries.
   You can see that there are four occurrences of each phrase.

**Figure 12.3** Term List after Modifications and Scrolling

<table>
<thead>
<tr>
<th>Term</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat food</td>
<td>4</td>
</tr>
<tr>
<td>dog food</td>
<td>4</td>
</tr>
<tr>
<td>any</td>
<td>3</td>
</tr>
<tr>
<td>bath</td>
<td>3</td>
</tr>
<tr>
<td>shake</td>
<td>3</td>
</tr>
<tr>
<td>kids</td>
<td>3</td>
</tr>
<tr>
<td>see</td>
<td>3</td>
</tr>
<tr>
<td>box</td>
<td>3</td>
</tr>
<tr>
<td>stay</td>
<td>3</td>
</tr>
<tr>
<td>roll</td>
<td>3</td>
</tr>
<tr>
<td>fluffi</td>
<td>3</td>
</tr>
<tr>

<td>3</td>
</tr>
<tr>
<td>hilar</td>
<td>3</td>
</tr>
<tr>
<td>best</td>
<td>3</td>
</tr>
<tr>
<td>leg</td>
<td>3</td>
</tr>
</tbody>
</table>

In the Phrase List, cat food and dog food are gray, since they are now locally being treated as terms in this Text Explorer report.

*JMP Pro*

**The remaining steps of this example can be completed only in JMP Pro.**

9. **JMP Pro** Click the red triangle next to Text Explorer for Survey Response and select *Latent Semantic Analysis, SVD*.

10. **JMP Pro** Click OK to accept the default values.
   Two SVD Plots appear in the report. The one on the left shows the first two singular vectors in the document space. The one on the right shows the first two singular vectors in the term space.

**Figure 12.4** SVD Plots
11. Select the three right-most points in the left SVD Plot.
   These three points represent survey responses that are clustered away from the rest of the points. To further investigate this cluster, you read the text of these responses.

12. Click the Show Text button that is above the left SVD Plot.

**Figure 12.5 Text of Selected Documents**

> There was this funny video of a cat trying to jump into someone's lap, but fell into the pool instead. [166]

> The funny cat video where the cats jumped through the window right into the bathtub was hilarious. [142]

> We made this funny video of the cat trying to climb the wall to chase a laser pointer. [153]

A window appears that contains the text of the three documents represented by the selected points. These survey responses are similar in that they all refer to some combination of “funny”, “cat”, and “video”. These documents have larger positive values for the first singular vector than the rest of the documents. These larger values indicate that they are different from the rest of the documents in that dimension.

Further investigation of the singular vector dimensions could lead to interpretations of what the dimensions represent. For example, many of the documents on the far right of the plot are responses that are about cats. On the far left, many of the responses are about dogs. Therefore, the first singular vector is picking up differences based on whether the response was about a cat or a dog.

**Launch the Text Explorer Platform**

Launch the Text Explorer platform by selecting Analyze > Text Explorer.

**Figure 12.6 The Text Explorer Launch Window**
For more information about the options in the Select Columns red triangle menu, see Using JMP. The Text Explorer launch window contains the following options:

**Text Columns** Assigns the columns that contain text data. If you specify multiple columns, a separate analysis is created for each column.

**Validation** In JMP Pro, you can enter a Validation column. If you click the Validation button with no columns selected in the Select Columns list, you can add a validation column to your data table. For more information about the Make Validation Column utility, see Predictive and Specialized Modeling.

The specification of a Validation column does not affect the calculation of the document-term matrix. However, when a Validation column is specified, only the training set is used for the Latent Class Analysis, Latent Semantic Analysis, Topic Analysis, and Discriminant Analysis options. The Validation column is used as the Generalized Regression validation method for the Term Selection option.

**ID** Assigns a column used to identify separate respondents in the Save Stacked DTM for Association output data table. This output data table is suitable for association analysis. This column is also used to identify separate respondents in the Latent Class Analysis report.

**By** Identifies a column that creates a report consisting of separate analyses for each level of the variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

**Note:** If you specify a By variable, the Customize Regex option and settings apply to all levels of the By variables.

**Language** Specifies the language used for text processing. This affects stemming and the built-in lists of stop words, recodes, and phrases. This option is independent of the language in which JMP is running. Unless the Language platform preference is set, the Language option is set according to the JMP Display Language preference. However, the Language option in Text Explorer does not support Korean. If the JMP Display Language is Korean, this option defaults to English.

**Maximum Words per Phrase** Specifies a maximum number of words that a phrase can contain to be included as a phrase in the analysis.

**Maximum Number of Phrases** Specifies the maximum number of phrases that appear in the Phrase List.

**Minimum Characters per Word** Specifies the number of characters that a word must contain to be included as a term in the analysis.

**Maximum Characters per Word** Specifies the largest number of characters (up to 2000) that a word can contain to be included as a term in the analysis.
**Stemming** (Available only when the Language option is set to English, German, Spanish, French, or Italian.) Specifies a method for combining terms with similar beginning characters but different endings. The following options are available:

- **No Stemming**  No terms are combined.
- **Stem for Combining**  Stems only the terms where two or more terms stem to the same term.
- **Stem All Terms**  Stems all terms.

**Note:** The use of the Stemming option also affects phrases that have been added to the Term List. Phrase identification occurs after terms within a phrase have been stemmed. For example, “dogs bark” and “dog barks” would both match the specified phrase “dog·bark.”

**Tokenizing** (Available only when the Language option is set to English, German, Spanish, French, or Italian.) Specifies a method for parsing the text into terms or tokens. The following tokenization options are available:

- **Regex**  Parses text using a default set of built-in regular expressions. If you want to add to, remove, or edit the set of regular expressions used to parse the text, select the **Customize Regex** option. See “Customize Regex in the Regular Expression Editor” on page 387.
- **Basic Words**  Text is parsed into words based on a set of characters that typically separate words. These characters include spaces, tabs, new lines, and most punctuation marks. If you want numbers to be parsed into terms for the analysis, select the **Treat Numbers as Words** option. If you do not select this option, pieces of text between delimiters that contain only numbers are ignored in the tokenizing step.

