*Relative inertia* is the proportion of the contribution of the point to the overall inertia. In the summary statistics table, the relative inertia is listed in the column labeled Inertia.
Partial Contributions to Inertia

The contribution of a row or column to the inertia of a dimension is calculated as follows:

\[ \text{contribution} = (\text{mass})(\text{coordinate})^2 / (\text{dimension inertia}) \]

Cochran’s Q Statistic

The Cochran’s Q test statistic is calculated as follows:

\[
Q = k(k-1) \frac{\sum_{j=1}^{b} \left( \sum_{i=1}^{k} X_{ij} - \frac{N}{k} \right)^2}{b \left( \sum_{i=1}^{k} \left( \sum_{j=1}^{k} X_{ij} - \sum_{j=1}^{k} X_{ij} \right) \right)}
\]

where

- \( k \) is the number of treatments
- \( b \) is the number of blocks
- \( X_{ij} \) is the response (0 or 1) for the \( i^{th} \) subject for the \( k^{th} \) treatment
- \( N \) is the grand total of positive responses across all subjects and treatments
The Structural Equation Models platform is available only in JMP Pro.

The Structural Equation Models platform enables you to fit a variety of models. These models include confirmatory factor analysis, path models with or without latent variables, measurement error models, and latent growth curve models. You can specify the model by selecting From and To variables and indicating how they are linked. The link is represented by either a unidirectional or a bidirectional arrow in the diagram. These selections populate two alternative views of the model: a dynamic path diagram and a list of model edges. The platform also checks for model identification as you specify the model.

Overview of Structural Equation Models

The Structural Equation Models (SEM) platform enables you to fit a wide variety of models that can be used to test theories of relationships among variables. The variables in the models can be observed (manifest variables) or unobserved (latent variables). Structural equation modeling is popular in the social and behavioral sciences.

By default, the platform specifies a model with means and variances for all variables. The platform then provides a model-building interface that enables you to see multiple views of the model while it is being built. It also provides some model details during the model construction process that alert you to untenable models prior to running the model.

After you fit one or more models, you can compare the fitted models and two baseline models in the Model Comparison report. The baseline models are an unrestricted model and an independence model. The unrestricted model is a fully saturated model, which fits all means, variances, and covariances of the specified Model Variables without imposing any structure on the data. The independence model fits all means and variances of the specified Model Variables. All covariances among the specified Model Variables are fixed to zero, which leads to a highly restrictive model.

The SEM platform uses the full information maximum likelihood (Finkbeiner 1979) method. This enables you to fully use all available information from the data even when there is a high proportion of observations with random missing values.

For more information about structural equation modeling, see the CALIS Procedure chapter in SAS Institute Inc. (2020a), Bollen (1989), and Kline (2016).

Note: All models in the Structural Equation Models platform are estimated with a mean structure, which means that a Constant term is included. If you do not want to place a structure on the means of the observed variables, then the means should be freely estimated as in the default model specification.

Types of Models

This section describes some of the various types of models that can be fit in the Structural Equation Models platform:

- Path Analysis enables you to test alternative explanatory models of the associations between observed variables. This technique is often used when only one variable is available per construct of interest in a study. Perhaps the simplest Path Analysis model is a standard regression model, in which \( X \) predicts \( Y \). The SEM platform enables you to fit this simple regression model but you can also specify more interesting models as well. For example, you might have variable \( Z \) that is presumed, based on theory or previous research, to be a mediator of the \( X \rightarrow Y \) relationship. In other words, \( X \) predicts \( Z \), which
then predicts Y. Thus, the original X ⇒ Y relationship might exist only because Z is excluded in the original model. Path analysis can be carried out in the SEM platform by performing the following steps:

1. Select all the observed variables in the launch window, click Model Variables, and click OK.

2. In the Model Specification report, select the predictors in the From List and the corresponding outcomes in the To List, and click the unidirectional arrow button.

**Note:** All exogenous variables (those that do not have any unidirectional arrows pointing at them) must be freely correlated in the model, unless a hypothesis of zero correlation is being tested. These covariances are specified with the bidirectional arrow button.

• **Confirmatory Factor Analysis** (CFA) enables you to test alternative measurement models. CFA is often used in survey development and as an initial step prior to fitting structural regression models. The SEM platform enables fitting of confirmatory factor analysis models by performing the following steps:

1. Select all the observed variables in the launch window, click Model Variables, and click OK.

2. Using the To List under Model Specification, select the variables that are presumed to load onto a latent variable.

3. Enter the name for the latent variable in the box below the To List, and click the add latent button.

4. Repeat this process until all the latent variables for the model have been specified.

Note that the SEM platform always includes a mean structure, so all of the observed variables are listed in the Means/Intercepts list as outcomes of the Constant term. Moreover, all latent variables are automatically identified by setting the loading of their first indicator to 1 (default) or their variance to 1 if the Standardized Latent Variables option was selected in the launch window. Finally, the traditional CFA model allows all latent variables to covary. You can specify these covariances by selecting all the latent variables in the From and To Lists and then clicking the bidirectional arrow button.

• **Structural Regression** (SR) models are also known as *path analysis with latent variables*. These models are often used after having identified an appropriate measurement model through confirmatory factor analysis (CFA). SR models enable you to test specific patterns of relationships between latent variables. In other words, while CFA does not impose any directionality in the effects between latent variables (all latent variables are allowed to freely covary), SR models do. In an example where management Leadership is hypothesized to lead to less team Conflict and more employee Satisfaction in the workplace, the Leadership latent variable can predict the Conflict and Satisfaction latent variables. You can specify these directional effects (regressions) after performing a CFA by performing the following steps:
1. Select all the observed variables in the launch window, click Model Variables, and click OK.

2. Using the To List under Model Specification, select the variables that are presumed to load onto a latent variable.

3. Enter the name for the latent variable next in the box below the To List, and click the add latent button.

4. Repeat this process until all the latent variables for the model have been specified.

5. In the Model Specification report, select the predictors in the From List and the corresponding outcomes in the To List, and click the unidirectional arrow button.

- **Latent Growth Curve (LGC)** models enable you to fit and test alternative latent trajectories to repeated measures data. These models are very similar to random effects models in the mixed models framework. Often, you want to compare a no-growth model with a linear model. In a no-growth model, individuals can vary in their starting point but have flat trajectories. In a linear model, individuals can vary in both their starting point and linear slope over time. If enough data are available, you can also compare these models with a quadratic model where individuals can vary in their starting point and their linear and quadratic rates of change over time. You can fit LGC models using the SEM platform model specification, but the platform streamlines the fitting of LGC models by performing the following steps:

  1. Select all the observed variables (repeated measures) in the launch window, click Model Variables, and click OK.

  **Note:** For the Latent Growth model shortcuts to specify the model correctly, the observed variables must be listed in ascending time order and must have equal time intervals.

  2. Using the Model Shortcuts option, select the Longitudinal Analysis > Intercept-Only Growth Curve model, and then click Run.

  3. Using the Model Shortcuts option, select the Longitudinal Analysis > Linear Latent Growth Curve model, and then click Run.

  4. Using the Model Shortcuts option, select the Longitudinal Analysis > Quadratic Latent Growth Curve model, and then click Run.

The Model Comparison table shows the alternative fit indices and the best model can be selected.

- **Conditional Latent Growth Curve** models can be used after identifying an ideal growth trajectory following the steps above. At this point, predictors of the intercept and change factors can be added to the model. These predictors might prove to be important factors for determining initial scores on a growth process and ensuing changes. To fit a conditional LGC, select all of the observed variables (repeated measures), including the
hypothesized predictors of the latent variables, in the launch window. Make sure that the
predictors are the last variables in the Model Variables list to facilitate the following steps:
1. Use the Model Shortcuts option to select the appropriate growth trajectory. This option
specifies all variables in the LGC model, including the predictors. Thus, you need to
exclude the predictors from the growth process and correctly specify them as
predictors.
2. Find the predictors in the Loadings list, select all the effects that involve them, and click
Remove.
3. Select the predictors in the From List and the Intercept or Slope in the To List.
4. Click the unidirectional arrow to specify the conditional LGC.

Note: If you have more than one predictor, their covariances must be specified by
selecting the predictors in the From and To Lists and clicking the bidirectional arrow
button.

Example of a Structural Equation Model

In this example, an employee in a human resources department wants to improve job
satisfaction. The example uses the Structural Equation Models platform to analyze responses
to a survey of 200 individuals regarding aspects of their job satisfaction. The survey contains
responses to 11 questions related to their job satisfaction. You seek to build a structural
regression model that relates the answers to the survey questions to the latent variables of
leadership characteristics, role conflict, and overall job satisfaction.

1. Select Help > Sample Data Library and open Job Satisfaction.jmp.
3. Select Support_L through Supervisor_S and click Model Variables.
4. Click OK.
   The Structural Equation Models report Model Specification outline appears.

Create Latent Variables

5. Select Support_L through Interact_L in the To List, type Leadership in the box below the To
   List, and click the add latent button.
6. Select Person_C through Inter_C in the To List, type Conflict in the box below the To List,
   and click the add latent button.
7. Select General_S through Supervisor_S in the To List, type Satisfaction in the box below the
   To List, and click the add latent button.
Add Loading and Regression Variables

8. Select Leadership in the From List, select Satisfaction in the To List, and click the unidirectional arrow button.

9. Select Leadership in the From List, select Conflict in the To List, and click the unidirectional arrow button.

10. Select Conflict in the From List, select Satisfaction in the To List, and click the unidirectional arrow button.

11. In the text box below Model Name (in the top left of the Model Specification report), type Path Analysis with Latent Variables.

12. Click Run.

13. (Optional.) Click the red triangle next to Structural Equation Model: Path Analysis with Latent Variables and select Path Diagram Settings > Layout > Top to Bottom.

14. (Optional.) Click the gray disclosure icon next to Parameter Estimates. Closing the Parameter Estimates report enables you to see the entire path diagram.

**Figure 8.2 Structural Equation Model Report**

The chi-square statistic for this model, listed in the Summary of Fit report, is 34.27 with 41 degrees of freedom. Note that the corresponding $p$-value is 0.7624, which is not significant. This indicates that there is not evidence to reject the null hypothesis that the model fits well. Therefore, you conclude that this model fits the data reasonably well.

The chi-square value depends on the sample size, and thus, some well-fitting models can still produce a significant chi-square value. The comparative fit index (CFI) and root mean
square error of approximation (RMSEA) provide additional guidance for determining model fit. These indices are bounded between 0 and 1. CFI values greater than 0.90 and RMSEA values less than 0.10 are preferred (Browne and Cudeck 1993; Hu and Bentler 1999). Here, the CFI of 1 and RMSEA of 0 indicate an excellent fit.

15. Click the red triangle next to Structural Equation Model: Path Analysis with Latent Variables and select **Standardized Parameter Estimates**.

**Figure 8.3 Standardized Parameter Estimates Report**

The estimates for the Loadings in the Standardized Parameter Estimates report help explain the measurement model that defines the latent variables. Standardized loadings are the correlation of the observed variable with the unobserved latent variable. Loadings
for all latent variables in the report range from 0.52 to 0.67, which suggests well-defined constructs for Leadership, Conflict, and Satisfaction.

In Figure 8.3, the parameter estimates under Regressions suggest a negative effect of Leadership on Conflict and of Conflict on Satisfaction, whereas Leadership has a positive effect on Satisfaction. Thus, higher scores on Leadership are associated with lower Conflict and more Satisfaction, and higher scores in Conflict are associated with lower scores in Satisfaction. The corresponding \( p \)-values for the parameter estimates are shown under Regressions. The Leadership \( \Rightarrow \) Conflict and Leadership \( \Rightarrow \) Satisfaction regression parameters are both significant at the \( \alpha = 0.05 \) level. Therefore, you conclude that there are nonzero relationships between the latent variables.

**Note:** You can also use the Regression parameter estimates in the Standardized Parameter Estimates report as effect sizes. These effect sizes are interpreted as the change in standard deviation units in the outcome for a one standard deviation change in the predictor.

16. Click the red triangle next to Structural Equation Model: Path Analysis with Latent Variables and select **Normalized Residuals Heat Map**.

**Figure 8.4 Normalized Residuals Heat Map**

The Normalized Residuals Heat Map has no values that exceed 2.0 units in the positive or negative direction; this is further evidence that the model fits the data well. The residuals can also diagnose ill-fitting models at a more granular level. The normalized residuals in this model do not show evidence of local misfit.
Launch the Structural Equation Models Platform

Launch the Structural Equation Models platform by selecting **Analyze > Multivariate Methods > Structural Equation Models**.

![Figure 8.5 Structural Equation Models Launch Window](image)

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Launch Window includes tabs for two different data formats.

**Wide Data Format**  Select for data tables where each row corresponds to a single observation and the columns contain variables to be used in the model. Rows that contain only missing values are excluded from the analysis.

**Summarized Data Format**  Select for data tables where the data are summarized as a correlation or covariance matrix. Means and standard deviations can also be specified as columns. If they are not specified, the means are assumed to be zero and the standard deviations are assumed to be the square root of the diagonal of the input matrix.
Launch Window Options

**Model Variables**  The columns that you want to include in the model. You must specify at least one column. All columns must have numeric data type and continuous modeling type.

For the Summarized Data Format, the Model Variables columns are the columns that contain the correlation or covariance matrix for the summarized data.

**By**  (Available only for Wide Data Format.) A column that creates a report consisting of separate analyses for each level of the variable. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

*Caution:* Using a By variable does not perform a multiple-group analysis.

**Mean**  (Available only for Summarized Data Format.) A column of means that correspond to the variables in each row of the correlation or covariance matrix. If they are not specified, the means are assumed to be zero.

**Std Dev**  (Available only for Summarized Data Format.) A column of standard deviations that correspond to the variables in each row of the correlation or covariance matrix. If they are not specified, the standard deviations are assumed to be the square root of the diagonal of the input matrix.

**Label**  (Available only for Summarized Data Format.) A column of labels that correspond to the variables in each row of the correlation or covariance matrix. If they are not specified, the variables in the Model Specification use the names of the columns that contain the input matrix.

**Standardize Latent Variables**  If selected, this option sets the scale of the latent variables by fixing their variance to one and allowing free estimation of all loadings.

**Fit Unrestricted Model**  If selected, the unrestricted model is automatically fit when you fit your first model. You can then compare your fitted model to the unrestricted model in the Model Comparison report. The unrestricted model is a fully saturated model, which fits all means, variances, and covariances of the specified Model Variables without imposing any structure on the data.

**Fit Independence Model**  If selected, the independence model is automatically fit when you fit your first model. You can then compare your fitted model to the independence model in the Model Comparison report. The independence model fits all means and variances of the specified Model Variables. All covariances among the specified Model Variables are fixed to zero, which leads to a highly restrictive model.
Sample Size  (Available only for Summarized Data Format.) Specifies the number of observations represented by the summarized data.

The Structural Equation Models Report

- “Model Specification Report”
- “Model Comparison Report”
- “Chi-Square Difference Test Report”
- “Structural Equation Model Fit Report”

Model Specification Report

The Model Specification report contains controls for specifying your model. When you click OK in the launch window, the default model of independence appears in the Diagram and Lists tabs of the Model Specification report. The independence model includes all means and variances of the specified Model Variables.

Specification Panel

The Specification panel contains controls for building your model.

Model Name  Enables you to specify a name for the model. When you click Run in the Action panel, a model report that uses the text in Model Name is created.

From List  Lists the model variables that were specified in the launch window as well as a Constant term. The Constant term estimates means of any observed or latent variable by regressing each variable on the Constant. Select one or more variables in this list and one or more variables in the To List before clicking one of the arrow buttons to add terms to the model. If you create a latent variable, the latent variable is added to the From List and the To List. You can filter the items in this list using the search filter controls at the top of the list. See “Search Filter Options” on page 197.

To List  Lists the model variables that were specified in the launch window as well as a Constant term. The Constant term estimates means of any observed or latent variable by regressing each variable on the Constant. Select one or more variables in the From List and one or more variables in this list before clicking one of the arrow buttons to add terms to the model. If you create a latent variable, the latent variable is added to the From List and the To List. Variables in the To List must be selected to add latent variables to the model. You can filter the items in this list using the search filter controls at the top of the list. See “Search Filter Options” on page 197.
Unidirectional Arrow  Specify the type of relationship between the selected variables in the From List and the To List. The unidirectional arrow is equivalent to a regression effect.

Bidirectional Arrow  Specify the type of relationship between the selected variables in the From List and the To List. The bidirectional arrow is equivalent to a covariance effect.

Add Latent  Adds a latent variable to the From and To lists. The variable is named based on the text in the box to the left of the button.

Note: You must select indicators for the latent variable in the To List prior to clicking the button.

Remove Latent  Removes any latent variables that are currently selected in either the From List or the To List. Removing a latent variable from the From and To lists also removes the latent variable from the model.

Model Shortcuts  Contains three categories of options to quickly build common models. Note that when you select one of these options, all current model specifications are cleared.

Specification Assist  Contains options that shortcut the process of adding covariances for either exogenous or endogenous variables.

Cross-Sectional Classics  Contains options for confirmatory factor analysis and mediation analysis.

Longitudinal Analysis  Contains options for common latent growth curve models: intercept-only, linear, quadratic, and latent basis growth curve. Additionally, the Fit and Compare Growth Models option enables you to fit no growth, linear growth, and quadratic growth models in one click.

Note: If variables in the To List are selected when you select one of the latent growth curve options, the model is applied only to the selected variables. Otherwise, the model is applied to all of the variables in the To List.

**Action Panel**

The buttons in the Action panel operate on the lists of specified model variables in the Lists tab. The following operations are available:

Fix To  Enables you to fix the parameter value of the currently selected effect to a constant value. When you fix the parameter value for a variable, the fixed value appears in parentheses after the name of the term.
**Note:** If you keep the default value of 0 when you click OK, the selected effects are removed from the model.

**Set Equal** Enables you to constrain the parameter values of two or more selected effects to be equal. When you set two or more effects to have equal parameter values, an arbitrary alphanumeric label (“c1”) appears in parentheses after the names of the terms. In the case of multiple sets of effects that have parameter values that are set equal to each other, sequential numbering is used (“c1”, “c2”, and so on).

**Note:** Equality constraints are allowed only within the same type of parameters.

**Free** Enables you to remove restrictions on the selected effects in the model. Restrictions include effects that have been set to a fixed value or effects that have been set equal to other effects.

**Remove** Removes the selected effects from the model.

**Undo** Undoes the last modification to the model.

**Redo** Redoes the last undone modification to the model.

**Run** Fits and creates a report for the currently specified model.

**Reset** Resets the model specification to the independence model, which is the default.

**Diagram Panel**

The Diagram panel contains buttons that enable you to adjust the layout of the model diagram. The first button enables you to rotate the manifest variables (represented by rectangles) in the diagram. The second button enables you to cycle through two different arrangements of the diagram. The third button enables you to customize the diagram. See “Customize the SEM Path Diagram” on page 207.

**Details Panel**

The Details panel contains information about the model that is currently specified in the Model Specification report. Information about the model includes the number of manifest variables, number of latent variables, number of freely estimated parameters, and number of degrees of freedom. You can also adjust the maximum number of iterations.
Diagram Tab

The Diagram tab contains a model diagram that enables you to visualize the currently specified model. Latent variables are represented by circles, and manifest variables are represented by rectangles. Unidirectional arrows represent loadings and regressions. Bidirectional arrows represent variances and covariances. A variance is specified by a bidirectional arrow from one variable to itself. A covariance is specified by a bidirectional arrow between two variables.

The path diagram is interactive, so you can drag items to arrange them. You can also use the arrow keys to move selected items in the path diagram. You can use the buttons in the Diagram panel to rearrange items in the path diagram. You can use the options in the path diagram pop-up menu to add or remove items in the path diagram. The path diagram pop-up menu appears when you right-click in the path diagram itself. The contents of the pop-up menu differ based on whether you click on part of the blank canvas or on an element of the path diagram. You can also zoom in or out in the path diagram by adjusting the zoom setting in the upper left corner of the path diagram. The path diagram also contains a Lock button in the top left corner that enables you to lock the positions of the items in the path diagram. When the path diagram is locked, the Lock button is blue. After making a selection in the path diagram, you can hide the selection by selecting the Selection > Hide Selection option in the pop-up menu. When items in the path diagram are hidden, an Unhide All button appears at the top of the path diagram that enables you to show all hidden items.

See “Customize the SEM Path Diagram” on page 207 for more information about path diagram customization options. See “Diagram Panel” on page 194, “Details Panel” on page 194, and “Path Diagram Settings” on page 201.

Tip: To copy the path diagram as an image, right-click the diagram and select Copy Diagram. To retain the highest possible quality, paste the clipboard image as a vector graphic.

Lists Tab

The Lists tab contains lists for each type of variable in the model. They are categorized by the arrows that are used to represent them in the model diagram. Unidirectional arrows are used to designate means or intercepts, loadings, and regressions. Bidirectional arrows are used to designate variances and covariances. Means and intercepts for the model appear only in the Lists tab and not in the Diagram tab.

You can filter the items in each list using the search filter controls at the top of each list. See “Search Filter Options” on page 197.
Status Tab

The Status tab contains checks for model identifiability. Structural equation models must be identified to obtain reliable estimates. Identification in the context of SEM means that one can derive unique solutions for every parameter in the model based on the population covariance matrix of the input data. Because you can specify such a variety of models in the SEM framework, there are a variety of rules for identifiability. The Status tab consists of three panels of information: Identification Rules, Model Details, and Data Details.

• The Identification Rules panel contains a list of up to eight rules that are appropriate for a specified model. Some rules are necessary and others are sufficient to guarantee model identification. If necessary rules fail, steps must be taken to correct them before fitting the model. If sufficient rules fail, you do not necessarily need to address any issues. Sometimes sufficient rules can fail without being evidence of anything wrong with the model. Note that all of the rules assume a positive definite covariance matrix. If the covariance matrix is not positive definite, a warning appears below the Model Details panel.

Tip: For more information about a particular identification rule, click on the row of the table for the rule and a description of the rule appears to the right of the table.

• The Model Details panel contains a list of descriptive values for the currently specified model. These values can be used to detect potential issues with the model.

• The Data Details panel contains a list of descriptive values for the input data. These values can be used to detect potential issues with the data.

If there are singularities in the specified data columns, the report contains a Singularity Details table.

The Status tab itself contains a dynamic icon that shows the current status of the specified model. The icon designates the status:

- All applicable identification rules pass.
- At least one necessary identification rule does not pass and you must take steps to correct the issues before fitting the model.
- At least one non-necessary identification rule does not pass and further investigation is needed to determine whether the model is correctly specified. Oftentimes, advanced applications of SEM lead to this situation; this does not suggest a problem with the model. Rather, it suggests that the identification rules cannot guarantee that the model is identified.
Search Filter Options

The From List, To List, and the list boxes that appear in the Lists tab in the Model Specification report contain search filters that enable you to filter the items in a specific list.

Click the down arrow button next to the search box to refine your search.

**Contains Terms** Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.

**Contains Phrase** Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).

**Starts With Phrase** Returns items that start with the search criteria.
Model Comparison Report

The Model Comparison report contains a table of all the models that have been fit. Use the check boxes in the Show column to control which model reports are shown below the Model Comparison report. The rest of the columns to the right of Model Name enable you to compare models based on various criteria.

The AICc Weight value for a model can be interpreted as the probability that a particular model is the true model given that one of the fitted models is the truth. Therefore, the model with the AICc weight closest to one is the best fit. The AICc weights are calculated using only nonmissing AICc values and are defined as follows:

\[
\text{AICcWeight} = \frac{\exp[-0.5(AICc - \text{min}(AICc))] \big/ \sum(\exp[-0.5(AICc - \text{min}(AICc))])}{\text{sum}(\exp[-0.5(AICc - \text{min}(AICc))])}
\]

where \( \text{min}(AICc) \) is the smallest AICc value among the fitted models.

For information about the other criteria in the Model Comparison report, see “Structural Equation Model Fit Report” on page 200.

**Note:** If a model does not converge, an asterisk appears at the beginning of the model name in the Model Comparison report.
To provide context for the performance of the fitted models, the following two models are shown by default in the Model Comparison report:

**Unrestricted**  Fits all means, variances, and covariances of the specified Model Variables without imposing any structure on the data.

**Independence**  Fits all means and variances of the specified Model Variables and fixes all covariances to zero.

### Model Comparison Report Options

Two options appear below the Model Comparison table. These options are available after you click on rows to highlight them in the Model Comparison table.

**Compare Selected Models**  (Available only when two or more rows of the table are highlighted.) Computes nested chi-square difference tests between all nested model combinations of the selected rows.

**Tip:** If any of the models that you select are not nested, a warning appears and the non-nested combination of models does not appear in the Chi-Square Difference Test report.

**Clear Selection**  (Available only when one or more rows of the table are highlighted.) Clears all selections from the rows of the table.

### Chi-Square Difference Test Report

The Chi-Square Difference Test report contains a table of nested chi-square tests. The table contains two columns that define the models. The first column contains the more constrained of the two models, and the second column contains the less constrained of the two models. The smaller model is nested within the larger model. The remaining columns show the differences in chi-square values, degrees of freedom, CFI, and RMSEA, as well as the $p$-values for the nested chi-square tests. The $\Delta$ notation in the column names indicates differences. A significant $\Delta$ chi-square value indicates that the additional constraints in the nested model produce a statistically significant increase in misfit and that the less constrained model should be retained. Because chi-square tests are influenced by sample size, such that they are more likely to be significant as sample sizes increase, the $\Delta$CFI and $\Delta$RMSEA should also be considered; ideally, the $\Delta$CFI should not exceed −0.01 and $\Delta$RMSEA should not exceed 0.015 (Chen 2007).

**Caution:** Difference tests in this report are meaningful only for nested models.
You can remove any row of the report by clicking the red X button. To remove the report entirely, you must remove all of the rows of the table. If you remove a Structural Equation Model node in the main report, any difference tests involving that model are removed from the table.