**Tip:** You can view the default set of delimiters using the **Display Options > Show Delimiters** option in a Text Explorer report that uses the Basic Words Tokenizing method.

**Customize Regex** (Available only with the Regex Tokenizing method.) Enables you to use the Text Explorer Regular Expression Editor window to modify the Regex settings. Use this option to accommodate non-traditional words. Examples include phone numbers or words formed by a combination of characters and numbers. Using the Customize Regex option is not recommended unless the default Regex method is not giving you the results that you need. This can happen when your text contains structures that the default Regex method does not recognize. See “Customize Regex in the Regular Expression Editor” on page 387.
**Treat Numbers as Words** (Available only with the Basic Words Tokenizing method.) Allows numbers to be tokenized as terms in the analysis. When this option is selected, the Minimum Characters per Word setting is ignored for terms that contain numeric digits.

After you click **OK** on the launch window, the Text Explorer Regular Expression Editor window appears if you selected **Customize Regex** in the launch window. Otherwise, the Text Explorer report appears.

**Note:** The processing of text input is not case-sensitive. All text is converted to lowercase internally prior to tokenization and all analysis steps. This conversion affects the processing of regular expressions and the aggregation of terms in the Text Explorer output.

**Customize Regex in the Regular Expression Editor**

When you select the **Customize Regex** option, the Text Explorer Regular Expression Editor appears. Use this window to parse text documents using a wide variety of built-in regular expressions, such as phone numbers, times, or monetary values. You can also create your own regular expression definitions.

**Note:** Using the Customize Regex option is recommended only if you are not getting desired results from the default Regex method. This can happen when your text contains structures that the default Regex method does not recognize.

**Tip:** If Japanese, Chinese (Simplified), or Chinese (Traditional) is specified as the Language option in the launch window, the list of Regex patterns contains a single Regex for the specified language. If you want to add other Regex patterns, it is recommended that you add them after the single Regex pattern. You should avoid using the Words pattern before the language-specific Regex pattern, because the Words pattern can gather long runs of Asian language characters into single words.
Parsing with the Script Editor Box

The script editor box at the top of the window shows you how the parsing would proceed for sample text. The results of parsing the regular expressions in the Regex Editor list are highlighted in colors that correspond to the colors in the Regex Editor list.

- Click the First, Previous, Next, and Last row buttons to populate the script editor box with text from your own data. This enables you to see how a given row of text data is parsed. You can also enter a row number in the edit box to populate the script editor box with text from a specific row in the data table.

- Click the Save to Column button to save a new column to the data table that contains the result of the regular expression tokenization. For more information about specifying the result of the regular expression, see “Editing the Regular Expressions” on page 389. The Save to Column button does not appear if you access the Regular Expression Editor through Cols > Utilities > New Column by Text Matching.

Note: The Save to Column button uses only the regular expression to match text. The following settings are not used: stop words, recodes, stemming, phrases, or minimum and maximum characters per word to modify the output of the regular expression.
Adding Regular Expressions

To add a regular expression to be used in tokenization, click the plus sign below the list. The Regex Library Selections window appears. This window contains all the built-in regular expressions as well as any recently modified regular expressions that you created in previous instances of the Regular Expression Editor. Built-in regular expressions are labeled. Custom regular expressions that are saved in your library are labeled with the name that you specified. Only the most recent expression for a given name is stored in the Regex Library.

Click the Recall button to populate the regular expressions list with the regular expressions from the most recent instance of the Regular Expression Editor. The recalled regular expressions are ones that were present in the previous instance of the editor when either the Save to Column button or the OK button was clicked.

Select one or more regular expressions in the list and click OK to add the selected regular expressions to be used in tokenization. Use the Delete Selected Item button to remove one or more custom regular expressions from the Regex Library. The Regex Library for each user is stored as a JSL file in a directory called TextExplorer. The location of this directory is based on your computer’s operating system:

- macOS: "~/Users/<username>/Library/Application Support/JMP/TextExplorer/

These files can be shared with other users, but you should not edit the file directly. Use the Regular Expression Editor instead.

Editing the Regular Expressions

Terms are tokenized by processing the regular expressions in the order specified in the Regex Editor panel. To change the order of the regular expressions, select a regular expression in the list and click the up or down arrow buttons below the list. You can also drag and drop items in the regular expression list to change the order of execution. A blue triangle represents the currently selected regular expression. To remove a regular expression and exclude it from the tokenization, select it in the list and click the minus sign below the list. The “Leftover” regular expression cannot be removed and must appear last in the sequence of regular expressions.

When you select a regular expression in the list, the editable fields in the Regex Editor panel refer to the selected regular expression. Click and type in any of these fields to edit them.

Each regular expression has the following attributes:

**Title** Specifies a name used to identify the regular expression in the current window (as well as in the Regex Library later).

**Regex** Specifies the regular expression definition. The regular expression must have at least one set of parentheses to designate the regular expression capture.
**Result**  Specifies what replaces the text matched by the regular expression. This value can be static text, blank, or the value of the regular expression capture. The regular expression capture is defined as the result of the Regex definition:

- To replace the matched text with static text, specify the static text in the Result field.
- To ignore the matched text, leave the Result field blank.
- To keep the text that results from the outer-most parentheses in the regular expression, use \"\1\" (without quotation marks) in the Result field.
- To keep the entire result of the regular expression, use \"\0\" (without quotation marks) in the Result field.

**Example**  (Optional) Specifies an example text string with colors indicating the behavior of the regular expression.

**Comment**  (Optional) Specifies a comment to explain the regular expression and its behavior.

**Color**  Specifies the color used to identify matches of the regular expression in the text in the Script Editor box and in the Example field. Use the arrow buttons to change the color.

**Note:** If the regular expression definition in the Regex field is invalid, a red X appears next to the name of the regular expression in the list of regular expressions.

**Creating a Custom Regular Expression**

Follow these steps to create your own custom regular expression:

1. Click the plus sign below the list.
2. In the Regex Library Selections window, note that the Blank regular expression is selected.
3. Click **OK**.
4. Edit the Regex definition in the Regex Editor panel.
5. Give your custom regular expression a unique name in the Title field.

**Tip:** When editing the Regex definition field, it is helpful to have the Log window open and visible. Some error messages appear only in the Log window. To open the Log window, select **View > Log**. There are many internet resources available for troubleshooting regular expressions, such as [https://regexr.com/](https://regexr.com/).
The **Word Separator List** button enables you to specify a list of characters that occur between words in the tokenization process. The *between-word characters* cannot begin a word, but they can appear inside a word if one of the regular expressions allows it. You can add or remove characters from the list in the window that appears when you click the button. By default, the only character in the list is a whitespace character. In the Separator Characters window, click the **Reset** button to undo any modifications to the list of separator characters. Modifications to the list of separator characters are applied only to the current regular expression tokenization.

The following steps describe the processing of the specified regular expressions and the required “Leftover” regular expression:

1. Compare the current character in the text stream to the list of separator characters.
   - If the character is in the list of separator characters, ignore the character, process any accumulated characters in the “Leftover” temporary string, move to the next character, and repeat step 1.
   - If the character is not in the list of separator characters, go to step 2.
2. Compare the string starting at the current character to each regular expression (one at a time, up to, but not including, the “Leftover” regular expression).
   - If the string starting at the current character matches one of the regular expressions, the following events occur. Any accumulated characters in the “Leftover” temporary string are processed. The value of the Result field is saved as a term. The current character in the text stream becomes the character following the matched string. The processing returns to step 1.
   - If the string starting at the current character does not match any of the regular expressions up to the “Leftover” regular expression, go to step 3.
3. Collect characters into the “Leftover” temporary string by appending the current character and setting the current character to the next character in the text stream. Return to step 1.
   - The “Leftover” temporary string is accumulated one character at a time, until one of the other regular expressions produces a match.
   - The default Result of the “Leftover” regular expression is to discard the accumulated “Leftover” temporary string.

**Tips:**

- If you set the Result of the “Leftover” regular expression to \1, you might want to add more separator characters, such as punctuation marks. This ensures that your results do not include the specified punctuation marks.
- Instead of changing the Result of the “Leftover” regular expression to \1, you might want to consider one or more of the following actions to capture terms of interest:
Text Explorer
Launch the Text Explorer Platform

- Add more regular expressions from the Regex Library.
- Create custom regular expressions.

The processing follows the above steps until reaching the end of the text string for each row in the data table.

Saving the Results to a Column in the Data Table

Click the **Save to Column** button to save to the data table a new column that contains the results of the regular expression tokenization. The new column is a character column with the same name as the text column specified in the Text Explorer launch window; a number is appended to the name so that the column names are unique. You can also use a stand-alone Regular Expression utility under Cols > Utilities > New Column by Text Matching. See *Using JMP*.

**Note:** When you save the results of the custom regular expression tokenization to a column in the data table, the regular expression process is run on the original text in each row of the data table. It is not run on the version of the text string that was converted to lowercase.

Closing the Text Explorer Regular Expression Editor

After you click **OK** in the Text Explorer Regular Expression Editor window, the following events occur:

1. The custom regular expressions defined in the Text Explorer Regular Expression Editor window are saved to the Regex Library.

   **Caution:** The custom Regex Library is saved only when you click **OK** and there are customized regular expressions. The most recently saved regular expressions will be available next time. Use unique names to keep additional regular expressions in the Regex Library. To ensure that a regular expression is available later, you can save a script from the Text Explorer report window.

2. The Text Explorer report appears. The report shows the result of using the specified regular expression settings to tokenize the text.
The Text Explorer Report

The Text Explorer report window contains the Summary Counts report and the Term and Phrase Lists report.

**Figure 12.8** Example of a Text Explorer Report

![Text Explorer for Survey Response](image)

### Summary Counts Report

The first table in the Text Explorer report window contains the following summary statistics:

- **Number of Terms**: The number of terms in the Term List.
- **Number of Cases**: The number of documents in the corpus.
- **Total Tokens**: The total number of terms in the corpus.
- **Tokens per Case**: The number of tokens divided by the number of cases.
- **Number of Non-Empty Cases**: The number of documents in the corpus that contain at least one term.
Portion of Non-Empty Cases  The proportion of documents in the corpus that contain at least one term.

Term and Phrase Lists

The Term and Phrase Lists report contains tables of terms and phrases found in the text after tokenization has occurred. See Figure 12.8 for an example of the Term and Phrase Lists report. The Count column in the Term List indicates the number of occurrences of the term in the corpus. The Count column in the Phrase List indicates the number of occurrences of the phrase in the corpus; the N column indicates the number of words in the phrase.

By default, the Terms List is sorted in descending count order; terms that are tied in count are sorted alphabetically. The Phrases List is sorted in descending count order; phrases that are tied in count are then sorted in descending length (N) order. Further ties in the Phrases List are sorted alphabetically. The sort order of each list can be changed to alphabetical sorting using the options in each list.

The phrases that appear in the Phrase List are determined by the settings of the Maximum Words per Phrase and Maximum Number of Phrases options in the launch window. Phrases that occur only one time in the data table do not appear in the Phrase List.

Phrases can be specified as terms at various scopes. Phrases in the Phrase List that have been specified as terms are colored based on the scope of the phrase specification (Table 12.1). For more information about specifying phrases in different scopes, see “Term Options Management Windows” on page 401.

Actions for Terms and Phrases

You can access options in the Term List and Phrase List tables by selecting items and then right-clicking in the left-most column of each table. You can save each table as a data table by right-clicking in the Count column of each table and selecting Make into Data Table.
Term List Pop-up Menu Options

When you right-click in the Term column of the Term List table, a pop-up menu appears with the following options:

**Select Rows**  
Selects rows in the data table that contain the selected terms.

**Show Text**  
Shows the documents that contain the selected terms.

**Note:** By default, only the first 10,000 documents are shown. If there are more than 10,000 documents that contain a selected term, a window appears that enables you to increase this limit.

**Alphabetical Order**  
Specifies the sort order of the Term List. When this option is selected, the terms are sorted in alphabetical order. When this option is not selected, the terms are sorted in descending Count order.