**Structural Equation Model Fit Report**

Each time you click Run, a Structural Equation Model report for the specified model appears. By default, this report contains a Summary of Fit report, a Parameter Estimates report, and a Path Diagram.

**Summary of Fit** Table of information about the model fit, including the convergence status and the estimation method. The following statistics are reported in this table:

- **Sample Size** The number of observations (rows) used to fit the model.

- **Rows with Missing** The number of observations (rows) that contained at least one missing value. All missing values are handled using full information maximum likelihood (Finkbeiner 1979).

- **Iterations** The number of iterations used to fit the model.

- **-2 Log Likelihood** The log-likelihood of the fitted model multiplied by -2. This value can be used to compare nested models; the difference between two models’ -2 Log Likelihood values is chi-square distributed with degrees of freedom equal to the difference of degrees of freedom between the models. See *Fitting Linear Models*.

- **Number of Parameters** The number of freely estimated parameters in the model.

- **AICc** The corrected Akaike information criterion. This value can be used to compare models, where a smaller number indicates a better model fit. See “AICc and BIC” on page 217.

- **BIC** The Bayesian information criterion. This value can be used to compare models, where a smaller number indicates a better model fit. See “AICc and BIC” on page 217.

- **ChiSquare** The chi-square statistic for the model.

- **DF** The degrees of freedom for the chi-square test for model fit.

- **Prob>ChiSq** The $p$-value of the chi-square statistic for the model.

- **CFI** The Bentler’s comparative fit index (CFI) provides additional guidance for determining model fit. The CFI is bounded between 0 and 1. Values greater than 0.90 are preferred (Browne and Cudeck 1993; Hu and Bentler 1999). See “CFI” on page 217.
RMSEA  The root mean square error of approximation (RMSEA) provides additional guidance for determining model fit. The RMSEA is bounded between 0 and 1. Values less than 0.10 are preferred (Browne and Cudeck 1993; Hu and Bentler 1999). See “RMSEA” on page 219.

Lower 90%  The 90% lower confidence limit for the RMSEA. See “RMSEA” on page 219.

Upper 90%  The 90% upper confidence limit for the RMSEA. See “RMSEA” on page 219.

Parameter Estimates  Table of estimates for the model parameters. The table is organized in sections for Means/Intercepts, Loadings, Regressions, and Variances. For each estimate, a standard error (Std Error), Wald test statistic (Wald Z), and a corresponding p-value (Prob>|Z|) are given.

Tip: The Parameter Estimates table contains hidden columns that identify the From and To components for each model parameter. To show these columns, right-click the table and select Columns > From and Columns > To.

Path Diagram  Shows the path diagram representation of the fitted model. See “Diagram Tab” on page 195.

Structural Equation Models Platform Options

The Structural Equation Models red triangle menu contains the following options:

Path Diagram Settings  Contains the following options to modify the path diagram display:

Customize Diagram  Enables you to customize many aspects of the path diagram. See “Customize Diagram Appearance Options” on page 209.

Layout  Contains two options that change the overall shape of the path diagram. You can choose between a Left to Right layout or a Top to Bottom layout.

Tip: You can also drag items in the path diagram to change the arrangement of specific items.

Copy Diagram  Saves an image of the path diagram to the clipboard. To retain the highest possible quality, paste the clipboard image as a vector graphic.

Copy Diagram Properties  Copies the current path diagram properties to the clipboard. You can then paste the properties into another SEM path diagram.

Paste Diagram Properties  Pastes the path diagram properties from the clipboard into the current SEM path diagram.
Descriptive Statistics  Contains the following options to produce descriptive statistics:

Univariate Simple Statistics  Shows or hides a univariate simple statistics report. The statistics in this report are estimated for each column independently from other columns that might have missing data.

Full Information Multivariate Statistics  Shows or hides a multivariate simple statistics report. The statistics in this report are estimated with full information maximum likelihood to account for missing data.

Launch Explore Outliers  Launches the Explore Outliers platform. See Predictive and Specialized Modeling.

Launch Explore Missing Values  (Not available when there are no missing values.) Launches the Explore Missing Values platform. See Predictive and Specialized Modeling.

Add Manifest Variables  Enables you to add new manifest variables to the current model. After you select new manifest variables to add, a new Structural Equation Models report is launched. The new report uses the existing model specification with the newly added manifest variables.

Remove Manifest Variables  Enables you to launch a new Structural Equation Models report with the specified manifest variables removed. After you select manifest variables to remove, a new report is launched. The new report uses the existing model specification with the specified manifest variables removed.

Copy Model Specification  Copies the current structural equation model specifications to the clipboard. You can then paste the model specifications into another SEM platform report.

Paste Model Specification  Pastes the model specifications from the clipboard into the current model specifications.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Model Options

After you click Run, a Structural Equation Model report for the specified model appears. This report has a red triangle menu that contains the following options:

Show Path Diagram  Shows or hides the path diagram in the model report.

Path Diagram Settings  Contains the following options to modify the path diagram for the model:

  Customize Diagram  Enables you to customize many aspects of the path diagram. See “Customize Diagram Appearance Options” on page 209.

  Layout  Contains two options that change the overall shape of the path diagram. You can choose between a Left to Right layout or a Top to Bottom layout.

   Tip: You can also drag items in the path diagram to change the arrangement of specific items.

Copy Diagram  Saves an image of the path diagram to the clipboard. To retain the highest possible quality, paste the clipboard image as a vector graphic.

Copy Diagram Properties  Copies the current path diagram properties to the clipboard. You can then paste the properties into another SEM path diagram.

Paste Diagram Properties  Pastes the path diagram properties from the clipboard into the current SEM path diagram.

Fit Indices  Shows or hides a report that contains a variety of index values that enable you to evaluate the fitted model. In addition to values that appear in the Summary of Fit report, the Fit Indices report also contains the following index values:

  TLI  The Tucker-Lewis index (TLI) provides additional guidance for determining model fit. This index is also known as the non-normed fit index (NNFI). The TLI is bounded between 0 and 1. Values greater than 0.95 are preferred (West et al. 2012). See “TLI” on page 218.

  NFI  The normed fit index (NFI) provides additional guidance for determining model fit. The NFI is bounded between 0 and 1. Values greater than 0.95 are preferred (West et al. 2012). See “NFI” on page 218.

  Revised GFI  The revised goodness-of-fit index provides additional guidance for determining model fit. The revised GFI is bounded between 0 and 1. Values greater than 0.95 are preferred (West et al. 2012). See “Revised GFI and Revised AGFI” on page 218.
**Revised AGFI**  The revised adjusted goodness-of-fit index provides additional guidance for determining model fit. The revised AGFI is bounded between 0 and 1 (West et al. 2012). See “Revised GFI and Revised AGFI” on page 218.

**RMR**   The root mean square residual (RMR) provides additional guidance for determining model fit. The residuals for the RMR are from the differences between the observed and model-implied covariances. The RMR is positive and smaller values are preferred (West et al. 2012). See “RMR and SRMR” on page 220.

**SRMR**  The standardized root mean square residual (SRMR) provides additional guidance for determining model fit. The residuals for the SRMR are from the standardized differences between the observed and model-implied covariances. The SRMR is positive and smaller values are preferred (West et al. 2012). See “RMR and SRMR” on page 220.

**Note:** For a description of the other values in the Fit Indices report, see “Structural Equation Model Fit Report” on page 200.

**Summary of Fit**  Shows or hides a report that contains details of the model fit.

**Parameter Estimates**  Shows or hides a report that contains the unstandardized parameter estimates for the model.

**Standardized Parameter Estimates**  Shows or hides a report that contains the standardized parameter estimates for the model.

**Confidence Intervals**  Shows or hides confidence intervals in the Parameter Estimates and Standardized Parameter Estimates reports.

**Prediction Profiler**  Enables you to view the effects of a set of predictors on the conditional expected values of a set of outcome variables. When you select this option, a window appears in which you must select one or more predictors and one or more outcomes. The predictions and 95% confidence intervals are based on the model-implied covariance matrix. For more information about the prediction profiler, see Profilers.

**Note:** The initial list of variables in the setup window is limited to variables that are consistent with the model. For example, the Select Predictors list contains only variables that predict something in the model and the Select Outcomes list contains only variables that are predicted by some other variable in the model. Check the Show All Variables box to see all model variables in both lists.

**Model Implied Covariances**  Shows or hides a report that contains the covariance matrix that is implied by the model.

**Model Implied Means**  Shows or hides a report that contains the means for each variable that are implied by the model.
Residuals Shows or hides a report that contains a matrix of the residuals for the model. This matrix is the difference between the model implied covariance matrix and the sample covariance matrix.

Normalized Residuals Shows or hides a report that contains a matrix of the normalized residuals for the model.

Normalized Residuals Heat Map Shows or hides a report that contains a heat map of the normalized residuals for the model.

RAM Matrices Shows or hides a report that contains the model matrices used in reticular action model (RAM) notation.

Covariance of Estimates Shows or hides a report that contains the covariance matrix of the parameter estimates for the model.

R² for Endogenous Variables (Available only when the model is recursive and contains endogenous variables.) Shows or hides a report that contains the R² values for each endogenous variable in the model. This value is calculated as 1 minus the ratio of the residual variance and the model-implied variance for each endogenous variable. The R² values represent how much variance is explained by the model in an endogenous variable. An endogenous variable is one that has a path directed at it in the path diagram.

Modification Indices Enables you to show all or a subset of the estimates of model modification indices. These values can be used to determine which parameters might be added to the model to improve model fit. Each table is sorted by the ChiSquare column in descending order.

All Modification Indices Shows or hides a table that contains the estimates of all the model modification indices. This table contains a column that indicates the parameter type for each estimate.

Modification Indices for Means Shows or hides a table that contains the estimates of the model modification indices for the means and intercepts.

Modification Indices for Loadings Shows or hides a table that contains the estimates of the model modification indices for the loading parameters.

Modification Indices for Regressions Shows or hides a table that contains the estimates of the model modification indices for the regression parameters.

Modification Indices for Covariances Shows or hides a table that contains the estimates of the model modification indices for the covariance parameters.

Assess Measurement Model (Available only for confirmatory factor models that do not have covariances among unique factors.) Shows or hides a variety of statistics and graphs for quantifying the reliability and validity of tests and measures, including indicator reliability, coefficients omega and H, and a construct validity matrix.
The construct validity matrix helps you determine whether latent variables are measuring what you think they are measuring:

- The lower triangular entries contain the latent variable correlations. These entries enable you to check how strongly correlated the latent variables are with each other and compare that to the hypothesized strength of correlation.

- The upper triangular entries are the squared latent variable correlations. These entries enable you to focus on the overlap in variance across latent variables. These statistics are particularly valuable when compared against the diagonal entries in the matrix.

- The diagonal entries contain the average amount of variance extracted by each latent variable, which is equivalent to the average of the indicator reliabilities for each latent variable. A good latent variable should have high values in the diagonal because its indicators have sufficient systematic variance to define it properly. Ideally, the diagonal entry for each latent variable should be higher than the entries above and to the right of it.

The visualization of the construct validity matrix enables you to compare the diagonal entries to the upper triangular entries.

**Save Columns**   Enables you to save columns based on the fitted structural equation model to the data table.

**Save Factor Scores**   (Available only when there are latent variables in the model.) Saves a column with the factor score computed using the regression method for each latent variable to the data table. The factor scores are calculated in a hidden column that is also added to the data table. This hidden column uses the Estimate Factor Score() JSL function. For more information about this function, see Help > Scripting Index.

**Save Bartlett Factor Scores**   (Available only when there are latent variables in the model.) Saves a column with the factor score computed using the Bartlett method for each latent variable to the data table. The factor scores are calculated in a hidden column that is also added to the data table. This hidden column uses the Estimate Bartlett Factor Score() JSL function. For more information about this function, see Help > Scripting Index.

**Save Prediction Formulas**   (Available only when there is at least one endogenous or dependent variable in the model.) Saves a column with a formula for the predicted values of the observed outcomes for each variable to the data table. When there are latent variables in the model, factor scores computed using the Bartlett method are also saved to the data table.
Save Observational Residuals  (Available only when there is at least one endogenous or dependent variable in the model.) Saves a column with the residual values of the observed outcomes for each variable to the data table. When there are latent variables in the model, factor scores computed using the Bartlett method are also saved to the data table.

Copy Model Specification  Copies the current structural equation model specifications to the clipboard. You can then paste the model specifications into another SEM platform report.

Recall in Model Specification  Sets the model in the Model Specification report to the specified model.

Remove Fit  Removes the specified model report from the report window.

Customize the SEM Path Diagram

You can customize the path diagram in many ways. Most of the customization options are in one or both of the following places: the pop-up menu in the path diagram and the Customize Diagram Appearance window.

- “Path Diagram Pop-Up Menu Options”
- “Customize Diagram Appearance Options”

Path Diagram Pop-Up Menu Options

The path diagram pop-up menu appears when you right-click in the path diagram itself. The specific set of options that are available in the menu depends on where you right-click in the diagram and if there are any elements of the path diagram selected when you right-click.

Selection  Contains options to make selections in the From and To Lists, add unidirectional and bidirectional arrows to the diagram, create new latent variables, hide selected items, and show all hidden items. Many of the options in this submenu are not enabled until you select items in the path diagram.

Tip: When items in the path diagram are hidden, an Unhide All button appears at the top of the path diagram that enables you to show all hidden items.

Show  Contains options to show or hide various elements of the path diagram. Select Show Default to return to the original set of shown elements.
Note: The Show Default option does not affect the setting of the Show Means/Intercepts option.

For path diagrams in fitted model reports, this submenu also contains options for changing which estimates appear on the arrows in the path diagram. You can choose between showing the unstandardized parameter estimates, the standardized parameter estimates, or no estimates.

**Select All of This Type**  (Available only when you right-click an item in the path diagram.) Selects all other items in the path diagram that are the same type as the item that you right-clicked.

**Select Latent Group(s)**  (Available only when you right-click on a latent variable item in the path diagram.) Selects the entire group of items associated with the selected latent variables. If no latent variables are selected, this option selects only the group of items associated with the latent variable that you right-clicked.

**Rename Variable**  (Available only when you right-click on a latent variable item in the path diagram.) Enables you to change the name of the latent variable in the path diagram.

Note: When you rename a latent variable in the path diagram, the name is updated in the From and To Lists.

**Add Regression(s)**  (Available only when you right-click on a variable in the path diagram.) Enables you to add a unidirectional arrow that represents a regression between the variable that you right-clicked and another variable in the path diagram. When you select this option, click the variable where you want the arrow to point.

**Add Covariance(s)**  (Available only when you right-click on a variable in the path diagram.) Enables you to add a bidirectional arrow that represents a covariance between the variable that you right-clicked and another variable in the path diagram. When you select this option, click the variable where you want the arrow to point.

**Customize Diagram**  Launches the Customize Diagram Appearance window. See “Customize Diagram Appearance Options” on page 209.

**Rotate Latent Groups**  Rotates latent variable indicators clockwise in 90-degree angle increments for the selected latent variables in the path diagram. If no latent variables are selected, this option rotates all latent variable indicators in the path diagram.

**Layout**  Enables you to select one of two arrangement options for the items in the path diagram.

**Copy Diagram**  Saves an image of the path diagram to the clipboard. To retain the highest possible quality, paste the clipboard image as a vector graphic.
Copy Diagram Properties  Copies the current path diagram properties to the clipboard. You can then paste the properties into another SEM path diagram.

Paste Diagram Properties  Pastes the path diagram properties from the clipboard into the current SEM path diagram.

Undo  Undoes the last change to the path diagram.

Redo  Redoes the last undone change to the path diagram.

Edit  Contains standard options for graphs in JMP. For more information about these options, see Using JMP.

Reset Layout  Resets the path diagram to the original settings.

Customize Diagram Appearance Options

The Customize Diagram Appearance window appears when you click the customize button in the Diagram panel, select Customize Diagram from the red triangle menu, or select Customize Diagram from the path diagram pop-up menu. The Customize Diagram Appearance window contains four panels as well as a drop-down menu that enables you to select from two preset color themes.

Theme Preset  Contains options for preset color themes. You can choose between a Black and White theme or a Blue theme. Select one of these to quickly update the settings to follow either theme.

Variable Appearance  Contains options for setting the fill color, border color, text color, and size of the items in the path diagram. You can set the appearance for manifest, latent, and constant variables, as well as the font for each of these items.

Path Settings  Contains options for the appearance of the arrows. You can set the thickness and transparency to fixed values or base them on the standardized estimates for each path arrow. You can also represent non-significant $p$-values with dashed lines, set the $\alpha$ level for non-significance, and change the color and font associated with the arrows. By default, the thickness of the arrows is fixed and the transparency of the arrows is proportional to the standardized parameter estimates.

Other Settings  Contains the following options:

Enable Grid  Shows or hides a grid in the path diagram that can be used to help align items in the diagram.

Lock Diagram  Locks or unlocks the placement of items in the path diagram. When the path diagram is locked, you cannot drag items around and the Lock indicator at the top of the path diagram is highlighted.
Show Means/Intercepts  Shows or hides the means and intercepts in the path diagram. The mean structure is not displayed in the path diagram by default.

Show Latent Indicators  Shows or hides the latent indicators in the path diagram.

Show Regressions  Shows or hides the arrows for regressions in the path diagram.

Show Variances  Shows or hides the arrows for variances in the path diagram.

Show Covariances  Shows or hides the arrows for covariances in the path diagram.

Show Equality Constraints  Shows or hides equality constraints in the path diagram.

Show R Squared Values  Shows or hides $R^2$ values for each node in the path diagram.

Fill Nodes with R Squared  Shows or hides a fill coloring for each node in the path diagram that corresponds to the $R^2$ value for each node.

Preview  Contains a preview of the path diagram appearance based on your current settings in the window.

Tip: Use the Save to Preferences button at the bottom of the Customize Diagram Appearance window to save the current settings in the window to your platform preferences so that future path diagrams use the same settings.

Additional Example of Structural Equation Models

In this example, you are building the structural equation model for industrialization and political democracy described in Bollen (1989), which uses data from 75 developing countries. The variables in the data table include four measures of democracy in 1960 and 1965, and three measures of industrialization in 1960. These variables are described in the Notes column property in each column of the data table. To view the Notes column property, right-click a column name, select Column Info, and select Notes under Column Properties. The type of structural equation model that you are building is a structural regression model.

There are four main steps to the model specification process: creating latent variables, adding the loading and regression variables, adding the covariance terms, and placing constraints on the loading variables.

1. Select Help > Sample Data Library and open Political Democracy.jmp.
3. Select Prod60 through Legis65 and click Model Variables.
4. Click OK.

The Structural Equation Models report Model Specification outline appears.
5. Click the **Lists** tab in the View panel box.

**Create Latent Variables**

6. Select `Prod60` through `Labor60` in the To List, type `Ind60` in the box below the To List, and click the add latent `➕` button.

7. Select `FrPress60` through `Legis60` in the To List, type `Dem60` in the box below the To List, and click the add latent `➕` button.

8. Select `FrPress65` through `Legis65` in the To List, type `Dem65` in the box below the To List, and click the add latent `➕` button.

**Add Loading and Regression Variables**

9. Select `Ind60` in the From List, select `Dem60` in the To List, and click the unidirectional arrow `➡️` button.

10. Select `Ind60` in the From List, select `Dem65` in the To List, and click the unidirectional arrow `➡️` button.

11. Select `Dem60` in the From List, select `Dem65` in the To List, and click the unidirectional arrow `➡️` button.
Figure 8.7 Loadings and Regressions

Add Covariances

12. Select FrOpp60 in the From List, select Legis60 and FrOpp65 in the To List, and click the bidirectional arrow button.

13. Select FrOpp65 in the From List, select Legis65 in the To List, and click the bidirectional arrow button.

14. Select FrPress60 in the From List, select FrPress65 in the To List, and click the bidirectional arrow button.

15. Select Fair60 in the From List, select Fair65 in the To List, and click the bidirectional arrow button.

16. Select Legis60 in the From List, select Legis65 in the To List, and click the bidirectional arrow button.
Add Constraints on Loadings

17. Select Dem60->FrOpp60 and Dem65->FrOpp65 in the Loadings list and click **Set Equal**.
18. Select Dem60->Fair60 and Dem65->Fair65 in the Loadings list and click **Set Equal**.
19. Select Dem60->Legis60 and Dem65->Legis65 in the Loadings list and click **Set Equal**.
The constraints on the loadings are designated by alphanumeric labels. For example, you can see that Dem60->FrOpp60 and Dem65->FrOpp65 are set equal because they both are labeled “c1”.

20. In the text box below Model Name, type Industrialization and Political Democracy.

21. Click Run.
The chi-square statistic for this model, which is listed in the Summary of Fit report, is 40.18 with 38 degrees of freedom. Note that the corresponding $p$-value is 0.3739, which is not significant. This indicates that there is not evidence to reject the null hypothesis that the model fits well. Therefore, you conclude that this model fits the data reasonably well.

The chi-square value depends on the sample size, and thus, some well-fitting models can still produce a significant chi-square value. The comparative fit index (CFI) and root mean square error of approximation (RMSEA) provide additional guidance for determining model fit. These indices are bounded between 0 and 1. CFI values greater than 0.90 and RMSEA values less than 0.10 are preferred (Browne and Cudeck 1993; Hu and Bentler 1999). Here, the CFI of 0.9968 and RMSEA of 0.0277 indicate a very good fit.
Figure 8.11 Structural Equation Model Parameter Estimates Report

Next, the parameter estimates under Regressions suggest positive effects of Ind60 on Dem60 and Dem65, as well as a positive effect of Dem60 on Dem65. Thus, higher scores on Ind60 are associated with higher Dem60 and Dem65, and higher scores in Dem60 are associated with higher scores in Dem65. The corresponding p-values for the parameter estimates are shown under Regressions. All 3 regression parameters are significant at the $\alpha = 0.05$ level. Therefore, you conclude that there are nonzero relationships between the latent variables.
Statistical Details for the Structural Equation Models Platform

Statistical Details for Summary of Fit Measures

**AICc and BIC**

The formulas for AICc and BIC are defined as follows:

\[
\text{AICc} = -2\log L + 2k + \frac{2k(k + 1)}{n - (k + 1)} \\
\text{BIC} = -2\log L + k\ln(n)
\]

where:

- \(-2\log L\) is twice the negative log-likelihood.
- \(n\) is the sample size.
- \(k\) is the number of parameters.

For more information about the likelihood-based measures in the Model Comparisons report, see *Fitting Linear Models*.

**CFI**

The comparative fit index (CFI) is calculated as follows:

\[
\text{CFI} = \frac{\max(\chi^2_0 - df_0, 0) - \max(\chi^2_{\min} - df_{\min}, 0)}{\max(\chi^2_0 - df_0, 0)}
\]

where:

- \(\chi^2_0\) is the chi-square statistic of the independence model.
- \(df_0\) is the degrees of freedom of the independence model.
- \(\chi^2_{\min}\) is the chi-square statistic of the fitted model.
- \(df_{\min}\) is the degrees of freedom of the fitted model.

For more information about the CFI, see Bentler (1990).
The Tucker-Lewis index (TLI) is defined as follows:

\[
\text{TLI} = \frac{\chi^2_0 - \chi^2_{min}}{\frac{\chi^2_0}{df_0} - \frac{\chi^2_{min}}{df_{min}}}
\]

where:

- \(\chi^2_0\) is the chi-square statistic of the independence model.
- \(df_0\) is the degrees of freedom of the independence model.
- \(\chi^2_{min}\) is the chi-square statistic of the fitted model.
- \(df_{min}\) is the degrees of freedom of the fitted model.

For more information, see West et al. (2012).

The Bentler-Bonett normed fit index (NFI) is defined as follows:

\[
\text{NFI} = \frac{\chi^2_0 - \chi^2_{min}}{\chi^2_0}
\]

where:

- \(\chi^2_0\) is the chi-square statistic of the independence model.
- \(\chi^2_{min}\) is the chi-square statistic of the fitted model.

For more information, see West et al. (2012).

The revised goodness-of-fit index (Revised GFI) is defined as follows:

\[
\text{Revised GFI} = \frac{p}{p + 2\left(\frac{\chi^2_{min} - df_{min}}{n - 1}\right)}
\]
where:
- $\chi^2_{\text{min}}$ is the chi-square statistic of the fitted model.
- $df_{\text{min}}$ is the degrees of freedom of the fitted model.
- $p$ is number of observed variables in the fitted model.
- $n$ is the sample size.

The revised adjusted goodness-of-fit index (Revised AGFI) is defined as follows:

$$\text{Revised AGFI} = 1 - \frac{p^*}{df_{\text{min}}} (1 - \text{Revised GFI})$$

where:
- $p^*$ is the number of unique entries in the covariance matrix and the mean vector of the observed variables.
- $df_{\text{min}}$ is the degrees of freedom of the fitted model.

For more information, see West et al. (2012).

**RMSEA**

The root mean square error of approximation (RMSEA) is calculated as follows:

$$\text{RMSEA} = \sqrt{\frac{\max(\chi^2_{\text{min}} - df_{\text{min}}, 0)}{n \times df_{\text{min}}}}$$

where:
- $n$ is the sample size.
- $df_{\text{min}}$ is the degrees of freedom of the fitted model.
- $\chi^2_{\text{min}}$ is the chi-square statistic of the fitted model.

The confidence limits for RMSEA are computed using the cumulative distribution function of the noncentral chi-square distribution $\Phi(\chi^2 \mid \lambda, d)$. The 90% confidence limits are computed as follows:

$$\text{Lower limit} = \sqrt{\frac{\lambda_L}{n \times df_{\text{min}}}}$$
$$\text{Upper limit} = \sqrt{\frac{\lambda_U}{n \times df_{\text{min}}}}$$
where:

- $\lambda_L$ satisfies $\Phi(\chi^2_{\min} | \lambda_L, df_{\min}) = 0.95$.
- $\lambda_U$ satisfies $\Phi(\chi^2_{\min} | \lambda_U, df_{\min}) = 0.05$.