**Numerical Order**  
(Available only when the Alphabetical Order option is selected.) Specifies the sort order of the Term List. When this option is selected, the items are split into string and numeric segments, and the numeric segments are then sorted in numerical order. For more information about the sorting rules used by the Numerical Order option, see *Using JMP*.

**Copy**  
Places the selected terms onto the clipboard.

**Color**  
Enables you to assign a color to the selected terms.

**Label**  
Places labels on the corresponding points in the Term SVD Plot for the selected terms.

**Containing Phrases**  
Selects the phrases in the Phrase List table that contain the selected terms.

**Save Indicators**  
Saves an indicator column to the data table for each term selected in the Term List. The value of the indicator column for each row is 1 if the document in that row contains the term and 0 otherwise.

**Save Formula**  
Saves a column formula to the data table for each term selected in the Term List. The column formula for each row evaluates to 1 if the document in that row contains the term and 0 otherwise. This is useful for new documents.

**Recode**  
Enables you to change the values for one or more terms. Select the terms in the list before selecting this option. After you select this option, the Recode window appears. See *Using JMP*.

**Add Stop Word**  
Adds the selected terms to the list of stop words and removes those terms from the Term List. This action also updates the Phrase List.
**Note:** If you add a stemmed word as a stop word, all of the tokens that correspond to that stem are added as stop words.

**Add Stem Exception** (Available only when the Language option is set to English, German, Spanish, French, or Italian.) Adds the selected terms to the list of terms that are excluded from stemming.

**Remove Phrase** (Available only when a specified phrase is selected in the Term List.)
Removes the selected phrase from the set of specified phrases and updates the Term Counts accordingly.

**Note:** If a phrase as been added as a Sentiment Phrase, the Remove Phrase option also removes the phrase from the list of sentiment terms in the current Sentiment Analysis report.

**Add Sentiment** (Available only when a Sentiment Analysis report is open in the current report window.) Adds the selected terms to the list of sentiment terms in the current Sentiment Analysis report.

**Note:** If you add a stemmed word as a sentiment term, all of the tokens that correspond to that stem are added as sentiment terms.

**Show Filter** Shows or hides a search filter above the Term List. See “Search Filter Options” on page 397.

**Make into Data Table** Creates a JMP data table from the report table.

**Make Combined Data Table** Searches the report for other tables like the one you selected and combines them into a single JMP data table.

**Phrase List Pop-up Menu Options**

When you right-click in the Phrase column of the Phrase List table, a pop-up menu appears with the following options:

**Select Rows** Selects rows in the data table that contain the selected phrases.

**Show Text** Shows the documents that contain the selected phrases.

**Save Indicators** Saves an indicator column to the data table for each phrase selected in the Phrase List. The value of the indicator column for each row is 1 if the document in that row contains the phrase and 0 otherwise.

**Alphabetical Order** Specifies the sort order of the Phrase List. When this option is selected, the terms are sorted in alphabetical order. When this option is not selected, the terms are sorted in descending Count order.
**Numerical Order**  (Available only when the Alphabetical Order option is selected.) Specifies the sort order of the Phrase List. When this option is selected, the items are split into string and numeric segments, and the numeric segments are then sorted in numerical order. For more information about the sorting rules used by the Numerical Order option, see *Using JMP*.

**Copy**   Places the selected phrases onto the clipboard.

**Select Contains**  Selects larger phrases in the Phrase List that contain the selected phrase.

**Select Contained**  Selects smaller phrases in the Phrase List and terms in the Term List that are contained by the selected phrase.

**Add Phrase**   Adds the selected phrases to the Term List and updates the Term Counts accordingly.

**Add Stop Word**   Adds the selected phrases to the list of stop words. This action also updates the Term List.

**Add Sentiment Phrase**  (Available only when a Sentiment Analysis report is open in the current report window.) Adds the selected phrases to the Term List and to the list of sentiment terms in the current Sentiment Analysis report.

**Show Filter**   Shows or hides a search filter above the Phrase List. See “Search Filter Options” on page 397.

**Make into Data Table**   Creates a JMP data table from the report table.

**Make Combined Data Table**   Searches the report for other tables like the one you selected and combines them into a single JMP data table.

**Search Filter Options**

Click the down arrow button next to the search box to refine your search.

**Contains Terms**   Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.

**Contains Phrase**   Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).

**Starts With Phrase**   Returns items that start with the search criteria.

**Ends With Phrase**   Returns items that end with the search criteria.

**Whole Phrase**   Returns items that consist of the entire string. A search for “text box” returns entries that contain only “text box”.

Regular Expression  Enables you to use the wildcard (*) and period (.) in the search box. Searching for “get.*name” looks for items that contain “get” followed by one or more words. It returns “Get Color Theme Names”, “Get Name Info”, and “Get Effect Names”, and so on.

Invert Result  Returns items that do not match the search criteria.

Match All Terms  Returns items that contain both strings. A search for “t test” returns elements that contain either or both of the search strings: “Pat Test”, “Shortest Edit Script” and “Paired t test”.

Ignore Case  Ignores the case in the search criteria.

Match Whole Words  Returns items that contain each word in the string based on the Match All Terms setting. If you search for “data filter”, and Match All Terms is selected, entries that contain both “data” and “filter” are returned.

---

## Text Explorer Platform Options

This section describes the options available in the Text Explorer platform.

- “Text Preparation Options”
- “Text Analysis Options”
- “Save Options”
- “Report Options”

## Text Preparation Options

The Text Explorer red triangle menu contains the following options for text preparation:

**Display Options**  Shows a submenu of options to control the report display.

- **Show Word Cloud**  Shows or hides the Word Cloud report. The Word Cloud red triangle menu enables you to change the layout and font for the word cloud. See “Word Cloud Options” on page 401.

  The word cloud can be interactively resized by changing the width. The height is then determined automatically. The rows in the Term List are linked to the terms in the Word Cloud.

- **Show Term List**  Shows or hides the Term List.