For more information, see Maydeu-Olivares et al. (2017).

**RMR and SRMR**

The formulas for RMR and SRMR are defined as follows:

$$RMR = \sqrt{\frac{1}{b} \sum_{i} \sum_{j} (s_{ij} - \hat{\sigma}_{ij})^2 + \sum_{i} (\bar{x}_i - \hat{\mu}_i)^2}$$

$$SRMR = \sqrt{\frac{1}{b} \sum_{i} \sum_{j} \frac{(s_{ij} - \hat{\sigma}_{ij})^2}{s_{ii} s_{jj}} + \sum_{i} \frac{(\bar{x}_i - \hat{\mu}_i)^2}{s_{ii}}}$$

where:

- $p$ is the number of manifest variables.
- $b$ is the number of unique entries in the covariance matrix and the mean vector of the observed variables:
  $$b = \frac{p(p + 1)}{2} + p$$
- $s_{ij}$ is the $(i, j)^{th}$ element of the input covariance matrix.
- $\hat{\sigma}_{ij}$ is the $(i, j)^{th}$ element of the predicted covariance matrix.
- $\bar{x}_i$ is the $i^{th}$ element of the vector of sample means.
- $\hat{\mu}_i$ is the $i^{th}$ element of the vector predicted means.

For more information, see the CALIS Procedure chapter in SAS Institute Inc. (2020a).
Factor analysis seeks to describe observed variables in terms of a smaller number of (unobservable) latent variables, or factors. Factor analysis is also known as common factor analysis and exploratory factor analysis. The factors are defined as linear combinations of the observed variables (plus error). They are constructed to explain variation that is common to the observed variables. A goal of factor analysis is to find a meaningful interpretation of the observed variables in terms of the unobserved factors. Another goal is to reduce the number of variables.

Factor analysis is used in many areas, with roots in psychology, sociology, and education. In these areas, factor analysis is used to understand how observed behavior can be interpreted in terms of underlying patterns and structures. For example, measures of participation in outdoor activities, hobbies, exercise, and travel, might all relate to a factor that can be described as “active versus inactive personality type”.

Use factor analysis when you need to explore or interpret underlying patterns and structure in your data. Also consider using it to summarize the information in your variables using a smaller number of latent variables.

Factor analysis models a set of observable variables in terms of a smaller number of unobservable factors. The factors are constructed to account for the correlation or covariance between the observed variables. Factor rotation is used to change the reference axes of the factors to increase their interpretability.

Consider a situation where you have ten observed variables, $X_1, X_2, \ldots, X_{10}$. Suppose you want to model these ten variables in terms of two latent factors, $F_1$ and $F_2$. For convenience, it is assumed that the factors are uncorrelated and that each has mean zero and variance one. The model that you want to derive is of the form:

$$X_i = \beta_{i0} + \beta_{i1}F_1 + \beta_{i2}F_2 + \varepsilon_i$$

It follows that $\text{Var}(X_i) = \beta_{i1}^2 + \beta_{i2}^2 + \text{Var}(\varepsilon_i)$. The portion of the variance of $X_i$ that is attributable to the factors, the common variance or communality, is $\beta_{i1}^2 + \beta_{i2}^2$. The remaining variance, $\text{Var}(\varepsilon_i)$, is the unique variance, and is considered to be a combination of specific and error variances that are unique to $X_i$.

The platform provides a scree plot for the eigenvalues of the correlation or covariance matrix. You can use this as a guide in determining the number of factors to extract. The platform's default number of factors is the number of eigenvalues that exceed one.

The platform provides two factoring methods for estimating the parameters of this model: Principal Axis and Maximum Likelihood. There are two Prior Communality options for estimating the proportion of variance contributed by common factors for each variable. These options impose assumptions on the diagonal of the correlation (or covariance) matrix. The Principal Components option treats the correlation matrix, which has ones on its diagonal (or the covariance matrix with variances on its diagonal), as the structure to be analyzed. The Common Factor Analysis option sets the diagonal entries to square multiple correlations. These are values that reflect the proportion of the variation shared with other variables.

Factor rotation is used to support interpretability of the extracted factors. The Factor Analysis platform provides a variety of rotation methods that encompass both orthogonal and oblique rotations.

In contrast to factor analysis, which looks at common variance, principal component analysis accounts for the total variance of the observed variables. See the “Principal Components” chapter on page 55.

For more information about factor analysis, see Jöreskog (1977) or Cudeck and MacCallum (2007).
Example of the Factor Analysis Platform

This example uses the Solubility.jmp sample data table to extract two factors explained by six solvents.

1. Select Help > Sample Data Library and open Solubility.jmp.
2. Select Analyze > Multivariate Methods > Factor Analysis.
3. Select 1-Octanol through Hexane and click Y, Columns.
4. Click OK.

The elbow on the scree plot indicates that a model with two factors is appropriate.

5. In the Model Launch outline, make the following selections:
   – Factoring Method = **Maximum Likelihood**

Label variables

---
The report lists the communality estimates, variance estimates, significance tests, measures of fit, rotated factor loadings, and a factor loading plot. The Rotated Factor Loadings and Factor Loading Plot suggest that Factor 1 relates to the Carbon Tetrachloride-Chloroform-Benzene-Hexane cluster of variables, and that Factor 2 relates to the Ether–1-Octanol cluster of variables. See “Factor Analysis Model Fit Options” on page 232 for details of the information shown in the report.

**Tip:** Click the points in the Factor Loading Plot to select and move the labels. Click in the lower right corner to increase the plot size to more easily view the labels.

---

**Launch the Factor Analysis Platform**

Launch the Factor Analysis platform by selecting **Analyze > Multivariate Methods > Factor Analysis**.

**Figure 9.4 Factor Analysis Launch Window**

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Columns**  The columns to be analyzed. These must have a Numeric data type.

**Weight**  A column containing a weight for each observation in the data table. A row is included in the analyses only when its value is greater than zero.

**Freq**  Assigns a frequency to each row in the analysis. This is useful when your data are summarized.

**By**  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.
Variance Estimation  Lists the methods for estimating the variance-covariance matrix for the analysis. For more information about the methods, see “The Multivariate Report” on page 35.

Variance Scaling  Lists the scaling methods for performing the factor analysis.

Correlations  Default method that enables analysis on correlations.

Covariances  Enables the analysis on a weighted correlation matrix where the weights are the variables’ variances.

Unscaled  Enables the analysis of variables that are already centered or scaled.

The Factor Analysis Report

The initial Factor Analysis report shows Eigenvalues and the Scree Plot. The eigenvalues are obtained from a principal components analysis. The scree plot graphs these eigenvalues. The initial number of factors in the Model Launch equals the number of eigenvalues that exceed 1.0. You can change the number of factors to extract.

Use the scree plot as a guide for the number of factors. The number of eigenvalues before the scree plot levels out provides an upper bound on the number of factors. For this example, two components (factors) are suggested by the scree plot.
The Eigenvalues table indicates that the first eigenvalue accounts for 79.75% of the variation and the second eigenvalue accounts for 15.75%. Therefore, the first two eigenvalues account for 95.50% of the total variation. The third eigenvalue explains only 2.33% of the variation, and the contributions from the remaining eigenvalues are negligible. Although the **Number of factors** box is initially set to 1, this analysis suggests that it is appropriate to extract 2 factors.

**Model Launch**

Configure the Factor Analysis from the Model Launch control panel. Click **Go** to obtain the results of the factor analysis.

Factoring method  Defines the method for extracting factors:

Principal Axis  Performs eigenvalue decomposition on a reduced correlation or covariance matrix, where the diagonal of the matrix is replaced by an estimate of the communality of the variables. This method is a computationally efficient method, but it does not allow for hypothesis testing.

Maximum Likelihood  Enables you to test hypotheses about the number of common factors and to obtain model fit statistics.

Note: The Maximum Likelihood method requires a positive definite correlation matrix. If your correlation matrix is not positive definite, select the Principal Axis method.

Prior Communality  Defines the method for estimating the proportion of variance contributed by common factors for each variable.

Principal Components (diagonals = 1)  Sets all communalities equal to 1, indicating that 100% of each variable’s variance is explained by all of the factors.

Tip: Using this option with Factoring Method set to Principal Axis results in principal component analysis.

Common Factor Analysis (diagonals = SMC)  Sets the communalities equal to squared multiple correlation (SMC) coefficients. For a given variable, the SMC is the R-Square for a regression of that variable on all other variables.

Number of factors  Specifies the number of factors to extract from the analysis. The default is the number of eigenvalues that are greater than or equal to 1.0. You can set the number of factors to at least one and no more than the number of variables.
Rotation method  Defines the method for rotation. The default is Varimax. See “Rotation Methods” on page 230 for a description of the available rotation methods.

Rotation Methods

Rotations are used to change the reference axes of the factors to make the factors more interpretable. Rotations are applied to the factors extracted from the data. Rotation methods are based on various complexity or simplicity functions. For more information about rotations see the FACTOR Procedure chapter in SAS Institute Inc. (2020c), Browne (2001), or Frank and Todeschini (1994).

After the initial extraction, the factors are uncorrelated with each other. If the factors are rotated by an orthogonal transformation, the rotated factors are also uncorrelated. If the factors are rotated by an oblique transformation, the rotated factors become correlated. Oblique rotations often produce more interpretable factors than do orthogonal rotations. However, a consequence of correlated factors is that there is no single unambiguous measure of the importance of a factor in explaining a variable.

Orthogonal Rotation Methods

Varimax  Maximizes the sum of the variances of the squared loadings of a factor on all variables. This common method results in each variable having either a small or large loading on each factor. (Orthomax with $\gamma = 1$.)

Biquartimax  An equally weighted solution of the Varimax and Quartimax rotations. (Orthomax with $\gamma = 0.5$.)

Equamax  A weighted solution between the Varimax rotation and the Quartimax rotation. (Orthomax with $\gamma = N/2$, where $N$ = number of factors.)

Factorparsimax  A solution that aims to minimize the complexity of factors. This method might result in cross-loadings as variable complexity is not considered in the algorithm. (Orthomax with $\gamma = N$, where $N$ = number of factors.)

Orthomax  A general weighted rotation method where the weight is denoted by $\gamma$. Many specific orthogonal rotation methods are Orthomax rotations with a specific $\gamma$.

Parsimax  Balances the variable and the factor complexity. (Orthomax with $\gamma = (I(N-1))/(I+N-2)$, where $I$ = the number of items and $N$ = number of factors.)

Quartimax  Minimizes the number of factors needed to explain each variable. (Orthomax with $\gamma = 1$.)

Oblique Rotation Methods

Biquartimin  A rotation to minimize the ratio of the covariances (Oblimin with $\tau = 0.5$.).
Covarimin  Oblique Varimax rotation. (Oblimin with $\tau = 1$).

Obbiquartimax  Oblique Biquartimax rotation.

Obequamax  Oblique Equamax rotation.

Obfactorparsimax  Oblique factor Parsimax rotation.

Oblimin  A general weighted oblique rotation method where the weight is denoted by $\tau$.
Many specific oblique rotation methods are Oblimin rotations with a specific $\tau$.

Obparsimax  Oblique Parsimax rotation.

Obquartimax  Oblique Quartimax rotation, equivalent to the Quartimin method.

Obvarimax  Oblique Varimax rotation.

Quartimin  Oblique Quartimin rotation, equivalent to oblique Quartimax (Oblimin with $\tau = 0$).

Promax  A two step rotation in which Varimax is performed first and then the Procrustes rotation is used to attain simple structure. This is a computationally efficient method that is an alternative to Oblimin.

---

**Factor Analysis Platform Options**

The Factor Analysis red triangle menu contains the following options:

**Eigenvalues**  Shows or hides a table of the eigenvalues of the original correlation, covariance, or unscaled matrix. The table includes the percent of the total variance represented by each eigenvalue, a bar chart illustrating the percent contribution, and the cumulative percent contributed by each successive eigenvalue. The number of eigenvalues that are greater than or equal to 1.0 can be taken as a guideline of the number of factors for analysis.

**Scree Plot**  Shows or hides a plot of the eigenvalues versus the number of components (or factors). The plot can be used as an additional guideline to determine the number of factors that contribute to the maximum amount of variance. The point at which the plotted line levels out can be used as the number of sufficient factors for analysis.

**Kaiser-Meyer-Olkin Test**  Shows or hides the results of the Kaiser-Meyer-Olkin (KMO) test. The test is an indicator of the proportion of variance that might be common variance, potentially due to underlying factors. The test statistic is calculated for each individual variable and for the set of all variables and is referred to as the Measure of Sampling Adequacy (MSA) in JMP. The following values indicate the suitability of the variables for factor analysis:
Factor Analysis
Factor Analysis Model Fit Options

– 0.00 to 0.49 unacceptable
– 0.50 to 0.59 miserable
– 0.60 to 0.69 mediocre
– 0.70 to 0.79 middling
– 0.80 to 0.89 meritorious
– 0.90 to 1.00 marvelous

**Note:** The KMO test is not available if the correlation matrix is singular.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

---

**Factor Analysis Model Fit Options**

The Factor Analysis Model Fit red triangle menu contains the following options:

**Prior Communality**  (Available only for Common Factor Analysis.) Shows or hides an initial estimate of the communality for each variable. For a given variable, this estimate is the squared multiple correlation coefficient (SMC), or RSquare, for a regression of that variable on all other variables.

**Eigenvalues**  (Available only for Common Factor Analysis.) Shows or hides the eigenvalues of the reduced correlation matrix and the percent of the common variance for which they account. The reduced correlation matrix is the correlation matrix with its diagonal entries replaced by the communality estimates. The eigenvalues indicate the common variance explained by the factors. The Cum Percent can exceed 100% because the reduced correlation matrix is not necessarily positive definite and can have negative eigenvalues. Note the table indicates the number of factors retained for analysis.
Unsorted and Unrotated Factor Loading  Shows or hides the factor loading matrix before sorting and rotation.

Unrotated Factor Loading  Shows or hides the factor loading matrix before rotation. Factor loadings measure the influence of a common factor on a variable. Because the unrotated factors are orthogonal, the factor loading matrix is the matrix of correlations between the variables and the factors. The closer the absolute value of a loading is to 1, the stronger the effect of the factor on the variable.

Use the slider and value to **Suppress Absolute Loading Values Less Than** the specified value in the table. Suppressed values appear dimmed according to the setting specified by **Dim Text**.

Use the **Dim Text** slider and value to control the table’s font transparency gradient for factor values less in absolute value than the specified **Suppress Absolute Loading Values Less Than** value.

Figure 9.7  Unrotated Factor Loading with Dim Text Controls

Note: The Unrotated Factor Loading matrix is ordered so that variables associated with the same factor appear next to each other.

Rotation Matrix  Shows or hides the values used for rotating the factor loading plot and the factor loading matrix.

Interfactor Correlations  (Available only for oblique rotations.) Shows or hides the matrix of correlations between factors.

Target Matrix  (Available only for the Promax rotation.) Shows or hides the matrix to which the varimax factor pattern is rotated.

Factor Structure  (Available only for oblique rotations.) Shows or hides the matrix of correlations between variables and common factors.

Final Communality Estimates  Shows or hides estimates of the communalities after the factor model has been fit. When the factors are orthogonal, the final communality estimate for a variable equals the sum of the squared loadings for that variable.
Standard Score Coefficients  Shows or hides a table of the multipliers used to estimate factor scores when saving rotated factors to the source data table.

Variance Explained by Each Factor  (Available only for orthogonal rotations.) Shows or hides the variance, percent, and cumulative percent, of common variance explained by each rotated factor.

Variance Explained by Each Factor Ignoring Other Factors  (Available only for oblique rotations.) Shows or hides the variance and percent of common variance explained by each rotated factor regardless of other factors.

Significance Test  (Available only for the Maximum Likelihood factoring method.) Provides the results of two Chi-square tests.

The first test is for H₀: No common factors. This null hypothesis indicates that none of the common factors explain the intercorrelations among the variables. This test is Bartlett’s Test for Sphericity, whose null hypothesis is that the correlation matrix of the factors is an identity matrix (Bartlett, 1954).

The second test is for H₀: N factors are sufficient, where N is the specified number of factors. Rejection of this null hypothesis indicates that more factors might be required to explain the intercorrelations among the variables (Bartlett, 1954). The Criterion is the log-likelihood objective function value.

Measures of Fit  (Available only for the Maximum Likelihood factoring method.) Shows or hides measures of fit: Chi-Squared without Bartlett’s Correction, AIC, BIC, Tucker-Lewis’s Index, and the root mean square error of approximation.

Measures of Factor Scores  Shows or hides measures of factor score determinacy: Multiple R, Multiple R Square, and Minimum Correlation. These measures are used to evaluate if the factor scores might be useful for secondary analyses.

Unsorted and Rotated Factor Loading  Shows or hides the unsorted factor loading matrix after rotation.

Rotated Factor Loading  Shows or hides the factor loading matrix after rotation. If the rotation is orthogonal, these values are the correlations between the variables and the rotated factors.

Use the slider and value to Suppress Absolute Loading Values Less Than the specified value in the table. Suppressed values appear dimmed according to the setting specified by Dim Text.

Use the Dim Text slider and value to control the table’s font transparency gradient. The lower the value, the more transparency the font for factor values less in absolute value than the specified Suppress Absolute Loading Values Less Than value.
Figure 9.8  Rotated Factor Loading with Dim Text Controls

Note: The Rotated Factor Loading matrix is ordered so that variables associated with the same factor appear next to each other.

Factor Loading Plot  Shows or hides a plot of the rotated factor loadings. When more than 2 factors are modeled, the loading plot is a matrix of plots.

Score Plot  Shows or hides a scatterplot of the estimated factor scores. When more than 2 factors are modeled, the score plot is a matrix of plots.

Score Plot with Imputation  (Available only if there are missing values.) Shows or hides a scatterplot of the estimated factor scores with imputed values for missing values.

Display Options  Enables you to show or hide arrows on the loading plots.

Save Rotated Factors  Saves the rotated factor scores and formulas to the data table.

Note: The formula cannot evaluate rows with missing values.

Remove Fit  Removes the fit model results from the Factor Analysis report. This option enables you to change the Model Launch configuration for a new report.
Multidimensional Scaling (MDS) is a technique that is used to create a visual representation of the pattern of proximities (similarities, dissimilarities, or distances) among a set of objects. For example, given a matrix of distances between cities, MDS can be used to generate a map of the cities in two dimensions.

Multidimensional Scaling is frequently used in consumer research where researchers have measures of perceptions about brands, tastes, or other product attributes. MDS is applicable to many other areas where one is interested in visualizing the proximity of objects based on a set of attributes or proximities.

Overview of the Multidimensional Scaling Platform

The Multidimensional Scaling platform generates a plot of proximities among a set of objects. This plot can be used to visually explore structure in a data set. MDS is a multivariate technique that is used to visualize the patterns of proximities (distances, similarities) among a set of objects in a small number of dimensions. MDS is applied to a distance matrix. The coordinates for the MDS plot are obtained by minimizing a stress function (the difference between the actual and predicted proximities).

The term distance can refer to a measure of physical distance, such as between cities. More often distance is a subjective assessment rather than a precise measurement. Proximities can measure perceived similarities between brands of a product, correlations of crime rates, or economic similarities for a sample of countries. Distance can also be called proximity or similarity (dissimilarity). If the data are given as an attribute list, then a distance matrix is first constructed from the attribute list.

For more information about multidimensional scaling, see Borg and Groenen (2005) or Jackson (2003).

Example of Multidimensional Scaling

This example uses the Flight Distances.jmp sample data table, which is a distance matrix of flight distances between 28 US cities. You can use MDS to construct a map of the cities in two dimensions that is based on the pairwise distances in the data table.

1. Select Help > Sample Data Library and open Flight Distances.jmp.
2. Select Analyze > Multivariate Methods > Multidimensional Scaling.
Figure 10.2 Completed Multidimensional Scaling Launch Window

4. Click **OK**.

   In the Multidimensional Scaling Plot, hover over data points to view the row number or row label. The next 7 steps are to label and rotate your MDS Plot.

5. Select the Flight Distances data table.

6. Right-click the column Cities and select **Label/Unlabel**.

7. Select **Rows > Row Selection > Select all Rows**.

8. Select **Rows > Label/Unlabel**.

9. Select the Multidimensional Scaling Plot.

10. Click the **Flip Vertical** button.

11. Click the **Flip Horizontal** button.

   The Flip Vertical and Flip Horizontal buttons enable you to change the orientation of the MDS Plot. The MDS results are invariant to orientation. When the results have a known orientation, such as physical locations, then you might want to rotate or flip your plot.

Launch the Multidimensional Scaling Platform

Launch the Multidimensional Scaling Platform by selecting **Analyze > Multivariate Methods > Multidimensional Scaling.**

**Figure 10.4** Multidimensional Scaling Launch Window

For more information about the options in the Select Columns red triangle menu, see *Using JMP.*

**Y, Columns**  The columns to be analyzed. These must have a Numeric data type.

**By**  A column or columns whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed using the other variables that you have specified. The results are presented in separate reports. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

**Note:** When using a distance matrix, the By variable requires a full matrix for each level of the By variable.

**Data Format**  MDS supports two data formats:

**Distance Matrix**  A full symmetric, lower, or upper triangular matrix where the number of rows equals the number of columns. The diagonal entries can either be zeros or missing.

**Attribute List**  A set of columns that contain measures of a quality or characteristic of an object. The objects are typically named in a column. The object column is not used in the analysis but rather is used as a label for the data points on the MDS plot.

**Transformation**  Supported transformations are Ratio, Interval, and Ordinal.
None  No transformation used.

Ratio  Data has an ordering from smallest to largest, the differences between values have meaning, and the scale has a true zero. Used to scale the MDS plot.

Interval  Data has an ordering from smallest to largest and the differences between values have meaning. Used to scale and shift the MDS plot.

Ordinal  Data has an ordering from smallest to largest. Used for ordinal data.

Set Dimensions  The number of dimensions for the visual representation of the proximities among your objects. Typically, two or three dimensions are used. With greater than three dimensions, the visualization becomes complex.

Note: The dimension selected can be between 1 to n - 1 where n = the number of objects, otherwise the dimension is set to 2.

The Multidimensional Scaling Report

The initial Multidimensional Scaling report shows these reports: Multidimensional Scaling Plot, the Shepard Diagram, and the Fit Details. If you specify three or more dimensions for the fit in the launch window, then the Multidimensional Scaling Plot provides controls for selecting the dimensions that you view.

Objects that are close together on the MDS plot share similar attributes. Adding labels and colors to the plot can help in the identification of similar groups. The Shepard diagram and summary of fit statistics provide measures of how well the MDS plot represents the proximities of the objects.

Multidimensional Scaling Plot

The MDS plot displays the multidimensional scaling in two dimensions. Below the plot are two buttons to flip the axis either in the vertical or horizontal direction. The MDS solution can be reflected, rotated, or translated without changing the inter-point proximities. The rotating or reflection of the axes is most common when working with geographical objects that have a known map orientation.

If more than two dimensions were used in the analysis, then you can toggle the dimensions shown in the plot using the Select Dimension controls below the plot. The first control defines the horizontal axis of the plot, and the second control defines the vertical axis of the plot.
Shepard Diagram

The Shepard plot is a plot of the actual or transformed proximities versus the predicted proximities. The plot indicates how well the Multidimensional Scaling Plot reflects the actual proximities. The Shepard is analogous to an Actual by Predicted plot. Ideally the points fall on the \( Y = X \) line, which is shown in red.

Fit Details

The Fit Details provides statistics that summarize how well the MDS proximities match the actual proximities as well as details about transformations when used.

**Stress**  
The value of the stress function (Stress1) that was minimized in the fitting procedure. Stress can be between 0 and 1 with lower values indicating a better fit.

**RSquare**  
The \( R^2 \) value for linear fit of the actual or transformed proximities versus the predicted proximities.

**Slope**  
If a ratio or interval transformation was used, the slope for the transformation is provided. It is the slope of the linear regression of the actual against transformed proximities.

**Intercept**  
If an interval transformation was used, the intercept for the transformation is provided. It is the intercept of the linear regression of the actual against transformed proximities.

Multidimensional Scaling Platform Options

The Multidimensional Scaling red triangle menu options give you the ability to customize reports according to your needs. The options available are determined by the type of data and the number of dimensions that you use for your analysis.

**MDS Plot**  
Shows or hides the MDS Plot.

**Diagnostics**  
Provides diagnostics for the MDS.

- **Shepard Diagram**  
  Shows a plot of actual proximity (or transformed proximity if a transformation is used) versus the predicted proximity. This report appears by default. See Shepard Diagram.

- **Waern Links**  
  Displays the Waern links on the MDS plot. Controls for the portion (smallest or largest) are available when this option is selected. See Waern Links.
Show Coordinates  Provides a report of the solution coordinates. These are the coordinates of the points on the Multidimensional Scaling Plot. The report shows the coordinates of up to three dimensions. Right-click in the report and select Columns to add additional dimensions to the report. The maximum number of dimensions is the number of dimensions set in the launch window.

Show Proximity  Provides a report of the proximities. The original and derived proximities (distances) are provided between each pair of objects. The pairs are identified in the From and To object columns. If a transformation was used, the transformed proximities are also included in the table.

Save Proximity  (Available only if Attribute List is the data format.) Saves the distance matrix to the data table.

3D Plot  (Available only if three or more dimensions are specified for Set Dimensions in the launch window.) Shows a 3-D plot of the first three dimensions.

Save Coordinates  Saves the solution coordinates to the data table in separate columns.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Waern Links

Waern links provide a visual check of the MDS results by comparing actual proximities to predicted proximities. The links join points on the Multidimensional Scaling Plot based on their actual proximities. The objects with the smallest (largest) proximities are connected. A typical scenario to consider is the smallest 33% of the proximities between objects. If the MDS Plot is a good representation of the proximities, then the links for the smallest actual proximities should connect the closest objects in the plot. If a link for a small proximity stretches across the plot connecting distant objects, then the MDS fit would be questioned.
**Waern Link Controls**

There is a list from which you can choose to show the Smallest Portion or the Largest Portion of links on the plot. The portion of links shown is controlled by entering a value in the box or by using the slider. Figure 10.5 shows Waern links for the *Teeth.jmp* data table for the 33% smallest portion.