- **Show Phrase List**  Shows or hides the Phrase List.
**Show Term and Phrase Options**  Shows buttons in the Term and Phrase Lists report corresponding to the options available in the pop-up menus for each list. See “Term and Phrase Lists” on page 394.

**Show Summary Counts**  Shows or hides the Summary Counts table. See “Summary Counts Report” on page 393.

**Show Stop Words**  Shows or hides a list of the stop words used in the analysis. A built-in list of stop words is used initially. To add a stop word, right-click it in the Term List and select **Add Stop Word** from the pop-up menu. See “Term Options Management Windows” on page 401.

**Show Recodes**  Shows or hides a list of the recoded terms. See “Term Options Management Windows” on page 401.

**Show Specified Phrases**  Shows or hides a list of the phrases that have been specified by the user to be treated as terms. See “Term Options Management Windows” on page 401.

**Show Stem Exceptions**  (Available only when the Language option is set to English, German, Spanish, French, or Italian.) Shows or hides the terms that are excluded from stemming. See “Term Options Management Windows” on page 401.

**Show Delimiters**  (Available only when the Language option is set to English, German, Spanish, French, or Italian and the selected Tokenizing method is Basic Words.) Shows or hides the delimiters used by the Basic Words Tokenizing method. To modify the set of delimiters used, you must use the **Add Delimiters()** or **Set Delimiters()** messages in JSL.

**Show Stem Report**  (Available only when the Language option is set to English, German, Spanish, French, or Italian and the selected Stemming method is not No Stemming.) Shows or hides the Stemming report that contains two tables of stemming results. The table on the left maps each stem to the corresponding terms. The table on the right maps each term to its corresponding stem.

**Show Selected Rows**  Opens a window that contains the text of the documents that are in the currently selected rows.

**Show Filters for All Tables**  Shows or hides filters that can be used for searching tables in the report. This option applies to the following tables: Stop Words, Specified Phrases, Stem Exceptions, Term List, Phrase List, and the Stem Report. For more information about the filter tool, see “Search Filter Options” on page 397.

**Term Options**  Shows a submenu of options that apply to the Term List.
**Stemming**  (Available only when the Language option is set to English, German, Spanish, French, or Italian.) See the description of stemming options in “Launch the Text Explorer Platform” on page 384.

**Include Builtin Stop Words**  Specifies if the stop words used in the tokenizing process include built-in stop words or not.

**Include Builtin Phrases**  Specifies if the phrases used in the tokenizing process include built-in phrases or not.

**Manage Stop Words**  Shows a window that enables you to add or remove stop words. The changes made can be applied at the User, Column, and Local levels. You can also specify Local Exceptions that exclude stop words that are specified in any of the other levels. See “Term Options Management Windows” on page 401.

**Manage Recodes**  Shows a window that enables you to add or remove recodes. The changes made can be applied at the User, Column, and Local levels. You can also specify Local Exceptions that exclude recodes that are specified in any of the other levels. See “Term Options Management Windows” on page 401.

**Manage Phrases**  Shows a window that enables you to add or remove the phrases that are treated as terms. The changes made can be applied at the User, Column, and Local levels. You can also specify Local Exceptions that exclude phrases that are specified in any of the other levels. See “Term Options Management Windows” on page 401.

**Manage Stem Exceptions**  (Available only when the Language option is set to English, German, Spanish, French, or Italian.) Shows a window that enables you to add or remove exceptions to stemming. The changes made can be applied at the User, Column, and Local levels. You can also specify Local Exceptions that exclude stem exceptions that are specified in any of the other levels. See “Term Options Management Windows” on page 401.

**Parsing Options**  Shows a submenu of options that apply to parsing and tokenization.

**Tokenizing**  (Available only when the Language option is set to English, German, Spanish, French, or Italian.) See the description of tokenizing options in “Launch the Text Explorer Platform” on page 384.

**Customize Regex**  (Available only with the Regex Tokenizing method.) Shows the Customize Regex window. This option enables you to modify the Regex settings for the current Text Explorer report.

**Note:** If you specified a By variable in the platform launch window, the Customize Regex option automatically broadcasts to all level of the By variables.
Treat Numbers as Words (Available only when the Language option is set to English, German, Spanish, French, or Italian and Basic Words is the selected Tokenizing method.) Allows numbers to be tokenized as terms in the analysis. Note that this option is affected by the setting for Minimum characters per word.

Word Cloud Options

The Word Cloud red triangle menu contains the following options:

Layout Specifies the arrangement of the terms in the Word Cloud. By default, the Layout is set to Ordered.

Ordered Presents the terms in horizontal lines ordered from most to least frequent.

Alphabetical Presents the terms in horizontal lines sorted in ascending alphabetical order.

Centered Presents the terms in a cloud and sized by frequency.

Coloring Specifies the coloring of the terms in the Word Cloud. By default, the Coloring is set to None.

None Colors each term the same color as it is colored in the Term List.

Uniform Color Colors each term the same color. You can change this color in the Legend.

Arbitrary Grays Colors each term in varying shades of gray.

Arbitrary Colors Colors each term in various colors. You can adjust the colors in the Legend.

By column values Colors each term on a gradient color scale. The scale is based on the score for a term generated by the Score Terms by Column option. You can adjust the colors and gradient in the Legend.

Font Specifies the font, style, and size of the terms in the Word Cloud.

Show Legend Shows or hides the legend for the Word Cloud.

Term Options Management Windows

Stop word, recode, phrase, and stem exception information can be specified for many different scopes. They can be stored in the following locations: the Text Explorer user library (User scope), the current project, a column property for the analysis column (Column scope), or in a platform script (Local scope). You can save the local specifications and local exceptions for a specific instance of Text Explorer by saving the script for the Text Explorer report.
The Term Options management windows are four similar windows that enable you to manage the collections of stop words, recodes, phrases, and stem exceptions. Figure 12.9 shows the Manage Stop Words window. The Manage Phrases and Manage Stem Exceptions are identical to the Manage Stop Words window. The Manage Recodes window differs slightly. See “Manage Recodes” on page 403.