For more information about Waern links, see Waern (1972).

**Figure 10.5** MDS Plot with Waern Links
Additional Example of the Multidimensional Scaling Platform

This example uses the Teeth.jmp sample data table, which is an attribute list of the counts of eight teeth types in 32 mammals. You can use MDS to explore the similarities of mammals based on their teeth. An interval transformation is used to illustrate the output from that transformation. The data do have an ordering that has a meaning (four teeth are twice as many as two teeth). One might explore other transformations such as the ordinal transformation.

1. Select Help > Sample Data Library and open Teeth.jmp.
2. Right-click the column MAMMAL and select Label/Unlabel.
3. Select Rows > Row Selection> Select all Rows.
4. Select Rows > Label/Unlabel
5. Select Analyze > Multivariate Methods > Multidimensional Scaling.
6. Select Top incisors through Bottom molars and click Y, Columns.
7. Select Data Format > Attribute List.
8. Select Transformation > Interval.
9. Click OK.
The Shepard Diagram and the Fit Details indicate that the MDS Plot is a good representation of similarities of animals due to similarities in their teeth. The Stress statistics of 0.093 is low and the $R^2$ fit of the transformed versus predicted proximities is
high at 0.96. In addition, the Fit Details provides the intercept and slope for the transformation of the actual proximities.

Statistical Details for the Multidimensional Scaling Platform

JMP uses a quasi Newton optimization method to minimize the Stress function to determine the MDS coordinates. This minimization leads to a set of coordinates in a predetermined number of dimensions that minimize the derived proximity measures for each pairwise set of the dimensions. When the data is ordinal, monotonic regression is used. Otherwise, standard least squares regression is used.

- "Stress"
- "Transformations"
- "Attributes List Format"

Stress

The following notation is used to define Stress:

- i, j - indexes for the number of objects
- \( d_{ij} \) - the derived distance between objects i and j
- \( \delta_{ij} \) - the observed relative distance between objects i and j
- \( f(\delta_{rs}) \) - transformation function for the distance

The Stress function is defined as follows:

\[
\text{Stress} = \left[ \frac{\sum_{i<j} [f(\delta_{ij}) - d_{ij}]^2}{\sum_{i<j} d_{ij}^2} \right]^{1/2}
\]

This measure of stress is also known as Kruskal’s Stress, Type I, or simply Stress1.
Transformations

The section uses the notation described in “Stress” on page 249. Transformations are used to scale the actual proximities. Transformations would be considered to improve the MDS representation of the actual proximities by taking into account specific structures in the data. The parameters in the transformation functions become additional parameters in the minimization algorithm.

**Ratio Transformation**

For ratio data:

\[
f(δ_{rs}) = bδ_{rs}\]

**Interval Transformation**

For interval data:

\[
f(δ_{rs}) = a + bδ_{rs}\]

**Ordinal Transformation**

For ordinal data the data is not transformed, rather the algorithm uses monotone regression rather than least squares regression.

**Attributes List Format**

When the data is an attributes list, it is converted to a distance matrix and then MDS is applied. The distance matrix is calculated using Euclidean distance. For each pair of items define the distance between the items by:

\[
δ_{ij} = \sqrt{\frac{\sum (x_{ki} - x_{kj})^2}{k}}
\]

where \(k\) is the number of attributes.

**Note:** For an advanced example of the MDS platform, see the San Francisco Crime Distances.jmp sample data table and the source script for that table. The script creates the distance matrix using pairwise correlations. The resulting distance matrix is then used to explore the relationships between crime categories.
The Item Analysis platform enables you to fit *item response theory* models. The Item Response Theory (IRT) method is used for the analysis and scoring of measurement instruments such as tests and questionnaires. Item response theory uses a system of models to relate a trait or ability to an individual’s probability of endorsing or correctly responding to an item. Frequently, the trait or ability of interest is not directly measurable and is therefore called *latent*. IRT can be used to study standardized tests, cognitive development, and consumer preferences. IRT is an alternative method to classical test theory (CTT) where the focus is on the total observed score rather than the item scores.

The Item Analysis platform implements the IRT method with the following outcomes:

- Measurement instruments are scored at the item level, providing insight into the contributions of each item on the latent response.
- Scores for both the responders and the items are produced on the same scale.
- Respondent and item scores are shown on a single plot.
- Item characteristic curves are shown. These curves can be used to explore the relationship between items and respondent’s underlying trait or ability.

For more information about item response theory, see de Ayala (2009).

Example of Item Analysis

This example uses the MathScienceTest.jmp sample data table, which is a subset of the data from the Third International Mathematics and Science Study (TIMSS) conducted in 1996. The data table contains scores (1 = correct or 0 = incorrect) for 1263 students on 14 questions. You examine the first four questions to understand the relationship between questions and respondent’s mathematical ability. The questions on the test are the items that are used to measure the latent mathematical ability. Fit a 2PL model to this data.

2. Select Analyze > Multivariate Methods > Item Analysis.
3. Select Q1 through Q4, click Y, Test Items and click OK.
From the dual plot you note that Q4 is the easiest of the four questions to answer as it has the lowest difficulty score at -1.78. Q3 is the hardest with a difficulty score of 0.46. Most of the respondents fall in the middle to lower end of the ability scale as shown by the data points in the center part of the graph. In the histogram, you can see that approximately 40% of the respondents fall slightly above zero on the ability scale.

**Note:** Ability scores are not computed for individuals with all incorrect or all correct answers. See “Fitting the IRT Model” on page 265.
4. Click the gray Characteristic Curves report disclosure icon to open.
5. Click the Item Analysis red triangle and select **Number of Plots Across**.
6. Enter 2 and click **OK**.
7. Click the gray Information Plot report disclosure icon to open.

**Figure 11.3** Item Response Example

Q1 has a flat characteristic curve and a flat information curve. This suggests that Q1 does not provide much information to discriminate respondents’ mathematical ability. The characteristic curve for Q2 is steep, which indicates that Q2 is useful for discriminating respondent ability. The vertical line in each plot is at the inflection point for the characteristic curve. This vertical line is the ability level at which the respondent has a 50% probability of answering the specified question correctly.

The information plot indicates that together the four questions analyzed provide the most information about ability levels between about -1 and 0. Including more questions of higher difficulty in the model could broaden the information curve.
Launch the Item Analysis Platform

Launch the Item Analysis platform by selecting Analyze > Multivariate Methods > Item Analysis.

Figure 11.4 Item Analysis Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Y, Test Items Assigns two or more columns to be analyzed. The columns must be numeric, continuous, and contain only 0s and 1s.

Tip: Use Cols > Recode if you need to recode your data to 0s and 1s. See Using JMP.

Freq Assigns a frequency variable to this role. This is useful if your data are summarized.

By Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variable.

Model Specifies the desired model from the following options:

- Logistic 2PL The 2-parameter logistic model.
- Logistic 3PL The 3-parameter logistic model.
- Logistic 1PL The 1-parameter logistic model with a Rasch parameterization.
Logistic 3PL Model Details

If you select Logistic 3PL for Model, you are prompted to enter a penalty for the guessing parameters after you click OK. For a 3PL model, the default value of the penalty is zero. However, you can enter a non-zero penalty for the c parameters (the guessing for each item). This penalty is similar to the type of penalty parameter that you would use in ridge regression. The penalty is on the variance of the estimated guessing parameters. The use of the penalty has the following benefits:

- Stabilizes the estimation of model parameters.
- Speeds up computations.
- Reduces the variability of the guessing parameter across items at the expense of some bias.

Large values of the penalty force the guessing parameters to zero while smaller values help reduce the variability of the guessing parameter across items. A value of zero can be used for no penalty.

Data Format

The Item Analysis platform requires a data table that contains a row for each individual and a column for each item. The item columns must be numeric and contain only 0s and 1s to indicate incorrect or correct responses, respectively. The MathScienceTest.jmp sample data table illustrates the required data format for an item response analysis of 1,263 individuals responses to 14 test questions.

The Item Analysis Report

- “Characteristic Curves”
- “Information Plot”
- “Dual Plot”
- “Parameter Estimates”

Characteristic Curves

The Characteristic Curves contains an item characteristic curve (ICC) for each item that you specified in the launch window. The Characteristic Curves are initially closed.
The item characteristic curve plots the probability of answering an item correctly versus ability. Ability is measured on a standardized scale, so a respondent with ability equal to 0 is a respondent of average ability. Data points for the observed probability of correct answers for fixed ability levels are plotted. Comparing the fitted characteristic curve to the data points provides a visual measure of goodness of fit of the model for each individual item. In addition, the characteristic plots have a background information curve and a vertical line at the characteristic curve inflection point. The background information curve is a plot of the slope of the item characteristic curve, which is maximized at the inflection point.

**Figure 11.5 Item Characteristic Curve**

![Image of Item Characteristic Curve](image)

**Tip:** You can adjust the number of characteristic curves that appear in each row of the report using the Number of Plots Across option in the Item Analysis red triangle menu.

**Information Plot**

The Information Plot report contains a plot of the overall information curve, which is constructed by summing the individual item information curves. The information plot provides insight into the appropriate ability levels that the test is able to measure. Figure 11.6 describes a test with items that are appropriate for assessing individuals with average to low levels of the ability more so than individuals with high levels of ability. This plot is initially closed.
Figure 11.6 Information Plot

Dual Plot

The Dual Plot report contains a plot that shows item difficulty and subject ability in one plot. Difficulty and ability use a common standardized scale shown on the y-axis. The items are plotted by their difficulty on the left side of the plot. The subjects are plotted to the right with data points and a histogram. The dual plot enables you to relate the difficulty of each item to the ability of each respondent.
Parameter Estimates

The Parameter Estimates report contains a table of estimated parameters for each item. The parameters provided depend on the model used in your analysis (1PL, 2PL, or 3PL).

Item  The test item.

Difficulty  The $b$ parameter or the measure of the difficulty of the item. A histogram of the difficulty parameters is shown beside the difficulty estimates.

Discrimination  (Available only for 2PL and 3PL models.) The $a$ parameter or the measure of the item discrimination. A histogram of the discrimination parameters is shown beside the discrimination estimates.

Lower Asymptote  (Available only for 3PL models.) The $c$ parameter or a measure of guessing.
Item Analysis Platform Options

**Number of Plots Across** Enables you to specify how many ICC plots to display in each row of plots in the Characteristic Curve report. The default is one ICC plot per row.

**Save Ability Formula** Saves the ability formula to a new column in the data table. This option uses the `IRT Ability()` JSL function. For more information about this function, see Help > Scripting Index.

See *Using JMP* for more information about the following options:

**Redo** Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script** Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script** Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Statistical Details for the Item Analysis Platform

Item response theory (IRT) uses a series of equations to relate items to an unobserved (latent) trait or ability. Items, or questions, are indicators of an underlying latent construct that cannot be directly observed. At the time of data collection, both the subject abilities and the item characteristics are unknown.

- “Item Response Curves”
- “Item Response Curve Models”
- “IRT Model Assumptions”
- “Fitting the IRT Model”
- “Ability Formula”
Item Response Curves

Item response curves (item characteristic curves) are used to describe the relationship between the ability, defined on an *ability* scale, and each item. An item response curve plots the probability of correctly answering an item against different levels of ability. An item with perfect discrimination has a 0% probability of correct answers for respondents with ability below a threshold and a 100% probability of a correct response for subjects with ability above the threshold.

**Figure 11.8** Characteristic Curve for an Item with Perfect Discrimination

A typical relationship between the probability of correctly answering an item and ability is an S-shaped function with lower and upper asymptotes. As a respondent’s ability increases, their probability of correctly answering the item increases to 100%. The shape of the curve for a specific item is related to the difficulty and discriminatory properties of the item.

**Figure 11.9** Typical Item Response Curve
Item Response Curve Models

One-, two-, and three-parameter logistic models can be used to model the item response curves. The three-parameter logistic (3PL) model is defined as follows:

$$P(\theta) = c + \frac{1 - c}{1 + e^{-(a)(\theta - b)}}$$

- $P(\theta)$ is the probability of answering the item correctly for an ability level $\theta$. For more information about fitting the item response theory model, see “Fitting the IRT Model” on page 265.
- The $a$ parameter defines the steepness of the curve at its inflection point. It provides an estimate of the discriminatory power of the item.
- The $b$ parameter defines the location of the inflection point on the Ability axis. It provides an estimate of the difficulty of an item.
- The $c$ parameter is the lower asymptote. It provides an estimate of the probability that an item is answered correctly by guessing.
- For the 2PL model, the $c$ parameter is set to 0.

$$P(\theta) = \frac{1}{1 + e^{-(a)(\theta - b)}}$$

- For the 1PL model, the $c$ parameter is set to 0 and the $a$ parameter is set to 1. This parameterization is also known as the Rasch model (Rasch 1980).

$$P(\theta) = \frac{1}{1 + e^{-(\theta - b)}}$$

The $a$ Parameter: Item Discrimination

In the 2PL and 3PL models, the $a$ parameter, or the steepness of the curve at its inflection point, provides a measure of the discriminatory power of an item. The discriminatory power, or discrimination, of an item refers to how well an item can distinguish between respondents with low ability levels versus those with high ability levels. A steep item response curve indicates that the item has strong discrimination. Respondents with low ability levels have a low probability of a correct response to the item while respondents with high ability have a high probability of a correct response. Items whose curves are relatively flat have low discrimination. Items with low discrimination are candidates to be dropped from the measurement instrument.
The **b Parameter: Item Difficulty**

The $b$ parameter, or the location of the inflection point with respect to ability, provides a measure of item difficulty. Item response curves with inflection points farther to the right on the ability scale are indicative of items that are more difficult to answer than items with inflection points to the left. In the 1PL and 2PL models, the $b$ parameter provides an estimate of the ability level required for a 50% probability of correctly answering the item.

**Figure 11.11  Logistic Curve for Several Values of $b$**

The **c Parameter: Guessing**

In the 3PL model, the $c$ parameter, or the lower asymptote of the item response curve, provides a measure of the guessing parameter. A nonzero lower asymptote represents the nonzero probability of a person with a very low ability level answering an item correctly.

---

**Figure 11.12** Logistic Model for Several Values of $c$

![Logistic Model Graph]

---

**IRT Model Assumptions**

The 2PL model is the default model in the Item Analysis platform. The 1PL model is appropriate when you can assume that all items have equal discriminating power. When this assumption is not appropriate, the 2PL or 3PL model should be used. The 2PL model has greater numerical stability than the 3PL model, especially for small data sets. In addition, in the 2PL model, $b$ can be interpreted as the ability level required for a 50% chance of a responder answering an item correctly.

The IRT model assumes that the underlying trait is unidimensional. That is, there is a single underlying latent construct. If there are several traits that have complex interactions with each other being measured, then a unidimensional model is not appropriate. The IRT model is appropriate for continuous latent variables. For a categorical latent variable, you should consider a latent class model. See the “Latent Class Analysis” chapter on page 329. IRT models are assumed to be item-invariant. Item-invariance means that $P(\theta)$ is interpreted as the probability of a correct response for a set of individuals with ability level $\theta$. If a large group of individuals with equal ability levels answered the item, $P(\theta)$ predicts the proportion who would answer the item correctly. This implies that IRT models would have the same parameters regardless of the group of subjects tested. In addition, the IRT model assumes local independence, which means that once the latent construct has been accounted for, the items are independent of one another.

---

**Fitting the IRT Model**

The IRT model is fit using Marginal Maximum Likelihood estimation (MMLE). MMLE is an alternative method to Joint Maximum Likelihood estimation (JLE). MMLE treats the subjects as random effects. The items and abilities are related as conditional probabilities. The formulas are defined as follows:

$$p(x|\theta, \theta) = \prod_{j=1}^{L} p_j(\theta)^{x_j}(1 - p_j(\theta))^{1-x_j}$$
where \( p(x|\theta, \varnothing) \) is the probability of a response vector \( x \) given the subject ability \( \theta \) and the vector of item parameters \( \varnothing \). The number of item parameters depends on the model used (1PL, 2PL, or 3PL).

MMLE integrates out the subject effects using Gaussian quadrature to obtain item parameter estimates. The probability of response vector \( x \) is calculated as follows:

\[
p(x) = \int_{-\infty}^{\infty} p(x|\theta, \varnothing) g(\theta|\nu) d\theta
\]

where \( g(\theta|\nu) \) is the distribution of the subjects and \( \nu \) is a vector of the population location and scale parameters. The normal distribution with mean 0 and standard deviation 1 is used for \( g(\theta|\nu) \) in JMP.

**Note:** A missing value for a test question is treated as an incorrect response. Ability scores are not calculated for individuals with all incorrect or all correct answers. The patterns of the responses for these subjects are included in the model estimation.

The MMLE procedure for fitting the IRT model can be compared to fitting a random effects model in two stages. The ability parameters are treated as random effects with variance of 1. In the first step, these random effects are integrated out using Gaussian quadrature. The item parameters are treated as fixed effects that are estimated using ML from the marginal likelihood with the ability parameters integrated out. The ability parameters are in essence best linear unbiased predictions that are estimated using the full unintegrated (joint) likelihood, treating the item parameters as known and held fixed at the values obtained in the first stage.

There are \( 2^L \) patterns of responses for \( L \) items. The ability level for each pattern can be calculated by finding the ability level with the highest probability for the response pattern by applying the following until \( \theta \) converges:

\[
\theta^{t+1}_i = \theta^t_i - \frac{\sum_{j=1}^{L} p_{ij}(t) X_i - \sum_{j=1}^{L} p_{ij}(t)(1 - p_{ij}(t))}{\sum_{j=1}^{L} p_{ij}(t)(1 - p_{ij}(t))}
\]

where:

\( \theta \) maximizes the likelihood of obtaining the response pattern
\( t \) is the number of iterations
\( L \) is the number of items
\( X_i \) is the observed score
$p_{ij}$ is the probability of a correct response on the $j^{th}$ item by the $i^{th}$ person based on the item parameters.

**Ability Formula**

The Save Ability Formula option from the Item Analysis red triangle menu saves the ability formula to a new column in the data table. This formula can be used to score additional subjects added to the data table or it can be copied to a new table to score a new set of subjects.

The function saved to the data table is called the IRT Ability function. The item parameter estimates are stored in a matrix in this function. For more information about this function, see Help > Scripting Index.
Hierarchical Clustering is a multivariate technique that groups together observations that share similar values across a number of variables. Use it to understand the clumping structure of your data.

Hierarchical clustering combines clusters successively. The method begins by treating each observation as its own cluster. Then, at each step, the two clusters that are closest in terms of distance are combined into a single cluster. The result is depicted as a tree, called a dendrogram.

Use hierarchical clustering for small data tables with no more than several tens of thousands of rows. The algorithm is time-intensive and can run slowly for larger data tables. For larger data tables, use K Means Cluster or Normal Mixtures.

**Note**: Hierarchical cluster supports character columns; K Means Cluster or Normal Mixtures require numeric columns.

Overview of the Hierarchical Clustering Platform

Hierarchical Clustering is one of four platforms that JMP provides for clustering observations. For a comparison of all four methods, see “Overview of Platforms for Clustering Observations” on page 271.

The hierarchical clustering method starts with each observation forming its own cluster. At each step, the clustering process calculates the distance between all pairs of clusters and combines the two clusters that are closest together. This process continues until all the points are contained in one cluster. Hierarchical clustering is also called agglomerative clustering because of the combining approach that it uses.

The agglomerative process is portrayed as a tree, called a dendrogram. To help you decide on a number of clusters, JMP provides a distance graph. You can select a number of clusters by determining when the distances between clusters no longer appear to be of practical importance.

Hierarchical clustering also supports character columns. There are two ways to define the distances.

- If a column is ordinal, then the value used for clustering is the index of the ordered category, treated as if it were continuous data. These values are standardized as if they were continuous data.
- If a column is nominal, then the distance between two observations where the categories match is zero. If the categories differ, the distance is one.

Hierarchical clustering enables you to choose among five rules for defining distances between clusters: Average, Centroid, Ward, Single, and Complete. Each rule can generate a different sequence of clusters.

Tip: The hierarchical clustering process starts with \( n(n + 1)/2 \) distances for \( n \) observations, except when the Fast Ward method is used. For this reason, this method can take a long time to run when \( n \) is large. For large numbers of numeric observations, consider K Means Cluster or Normal Mixtures.

Overview of Platforms for Clustering Observations

Clustering is a multivariate technique that groups together observations that share similar values across a number of variables. Typically, observations are not scattered evenly through \( p \)-dimensional space, where \( p \) is the number of variables. Instead, the observations form clumps, or clusters. Identifying these clusters provides you with a deeper understanding of your data.
Note: JMP also provides a platform that enables you to cluster variables. See the “Cluster Variables” chapter on page 345.

JMP provides four platforms that you can use to cluster observations:

- Hierarchical Cluster is useful for smaller tables with up to several tens of thousands of rows and allows character data. Hierarchical clustering combines rows in a hierarchical sequence that is portrayed as a tree. You can choose the number of clusters that is most appropriate for your data after the tree is built.

- K Means Cluster is appropriate for larger tables with up to millions of rows and allows only numerical data. You need to specify the number of clusters, $k$, in advance. The algorithm guesses at cluster seed points. It then conducts an iterative process of alternately assigning points to clusters and recalculating cluster centers.

- Normal Mixtures is appropriate when your data come from a mixture of multivariate normal distributions that might overlap and allows only numerical data. For situations where you have multivariate outliers, you can use an outlier cluster with an assumed uniform distribution.

  You need to specify the number of clusters in advance. Maximum likelihood is used to estimate the mixture proportions and the means, standard deviations, and correlations jointly. Each point is assigned a probability of being in each group. The EM algorithm is used to obtain estimates.

- Latent Class Analysis is appropriate when most of your variables are categorical. You need to specify the number of clusters in advance. The algorithm fits a model that assumes a multinomial mixture distribution. A maximum likelihood estimate of cluster membership is calculated for each observation. An observation is classified into the cluster for which its probability of membership is the largest.
Some of the clustering platforms have options to handle outliers in the data. However, if your data has outliers, it is best to explore them first prior to analyzing. This can be done using the Explore Outliers Utility. For more information, see the Modeling Utilities chapter in *Predictive and Specialized Modeling*.

### Example of Clustering

In this example, we group together countries by their 2009 crude birth and death rates per 1,000 people.

1. Select Help > Sample Data Library and open Birth Death Subset.jmp
2. Select Analyze > Clustering > Hierarchical Cluster.
4. Select country and click Label.
   This selection ensures that the country column, rather than the row number, is used to label the dendrogram that appears when you click OK.
5. Click OK.
6. Click the Hierarchical Clustering red triangle and select Color Clusters.

---

The dendrogram shows how the clustering is conducted. The clustering process can be viewed by reading the dendrogram from left to right. Each step consists of combining the two closest clusters into a single cluster.

In the dendrogram, the relative distances between clusters are given by the horizontal distances between vertical lines that join the clusters. For example, Afghanistan and Zaire differ more than Malaysia differs from the cluster consisting of Mexico and Venezuela.

The plot that appears beneath the dendrogram has a point for each step where two clusters are joined into a single cluster. The horizontal coordinates represent the numbers of clusters and they decrease from left to right. The vertical coordinate of the point is the distance between the two clusters that are joined to form the specified number of clusters. You can click either diamond in the dendrogram and drag the line to choose the number of clusters that best represent the data. You can also use the Number of Clusters option in the Hierarchical Clustering red triangle menu to choose the number of clusters.

The distance graph has a noticeable change in slope at four clusters. The change in slope indicates that the differences in clusters that are joined up to the point where four clusters remain, are comparatively small. This suggests that four is a good choice for the number of clusters. Note that this is the number of clusters that was shown by default.
7. Click the Hierarchical Clustering red triangle and select **Constellation Plot**.

**Figure 12.3** Constellation Plot

This constellation plot arranges the countries as endpoints and each cluster join as a new point. The lines represent membership in a cluster. The length of a line between cluster joins approximates the distance between the clusters that were joined. The constellation plot indicates that the cluster that contains Afghanistan and Zaire is about as distant from the cluster of remaining countries as are the two clusters that consist of the remaining countries in the upper half of the plot and those in the lower half of the plot.
Launch the Hierarchical Cluster Platform

Launch the Hierarchical Cluster platform by selecting Analyze > Clustering > Hierarchical Cluster.

Figure 12.4 Hierarchical Cluster Launch Dialog

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Y, Columns The variables used for clustering observations.

Ordering Sorts clusters by their mean values based on the specified column.

Tip: Use the first principal component obtained by conducting a principal components analysis as an Ordering column. The clusters are sorted by these values.

Attribute ID (Available only if Data is stacked is selected as the data structure.) Specifies the variables that are stacked.

Object ID (Available only if Data are summarized or Data is stacked is selected as the data structure.) A column or columns that provide a unique identifier for each unit for which measurements are stacked.

Label A column of values used to label the dendrogram in the report.

Note: If the selected data structure is Data is distance matrix, the Label column must have a character data type.
**By**  A column whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed. The results are presented in separate reports. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

The launch window has the following menus and options:

- “Clustering Method”
- “Method for Distance Calculation”
- “Data Structure”
- “Transformations to Y, Columns Variables”

**Clustering Method**

Hierarchical is the default clustering method, but the dialog enables you to switch to KMeans or Normal Mixtures. If you select KMeans or Normal Mixtures, when you click OK, a Control Panel appears where you can select any of the following as Method:

**K-Means Clustering**  See the “K Means Cluster” chapter on page 297.

**Normal Mixtures**  See the “Normal Mixtures” chapter on page 315.

**Robust Normal Mixtures**  See “Normal Mixtures Report” on page 323 in the “Normal Mixtures” chapter.

**Self Organizing Map**  See “Self Organizing Map” on page 310 in the “K Means Cluster” chapter.

**Method for Distance Calculation**

Select a method used to calculate distances. For distance formulas, see “Distance Method Formulas” on page 295.

**Ward**  In Ward’s minimum variance method, the distance between two clusters is the ANOVA sum of squares between the two clusters summed over all the variables. At each generation, the within-cluster sum of squares is minimized over all partitions obtainable by merging two clusters from the previous generation. The sums of squares are easier to
interpret when they are divided by the total sum of squares to give the proportions of variance (squared semipartial correlations).

Ward’s method joins clusters to maximize the likelihood at each level of the hierarchy under the assumptions of multivariate normal mixtures, spherical covariance matrices, and equal sampling probabilities.

Ward’s method tends to join clusters with a small number of observations and is strongly biased toward producing clusters with approximately the same number of observations. It is also very sensitive to outliers. See Milligan (1980).

**Average**  The distance between two clusters is the average distance between pairs of observations. Average linkage tends to join clusters with small variances and is slightly biased toward producing clusters with the same variance. See Sokal and Michener (1958).

**Centroid**  The distance between two clusters is defined as the squared Euclidean distance between their means. The centroid method is more robust to outliers than most other hierarchical methods but in other respects might not perform as well as Ward’s method or average linkage. See Milligan (1980).

**Single**  The distance between two clusters is the minimum distance between an observation in one cluster and an observation in the other cluster. Single linkage has many desirable theoretical properties but has performed poorly in Monte Carlo studies. See Jardine and Sibson (1971), Fisher and Van Ness (1971), Hartigan (1981), and Milligan (1980). Single linkage was originated by Florek et al. (1951a, 1951b) and later reinvented by McQuitty (1957) and Sneath (1957).

By imposing no constraints on the shape of clusters, single linkage sacrifices performance in the recovery of compact clusters in return for the ability to detect elongated and irregular clusters. Single linkage tends to chop off the tails of distributions before separating the main clusters. See Hartigan (1981).

**Complete**  The distance between two clusters is the maximum distance between an observation in one cluster and an observation in the other cluster. Complete linkage is strongly biased toward producing clusters with approximately equal diameters and can be severely distorted by moderate outliers. See Milligan (1980).

**Fast Ward** Applies an algorithm that computes Ward’s method more quickly for large numbers of rows. The computation time is shorter because this algorithm does not require the calculation of a distance matrix. It is used automatically whenever there are more than 2,000 rows.
Data Structure

These options describe the form of the data that is used in calculating multivariate distances:

**Data as usual** Data that are rectangular with one row for each observation and one column for each variable.

**Data as summarized** Data that are summarized by the levels of one or more identifying columns. When you select this option, an Object ID text box appears in the launch window. Specify the identifying columns as the Object ID. The **Data as summarized** option calculates level means and treats these means as your input data.

**Data is distance matrix** Data that consist of distances between observations. For $n$ observations, the distance table should have $n$ rows and $n + 1$ columns. One column (usually the first) must contain a unique identifier for each of the $n$ observations. The remaining columns contain distances between that observation and the $n$ observations. Note the following:

- The diagonal elements of the table should be zero or missing, because the distance between a point and itself is zero. Values that are not zero or missing are treated as zero, and a note appears in the report.

- The distance columns can be a symmetric square matrix, or they can be upper or lower triangular with missing entries in the lower or upper portion. If the distances are given as a square matrix, a warning appears in the report if the table is not symmetric.

- You can begin with a different data structure and then save a distance matrix. See “Save Distance Matrix” on page 287.

When you select the **Data is distance matrix** option, enter the distance columns as Y, Columns and the identifier column as Label. The Label column must have the Character data type. For an example, see “Example of a Distance Matrix” on page 288.

**Data is stacked** Data that have a single response of interest and multiple rows for each object.

When you select the **Data is stacked** option, Attribute ID and Object ID text boxes appear in the launch window.

- Enter a *single* column as Y, Columns.

- Enter columns that describe groupings of the Y, Columns variable as Attribute ID. If only two columns are entered and if you select Add Spatial Measures, then you can add spatial components to be used in the cluster analysis. See “Add Spatial Measures” on page 281.
Enter the identifying columns for objects as Object ID.

The analysis that is conducted is equivalent to splitting the Y, Column variable by the Attribute ID columns and then performing hierarchical clustering without standardizing the response columns.

**Tip:** Use this option together with the Add Spatial Measures option to perform two-dimensional spatial clustering. For example, wafer data are often recorded using one row for each die. Interest centers around clustering wafers. See “Example of Wafer Defect Classification Using Spatial Measures” on page 290.

**Caution:** Because there is a single measurement column, the Standardize Data option is not appropriate for stacked data.

### Not Enough Nonmissing Data Alert

The JMP alert **Not enough nonmissing data** can be difficult to understand when you are using the **Data as summarized** or **Data is stacked** data structures. The alert occurs in the following situations:

- **For Data as usual**, when all rows or all but one row are missing at least one value for a Y, Columns variable.
- **For Data as summarized**, when your data are summarized across the Object ID columns, all rows or all but one row are missing at least one value of the summarized Y, Column variables. To see the data structure that the Cluster platform is analyzing, select Tables > Summary, enter the Object ID columns as Group and the Y, Columns variables as Statistics > Mean.
- **For Data is stacked**, when your data are split across the Attribute ID columns, all rows or all but one row are missing at least one value of the split Y, Column values. To see the data structure that the Cluster platform is analyzing, select Tables > Split, enter the Attribute ID columns as Split By, the Y, Columns variable as Split Columns, and the Object ID columns as Group.

### Transformations to Y, Columns Variables

The following options specify the form of the Y, Columns variables to be used in the cluster analysis:

**Standardize Data**  Addresses the issue of different measurement scales for continuous and ordinal columns. Except when the **Data is stacked** option is selected, the values in each column are standardized by subtracting the column mean and dividing by the column standard deviation. Deselect the Standardize Data check box if you do not want the cluster distances computed on standardized values.
**Standardize Robustly**  Reduces the influence of outliers on estimates of the mean and standard deviation for continuous and ordinal columns. This option uses Huber M-estimates of the mean and standard deviation (Huber 1964; Huber 1973; Huber and Ronchetti 2009). For columns with outliers, this option gives the standardized values greater representation in determining multivariate distances.

**Note:** If both Standardize Data and Standardize Robustly are selected, each column is standardized by subtracting its robust column mean and dividing by its robust standard deviation. This option is useful when columns represent different measurement scales or when observations tend to be outliers in only specific dimensions.

**Note:** If Standardize Data is unchecked and Standardize Robustly is selected, the robust mean and robust standard deviation for the values in all columns combined are used to standardize each column. This option can be useful when columns all represent the same measurement scale and when observations tend to be outliers in all dimensions.

**Missing value imputation**  Imputes missing values. If the number of variables is either 50 or less, or less than half the number of rows, multivariate normal imputation is used. Otherwise, multivariate SVD imputation is used.

Multivariate normal imputation calculates pairwise covariances to construct a covariance matrix for the response columns. Then each missing value is imputed by a method that is equivalent to regression prediction using all the predictors with no missing values for the given observation. If the constructed covariance matrix is not positive definite, missing values are imputed using their column means.

Multivariate SVD imputation avoids constructing a covariance matrix by using the singular value decomposition. See *Predictive and Specialized Modeling*.

**Caution:** Missing value imputation assumes that there are no clusters, that the data come from a single multivariate normal distribution, and that the values are missing completely at random. Because these assumptions are usually not reasonable in practice, use this feature with caution. However, the feature can produce more informative results than discarding most of your data.

**Add Spatial Measures**  (Available only if Data is stacked is selected as the data structure.) Select the Add Spatial Measures option when your data are stacked and contain two attribute columns that correspond to spatial coordinates (horizontal and vertical coordinates, for example). This option opens a window in which you can select and weight spatial components to aid in clustering defect patterns. This is a specialty method and is applicable in only very specific settings. See “Spatial Measures” on page 293 and “Example of Wafer Defect Classification Using Spatial Measures” on page 290.
Hierarchical Cluster Report

The Hierarchical Cluster report displays the method used, a dendrogram, and the Clustering History table. If you assigned a column as a Label in the launch window, the column’s values identify each observation in the dendrogram.

- “Dendrogram Report”
- “Illustration of Dendrogram and Distance Graph”
- “Clustering History Report”

Dendrogram Report

The dendrogram is a tree diagram that represents the agglomeration of observations into clusters. The dendrogram also gives information about the degree of dissimilarity of clusters.

The clustering process can be viewed by reading the dendrogram from left to right. Each step consists of combining the two closest clusters into a single cluster.

- The joining of clusters is indicated by horizontal lines that are connected by vertical lines.
- The horizontal position of the vertical line represents the distance between the two clusters that are most recently joined to form the specified number of clusters.

Note: When the number of observations is less than 256, the distances are proportional to the distances shown in the Distance Graph. Otherwise, Geometric Spacing is used. See “Dendrogram Scale” on page 285.

You can perform the following tasks:

- Click and drag the diamond-shaped handle at either the top or bottom of the dendrogram to identify a given number of clusters.
- Click any cluster stem to select all the members of the cluster in the dendrogram and in the data table.

Distance Graph

The Distance Graph is the plot that appears beneath the dendrogram. This graph has a point for each step where two clusters are joined into a single cluster. The horizontal coordinates represent the numbers of clusters, which decrease from left to right. The vertical coordinate of the point is the distance between the clusters that were joined at the given step.
You can click and drag either diamond-shaped handle in the dendrogram to control the chosen number of clusters. When you click and drag the diamond, a vertical line appears in the plot that moves to correspond to the number of clusters. Often there is a point where the slope of the distance graph levels off. Such a point suggests a natural break and helps you determine the number of clusters.

**Illustration of Dendrogram and Distance Graph**

Consider the dendrogram report for Birth Death Subset.jmp in “Example of Clustering” on page 273.

**Figure 12.5** Dendrogram Report for Birth Death Subset.jmp

The diamonds are set at four clusters. The two clusters that are most recently joined to form the four cluster model are the cluster consisting of Algeria to Bangladesh and the cluster consisting of Iraq to Saudi Arabia. The distance between these two clusters is the point on the distance plot indicated by the vertical line when the diamond is set to 4. The distance is given in the Clustering History report next to Number of Clusters equal to 4. There, it is shown that the distance is 1.618708760 and that clusters beginning with Algeria and Iraq are combined to yield four clusters.
The two clusters that are combined to yield five clusters are the cluster that consists of Australia to Korea, South, and the cluster that consists of Austria to Korea, North. The vertical join line in the dendrogram for these clusters is at about the same horizontal distance from the left as the vertical join line for the clusters that were joined to form the four-cluster model, Algeria to Bangladesh and Iraq to Saudi Arabia. It follows that there is not much difference in terms of distance between the clusters joined to form the four-cluster model and those joined to form the five-cluster model.

The fact that the distance plot levels off starting with the four-cluster model indicates that the cluster groupings up to that point do not account for much distance between clusters. However, the four-cluster model shows good separation between clusters.

**Clustering History Report**

The Clustering History table contains the clustering history.

**Number of Clusters** Lists the numbers of clusters that result after the joining indicated by the Leader and Joiner is performed. The number of clusters begins with the first join, when there are \( n-1 \) clusters, where \( n \) is the number of objects. The report lists the number of clusters in decreasing order until all objects are contained in one cluster. In this way, the Clustering History follows the order of the dendrogram from left to right.

**Distance** The distance between clusters, calculated according to the distance method that you select on the launch window. See “Method for Distance Calculation” on page 277.

**Leader** A representative of the first cluster in the dendrogram being joined. The cluster order and the representative shown in the Leader column is a consequence of how the data are sorted and has no intrinsic meaning.

**Joiner** A representative of the second cluster in the dendrogram being joined. The cluster order and the representative shown in the Joiner column is a consequence of how the data are sorted and has no intrinsic meaning.

**Hierarchical Cluster Options**

The Hierarchical Clustering red triangle menu contains the following options:

**Color Clusters** Colors the labels for dendrogram and their associated join bars according to cluster membership. Also assigns the corresponding colors to the rows of the data table. The colors update if you change the number of clusters. If you deselect this option, the colors are no longer updated based on the number of clusters.
**Mark Clusters**  Assigns markers to the rows of the data table corresponding to the cluster to which the row belongs. The markers update if you change the number of clusters. If you deselect this option, the markers are no longer updated based on the number of clusters.

**Number of Clusters**  Prompts you to enter a number of clusters and positions the dendrogram slider to that number.

**Cluster Criterion**  Gives the Cubic Clustering Criterion (CCC) for the entire range of number of clusters. The CCC is used to estimate the number of clusters. It can be used with any distance-based clustering algorithm. Larger values of the CCC indicate better fit in terms of number of clusters. See SAS Institute Inc. (1983). (Not available when Data is distance matrix is selected.)

**Show Dendrogram**  Shows or hides the Dendrogram report.

**Dendrogram Scale**  Contains the following options for scaling the dendrogram:

- **Distance Scale**  Shows the horizontal distances between any two join points as the distances between the two clusters joined at that point, based on the distance method specified on the launch window. The distance scale is the same scale as used in the Distance Graph and is the default scale for the dendrogram.

- **Even Spacing**  Shows the horizontal distances between any two join points as equal.

- **Geometric Spacing**  Increases the horizontal distances between join points as the number of clusters increases. This option is useful when there are many objects and you want the smaller clusters to be more visible than the larger clusters.

**Distance Graph**  Shows or hides the distance plot beneath the dendrogram.

**Show NCluster Handle**  Shows or hides the handles on the dendrogram used to manually change the number of clusters.

**Zoom to Selected Rows**  Selects and enlarges a particular cluster after you select the cluster in the dendrogram. Alternatively, you can double-click the cluster to zoom in on it. Use Release Zoom to return to the original view.

**Release Zoom**  Returns the dendrogram to the original view after zooming.

**Pivot on Selected Cluster**  Reverses the order of the two sub-clusters of the currently selected cluster.

**Color Map**  Gives the option to add a color map, or heat map, showing each Y, Column variable colored by value. Several color theme choices are available in a submenu.

**Two Way Clustering**  Clusters by the variables specified in Y, Columns as well as rows. A color map is added with a dendrogram for the Y, Column variables at its base. Typically,
for two-way clustering, your variables are measured on the same scale and you do not select Standardize Data. (Not available when Data is stacked is selected.)

**Positioning**  Provides options for changing the positions of labels and other parts of the dendrogram.

**Legend**  Shows or hides a legend for the colors used in color maps. This option is available only if a color map is enabled.

**More Color Map Columns**  Adds a color map for specified columns. (Not available when Data as summarized, Data is distance matrix, or Data is stacked is selected.)

**Constellation Plot**  Shows or hides an alternative way to present the information in the hierarchical clustering dendrogram. Each observation (row) is represented by an endpoint and each cluster join is represented by a new point. The lines that are drawn represent cluster membership. The lengths of the lines represent the distance between clusters. Longer lines represent greater distances between clusters.

You can hover over the lines in the constellation plot to see their length. However, the length values are meaningful only with respect to each other. The axis scaling, orientation of points, and angles of the lines are arbitrary. They are determined such that the ends of the nodes are spaced out and the plot does not appear cluttered, which is important with larger data sets.

To turn off the labels on the endpoints, right-click inside the Constellation Plot and deselect Show Labels.

**Save Constellation Coordinates**  Saves the coordinates of the constellation plot to the data table. (Not available when Data as summarized, Data is distance matrix, or Data is stacked is selected.)

**Save Clusters**  Creates a data table column that contains the cluster number. If Add Spatial Measures is selected on the launch window, the cluster numbers are also saved to the Hough Data Table.

**Save Formula for Closest Cluster**  Creates a data table column that contains a formula for the closest cluster. This option calculates the squared Euclidean distance to each cluster’s centroid and selects the cluster that is closest. Note that this formula does not always reproduce the cluster assignment given by Hierarchical Clustering since the clusters are determined differently. However, the cluster assignment is very similar. (Not available when Data as summarized, Data is distance matrix, or Data is stacked is selected.)

**Save Display Order**  Creates a data table column that contains the order in which the row appears in the dendrogram.

**Save Cluster Hierarchy**  Creates a data table that contains the information needed to write a script for a custom dendrogram. For each cluster join, there are three rows: the first for the
joiner, the second for the leader, and the third for the result, giving the cluster centers, size, and other information.

**Save Cluster Tree**  Creates a new data table that contains information needed to compare cluster trees between JMP and SAS. For each cluster join, there is one row for each new cluster, with the cluster’s size and other information.

**Save Distance Matrix**  Creates a new data table that contains the distances between the observations.

**Save Cluster Means**  Creates a new data table that contains the number of rows and the means of each column in each cluster.

**Cluster Summary**  (Not available when *Data is distance matrix* is selected.) Displays the following information:

- **Cluster Means**  A table that gives, for each cluster, the number of observations (or Object IDs, if the data are stacked) and means for each variable.

- **Cluster Standard Deviations**  A table that gives, for each cluster, the number of observations (or Object IDs, if the data are stacked) and standard deviations for each variable.

- **Cluster Means Plot**  Either a parallel plot or a two-dimensional heat map of the cluster means.

  The plot is a parallel plot unless *Data is stacked* is selected and there are two Attribute ID variables. For the parallel plot, the axis for each variable is scaled.

  - If Standardize Data were selected, the axis ranges from two standard deviations above and below the mean, where the standard deviation and mean are computed for the raw data. If a cluster mean falls beyond this range, the axis is extended to include it.

  - If Standardize Data were not selected, there is a common vertical axis whose scaling is displayed. (The scaling is equivalent to the Scale Uniformly option in Graph Builder).

  When *Data is stacked* is selected and there are two Attribute ID variables, two-dimensional plots of the mean of the Y variable at each location are shown for each cluster. These plots are colored using a Blue to Gray to Red color gradient.

- **Column Summary**  For each variable, gives the RSquare value that represents the proportion of variation explained by the clusters. This number is the RSquare value for a regression of the variable on the clusters. The option also gives a bar graph of RSquare values.

- **Scatterplot Matrix**  Creates a scatterplot matrix using all the variables. (Not available when *Data as summarized*, *Data is distance matrix*, or *Data is stacked* is selected.)
Parallel Coord Plots  Creates a parallel coordinate plot for each cluster. (Not available when Data as summarized, Data is distance matrix, or Data is stacked is selected.) The axes are scaled as described for the Cluster Means Plot. See “Cluster Means Plot” on page 287.

Cluster Treatment Comparisons  (Available only if you hold Shift and click the Hierarchical Clustering red triangle.) Select a response column and a two-level treatment column. Creates a Hierarchically Clustered Differences report.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Additional Examples of the Hierarchical Clustering Platform

- “Example of a Distance Matrix”
- “Example of Wafer Defect Classification Using Spatial Measures”

Example of a Distance Matrix

The proper data table structure for a distance matrix consists of the following:

- An identifier column (usually the first column) that has a Character data type.
- A set of \( n \) columns, where \( n \) is also the number of rows. These \( n \) columns define a symmetric matrix with zero or missing values on the diagonal.

Notice that the distance matrix in Flight Distances.jmp follows the preceding format.

1. Select Help > Sample Data Library and open Flight Distances.jmp.
2. Select Analyze > Clustering > Hierarchical Cluster.
3. In the list at the bottom left corner of the launch window, change **Data as usual** to **Data is distance matrix**.

4. Select Cities and click **Label**.

5. Select all remaining columns and click **Y, Columns**.

**Figure 12.6** Completed Distance Matrix Launch Window

6. Click **OK**.

7. Click the Hierarchical Clustering red triangle and select **Color Clusters**.
In the Dendrogram report for the flight distances, the placement of the diamonds indicates that the model has grouped the cities into three clusters. The clusters are color-coded on the dendrogram. For more information about how to interpret the report, see “Dendrogram Report” on page 282.

**Example of Wafer Defect Classification Using Spatial Measures**

A specialty clustering option called Spatial Measures is available in the Hierarchical Cluster platform. In this example, you use this option to cluster wafers. For information about the option, see “Spatial Measures” on page 293.

1. Select **Help > Sample Data Library** and open Wafer Stacked.jmp.
2. Select **Analyze > Clustering > Hierarchical Cluster**.
3. In the list in the lower left corner, change **Data as usual** to **Data is stacked**.
   Additional options for stacked data appear in the launch window.
4. Select **Defects** and click **Y, Columns**.
5. Select **X_Die** and **Y_Die** and click **Attribute ID**.
6. Select Lot and Wafer and click Object ID.
7. Select Add Spatial Measures from the list of options in the lower left corner.

**Figure 12.8** Completed Clustering Launch Window

8. Click OK.

**Figure 12.9** Spatial Components Window

Because Defects is measured at 1423 locations, there are 1423 Attributes variables.
9. Click OK to accept the selections in the Spatial window.

Two windows open: the Hierarchical Clustering report and the Wafer Stacked Defects Spatial data table.
10. In the Dendrogram plot, click and drag the diamond-shaped handle at the top to explore various numbers of clusters. As you drag the handle, the vertical line in the distance graph below the dendrogram moves to the corresponding number of clusters. The vertical coordinate gives the distance between the clusters that were joined at the given step. The graph seems to level off when the number of clusters is 7.

11. Click the Hierarchical Clustering red triangle and select **Number of Clusters**.

12. Enter 7 and click **OK**.

13. Click the Hierarchical Clustering red triangle and select **Cluster Summary**.

**Figure 12.10** Cluster Summary Report

The wafer maps indicate the spatial nature of defects for each cluster. Cluster 1 contains 104 wafers with relatively few defects that are spread throughout the wafers. Cluster 3 has 5 wafers with defects concentrated at the extremes of the top and bottom hemispheres. You can view the maps for individual wafers and their Hough space maps in the data table produced by the cluster analysis. See “**Spatial Measures**” on page 293.

---

**Statistical Details for the Hierarchical Clustering Platform**

- “**Spatial Measures**”
- “**Distance Method Formulas**”
Spatial Measures

To use the Add Spatial Measures option, your data must be stacked and contain two attribute columns that correspond to spatial coordinates. Some of the spatial measures are constructed using the Hough transform. See White et al. (2008) and Ballard (1981). See “Example of Wafer Defect Classification Using Spatial Measures” on page 290.

Choose Spatial Components Window

The Choose Spatial Components window appears if you do the following in the launch window:

- Select the Data is stacked data structure
- Specify two columns as Attribute ID that correspond to spatial coordinates
- Specify an Object ID
- Select Add Spatial Measures

In the Choose Spatial Components window, you select and weight spatial components for your cluster analysis. These components are used to construct the variables used in the cluster analysis. A new table with a row for each object opens. This table contains the calculated spatial components for each object.

Variables

The types of variables that are constructed and used in the cluster analysis. The variables are constructed using spatial components and the response, Y.

Attributes

The value of the Y variable calculated at each location for each object, as defined by the two Attribute ID variables.

Angle, Pie

Variables that reflect wedge shapes or hemispherical shapes.

Radius, Circle

The variables that reflect circular shapes.

Streak Angle

The variables that reflect streaks that have the same angle.

Streak Position

The variables that reflect streaks with the same spatial position.

Position in Shot

The variables that are based on the position of the die in the shot. Position in Shot variables are represented as ShotPos[vShotSize, hShotSize], where vShotSize and hShotSize are the defined vertical and horizontal shot sizes.
**Shot** The variables that identify which rectangle an object is in, where you specify the number of horizontal and vertical positions of objects in the rectangle. The term *shot* is used in semiconductor wafer data to identify which dies are imaged together across a wafer.

Enter values for Shot Horizontal Size and Shot Vertical Size. Specifying a horizontal shot size of 4 and a vertical shot size of 5 indicates that there are up to 20 dies in a shot. The total number of identifiers created is calculated as follows:

\[
\text{floor}\left(\frac{h\text{Size}+h\text{ShotSize}-1}{h\text{ShotSize}}\right) \times \text{floor}\left(\frac{v\text{Size}+v\text{ShotSize}-1}{v\text{ShotSize}}\right)
\]

where \(h\text{Size}\) and \(v\text{Size}\) are the maximum numbers of horizontal and vertical positions, respectively, \(h\text{ShotSize} = \text{Shot Horizontal Size}\), and \(v\text{ShotSize} = \text{Shot Vertical Size}\).

---

**Note:** Shot variables are represented as \(\text{Shot}[\text{vert}, \text{horiz}]\), where \(\text{vert}\) and \(\text{horiz}\) represent the vertical and horizontal die locations, respectively.

---

**Number** The total number of variables of the given type that are constructed.

**Weight** A measure of importance for the given type of variable used in determining the clusters.

---

### Spatial Measures Reports

When you click OK in the Choose Spatial Components window, two windows appear.

**Hierarchical Clustering Report**

When you conduct an analysis with stacked data and two Attribute IDs, the Cluster Summary report shows spatial maps of the Y variable. Each plot is a two-dimensional plot that displays the cluster mean for each location defined by the Attribute ID variables. The plot uses a Blue to Gray to Red color gradient with a Quantile scale. Using the quantile scale mitigates the effect of outliers.

**Spatial Data Table**

The data table for Spatial measures has a row for each unique Object ID. Columns are displayed using a Blue to Gray to Red default color gradient to show the Y variable. The table contains the following columns:

**Object** An expression column that shows a heat map of the Y variable at each spatial location defined by the two Attribute ID variables.

**Hough** An expression column that shows a heat map of the Hough space for each object. See White et al. (2008).
**Spatial Measures**  A column for each spatial measure that shows the computed values for each object. Cells are colored by value.

**Distance Method Formulas**

This section provides the formulas used in calculating distances based on the Method that you select on the launch window. For a description of the methods, see “Method for Distance Calculation” on page 277.