Figure 12.9 Manage Stop Words Window

Manage Stop Words

The Manage Stop Words window contains multiple lists of stop words that represent the different scopes (or locations) of specified stop words. Below each list is a text edit box and an add button. These controls enable you to add custom stop words to each scope. You can move stop words from one scope to another by dragging them. You can copy and paste items from one list to another list. Two buttons at the bottom of the window move the selected items from one scope to the next, either left or right. The X button removes the selected items from their current scope. You can edit existing items in the lists by double-clicking on an item and changing the text.

**Language** specifies the list of built-in stop words and to which language the user library selections are saved. If you select Apply Items for Language, the changes are saved to the main user library. The Language setting applies only to the Built-in, User, and Project scopes.

**Built-in (Locked)** lists the built-in list of stop words for the specified language. You can exclude a built-in stop word by placing it in the Local Exceptions list.

**User** lists the stop words in the user library for the specified language.

**Project** (Available only when Text Explorer is launched within a project.) Lists the stop words in the current project for the specified language.
**Column**  Lists the stop words in the “Stop Words” column property for the text column.

**Local**  Lists the stop words in the local scope. You can specify them when Text Explorer is launched via JSL. These stop words are used only in the current Text Explorer platform report.

**Local Exceptions**  Lists words that are not treated as stop words in the current Text Explorer platform. You can specify them when Text Explorer is launched via JSL. The words listed in Local Exceptions override words listed in all of the other scopes.

**Import**  Enables you to import stop words from a text file. The stop words are copied to the clipboard. You can paste them into any of the lists other than Built-in.

**Export**  Enables you to export stop words to the clipboard or to a text file. An Export window appears that enables you to select the scopes for which you would like to export stop words and the location of the export.

The user library files are located in a `TextExplorer` directory. The location of this directory is based on your computer’s operating system:

- **Windows:** `C:/Users/<username>/AppData/Roaming/SAS/JMP/TextExplorer/<lang>/`
- **macOS:** `~/Users/<username>/Library/Application Support/JMP/TextExplorer/<lang>/`

The main user library files are located in the `TextExplorer` directory itself. These files are not language-specific.

When you click OK, changes to the User, Project, and Column lists are saved to the user library, the project, and the column properties, respectively. Anything specified in the Local and Local Exceptions lists is saved only when you save the script of the Text Explorer report.

If you are saving stop words to the user library, the file is named `stopwords.txt`. If you are saving to a column property, the property is called “Stop Words”.

**Manage Recodes**

The Manage Recodes window differs slightly from the Manage Stop Words window. Instead of one text edit box below each list, there are two text edit boxes. The old value (specified in the top box) is recoded to the new value (specified in the bottom box).

If you are saving recodes to the user library, the file is named `recodes.txt`. If you are saving to a column property, the property is called “Recodes”.

**Manage Phrases**

If you are saving phrases to the user library, the file is named `phrases.txt`. If you are saving to a column property, the property is called “Phrases”.
Manage Stem Exceptions

If you are saving stem exceptions to the user library, the file is named stemExceptions.txt. If you are saving to a column property, the property is called “Stem Exceptions”.

**Note:** The Local Exceptions list in the Manage Stem Exceptions window lists stem exceptions that are excluded from the stem exception list. The words in this list are involved in the stemming operation.

Manage Negation Terms

The Manage Negation Terms window is available in the Sentiment Analysis report. See “Sentiment Analysis” on page 423.

If you are saving negation terms to the user library, the file is named negations.txt. If you are saving to a column property, the property is called “Negation Terms”.

**Note:** Terms that appear in the Local or Local Exceptions lists apply only to the current Sentiment Analysis report.

Manage Intensifier Terms

The Manage Intensifier Terms window, which is available in the Sentiment Analysis report, differs slightly from the Manage Stop Words window. In addition to the text edit box below each list, there is a Multiplier control. The Multiplier control enables you specify an intensification multiplier for a term when you add it to the set of intensifier terms. See “Sentiment Analysis” on page 423.

If you are saving intensifier terms to the user library, the file is named intensifiers.txt. If you are saving to a column property, the property is called “Intensifier Terms”.

**Note:** Terms that appear in the Local or Local Exceptions lists apply only to the current Sentiment Analysis report.

Manage Sentiment Terms

The Manage Sentiment Terms window, which is available in the Sentiment Analysis report, differs slightly from the Manage Stop Words window. In addition to the text edit box below each list, there is a Score control. The Score control enables you specify a sentiment score for a term when you add it to the set of sentiment terms. See “Sentiment Analysis” on page 423.

If you are saving sentiment terms to the user library, the file is named sentiments.txt. If you are saving to a column property, the property is called “Sentiment Terms”.

Note: Terms that appear in the Local or Local Exceptions lists apply only to the current Sentiment Analysis report.

Text Analysis Options

The Text Explorer red triangle menu contains the following analysis options:

**Latent Class Analysis**  Performs a latent class analysis on the binary weighted document term matrix using sparse matrix routines. See “Latent Class Analysis” on page 409.

When you select Latent Class Analysis from the Text Explorer red triangle menu, a Specifications window appears with the following options:

- **Maximum Number of Terms**  The maximum number of terms included in the latent class analysis.
- **Minimum Term Frequency**  The minimum number of occurrences a term must have to be included in the latent class analysis.
- **Number of Clusters**  The number of clusters in the latent class analysis.

**Discriminant Analysis**  Predicts membership of each document in a group or category based on the document term matrix. See “Discriminant Analysis” on page 416.

**Term Selection**  Analyzes which terms best explain different responses. Term Selection can also be useful for sentiment analysis when the responses are ratings. See “Term Selection” on page 418.

**Sentiment Analysis**  (Available only when the Language option is set to English.) Identifies sentiment terms in document using lexical analysis and scores documents for positive, negative, and overall sentiment. See “Sentiment Analysis” on page 423.