The formulas use the following notation, where lowercase symbols generally pertain to observations and uppercase symbols to clusters:

- \( n \) is the number of observations
- \( v \) is the number of variables
- \( x_i \) is the \( i \)th observation
- \( C_K \) is the \( K \)th cluster, subset of \( \{1, 2, \ldots, n\} \)
- \( N_K \) is the number of observations in \( C_K \)
- \( \bar{x} \) is the sample mean vector
- \( \bar{x}_K \) is the mean vector for cluster \( C_K \)
- \( \|x\| \) is the square root of the sum of the squares of the elements of \( x \) (the Euclidean length of the vector \( x \))
- \( d(x_i, x_j) = \|x_i - x_j\|^2 \)

**Average Linkage**  The distance for the average linkage cluster method is:

\[
D_{KL} = \sum_{i \in C_K} \sum_{j \in C_L} \frac{d(x_i, x_j)}{N_K N_L}
\]

**Centroid Method**  The distance for the centroid method of clustering is:

\[
D_{KL} = \|\bar{x}_K - \bar{x}_L\|^2
\]

**Ward’s**  The distance for Ward’s method is:

\[
D_{KL} = \frac{\|\bar{x}_K - \bar{x}_L\|^2}{\frac{1}{N_K} + \frac{1}{N_L}}
\]
Single Linkage \hspace{1em} The distance for the single linkage cluster method is:
\[ D_{KL} = \min_{i \in C_K} \min_{j \in C_L} d(x_i, x_j) \]

Complete Linkage \hspace{1em} Distance for the Complete linkage cluster method is:
\[ D_{KL} = \max_{i \in C_K} \max_{j \in C_L} d(x_i, x_j) \]
Use the K Means Cluster platform to group observations that share similar values across a number of variables. Use the k-means method with larger data tables, ranging from approximately 200 to 100,000 observations.

The K Means Cluster platform constructs a specified number of clusters using an iterative algorithm that partitions the observations. The method, called k-means, partitions observations into clusters so as to minimize distances to cluster centroids. You must specify the number of clusters, $k$, in advance. However, you can compare the results of different values of $k$ to select an optimal number of clusters for your data.

Overview of the K Means Cluster Platform

K Means Cluster is one of four platforms that JMP provides for clustering observations. For a comparison of all four methods, see “Overview of Platforms for Clustering Observations” on page 299.

The K Means Cluster platform forms a specified number of clusters using an iterative fitting process. The \( k \)-means algorithm first selects a set of \( k \) points called *cluster seeds* as an initial guess for the means of the clusters. Each observation is assigned to the nearest cluster seed to form a set of temporary clusters. The seeds are then replaced by the cluster means, the points are reassigned, and the process continues until no further changes occur in the clusters.

The \( k \)-means algorithm is a special case of the \( EM \) algorithm, where \( E \) stands for Expectation, and \( M \) stands for maximization. In the case of the \( k \)-means algorithm, the calculation of temporary cluster means represents the Expectation step, and the assignment of points to the closest clusters represents the Maximization step.

K-Means clustering supports only numeric columns. K-Means clustering ignores modeling types (nominal and ordinal) and treats all numeric columns as continuous.

You must specify the number of clusters, \( k \), or a range of values for \( k \), in advance. However, you can compare the results of different values of \( k \) to select an optimal number of clusters for your data.

For background on K-Means clustering, see the FASTCLUS Procedure chapter in SAS Institute Inc. (2020d) and Hastie et al. (2009).

Overview of Platforms for Clustering Observations

Clustering is a multivariate technique that groups together observations that share similar values across a number of variables. Typically, observations are not scattered evenly through \( p \)-dimensional space, where \( p \) is the number of variables. Instead, the observations form clumps, or clusters. Identifying these clusters provides you with a deeper understanding of your data.

*Note:* JMP also provides a platform that enables you to cluster variables. See the “Cluster Variables” chapter on page 345.

JMP provides four platforms that you can use to cluster observations:

- Hierarchical Cluster is useful for smaller tables with up to several tens of thousands of rows and allows character data. Hierarchical clustering combines rows in a hierarchical sequence that is portrayed as a tree. You can choose the number of clusters that is most appropriate for your data after the tree is built.
• K Means Cluster is appropriate for larger tables with up to millions of rows and allows only numerical data. You need to specify the number of clusters, $k$, in advance. The algorithm guesses at cluster seed points. It then conducts an iterative process of alternately assigning points to clusters and recalculating cluster centers.

• Normal Mixtures is appropriate when your data come from a mixture of multivariate normal distributions that might overlap and allows only numerical data. For situations where you have multivariate outliers, you can use an outlier cluster with an assumed uniform distribution.

You need to specify the number of clusters in advance. Maximum likelihood is used to estimate the mixture proportions and the means, standard deviations, and correlations jointly. Each point is assigned a probability of being in each group. The EM algorithm is used to obtain estimates.

• Latent Class Analysis is appropriate when most of your variables are categorical. You need to specify the number of clusters in advance. The algorithm fits a model that assumes a multinomial mixture distribution. A maximum likelihood estimate of cluster membership is calculated for each observation. An observation is classified into the cluster for which its probability of membership is the largest.

Some of the clustering platforms have options to handle outliers in the data. However, if your data has outliers, it is best to explore them first prior to analyzing. This can be done using the Explore Outliers Utility. For more information, see the Modeling Utilities chapter in Predictive and Specialized Modeling.
Example of K Means Cluster

In this example, you use the Cytometry.jmp sample data table to cluster observations using K Means Cluster. Cytometry is used to detect markers of the surface of cells and the readings from these markers help diagnose certain diseases. In this example, the observations are grouped based on readings of four markers in a cytometry analysis.

1. Select Help > Sample Data Library and open Cytometry.jmp
2. Select Analyze > Clustering > K Means Cluster.
4. Click OK.
5. Enter 3 next to Number of Clusters.
6. Enter 15 next to Range of Clusters (Optional).

Because the Range of Clusters is set to 15, the platform provides fits for 3 to 15 clusters. You can then determine your preferred number of clusters.

7. Click Go.

**Figure 13.2** Cluster Comparison Report

</tbody>
</table>

The Cluster Comparison report appears at the top of the report window. The best fit is determined by the highest CCC value. In this case, the best fit occurs when you fit 11 clusters.

8. Scroll to the K Means NCluster=11 report.
The Cluster Summary report shows the number of observations in each of the eleven clusters. The Cluster Means report shows the means of the four marker readings for each cluster.

9. Click the K Means NCluster=11 red triangle and select **Parallel Coord Plots**.
The Parallel Coordinate Plots display the structure of the observations in each cluster. Use these plots to see how the clusters differ. Clusters 4, 6, 7, 8, and 9 tend to have comparatively low CD8 values and high CD4 values. Cluster 1, on the other hand, has higher CD8 values and lower CD4 values.

10. Click the K Means NCluster=11 red triangle and select **Biplot.**
A legend that identifies the colors of the clusters is shown to the right of the plot. The clusters that appear to be most separated from the others based on their first two principal components are clusters 3, 10, and 11. This is supported by their parallel coordinate plots in Figure 13.4, which differ from the plots for the other clusters. Use the list below the plot to see the biplot for other combinations of principal components.

### Launch the K Means Cluster Platform

Launch the K Means Cluster platform by selecting **Analyze > Clustering > K Means Cluster**.
For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Columns**  
The variables used for clustering observations.

**Note:** K-Means clustering supports only numeric columns.

**Weight**  
A column whose numeric values assign a weight to each row in the analysis.

**Freq**  
A column whose numeric values assign a frequency to each row in the analysis.

**By**  
A column whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed. The results are presented in separate reports. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

### Launch Window Options

**Columns Scaled Individually**  
Scales each column independently of the other columns. Use when variables do not share a common measurement scale, and you do not want one variable to dominate the clustering process. For example, one variable might have values that are between 0 and 1000, and another variable might have values between 0 and 10. In this situation, you can use the option so that the clustering process is not dominated by the first variable.

When you click OK, a Control Panel appears. See “Iterative Clustering Control Panel” on page 306.

### Iterative Clustering Report

When you click OK in the launch window, the Iterative Clustering report window appears, showing a Control Panel for fitting models. See “Iterative Clustering Control Panel” on page 306. As you fit models, additional reports are added to the window. See “K Means Report” on page 307.

### Iterative Clustering Options

See *Using JMP* for more information about the following options:

**Local Data Filter**  
Shows or hides the local data filter that enables you to filter the data used in a specific report.
**Redo** Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script** Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script** Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

---

**Iterative Clustering Control Panel**

The Control Panel for the Cytometry.jmp data table is shown in Figure 13.7. You can iteratively fit different numbers of clusters or you can specify a range using the Range of Clusters option.

**Figure 13.7 Iterative Clustering Control Panel**

The Control Panel has the following options:

**Method** The following clustering methods are available:

- **KMeans Clustering** Described in this chapter.
- **Self Organizing Map** Described in “Self Organizing Map Control Panel” on page 310.

**Number of Clusters** Designates the number of clusters to form.

**Range of Clusters (Optional)** Provides an upper bound for the number of clusters to form. If a number is entered here, the platform creates separate analyses for every integer between Number of Clusters and the value entered as Range of Clusters (Optional).

**Go** Unless Single Step is selected, fits the clusters automatically.
**Single Step**  Enables you to step through the clustering process one iteration at a time. When you select Single Step and click Go, a K Means Cluster report appears with no cluster assignments but containing a Go and a Step button.

- Click the Step button to step through the iterations one at a time.
- Click the Go button to fit the clusters automatically.

**Use within-cluster std deviations**  Scales distances using the estimated standard deviation of each variable for observations within each cluster. If you do not select this option, distances are scaled by an overall estimate of the standard deviation of each variable.

**Shift distances using sampling rates**  Adjusts distances based on the sizes of clusters. If you have unequally sized clusters, an observation should have a higher probability of being assigned to larger clusters because there is a higher prior probability that the observation comes from a larger cluster.

---

### K Means Report

When you click Go in the Control Panel, the following reports appear:

- One or more K Means reports. The reports are dynamically named K Means NCluster=<k> depending on, k, the number of clusters fit. A K Means NCluster=<k> report appears for each fit that you conduct.

The Cluster Comparison report and the KMeans NCluster=11 report for the Cytometry.jmp data table, with the variables CD3 through MCB as Y, Columns, are shown in Figure 13.2 and “K Means NCluster=11 Report” on page 302.

---

### Cluster Comparison Report

The Cluster Comparison report gives fit statistics to compare the various models. The fit statistic is the Cubic Clustering Criterion (CCC). Larger values of CCC indicate better fit. The best fit is indicated with the designation Optimal CCC in a column called Best. See SAS Institute Inc. (1983). Constant columns are not included in the CCC calculation.

---

### K Means Report

Each K Means report gives the following summary statistics for each cluster:

- The Cluster Summary report gives the number of clusters and the observations in each cluster, as well as the number of iterations required.
• The Cluster Means report gives means for the observations in each cluster for each variable.
• The Cluster Standard Deviations report gives standard deviations for the observations in each cluster for each variable.

K Means Report Options

Each K Means report contains the following options:

**Biplot**  Shows a plot of the points and clusters in the first two principal components of the data, along with a legend identifying the cluster colors. Circles are drawn around the cluster centers and the size of the circles is proportional to the count inside the cluster. The shaded area is the density contour around the mean. By default, this area indicates where 90% of the observations in that cluster would fall (Mardia et al. 1980). Use the list below the plot to change the plot axes to other principal components. Alternatively, use the arrow button to cycle through all possible axes combinations. An option to save the cluster colors to the data table is also located below the plot. See “Save Colors to Table” on page 309. The eigenvalues are shown in decreasing order.

**Note:** If Columns Scaled Individually is checked in the launch window, the biplot uses a correlation matrix. If Columns Scaled Individually is not checked, the biplot uses a covariance matrix.

**Biplot Options**  Contains the following options for controlling the appearance of the Biplot:

**Show Biplot Rays**  Shows the biplot rays. The labeled rays show the directions of the covariates in the subspace defined by the principal components. They represent the degree of association of each variable with each principal component.

**Biplot Ray Position**  Enables you to specify the position and radius scaling of the biplot rays. By default, the rays emanate from the point (0,0). In the plot, you can drag the rays or use this option to specify coordinates. You can also adjust the scaling of the rays to make them more visible with the radius scaling option.

**Biplot Contour Density**  Enables you to specify the confidence level for the density contours. The default confidence level is 90%.

**Mark Clusters**  Assigns markers that identify the clusters to the rows of the data table.

**Biplot 3D**  Shows a three-dimensional biplot of the data. Available only when there are three or more variables.

**Parallel Coord Plots**  Creates a parallel coordinate plot for each cluster. The plot report has options for showing and hiding the data and means. See Essential Graphing.
**Scatterplot Matrix**  Creates a scatterplot matrix using all of the Y variables.

**Save Colors to Table**  Assigns colors that identify the clusters to the rows of the data table. If there is a Biplot in the report window, the colors saved to the data table match the colors of the clusters in the Biplot. If the colors are changed in the Biplot and the Save Colors To Table option is selected again, the colors in the table update to match those in the Biplot.

**Note:** When any of the Save options are selected, each saved column contains a Notes column property that specifies the number of clusters for that particular column’s data. This enables you to save columns from more than one cluster fit and use the column property to identify which clustering fit the saved column is from.

**Save Clusters**  Saves the following two columns to the data table:

- The Cluster column contains the number of the cluster to which the given row is assigned.
- (Not available for Self Organizing Maps.) The Distance column contains the squared Euclidean distance between the given observation and its cluster mean. For each variable, the difference between the observation’s value and the cluster mean on that variable is divided by the overall standard deviation for the variable. These scaled differences are squared and summed across the variables.

**Save Cluster Distance**  (Not available for Self Organizing Maps.) Saves a Distance column to the data table. This column is the same as the Distance column obtained from the **Save Clusters** option.

**Save Cluster Formula**  Saves a formula column called Cluster Formula to the data table. This is the formula that identifies cluster membership for each.

**Save Distance Formula**  (Not available for Self Organizing Maps.) Saves a formula column called Distance Formula to the data table. This is the formula that calculates the distance to the assigned cluster.

**Save K Cluster Distances**  (Not available for Self Organizing Maps.) Saves $k$ columns containing the squared Euclidean distances to each cluster center.

**Save K Distance Formulas**  (Not available for Self Organizing Maps.) Saves $k$ columns containing the formulas for the squared Euclidean distances to each cluster center.

**Publish Cluster Formulas**  Publishes to the Formula Depot the same scoring code used in the Save Cluster Formula option.

**Simulate Clusters**  Creates a new data table containing simulated cluster observations on the Y variables, using the cluster means and standard deviations.

**Remove**  Removes the clustering report.
Self Organizing Map

The Self-Organizing Map (SOM) technique was developed by Teuvo Kohonen (1989, 1990) and extended by other neural network enthusiasts and statisticians. The original SOM was cast as a learning process, like the original neural net algorithms, but the version implemented here is a variation on $k$-means clustering. In the SOM literature, this variation is called a batch algorithm using a locally weighted linear smoother.

The goal of a SOM is not only to form clusters in a particular layout on a cluster grid, such that points in clusters that are near each other in the SOM grid are also near each other in multivariate space. In classical $k$-means clustering, the structure of the clusters is arbitrary, but in SOMs the clusters have a grid structure. The grid structure helps interpret the clusters in two dimensions: clusters that are close are more similar than distant clusters. See “Description of SOM Algorithm” on page 311.

Self Organizing Map Control Panel

Select the Self Organizing Map option from the Method list in the Iterative Clustering Control Panel.

![Self Organizing Map Control Panel](image)

Some of the options on the panel are described in “Iterative Clustering Control Panel” on page 306. The remaining options are described below.

**N Rows**  The number of rows in the cluster grid.

**N Columns**  The number of columns in the cluster grid.

**Bandwidth**  Specifies the effect of neighboring clusters for predicting centroids. A smaller bandwidth results in putting more weight on closer clusters.
Self Organizing Map Report

The Cluster Comparison Report shows the total number of clusters and also the number of rows requested. The SOM report is named according to the Grid size requested. The Bandwidth is given at the top of the SOM Grid report. The report itself is analogous to the K Means NCluster report. See “K Means Report” on page 307.

For more information about the red triangle options for Self Organizing Maps, see “K Means Report Options” on page 308.

Description of SOM Algorithm

This section contains the steps of the SOM implementation in JMP.

- Initial cluster seeds are selected in a way that provides a good coverage of the multidimensional space. JMP uses principal components to determine the two directions that capture the most variation in the data.
- JMP then lays out a grid in this principal component space with its edges 2.5 standard deviations from the middle in each direction. The clusters seeds are determined by translating this grid back into the original space of the variables.
• The cluster assignment proceeds as with \( k \)-means. Each point is assigned to the cluster closest to it.

• The means are estimated for each cluster as in \( k \)-means. JMP then uses these means to set up a weighted regression with each variable as the response in the regression, and the SOM grid coordinates as the regressors. The weighting function uses a kernel function that gives large weight to the cluster whose center is being estimated. Smaller weights are given to clusters farther away from the cluster in the SOM grid. The new cluster means are the predicted values from this regression.

• These iterations proceed until the process has converged.

Additional Example of K Means Cluster Platform

Example of a Self-Organizing Map

This example uses the Iris.jmp sample data table, which includes measurements of sepal length, sepal width, petal length, and petal width for three species of irises.

1. Select Help > Sample Data Library and open Iris.jmp.
2. Select Analyze > Clustering > K Means Cluster.
4. Click OK.
5. Select Self Organizing Map from the Method menu on the Control Panel.
6. Set N Rows equal to 1 and N Columns equal to 2.
7. Click Go.
9. Set N Rows equal to 1 and N Columns equal to 3.
10. Click Go.
12. Set N Rows equal to 2 and N Columns equal to 2.
13. Click Go.

Figure 13.10  SOM Cluster Comparison
The Cluster Comparison report appears at the top of the report window. The best fit is determined by the highest CCC value. Notice the number of clusters that gives the largest CCC is 3, which is the number of species.

14. Scroll to the SOM Grid 1 by 3 report. We can see the classification was not perfect; each cluster should represent each species, with 50 rows for each.

Figure 13.11  Self-Organizing Map Report for Iris.jmp

15. In the data table, select the Species column and select Rows > Color or Mark by Column.
16. Select the Classic option under Markers.
17. Click OK.
18. Click the red triangle menu next to SOM Grid 1 by 3 and select Biplot.
We can see that all rows from Cluster 3 are correctly identified as the setosa species. The other two species, virginica and versicolor, overlap slightly and can be mistaken for each other.
Use Normal Mixtures for clustering when your data come from overlapping normal distributions. You need to specify the number of clusters in advance.

Normal mixtures is an iterative technique based on the assumption that the joint probability distribution of the observations is approximated using a mixture of multivariate normal distributions. These mixtures represent different clusters. The individual clusters have multivariate normal distributions.

When clusters are well separated, hierarchical and $k$-means clustering work well. But when clusters overlap, normal mixtures provides a better alternative, because it is based on cluster membership probabilities, rather than arbitrary cluster assignments based on borders.

Overview of the Normal Mixtures Clustering Platform

Normal Mixtures is one of four platforms that JMP provides for clustering observations. For a comparison of all four methods, see “Overview of Platforms for Clustering Observations” on page 317.

Normal mixtures is an iterative clustering technique for numerical variables. However, it also predicts the proportion of responses expected within each cluster. Normal mixtures assumes that the joint probability distribution of the measurement columns can be approximated using a mixture of multivariate normal distributions, which represent different clusters. Mean vectors and covariance matrices are estimated for each cluster. See McLachlan and Krishnan (1997) and Section 9.6 in Hand et al. (2001).

Note: The Normal Mixtures algorithm involves iterating through random guesses for the cluster centers. Because of this, results from different runs of the analysis might differ slightly.

If you suspect that you have multivariate outliers, you have two options. You can use an outlier cluster or the Explore Outliers Utility. The outlier cluster option assumes a uniform distribution and is less sensitive to outliers than the standard Normal Mixtures method. The Explore Outliers Utility enables you to explore and handle outliers prior to analysis. See “Outlier Cluster” on page 323 and Predictive and Specialized Modeling.

Overview of Platforms for Clustering Observations

Clustering is a multivariate technique that groups together observations that share similar values across a number of variables. Typically, observations are not scattered evenly through \( p \)-dimensional space, where \( p \) is the number of variables. Instead, the observations form clumps, or clusters. Identifying these clusters provides you with a deeper understanding of your data.

Note: JMP also provides a platform that enables you to cluster variables. See the “Cluster Variables” chapter on page 345.

JMP provides four platforms that you can use to cluster observations:

- Hierarchical Cluster is useful for smaller tables with up to several tens of thousands of rows and allows character data. Hierarchical clustering combines rows in a hierarchical sequence that is portrayed as a tree. You can choose the number of clusters that is most appropriate for your data after the tree is built.
- K Means Cluster is appropriate for larger tables with up to millions of rows and allows only numerical data. You need to specify the number of clusters, \( k \), in advance. The
algorithm guesses at cluster seed points. It then conducts an iterative process of alternately assigning points to clusters and recalculating cluster centers.

- Normal Mixtures is appropriate when your data come from a mixture of multivariate normal distributions that might overlap and allows only numerical data. For situations where you have multivariate outliers, you can use an outlier cluster with an assumed uniform distribution.

You need to specify the number of clusters in advance. Maximum likelihood is used to estimate the mixture proportions and the means, standard deviations, and correlations jointly. Each point is assigned a probability of being in each group. The EM algorithm is used to obtain estimates.

- Latent Class Analysis is appropriate when most of your variables are categorical. You need to specify the number of clusters in advance. The algorithm fits a model that assumes a multinomial mixture distribution. A maximum likelihood estimate of cluster membership is calculated for each observation. An observation is classified into the cluster for which its probability of membership is the largest.

### Table 14.1 Summary of Clustering Methods

Some of the clustering platforms have options to handle outliers in the data. However, if your data has outliers, it is best to explore them first prior to analyzing. This can be done using the Explore Outliers Utility. For more information, see the Modeling Utilities chapter in *Predictive and Specialized Modeling*. 
Example of Normal Mixtures Clustering

Cytometry is used to measure various characteristics of cells. Measurements of cell markers help diagnose certain diseases. In this example, you cluster observations based on readings of four markers in a cytometry analysis.

1. Select Help > Sample Data Library and open Cytometry.jmp
2. Select Analyze > Clustering > Normal Mixtures
4. Click OK.
5. Enter 6 next to Number of Clusters.
6. Click Go.

Note: Your results might differ because the algorithm has a random starting value.

Figure 14.2 Normal Mixtures NCluster=6 Report

The Cluster Summary report shows the number of observations in each of the six clusters. The Cluster Means report shows the means of the four marker readings for each cluster.

7. Click the red triangle next to Normal Mixtures NCluster=6 and select Biplot 3D.
**Note:** Your biplot 3D might appear differently because the algorithm has a random starting value.

**Figure 14.3** 3D Biplot of Cytometry Data

The plot shows contours for the normal densities that are fit to the clusters. Note that one cluster appears to be distinctly separated from the other clusters based on the first three principal components.
Launch the Normal Mixtures Clustering Platform

Launch the Normal Mixtures Clustering platform by selecting Analyze > Clustering > Normal Mixtures.

**Figure 14.4** Normal Mixtures Launch Window

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Columns** The variables used for clustering observations.

**Note:** Normal Mixtures clustering supports only numeric columns.

**Weight** A column whose numeric values assign a weight to each row in the analysis.

**Freq** A column whose numeric values assign a frequency to each row in the analysis.

**By** A column whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed. The results are presented in separate reports. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

When you click OK, a Control Panel appears. See “Model Based Clustering Control Panel” on page 322.
Model Based Clustering Report

When you click OK in the launch window, the Model Based Clustering report window opens, showing a Control Panel for fitting models. See “Model Based Clustering Control Panel” on page 322. As you fit models, additional reports are added to the window. See “Normal Mixtures Report” on page 323.

Model Based Clustering Options

See Using JMP for more information about the following options:

- **Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

- **Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

- **Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

Model Based Clustering Control Panel

The Control Panel for the Cytometry.jmp data table, with the variables CD3 through MCB as Y, Columns, is shown in Figure 14.5. You can fit various numbers of clusters using the Control Panel iteratively or you can specify a range using the Range of Clusters option.

**Figure 14.5**  Control Panel for Normal Mixtures Method
The Model Based Clustering Control Panel has these options:

**Number of Clusters** Designates the number of clusters to form.

**Range of Clusters (Optional)** Provides an upper bound for the number of clusters to form. If a number is entered here, the platform creates separate analyses for every integer between **Number of clusters** and the value entered as **Range of Clusters (Optional)**.

**Go** Fits the clusters.

**Diagonal Variance** Constrains the off-diagonal elements of the covariance matrix to zero. The platform fits multivariate normal distributions that have no correlations between the variables.

**Note:** The Diagonal Variance option is sometimes necessary to avoid obtaining a singular covariance matrix when there are fewer observations than variables. It can also be used to avoid estimating very large covariance matrices for large numbers of variables.

**Outlier Cluster** Fits a cluster to catch outliers that do not fall into any of the normal clusters. If this cluster is created, it is designated Cluster 0, and the count of observations appears in the Cluster Summary report. The distribution of observations that fall in the outlier cluster is assumed to be uniform over the hypercube that encompasses the observations.

**Advanced Controls** The following advanced controls are available:

- **Tours** The number of independent restarts of the estimation process. Each restart has a different starting value. Independent starts help guard against finding local solutions.

- **Maximum Iterations** The maximum number of iterations of the convergence stage of the EM algorithm.

- **Converge Criterion** The difference in the likelihood at which the EM iterations terminate.

---

**Normal Mixtures Report**

When you click Go in the Control Panel, the following reports appear:

- One or more Normal Mixtures reports. The reports are dynamically named Normal Mixtures NCluster=<k>, depending on k, the number of clusters fit. A Normal Mixtures NCluster=<k> report appears for each fit that you conduct.
The Cluster Comparison report and the Normal Mixtures NCluster=6 report for the Cytometry.jmp data table, with the variables CD3 through MCB as Y, Columns, are shown in Figure 14.2 and “Normal Mixtures NCluster=6 Report” on page 319.