**Singular Value Decomposition Specifications Windows**

The analysis options in the Text Explorer platform are based on the Document Term Matrix (DTM). The DTM is formed by creating a column for each term in the Term List (up to a specified Maximum Number of Terms). Each text document (equivalent to a row in the data table) corresponds to a row of the DTM. The values in the cells of the DTM depend on the type of weighting specified by the user in the Specifications window.
Figure 12.10 shows the Singular Value Decomposition Specifications window. When you select options from the Text Explorer red triangle menu that perform a singular value decomposition on the document term matrix, the Specifications window appears with the following options:

**Maximum Number of Terms**  The maximum number of terms included in the singular value decomposition.

**Minimum Term Frequency**  The minimum number of occurrences a term must have to be included in the singular value decomposition.

**Weighting**  The weighting scheme that determines the values that go into the cells of the document term matrix. The weighting scheme options are described in “Document Term Matrix Specifications Window” on page 407.

**Number of Singular Vectors**  The number of singular vectors in the singular value decomposition. The default value is the minimum of the number of documents, the number of terms, or 100.

**Centering and Scaling**  Options for centering and scaling of the document term matrix. You can choose between **Centered and Scaled**, **Centered**, and **Uncentered**. By default, the document term matrix is both centered and scaled.

**Save Options**

The Text Explorer red triangle menu contains the following options to save information to data tables, table columns, and column properties:

**Save Document Term Matrix**  Saves columns to the data table for each column of the document term matrix (up to a specified Maximum Number of Terms).

**Save Stacked DTM for Association**  Saves a stacked version of the document-term matrix to a JMP data table. The stacked format is appropriate for analysis in the Association Analysis platform. See Predictive and Specialized Modeling. If you specify an ID
variable in the Text Explorer launch window, the ID variable is used to identify the rows that each term came from in the original text data table. The stacked table also contains a table script to launch Association Analysis.

**Save DTM Formula**  Saves a formula column with the Vector modeling type to the data table. The length of the vector depends on user-specified options for the maximum number of terms, the minimum term frequency, and the weighting. The resulting column uses the Text Score() JSL function. For more information about this function, see Help > Scripting Index.

**Save Term Table**  Creates a JMP data table that contains each term from the Term List, the number of occurrences, and the number of documents that contain each term. If you select the Score Terms by Column option after selecting Save Term Table, a column containing scores for each term is added to the data table created by the Save Term Table option.

**Score Terms by Column**  Saves scores based on values in a specified column to the JMP data table created by the Save Term Table option. The scores for each term are the mean value of the specified column weighted by the number of occurrences of the term in each row. If you have already selected the Save Term Table option, the Score Terms by Column option adds a column containing scores to the data table created by the Save Term Table option. Otherwise, the JMP data table for the term table is created. When the specified column is not Continuous, columns containing scores for each level in the specified column are created.

**Document Term Matrix Specifications Window**

When you select the Save Document Term Matrix and Save DTM Formula options from the Text Explorer red triangle menu, the Document Term Matrix Specifications window appears with the following options:

- **Maximum Number of Terms**  The maximum number of terms included in the document term matrix.

- **Minimum Term Frequency**  The minimum number of occurrences a term must have to be included in the document term matrix.

- **Weighting**  The weighting scheme that determines the values that go into the cells of the document term matrix.

The following options are available for Weighting:

- **Binary**  Assigns 1 if a term occurs in each document and 0 otherwise. This is the default weighting, unless an SVD analysis has previously been run.

- **Ternary**  Assigns 2 if a term occurs more than once in each document, 1 if it occurs only once and 0 otherwise.
**Frequency**  Assigns the count of a term’s occurrence in each document.

**Log Freq**  Assigns $\log_{10}(1 + x)$, where $x$ is the count of a term’s occurrence in each document.

**TF IDF**  Assigns $TF \times \log_{10}( nDoc / nDocTerm )$. Abbreviation for term frequency - inverse document frequency. This is the default weighting. The terms in the formula are defined as follows:

- $TF = \text{frequency of the term in the document}$
- $nDoc = \text{number of documents in the corpus}$
- $nDocTerm = \text{number of documents that contain the term}$

**Note:** If you select Save Document Term Matrix or Save DTM Formula after you have run an SVD analysis, the Specifications window contains the specifications from the most recent SVD analysis.

**Report Options**

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Latent Class Analysis

In the Text Explorer platform, latent class analysis enables you to group the documents from the corpus into clusters of similar documents. The Latent Class Analysis report contains the model specifications, the Bayesian Information Criterion (BIC) value for the model and a Show Text button. If one or more clusters in the Cluster Mixture Probabilities table is selected, the Show Text button opens a window that contains the text of the documents that are deemed most likely to belong to the selected cluster.

The Latent Class Analysis red triangle menu contains the following options:

Display Options  Specifies the contents of the Latent Class Analysis report. By default, all of the report options are shown except for the word clouds for each cluster.

Cluster Mixture Probabilities  Shows or hides a table of the probability of an observation belonging to each cluster.

Tip: You can select one or more rows in the Mixture Probabilities by Cluster table to select the observations assigned to the corresponding clusters.

Term Probabilities by Cluster  Shows or hides a table of terms with an estimate for each cluster of the conditional probability that a document contains the term, given that the document belongs to a particular cluster. By default, the terms in this table are sorted by descending frequency in the corpus.

The Cluster Most Characteristic column shows the cluster that the term occurs in at the highest rate.

The Cluster Most Probable column shows the cluster in which a randomly chosen document that contains the term is most likely to be found.

Top Terms by Cluster  Show or hides a table of the ten terms with the highest scores in each cluster. The score $S_{t,c}$ for term $t$ in cluster $c$ is calculated as follows:

$$S_{t,c} = 100 \cdot \text{mean}(p_t) \cdot \log_{10} \left( \frac{p_{t,c}}{\text{mean}(p_t)} \right)$$

where $\text{mean}(p_t)$ is the mean of the term probabilities by cluster for term $t$ and $p_{t,c}$ is the term probability by cluster for term $t$ in cluster $c$.

MDS Plot  Shows or hides a multidimensional scaling plot, which is a two-dimensional representation of the proximity of the clusters. For more information about MDS plots, see Multivariate Methods. The Show Text button opens a window that contains the text of the selected documents.
Cluster Probabilities by Row  Shows or hides the Mixture Probabilities table, which displays probabilities of cluster membership for each row. The Most Likely Cluster column indicates the cluster with the highest probability of membership for each row.

Word Clouds by Cluster  Shows or hides a matrix of word clouds, one for each cluster.

Rename Clusters  Enables you to add descriptive names for one or more of the clusters.

Save Probabilities  Saves the values in the Mixture Probabilities table to the corresponding rows in the data table.

Save Probability Formulas  Saves a formula column to the data table for each cluster as well as a formula column for the most likely cluster.

The score formula that is saved uses the Text Score() JSL function with the weighting argument set to “LCA”.

Color by Cluster  Colors each row in the data table according to its most likely cluster.

Remove  Removes the Latent Class Analysis report from the Text Explorer report.

For more information about latent class analysis, see Multivariate Methods.

Note: The LCA algorithm that is used in the Text Explorer platform takes advantage of the sparsity of the document term matrix. For this reason, the LCA results in the Text Explorer platform do not exactly match the results in the Latent Class Analysis platform.

Latent Semantic Analysis (SVD)

In the Text Explorer platform, latent semantic analysis is centered around computing a partial singular value decomposition (SVD) of the document term matrix (DTM). This decomposition reduces the text data into a manageable number of dimensions for analysis. Latent semantic analysis is equivalent to performing principal components analysis (PCA).

The partial singular value decomposition approximates the DTM using three matrices: \( U \), \( S \), and \( V' \). The relationship between these matrices is defined as follows:

\[
DTM \approx U * S * V'
\]

Define \( nDoc \) as the number of documents (rows) in the DTM, \( nTerm \) as the number of terms (columns) in the DTM, and \( nVec \) as the specified number of singular vectors. Note that \( nVec \) must be less than or equal to \( \min(nDoc, nTerm) \). It follows that \( U \) is an \( nDoc \) by \( nVec \) matrix that contains the left singular vectors of the DTM. \( S \) is a diagonal matrix of dimension \( nVec \). The diagonal entries in \( S \) are the singular values of the DTM. \( V' \) is an \( nVec \) by \( nTerm \) matrix. The rows in \( V' \) (or columns in \( V \)) are the right singular vectors.
The right singular vectors capture connections among different terms with similar meanings or topic areas. If three terms tend to appear in the same documents, the SVD is likely to produce a singular vector in $V'$ with large values for those three terms. The $U$ singular vectors represent the documents projected into this new term space.

Latent semantic analysis also captures indirect connections. If two words never appear together in the same document, but they generally appear in documents with another third word, the SVD is able to capture some of that connection. If two documents have no words in common but contain words that are connected in the dimension-reduced space, they map to similar vectors in the SVD output.

The SVD transforms text data into a fixed-dimensional vector space, making it amenable to all types of clustering, classification, and regression techniques. The Save options enable you to export this vector space to be analyzed in other JMP platforms.

The DTM, by default, is centered, scaled, and divided by $n_{Doc}$ minus 1 before the singular value decomposition is carried out. This analysis is equivalent to a PCA of the correlation matrix of the DTM.

You can also specify Centered or Uncentered in the Specifications window.

- If you specify Centered, the DTM is centered and divided by $n_{Doc}$ minus 1 before the singular value decomposition. This analysis is equivalent to a PCA of the covariance matrix of the DTM.

- If you specify Uncentered, the DTM is divided by $n_{Doc}$ before the singular value decomposition. This analysis is equivalent to a PCA of the unscaled DTM.

The SVD implementation takes advantage of the sparsity of the DTM even when the DTM is centered.

**JMP PRO**

**SVD Report**

The Latent Semantic Analysis option in the Text Explorer platform produces two SVD plots and a table of the singular values from the singular value decomposition.

**JMP PRO**

**SVD Plots**

The first plot contains a point for each document. For a given document, the point that is plotted is defined by the document’s values in the first two singular vectors (the first two columns of the $U$ matrix) multiplied by the diagonal singular values matrix ($S$). This plot is equivalent to the Score Plot in the Principal Components platform. Each point in this plot represents a document (row of the data table). You can select the points in this plot to select the corresponding rows in the data table.
The second plot contains a point for each term. For a given term, the point that is plotted is defined by the term’s values in the first two singular vectors (the first two rows of the \( V' \) matrix) multiplied by the diagonal singular values matrix (\( S \)). This plot is equivalent to the Loadings Plot in the Principal Components platform. In this plot, the points correspond to rows in the Term List table.

Above each of the SVD Plots, you can click a Show Text button to open a window that contains the text of the selected points in the plot.

**Singular Values**

Below the document and term SVD plots, a table of the singular values appears. These are the diagonal entries of the \( S \) matrix in the singular value decomposition of the document term matrix. The Singular Values table also contains a column of corresponding eigenvalues for the equivalent principal components analysis. Like in the Principal Components platform, there are columns for the percent and cumulative percent of variation explained by each eigenvalue (or singular value). You can use the Cum Percent column to decide what percent of variance from the DTM you want to preserve, and then use the corresponding number of singular vectors.

**SVD Report Options**

The SVD red triangle menu in the Text Explorer platform contains the following options:

- **SVD Scatterplot Matrix**  Shows or hides a scatterplot matrix of the term and document singular value decomposition vectors. You are prompted to select the size of the scatterplot matrix when you select this option. This scatterplot matrix enables you to visualize more than the first two dimensions of the singular value decomposition. The Show Text button opens a window that contains the text of the selected documents.
**Chapter 12 Text Explorer**

**Basic Analysis Latent Semantic Analysis (SVD)**

**Topic Analysis, Rotated SVD**  Performs a varimax rotated partial singular value decomposition of the document term matrix to produce groups of terms called topics. You can select this option multiple times to find different numbers of topics. See “Topic Analysis” on page 414.

**Cluster Terms**  Shows or hides a hierarchical clustering analysis of the terms in the data. To the right of the dendrogram, there are options to set the number of clusters and save the clusters to a data table. For each term, this data table contains its frequency, the number of documents that contain it, and its assigned cluster. For more information about hierarchical clustering and dendrograms, see *Multivariate Methods*. 

---

**Figure 12.11 SVD Scatterplots of Document and Term Spaces**