**Cluster Comparison Report**

The Cluster Comparison report gives fit statistics to compare the various models. The fit statistics are BIC and AICc. Smaller values of each indicate better fit. The best fit is indicated in a column called Best.

**Normal Mixtures Report**

The Normal Mixtures report gives summary statistics for each cluster:

- The Cluster Summary report gives the number of observations and proportion for each cluster.
- The Cluster Means report gives means for the observations in each cluster for each variable.
- The Cluster Standard Deviations report gives standard deviations for the observations in each cluster for each variable.
- The -LogLikelihood table gives the negative log-likelihood, BIC, and AICc. See *Fitting Linear Models*.
- The Correlations for Normal Mixtures report gives the estimated correlation matrix for each cluster.

**Normal Mixtures Report Options**

**Biplot** Shows a plot of the points and clusters in the first two principal components of the data, along with a legend identifying the cluster colors. Circles are drawn around the cluster centers and the size of the circles is proportional to the count inside the cluster. The shaded area is the density contour around the mean. By default, this area indicates where 90% of the observations in that cluster would fall (Mardia et al. 1980). Use the list below the plot to change the plot axes to other principal components. Alternatively, use the arrow button to cycle through all possible axes combinations. An option to save the cluster colors to the data table is also located below the plot. See “Save Colors to Table” on page 325. The eigenvalues are shown in decreasing order.

**Note:** The biplot always uses the correlation matrix to calculate the principal components.

**Biplot Options** Contains options for controlling the appearance of the Biplot.
**Show Biplot Rays**  Shows the biplot rays. The labeled rays show the directions of the covariates in the subspace defined by the principal components. They represent the degree of association of each variable with each principal component.

**Biplot Ray Position**  Enables you to specify the position and radius scaling of the biplot rays. By default, the rays emanate from the point (0,0). In the plot, you can drag the rays or use this option to specify coordinates. You can also adjust the scaling of the rays to make them more visible with the radius scaling option.

**Biplot Contour Density**  Enables you to specify the confidence level for the density contours. The default confidence level is 90%.

**Mark Clusters**  Assigns markers that identify the clusters to the rows of the data table.

**Biplot 3D**  Shows a three-dimensional biplot of the data. Available only when there are three or more variables.

**Parallel Coord Plots**  Creates a parallel coordinate plot for each cluster. The plot report has options for showing and hiding the data and means. See *Essential Graphing*.

**Scatterplot Matrix**  Creates a scatterplot matrix using all of the Y variables.

**Save Colors to Table**  Assigns colors that identify the clusters to the rows of the data table. If there is a Biplot in the report window, the colors saved to the data table match the colors of the clusters in the Biplot. If the colors are changed in the Biplot and the Save Colors To Table option is selected again, the colors in the table update to match those in the Biplot.

**Note:** When any of the Save options are selected, each saved column contains a Notes column property that specifies the number of clusters for that particular column’s data. This enables you to save columns from more than one cluster fit and use the column property to identify which clustering fit the saved column is from.

**Save Clusters**  Adds a column called Cluster that contains the number of the cluster to which the given row is assigned to the data table. For normal mixtures, this is the cluster that is most likely.

**Save Cluster Formula**  Adds a formula column called Cluster Formula to the data table. This formula identifies which cluster the row belongs to.

**Publish Cluster Formulas**  Publishes to the Formula Depot the same scoring code used in the Save Cluster Formula option. If Publish Cluster Formulas is selected and Run Script is chosen from the model within the Formula Depot, the columns saved to the data table should match those that are saved when Save Cluster Formula is selected.

**Save Mixture Probabilities**  Adds a column called Prob Cluster <k> for each cluster that contains the probability an observation belongs to that cluster.
Save Mixture Formulas  Adds columns to the data table that contain the formulas used to calculate the mixture probabilities. Use these formula columns to score probabilities for excluded data, or data that you add to the table.

**Dist Formula <k>**  The estimated multivariate normal density function for Cluster <k> evaluated at the observation.

**Dist Total**  The sum of the distance formula columns. The formula in this column is equivalent to the formula in the Mixture Density column created by the Save Density Formula option.

**Prob Formula <k>**  The probability that the observation belongs to Cluster <k>. These columns contain the formulas that give the values in the Prob Cluster <k> columns created by the Save Mixture Probabilities option. The column formula for calculating the mixture probabilities is:

\[
\text{Prob Formula } <k> = \frac{\text{Dist Formula } <k>}{\text{Dist Total}}
\]

Save Density Formula  Adds a column called Mixture Density that contains the estimated density function for the normal mixture to the data table.

Simulate Clusters  Uses the mixture density to simulate predictor values. Saves these and the clusters into which they are classified in a new data table.

Remove  Removes the clustering report.

---

**Statistical Details for the Normal Mixtures Clustering Platform**

Normal Mixtures uses the EM algorithm to do fitting because it is more stable than the Newton-Raphson algorithm. In addition, JMP uses a Bayesian regularized version of the EM algorithm, which allows smooth handling of cases where the covariance matrix is singular. Since the estimates are heavily dependent on initial guesses, the platform iterates through a number of tours. Each tour has randomly selected points for the initial center.

Doing multiple tours makes the estimation process somewhat expensive, so considerable patience is required for large problems. Controls enable you to specify the tour and iteration limits.
Latent class analysis enables you to find clusters of observations for categorical response variables. A latent variable is an unobservable grouping variable. Each level of the latent variable is called a latent class. The Latent Class Analysis platform fits a latent class model and determines the most likely cluster or latent class for each observation. In most situations, a subject matter expert uses the results of a latent class analysis to create definitions for each latent class based on the characteristics of the class.

Overview of the Latent Class Analysis Platform

The Latent Class Analysis platform fits a latent class model to categorical response variables and determines the most likely cluster or latent class for each observation. A latent variable is an unobservable grouping variable. Each level of the latent variable is called a latent class. For example, latent classes could be clusters of survey respondents that are grouped by their preference for risk.

The model takes the form of a multinomial mixture model. There are two sets of parameters in the model: the $\gamma$ parameters and the $\rho$ parameters. The $\gamma$ parameters represent the overall probabilities of cluster membership. The $\rho$ parameters represent the probabilities of observing a given response conditional on cluster membership. A latent class is characterized by a pattern of these conditional probabilities.

In order for the analysis results to be meaningful, a subject matter expert must interpret the clusters that the platform generates. This subject matter expert examines characteristics of the latent classes and constructs a definition for each class based on those characteristics.

**Note:** Rows with missing values in any of the response columns are excluded from the analysis.

For more information about latent class models, see Collins and Lanza (2010) and Goodman (1974).

Example of Latent Class Analysis

This example uses the Latent Class Analysis platform to analyze responses to a 2005 survey of US high school students. The survey asked students a variety of multiple choice questions regarding health-risk behaviors.

In this example, you fit a latent class model to identify clusters of students based on their responses to 12 questions. The columns that you analyze were obtained from multiple choice survey questions by binning the responses into two classes (Yes/No).

1. Select Help > Sample Data Library and open Health Risk Survey.jmp.
2. In the Health Risk Survey data table, click the green triangle next to the Launch LCA Platform script.
   The script selects the 12 columns of interest, opens the Latent Class Analysis launch window, and enters the 12 columns of interest as Y.
Note: To launch the LCA Platform on your own, select Analysis > Clustering > Latent Class Analysis.

3. Type 5 in the box next to Up to.

This option fits latent class models for 3 and up to 5 clusters.

4. Click OK.

**Figure 15.2 Cluster Comparison Report**

<td>379648</td>
<td>765196</td>
<td>760576</td>
<td>Smallest BIC Smallest AIC</td>
</tr>
</tbody>
</table>

The Latent Class Analysis outline contains a Cluster Comparison report and three separate Latent Class Model reports. The Latent Class Model reports show the models for three, four, and five clusters. In the Cluster Comparison report, the model with five clusters has the smallest BIC and AIC, which indicates that it is the best fitting model out of the three. This is the model that you analyze.

5. In the Latent Class Model for 5 Clusters report, examine the bar charts under Parameter Estimates. Note the following:
   - Cluster 1 has mostly No answers to all of the risk behaviors.
   - Cluster 2 has high numbers of Yes answers for the four risk behaviors before the age of 13.
   - Cluster 3 has high numbers of Yes answers for driving when drinking and five or more drinks in the past 30 days.
   - Cluster 4 has high numbers of Yes answers for most of the risk behaviors except for the ones before the age of 13.
   - Cluster 5 has the highest number of Yes answers for most of the risk behaviors.

Use this information to give the clusters meaningful names.

6. Click the red triangle next to Latent Class Model for 5 Clusters and select Rename Clusters:
   - Enter Low Risk for Cluster 1.
   - Enter Early Risk-Takers for Cluster 2.
   - Enter Drinkers for Cluster 3.
   - Enter Late High Risk for Cluster 4.
   - Enter High Risk for Cluster 5.

7. Click OK.
8. Click **OK** in the JMP Alert that appears.

**Note:** The new cluster names are not saved to scripts.

---

**Figure 15.3** Partial Parameter Estimates Report

Figure 15.3 shows parameter estimates for the first eight variables in the analysis. The new cluster names appear in the report window.

Next, compare cluster membership to the demographic question “In what grade are you”.

9. Click the red triangle next to Latent Class Model for 5 Clusters and select **Save Mixture and Cluster Formulas**.

10. Select **Graph > Graph Builder**.

11. Enter *In what grade are you* as **X**.

12. Enter *Most Likely Cluster Formula* as **Y**.

13. Select the Mosaic element.

14. Click **Done**.
Observe that most of the respondents fall into the Low Risk cluster. The class labeled Drinkers includes more respondents as the grade level increases.
Launch the Latent Class Analysis Platform

Launch the Latent Class Analysis platform by selecting Analyze > Clustering > Latent Class Analysis.

Figure 15.5  Latent Class Analysis Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The Latent Class Analysis platform launch window contains the following options:

Y  The column or columns that you want to analyze. You can analyze columns with nominal, ordinal, or multiple response modeling types. To analyze nominal or ordinal responses, two or more columns are required. Only one column is required if it contains multiple responses and has a multiple response modeling type.

Weight  A column whose numeric values assign a weight to each row in the analysis.

Freq  A column whose numeric values assign a frequency to each row in the analysis.

ID  A column used to identify separate respondents. This identification is used in some output tables.

By  A column that creates a report consisting of separate analyses for each level of the variable. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

Number of Clusters  The number of clusters to be computed in the analysis.

Up to  Specifies a maximum number of clusters. If this number exceeds the value specified for Number of Clusters, a model report is produced with a number of clusters equal to
The Latent Class Analysis Report

The initial Latent Class Analysis report contains a Cluster Comparison and Latent Class Model reports for each specified number of clusters.

Cluster Comparison Report

The Cluster Comparison report gives fit statistics to compare the various models. The fit statistics are the negative log-likelihood (-LogLikelihood), BIC, and AIC. Smaller values of each indicate better fit. The best fit is indicated in a column called Best. See Fitting Linear Models.

Latent Class Model Report

Each Latent Class Model Report is dynamically named Latent Class Model for <k> Clusters, depending on k, the number of clusters fit. The reports contains the following results and outlines:

- “Model Summary” on page 337
- “Parameter Estimates” on page 337
- “Transposed Parameter Estimates” on page 338
- “Effect Sizes” on page 338
- “MDS Plot” on page 338
- “Mixture Probabilities” on page 338
Model Summary

By default, a summary of the model for the specified number of clusters appears at the top of each Latent Class Model report. The model summary contains the -LogLikelihood, Number of Parameters, BIC, and AIC. These summary values can be used to determine how well the model fits the data. Lower values of -LogLikelihood, BIC, and AIC indicate better fits. See Fitting Linear Models. The Number of Parameters value gives the number of unique parameters in the latent class model. See “Statistical Details for the Latent Class Analysis Platform” on page 342.

Parameter Estimates

The Parameter Estimates report contains tabular and graphical summaries of the parameter estimates and is displayed by default. Each summary contains rows corresponding to the model clusters.

The Overall column shows the probability of an observation belonging to each cluster. (These are the $\gamma$ parameters. See “Statistical Details for the Latent Class Analysis Platform” on page 342.)

The remaining columns in the displays are grouped with vertical dividers according to the Y columns specified in the Latent Class Analysis launch window:

- Each group of categorical response columns has a column for each level within the respective response. In each group, the value in a given row and column is the conditional probability of the response indicated by the column, given that the observation belongs to the cluster identified by the row. (These are the $\rho$ parameters.)

- Each group of multiple response columns has a column for each category within the multiple response. In each group, the value in a given row and column is the conditional probability of a response at the lower level of the indicated category, given that the observation belongs to the cluster identified by the row. (These are the $\rho$ parameters.)

The graphical display shows the conditional probability values as share charts. For each cluster and each Y, the conditional probabilities given cluster membership are plotted as a horizontal stacked bar chart. For a binary or nominal response column, the percentages in these charts sum to one for each response. For a multiple response column, the percentages are of the lower level of each of the categories and do not sum to one. The stacking of bars follows the order of appearance of the variables in the table of values. You can also hover over the bars to view the levels or categories of the variable.

**Tip:** You can select one or more rows in either table in the Parameter Estimates report to select the observations assigned to the corresponding clusters.
Transposed Parameter Estimates

The Transposed Parameter Estimates report contains a table that is the transpose of the Parameter Estimates report table. Here the clusters are shown as columns. The conditional probabilities for each cluster are shown for each response category of each Y column in the analysis.

**Note:** The estimates from the Overall column are not included in the transposed table.

Effect Sizes

The Effect Sizes table compares the Y columns across clusters and is displayed by default. The statistics in each row of this table are obtained from a contingency table analysis of expected counts for cluster membership by levels or categories of a Y column. The expected counts are obtained by multiplying the number of observations in each cluster by the conditional probabilities for each level or category of the Y column.

For each response, the Pearson chi-square statistic, $\chi^2$, is calculated for the contingency table of expected counts for levels by clusters. Let $n$ represent the number of observations. The value in the Effect Size column is defined as follows:

$$\text{Effect Size} = \frac{\chi^2}{n}$$

Each value in the LR Logworth column shows -log10($p_{LR}$) where $p_{LR}$ is the likelihood ratio test $p$-value for the contingency table of expected counts. A Logworth value above 2 corresponds to significance at the 0.01 significance level.

**Tip:** You can select one or more rows in the Effect Sizes table to select the corresponding columns in the data table.

MDS Plot

The MDS Plot contains one point for each cluster and is displayed by default. It is a two-dimensional representation of cluster proximity. Clusters that are closer together are more similar. The plot is created from a dissimilarity matrix of the $\rho$ parameters. For more information about MDS plots, see the “Multidimensional Scaling” chapter on page 237.

Mixture Probabilities

The Mixture Probabilities table displays probabilities of cluster membership for each row. The Most Likely Cluster column indicates the cluster with the highest probability of membership for each row.
Note: Rows that contain a missing value for one or more of the Y columns are excluded from the analysis and do not appear in the Mixture Probabilities table.

Latent Class Analysis Platform Options

- “Latent Class Analysis Options”
- “Latent Class Model Options”

Latent Class Analysis Options

The Latent Class Analysis red triangle menu contains the following options:

New Number of Clusters  Enables you to run another analysis using a different number of clusters. The new analysis report is appended to the current report.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Latent Class Model Options

The Latent Class Model for <k> Clusters red triangle menu contains the following options:

Model Reports  Enables you to show or hide the available model reports. For more information about the model reports, see “The Latent Class Analysis Report” on page 336.

Color by Cluster  Colors each row in the data table according to its most likely cluster. For an example, see “Additional Example of the Latent Class Analysis Platform” on page 340.
Save Mixture and Cluster Formulas  Saves a formula column to the data table for each cluster as well as a formula column for the most likely cluster.

Save Cluster Formula Only  Saves a column to the data table with a formula that determines the most likely cluster.

Publish Probability Formulas  Creates probability formulas and saves them as formula column scripts in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See *Predictive and Specialized Modeling*.

Save Mixture Probabilities  Saves the values in the Mixture Probabilities table to the corresponding rows in the data table.

Save Cluster Only  Saves a new column to the data table that contains the most likely cluster for each row. This column does not contain a formula.

Rename Clusters  Enables you to give meaningful names to the clusters in the report.

Note: The new cluster names are not saved to a script unless you have specified a random seed for the report. Setting a random seed is available only when you launch the report via a script.

Remove Fit  Removes the specified clustering report from the report window.

---

**Additional Example of the Latent Class Analysis Platform**

**Plot Probabilities of Cluster Membership**

This example uses the Car Poll.jmp sample data table, which contains survey data for car owners and car makes. You are interested in classifying the car owners into three clusters and producing a plot to visualize the probabilities of cluster membership. A ternary plot provides a good visualization when you have three clusters.

1. Select **Help > Sample Data Library** and open Car Poll.jmp.
2. Select **Analyze > Clustering > Latent Class Analysis**.
3. Select all of the columns except age and click Y.
4. Click OK.
5. Click the red triangle next to Latent Class Model for 3 Clusters and select **Color by Cluster**.
6. Click the red triangle next to Latent Class Model for 3 Clusters and select **Save Mixture Probabilities**.
7. In the Car Poll data table window, select the LCA Cluster Probabilities column group from the column list.

8. Select **Graph > Ternary Plot**.

9. Click **X, Plotting**.

10. Click **OK**.

**Figure 15.6** Ternary Plot of Cluster Membership Probabilities

In the ternary plot of cluster probabilities for each observation, most of the cluster membership probabilities fall near the vertices. This indicates that they have high values for one cluster and lower values for the other two. However, there are some points in the middle of the plot, indicating that these observations do not have high probabilities of cluster membership for any of the clusters. These observations might warrant closer inspection or they might indicate that more clusters are needed to better represent the data.

**Note:** Your results might be different because a random seed was not specified.
Statistical Details for the Latent Class Analysis Platform

- “Latent Class Model Fit”
- “Maximum Number of Clusters”

Latent Class Model Fit

This section describes the latent class model that is fit in the Latent Class Analysis platform. For more information about latent class models, see Collins and Lanza (2010) and Agresti (2013).

Note: The LCA algorithm that is used in the Text Explorer platform takes advantage of the sparsity of the document term matrix. For this reason, the LCA results in the Text Explorer platform do not exactly match the results in the Latent Class Analysis platform.

Let $j = 1, ..., J$ represent the observed columns of responses. These are the $Y$ columns in the Latent Class Analysis platform launch window. Denote the number of levels for column $j$ by $R_j$.

A multidimensional contingency table of the $J$ variables contains $W = R_1 \times \ldots \times R_J$ cells. Each of these cells is defined by its response pattern for the $J$ variables. Therefore, each response pattern is a $J$-length vector of the form $y = y_1, ..., y_J$. Define $Y$ to be the $W$ by $J$ array of all the response patterns considered as row vectors. Each element, $y_w$, in $Y$ has a probability $Pr(y_w)$. These probabilities sum to 1:

$$
\sum_{w=1}^{W} Pr(y_w) = 1
$$

Consider the following notation:

- $C$ is the number of clusters in the latent class model.
- $\gamma_c$ is the probability of membership in cluster $c$. (The $\gamma_c$ are the latent class prevalences.) These parameters sum to 1.
- $r_{jk}$ is the $k^{th}$ level of the $j^{th}$ response.
- $\rho_{jklc}$ is the probability of observing response $r_{jk}$ in column $j$ conditional on membership in class $c$. (The $\rho_{jklc}$ are the item-response probabilities.) For a given cluster and response variable $j$, the sum of the $\rho_{jklc}$ is 1.
- $I(y_j = r_{jk})$ is an indicator function that equals 1 when the $y_j$ response is the $k^{th}$ level of the $j^{th}$ response, and 0 otherwise.
The probability of observing a specific vector of responses \( y_w = y_1, ..., y_j \) is the sum of the conditional probabilities of observing that vector of responses for each of the \( C \) latent classes:

\[
\Pr(y) = \sum_{c=1}^{C} \gamma_c \prod_{j=1}^{J} \prod_{k=1}^{R_j} \rho_{j,k|c}^{I(y_j = r_{j,k})}
\]

This equation is the denominator in the Prob Formula Cluster formulas that you can save to the data table by selecting the Save Mixture and Cluster Formulas option from the Latent Class Analysis red triangle menu. The formula in the Prob Formula Cluster column gives \( \Pr(Cluster = c \mid y_w) \), which equals \( \Pr(y_w \mid Cluster = c) / \Pr(y_w) \).

The \( \gamma \) and \( \rho \) parameters for latent class models are estimated using the iterative Expectation-Maximization (EM) algorithm. The number of unique parameters in a latent class model is defined as follows:

\[
J \left( C - 1 \right) + C \sum_{j=1}^{J} (R_j - 1)
\]

**Maximum Number of Clusters**

The maximum number of clusters that can be fit in an LCA model depends on the model degrees of freedom. The degrees of freedom in an LCA model are based on the size of the contingency table created by the columns. The size of the contingency table is the number of cells in the table that contain at least one observation and is denoted as \( K \). If all cells contain at least one observation, \( K \) is the product of the number of levels of the response columns. The formula for degrees of freedom is defined as follows:

\[
DF = K - \{nCluster - 1 + nCluster(nTotalLevels - nCols)\} - 1
\]

where

- \( nCluster = \) the number of clusters
- \( nTotalLevels = \) the sum of the levels of the response columns
- \( nCols = \) the number of response columns

In order for the LCA model to be adequately fit, the degrees of freedom must be positive. Therefore, to ensure \( DF > 0 \), the maximum number of clusters is defined as follows:

\[
\max(nCluster) < \text{floor}[K/(1 + nTotal Levels - nCols)]
\]
Variable clustering provides a method for grouping similar variables into representative groups. Each cluster can be represented by a single component or variable. The component is a linear combination of all variables in the cluster. Alternatively, the cluster can be represented by the variable identified to be the most representative member in the cluster.

You can use Cluster Variables as a dimension-reduction method. Instead of using a large set of variables in modeling, either the cluster components or the most representative variable in the cluster can be used to explain most of the variation in the data. In addition, dimension reduction using Cluster Variables is often more interpretable than dimension reduction using principal components.

Overview of the Cluster Variables Platform

Principal components analysis constructs components that are linear combinations of all the variables in the analysis. In contrast, the Cluster Variables option constructs components that are linear combinations of variables in a cluster of similar variables. The entire set of variables is partitioned into clusters. For each cluster, a cluster component is constructed using the first principal component of the variables in that cluster. This cluster component is the linear combination that explains as much of the variation as possible among the variables in that cluster.

You can use the Cluster Variables option as a dimension-reduction method. A substantial part of the variation in a large set of variables can often be represented by cluster components or by the most representative variable in the cluster. These new variables can then be used in predictive or other modeling techniques. The new cluster-based variables are usually more interpretable than principal components based on all the variables.

Principal components constructed from a common set of variables are orthogonal. However, cluster components are not orthogonal because they are constructed from distinct sets of variables.

When you have a large set of variables, the Cluster Variables platform uses an algorithm based on the singular value decomposition to shorten computation time. For additional background, see “Wide Linear Methods and the Singular Value Decomposition” on page 361 in the “Statistical Details” appendix.

Example of the Cluster Variables Platform

The Diabetes.jmp sample data table contains ten baseline variables used in modeling disease progression. In this example, you cluster the continuous baseline variables.

1. Select Help > Sample Data Library and open Diabetes.jmp.
2. Select Analyze > Clustering > Cluster Variables.
3. Select the columns Age through Glucose except for Gender (Age, BMI, BP, Total Cholesterol, LDL, HDL, TCH, LTG, and Glucose) and click Y, Columns.
   
   The Gender column cannot be included because Cluster Variables requires numeric continuous variables.
4. Click OK.
Cluster Variables

Example of the Cluster Variables Platform

Multivariate Methods

Figure 16.2 Cluster Variables Report for Diabetes Data

The Cluster Summary report shows that the variables were grouped into three clusters:

- **Cluster 1** consists of TCH, HDL, LTG, and BMI, as shown in the Cluster Members report. The Cluster Summary report shows that TCH is the most representative variable for Cluster 1 and that for the variables in Cluster 1, 62.8% of the variation is explained by the first principal component.

- **Cluster 2** consists of Total Cholesterol and LDL. The Cluster summary report shows that Total Cholesterol is the most representative variable for Cluster 2 and that for the variables in Cluster 2, 94.8% of the variation is explained by the first principal component.
Cluster 3 consists of BP, Age, and Glucose. The Cluster Summary report shows that the most representative variable is BP and that for the variables in Cluster 3, 56.2% of the variation is explained by the first principal component.

Launch the Cluster Variables Platform

Launch the Cluster Variables platform by selecting **Analyze > Clustering > Cluster Variables**.

Figure 16.3  Cluster Variables Launch Dialog

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Columns**  The variables to be clustered. Variables must be numeric and continuous.

**Weight**  A column whose numeric values assign a weight to each row in the analysis.

**Freq**  A column whose numeric values assign a frequency to each row in the analysis.

**By**  A column whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed. The results are presented in separate reports. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

The Cluster Variables Report

By default, the Cluster Variables report displays the following:

- **“Color Map on Correlations”** on page 350
- **“Cluster Summary”** on page 350
Cluster Variables
The Cluster Variables Report

- “Cluster Members” on page 351
- “Standardized Components” on page 351

Tip: In any of the Cluster Variables reports, select rows in order to select the corresponding columns in the data table. Press Ctrl and click the row to deselect the column in the data table.

Color Map on Correlations

The Color Map on Correlations report displays a color map of the correlations between variables. The variables are arranged in the order in which they are listed in the Cluster Members report. This arrangement ensures that members of the same cluster are adjacent in the correlation plot. See “Example of Color Map on Correlations” on page 353.

Tip: Hover over a square on the color map to see the variables involved in that square and their correlation.

Variables in the same cluster tend to have higher absolute correlations (deeper red or blue colors) than variables in different clusters. Therefore, the squares formed by the cells of the correlation map that correspond to the variables for a given component often stand out along the diagonal.

Correlations are computed using the row-wise method. This method excludes any observation with missing data on any of the variables from the correlation calculation. For more information about the row-wise estimation method, see “Estimation Methods” on page 47 in the “Correlations and Multivariate Techniques” chapter.

Cluster Summary

The Cluster Summary report gives the following information:

Cluster The cluster identifier.
Number of Members The number of variables in the cluster.
Most Representative Variable The cluster variable that has the largest squared correlation with its cluster component.
Cluster Proportion of Variance Explained The cluster’s proportion of variance explained by the first principal component among the variables in the cluster. If there is only one variable in the cluster, then this is 1. This statistic is based only on variables within the cluster rather than on all variables.
Total Proportion of Variation Explained  The overall proportion of variance explained by the cluster component. This is equivalent to using only the variables within each cluster to calculate the first principal component.

A note beneath the table gives the total proportion of variation explained by all the cluster components.

Cluster Members

The Cluster Members report gives the following:

Cluster    The cluster identifier.
Members    The variables included in the cluster.
RSquare with Own Cluster  The squared correlation of the variable with its cluster component.
RSquare with Next Closest    The squared correlation of the variable with the cluster component for its next closest cluster. The next closest cluster is the cluster for which the squared correlation of the variable with the cluster component is the second highest.
1 - RSquare Ratio    A measure of the relative closeness between the cluster to which a variable belongs and its next closest cluster. It is defined as follows:

\[ \frac{1 - \text{RSquare with Own Cluster}}{1 - \text{RSquare with Next Closest}} \]

Standardized Components

The Standardized Components report gives the coefficients that define the cluster components. These coefficients are the eigenvectors of the first principal component within each cluster.

Cluster Variables Platform Options

The Variable Clustering red triangle menu contains the following options:

**Color Map on Correlations**  Shows or hides the Color Map on Correlations plot. See “Color Map on Correlations” on page 350.

**Cluster Summary**    Shows or hides the Cluster Summary report. See “Cluster Summary” on page 350.
Additional Examples of the Cluster Variables Platform

- “Example of Color Map on Correlations”
- “Example of Cluster Variables Platform for Dimension Reduction”
Example of Color Map on Correlations

In this example, you construct and examine a Color Map on Correlations.

1. Select Help > Sample Data Library and open Cherts.jmp.
2. Select Analyze > Clustering > Cluster Variables.
3. Select all continuous variables and click Y, Columns.
4. Click OK.
5. Close the Cluster Summary and the Standardized Components reports.
6. Hover over the cell in the second row and first column of the Color Map.
   A tooltip appears, showing that the variables corresponding to this cell are La and Eu, and that their correlation is 0.822829.

Figure 16.4  Color Map on Correlations for Cherts.jmp
The Cluster Members report shows that there are four variables in Cluster 1. In the Color Map on Correlations, the four-by-four square of cells in the upper left corner that corresponds to these five variables shows a distinct pattern of positive correlations. The color map also shows patterns of positive correlations for the variables in Clusters 2, 4, and 5. The two-by-two square of cells in the lower right corner of the color map that corresponds to the two Cluster 6 variables shows that they are negatively correlated. See “Color Map on Correlations” on page 350.

Example of Cluster Variables Platform for Dimension Reduction

In this example, you use the Cluster Variables platform as a dimension-reduction tool for modeling. The Penta.jmp sample data table contains 15 variables used to predict the response variable, log RAI. Use Cluster Variables to reduce this number.

Cluster Variables

1. Select Help > Sample Data Library and open Penta.jmp.
2. Select Analyze > Clustering > Cluster Variables.
3. Select all of the continuous variables, except logRAI and click Y, Columns.
4. Click OK.
5. Click the Variable Clustering red triangle and select Save Cluster Components.

Five grouped formula columns are added to the data table.
Figure 16.5 Cluster Variables Report for Penta.jmp

The Cluster Summary and Cluster Members reports show that the variables are clustered into five groups, so there are five Cluster Component variables.

Fit Models

Next, fit and compare two models to predict logRAI:

- A model using all continuous variables as predictors.
- A model using the Cluster Components as predictors.

1. Click the Variable Clustering red triangle and select Launch Fit Model.
2. Select logRAI and click Y.
Notice that the Most Representative Variables the five clusters have been entered in the Construct Model Effects list. However, you want to enter all predictors.

3. Select all of the continuous variables from S1 to P5 and click **Add**.
   
   Be careful not to include **Obs Name**.

4. Select the box next to **Keep dialog open**.

5. Click **Run**.

**Figure 16.6** Fit Least Squares Report for Model with All Continuous Predictors

6. In the Fit Model window, select all variables in the Construct Model Effects window and click **Remove**.

7. Select the Cluster Components group and click **Add**.

8. Click **Run**.
The model that includes the five Cluster Components as the only predictors explains a substantial amount of the variation in the response, with an adjusted RSquare of 0.784. The model that uses all fifteen predictors has only a slightly higher adjusted RSquare of 0.853 (Figure 16.6).

## Statistical Details for the Cluster Variables Platform

### Variable Clustering Algorithm

The clustering algorithm iteratively splits clusters of variables and reassigns variables to clusters until no more splits are possible. The initial cluster consists of all variables. The algorithm was developed by SAS and is implemented in PROC VARCLUS (SAS Institute Inc. 2020g).

**Note:** The algorithm uses only observations for which there are no missing values for any variable in the Y, Columns list.

These are the iterative steps in the algorithm:

1. For all clusters, do the following:
   a. Compute the principal components for the variables in each cluster.
b. If the second eigenvalues for all of the clusters are less than one, then terminate the algorithm.

2. Partition the cluster whose second eigenvalue is the largest (and greater than 1) into two new clusters using the following steps:
   a. Rotate the principal components for the variables in the current cluster using an orthoblique rotation.
   b. Define one cluster to consist of the variables in the current cluster whose squared correlations to the first rotated principal component are higher than their squared correlations to the second principal component.
   c. Define the other cluster to consist of the remaining variables in the original cluster. These are the variables that are more highly correlated with the second principal component.
   d. Compute the principal components of the two new clusters.

3. Test to see whether any variable in the data set should be assigned to a different cluster. For each variable, do the following:
   a. Compute the variable’s squared correlation with the first principal component for each cluster.
   b. Place the variable in the cluster for which its squared correlation is the largest.

**Note:** An orthoblique rotation is also known as a raw quartimax rotation. See Harris and Kaiser (1964).
This appendix discusses Wide Linear methods and the use of the singular value decomposition.

Wide Linear Methods and the Singular Value Decomposition

Wide Linear methods in the Cluster, Principal Components, and Discriminant platforms enable you to analyze data sets with thousands (or even millions) of variables. Most multivariate techniques require the calculation or inversion of a covariance matrix. When your multivariate analysis involves a large number of variables, the covariance matrix can be prohibitively large so that calculating it or inverting it is problematic and computationally expensive.

Suppose that your data consist of \( n \) rows and \( p \) columns. The rank of the covariance matrix is at most the smaller of \( n \) and \( p \). In wide data sets, \( p \) is often much larger than \( n \). In these cases, the inverse of the covariance matrix has at most \( n \) nonzero eigenvalues. Wide Linear methods use this fact, together with the singular value decomposition, to provide efficient calculations. See “Calculating the SVD” on page 363.

The Singular Value Decomposition

The singular value decomposition (SVD) enables you to express any linear transformation as a rotation, followed by a scaling, followed by another rotation. The SVD states that any \( n \) by \( p \) matrix \( X \) can be written as follows:

\[
X = U \text{Diag}(\Lambda)V'
\]

Let \( r \) be the rank of \( X \). Denote the \( r \) by \( r \) identity matrix by \( I_r \).

The matrices \( U, \text{Diag}(\Lambda), \) and \( V \) have the following properties:

- \( U \) is an \( n \) by \( r \) semi-orthogonal matrix with \( U'U = I_r \)
- \( V \) is a \( p \) by \( r \) semi-orthogonal matrix with \( V'V = I_r \)
- \( \text{Diag}(\Lambda) \) is an \( r \) by \( r \) diagonal matrix with positive diagonal elements given by the column vector \( \Lambda = (\lambda_1, \lambda_2, ..., \lambda_r)' \) where \( \lambda_1 \geq \lambda_2 \geq ... \geq \lambda_r > 0 \).

The \( \lambda_i \) are the nonzero singular values of \( X \).

The following statements relate the SVD to the spectral decomposition of a square matrix:

- The squares of the \( \lambda_i \) are the nonzero eigenvalues of \( XX' \).
- The \( r \) columns of \( V \) are eigenvectors of \( XX' \).

Note: There are various conventions in the literature regarding the dimensions of the matrices \( U, V, \) and the matrix containing the singular values. However, the differences have no practical impact on the decomposition up to the rank of \( X \).
The SVD and the Covariance Matrix

This section describes how the eigenvectors and eigenvalues of a covariance matrix can be obtained using the SVD. When the matrix of interest has at least one large dimension, calculating the SVD is much more efficient than calculating its covariance matrix and its eigenvalue decomposition.

Let \( n \) be the number of observations and \( p \) the number of variables involved in the multivariate analysis of interest. Denote the \( n \) by \( p \) matrix of data values by \( X \).

The SVD is usually applied to standardized data. To standardize a value, subtract its mean and divide by its standard deviation. Denote the \( n \) by \( p \) matrix of standardized data values by \( X_s \). Then the covariance matrix of the standardized data is the correlation matrix for \( X \) and is defined as follows:

\[
\text{Cov} = \frac{X_s'X_s}{n - 1}
\]

The SVD can be applied to \( X_s \) to obtain the eigenvectors and eigenvalues of \( X_s'X_s \). This allows efficient calculation of eigenvectors and eigenvalues when the matrix \( X \) is either extremely wide (many columns) or tall (many rows). This technique is the basis for Wide PCA. See “Principal Components Report” on page 62 in the “Principal Components” chapter.

The SVD and the Inverse Covariance Matrix

Some multivariate techniques require the calculation of inverse covariance matrices. This section describes how the SVD can be used to calculate the inverse of a covariance matrix.

Denote the standardized data matrix by \( X_s \) and define \( S = X_s'X_s \). The singular value decomposition allows you to write \( S \) as follows:

\[
S = (UDiag(\Lambda)V')'(UDiag(\Lambda)V') = VDiag(\Lambda)^2V'
\]

If \( S \) is of full rank, then \( V \) is a \( p \) by \( p \) orthonormal matrix, and you can write \( S^{-1} \) as follows:

\[
S^{-1} = (VDiag(\Lambda)^2V')^{-1} = VDiag(\Lambda)^{-2}V'
\]

If \( S \) is not of full rank, then \( Diag(\Lambda)^{-1} \) can be replaced with a generalized inverse, \( Diag(\Lambda)^+ \), where the diagonal elements of \( Diag(\Lambda) \) are replaced by their reciprocals. This defines a generalize inverse of \( S \) as follows:

\[
S^{-} = V(Diag(\Lambda)^+)^2V'
\]

This generalized inverse can be calculated using only the SVD.
For more information about the application of the SVD for wide linear discriminant analysis, see “Wide Linear Discriminant Method” on page 117 in the “Discriminant Analysis” chapter.

Calculating the SVD

In the Multivariate Methods platforms, JMP calculates the SVD of a matrix following the method suggested in Golub and Kahan (1965). Golub and Kahan’s method involves a two-step procedure. The first step consists of reducing the matrix $M$ to a bidiagonal matrix $J$. The second step consists of computing the singular values of $J$, which are the same as the singular values of the original matrix $M$. The columns of the matrix $M$ are usually standardized in order to equalize the effect of the variables on the calculation. The Golub and Kahan method is computationally efficient.

Quality and Process Methods describes a number of methods and tools that are available in JMP to help you evaluate and improve quality and process performance:

- Control charts provide feedback on key variables and show when a process is in, or out of, statistical control. Chapter 3, “Control Chart Builder” describes the JMP approach to creating control charts using an interactive control chart platform called Control Chart Builder.

- The Measurement Systems Analysis platform assesses the precision, consistency, and bias of a system. Before you can study a process, you need to make sure that you can accurately and precisely measure the process. If variation comes from the measurement itself, then you are not reliably learning about the process. Use this analysis to find out how your system is performing. See Chapter 4, “Measurement Systems Analysis”.

- The Variability/Attribute Gauge Chart platform creates variability or attribute gauge charts. Variability charts analyze continuous measurements and reveal how your system is performing. Attribute charts analyze categorical measurements and show you measures of agreement across responses. You can also perform a gauge study to see measures of variation in your data. See Chapter 5, “Variability Gauge Charts” and Chapter 6, “Attribute Gauge Charts”.

- The Process Capability platform measures the ability of a process to meet specification limits. You can compare process performance, summarized by process centering and variability, to specification limits. The platform calculates capability indices based on both long-term and short-term variation. The analysis helps identify the variation relative to the specifications; this enables you to achieve increasingly higher conformance values. See Chapter 7, “Process Capability”.

- CUSUM charts enable you to make decisions based on the cumulative sum. These charts can detect small shifts in a process. See Chapter 8, “CUSUM Control Charts”.

- Exponentially weighted moving average (EWMA) charts can also be used to detect small shifts in a process. See Chapter 9, “EWMA Control Charts”.

- When you need to monitor multiple process characteristics simultaneously, see Chapter 10, “Multivariate Control Charts”.

- The Model Driven Multivariate Control Chart (MDMVCC) platform enables you to build a control chart based on principal components or partial least squares models. See Chapter 11, “Model Driven Multivariate Control Charts”.

Chapter 2
Introduction to Quality and Process Methods
Tools for Process and Product Improvement
• Chapter 12, “Legacy Control Charts” describes the older control chart platforms in JMP. Instead of using these platforms, you are encouraged to use the Control Chart Builder platform, as well as the new CUSUM and EWMA Control Chart platforms.

• The Pareto Plot platform shows the frequency of problems in a quality related process or operation. Pareto plots help you decide which problems to solve first by highlighting the frequency and severity of problems. See Chapter 13, “Pareto Plots”.

• The Diagram platform constructs cause-and-effect diagrams, which organize the sources of a problem for brainstorming or as a preliminary analysis to identify variables for further experimentation. Once complete, further analysis can be done to identify the root cause of the problem. See Chapter 14, “Cause-and-Effect Diagrams”.

• The Manage Spec Limits utility enables you to quickly add or edit many specification limits for several columns at once. See “Manage Spec Limits Utility” on page 403 in the “Quality Utilities” chapter.

• The Operating Characteristic (OC) Curves utility enables you to construct OC curves for control charts and attribute acceptance sampling plans. See “Operating Characteristic Curves Utility” on page 407 in the “Quality Utilities” chapter.
A control chart is a graphical and analytic tool for monitoring process variation. The natural variation in a process can be quantified using a set of control limits. Control limits help distinguish common-cause variation from special-cause variation. Typically, action is taken to identify and eliminate special-cause variation. It is also important to quantify the common-cause variation in a process, as this determines the capability of a process.

Use Control Chart Builder to create control charts of your process data. Control Chart Builder can be launched as an interactive workspace or from specific control chart menu options. In the interactive workspace, you select the variables that you want to chart and drag them into zones. JMP automatically chooses an appropriate chart type based on the data. You can quickly create another type of chart, or change the current settings for an existing chart.

Chapter 3
Quality and Process Methods

Sigma Calculations for Three Way Control Charts................................. 96
Overview of Control Chart Builder

A control chart is a graphical and analytic tool for monitoring process variation and identifying special-cause variation in a process. Establishing control limits to filter out routine variation helps determine whether a process is stable and predictable. If the variation in a process is more than desired, the process can be adjusted to create higher quality output with potential cost savings.

All processes exhibit measurement variation as the process is monitored over time. There are two types of variation in process measurements:

- **Routine or common-cause** variation. Measurements from a stable process still exhibit random variation. When process measurements exhibit only common-cause variation, the measurements stay within expected limits.

- **Abnormal or special-cause** variation. Special-cause variation is indicated by patterns observed on the control chart. Examples include a shift in the process mean, points above or below the control limits, or measurements that trend up or down. These shifts in the process measurements can be caused by factors such as a broken tool or machine, equipment degradation, or changes to raw materials. A change or defect in the process is often identifiable by abnormal variation in the process measurements.

Control Chart Builder enables you to create several types of control charts including Shewhart and Rare Event control charts. Shewhart control charts are broadly classified into control charts for variables and control charts for attributes. Rare event charts are designed for events that occur infrequently. JMP provides a flexible, user-defined approach to building control charts. You can construct control charts in the following ways:

- Use the interactive Control Chart Builder workspace. When you drag a data column to the workspace, Control Chart Builder creates an appropriate chart based on the data type and sample size.

- Use the control chart menu options to build a specific control chart using a launch window.

Once an initial chart is created through either method above, use the menus and other options to change the type of chart, change the statistic on the chart, reformat the chart, or add additional charts.
Example of Control Chart Builder

The Socket Thickness.jmp sample data table contains measurements for the thickness of sockets. There has been an increase in the number of defects during production and you want to investigate why this is occurring. This example illustrates how to perform this investigation in Control Chart Builder using either the interactive approach or the launch window approach. The second approach is convenient if you know which type of control chart you want to build.

Control Chart Builder Interactive Method

Use the interactive Control Chart Builder workspace to investigate the variability in the process data.

1. Select Help > Sample Data Library and open Quality Control/Socket Thickness.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Thickness to the Y zone.
4. Drag Hour to the Subgroup zone (at bottom).

Figure 3.2 Control Charts for Socket Thickness

Looking at the Average chart, you can see that there are several points below the lower control limit of 7.788772. You want to see whether another variable might be contributing to the problem.

5. Drag Cavity into the Phase zone.
6. Click Done.
From the Average chart, you can conclude the following:

- There are differences between the cavities, indicating the need for separate control limits for each cavity.
- Cavity 1 is producing sockets with an average thickness above that of the other cavities. This indicates that further investigation of the differences between cavities is warranted.
- All of the cavities have points that are outside the control limits. Therefore, you should investigate the lack of control in the process for each cavity.

The Range chart for each cavity shows that the within-subgroup measurements are in control and are similar across cavities.

Control Chart Builder Launch Window Method

Use the XBar Control Chart launch window to obtain the same chart as Figure 3.3.

1. Select Help > Sample Data Library and open Quality Control/Socket Thickness.jmp.
2. Select Analyze > Quality and Process > Control Chart > XBar Control Chart.
3. Select Thickness and click Y.
4. Select Hour and click Subgroup.
5. Select Cavity and click Phase.
6. Click OK.

You should see the same control chart that appears in Figure 3.3.
Control Chart Types

Control Chart Builder enables you to create several types of control charts, including Shewhart Variable, Shewhart Attribute, and Rare Event charts.

• “Shewhart Control Charts for Variables”
• “Shewhart Control Charts for Attributes”
• “Rare Event Control Charts”
• “Control Chart Types”

Shewhart Control Charts for Variables

Control charts for variables are classified according to the subgroup summary statistic plotted on the chart.

• XBar charts are a type of location chart that display subgroup means (averages).
• R charts are a type of dispersion chart that display subgroup ranges (maximum – minimum).
• S charts are a type of dispersion chart that display subgroup standard deviations.
• Presummarize charts display both subgroup means and standard deviations.
• Individual Measurement charts are a type of location chart that display individual measurements.
• Moving Range charts are a type of dispersion chart that display moving ranges of two successive measurements.

Note: If you remove a dispersion chart or turn off the preference Show Two Shewhart Charts in File > Preferences > Platforms > Control Chart Builder, you will see only the location chart. Any associated scripts will contain the JSL option Show Two Shewhart Charts set to off (0).

XBar, R, and S Charts

For quality characteristics measured on a continuous scale, a typical analysis shows both the process mean and its variability with a mean chart aligned above its corresponding R or S chart.
Individual Measurement Charts

Individual Measurement charts display individual measurements. Individual Measurement charts are appropriate when only one measurement is available for each sampling time point. If you are charting individual measurements, the individual measurement chart shows above its corresponding moving range chart. Moving Range charts display moving ranges of two successive measurements.

Presummarize Charts

If your data consist of repeated measurements of the same process unit, you can combine these into one measurement for the unit. Pre-summarizing is not recommended unless the data contain repeated measurements on each process or measurement unit.

Presummarize summarizes the process column into sample means and/or standard deviations, based either on the sample size or sample label chosen. Then it charts the summarized data based on the options chosen in the window.

Levey-Jennings Charts

Levey-Jennings charts show a process mean with control limits based on a long-term sigma. The control limits are placed at 3s distance from the center line. The standard deviation, s, for the Levey-Jennings chart is calculated the same way standard deviation is in the Distribution platform.

Shewhart Control Charts for Attributes

Attributes charts are applicable for count data. Attribute charts are based on binomial and Poisson models. Because the counts are measured per subgroup, it is important when comparing multiple charts to determine whether you have a similar number of items in the subgroups between the charts. Attribute charts, like variables charts, are classified according to the subgroup sample statistic plotted on the chart.

<table>
<thead>
<tr>
<th>Distribution Used to Calculate Sigma</th>
<th>Statistic Type: Proportion</th>
<th>Statistic Type: Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial</td>
<td>P chart</td>
<td>NP chart</td>
</tr>
<tr>
<td>Poisson</td>
<td>U chart</td>
<td>C chart</td>
</tr>
</tbody>
</table>
Control Chart Builder makes some decisions for you based on the variable selected. Once the basic chart is created, you can use the menus and other options to change the type, the statistic, and the format of the chart.

- **P charts** display the proportion of nonconforming (defective) items in subgroup samples, which can vary in size. Because each subgroup for a P chart consists of \( N_i \) items, and an item is judged as either conforming or nonconforming, the maximum number of nonconforming items in a subgroup is \( N_i \).

- **NP charts** display the number of nonconforming (defective) items in subgroup samples. Because each subgroup for an NP chart consists of \( N_i \) items, and an item is judged as either conforming or nonconforming, the maximum number of nonconforming items in subgroup \( i \) is \( N_i \).

- **C charts** display the number of nonconformities (defects) in a subgroup sample that usually, but does not necessarily, consists of one inspection unit.

- **U charts** display the number of nonconformities (defects) per unit in subgroup samples that can have a varying number of inspection units.

**Rare Event Control Charts**

A Rare Event chart is a control chart that provides information about a process where the data comes from rarely occurring events. Tracking processes that occur infrequently on a traditional control chart tend to be ineffective. Rare event charts were developed in response to the limitations of control charts in rare event scenarios. Control Chart Builder provides two types of rare event charts (G charts and T charts). The difference between a G chart and a T chart is the quantity used to measure distance between rare events. The G chart measures counts of events between incidents, whereas the T chart measures time intervals between incidents.

<table>
<thead>
<tr>
<th>Distribution Used to Calculate Sigma</th>
<th>Chart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negative Binomial</td>
<td>G chart</td>
</tr>
<tr>
<td>Weibull</td>
<td>T chart</td>
</tr>
</tbody>
</table>
G charts

A G chart measures the number of events between rarely occurring errors or nonconforming incidents, and creates a chart of a process over time. Each point on the chart represents the number of units between occurrences of a relatively rare event. For example, in a production setting, where an item is produced daily, an unexpected line shutdown can occur. You can use a G chart to look at the number of units produced between line shutdowns.

When reading a G chart, the points above the upper control limit indicate that the number of events between errors has increased. If the number of events between rarely occurring errors or nonconforming incidents has increased, that is good. Therefore, a point flagged as out of control above the limits is generally considered a desirable effect when working with G charts.

T charts

A T chart measures the time intervals elapsed since the last event. Each point on the chart represents a number of time intervals that have passed since a prior occurrence of a rare event. A T chart can be used for numeric, nonnegative data, date/time data, and time-between data. Since a traditional plot of these data might contain many points at zero and an occasional point at one, using a T chart avoids flagging numerous points as out of control. The data points for a T chart in Control Chart Builder are restricted to integer values.

When reading a T chart, the points above the upper control limit indicate that the amount of time between events has increased. This means that the rate of adverse events has decreased. Therefore, a point flagged as out of control above the limits is generally considered a desirable effect when working with T charts.

Control Chart Types

The most common control charts are available in Control Chart Builder and in the platforms in the Analyze > Quality and Process > Control Chart menu. Use Control Chart Builder as your first choice to easily and quickly generate charts. JMP automatically chooses the appropriate chart type based on the data. Table 3.3 through Table 3.7 summarize the different control chart types.

Launch Control Chart Builder

You can launch Control Chart Builder in the following two ways:

- If you are not sure what type of control chart is appropriate for your data, select Analyze > Quality and Process > Control Chart Builder. This method enables you to drag data columns to the workspace and Control Chart Builder creates an appropriate chart based on the data type and sample size. See “Control Chart Builder Interactive Workspace” on page 42.

- If you know which type of control chart is appropriate for your data, select the appropriate chart from the Analyze > Quality and Process > Control Chart submenu. This displays a control chart launch window. See “Launch Windows for Specific Control Charts” on page 44. There are control chart builder launch windows for the following control charts:
  - I/MR Control Chart
  - XBar Control Chart
  - Run Chart
  - P Control Chart
  - NP Control Chart
  - C Control Chart
  - U Control Chart
  - Levey Jennings Control Chart
  - I/MR on Means Control Chart
  - Three Way Control Chart

Note: The CUSUM Control Chart, EWMA, and Multivariate Control Charts launch in their own platforms instead of launching in Control Chart Builder, and are documented separately. See the “CUSUM Control Charts” chapter on page 247, the “Multivariate Control Charts” chapter on page 277, and the “EWMA Control Charts” chapter on page 263.

Once you click OK in a launch window, the Control Chart Builder window appears with the Control Panel hidden by default. All other options and features are the same.
Control Chart Builder Interactive Workspace

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

To begin creating a control chart, drag variables from the **Select Columns** box into the zones. If you drop variables in the center, JMP guesses where to put them based on whether the variables are continuous or categorical. The Control Chart Builder workspace contains the following zones:

**Y** Assigns the process variable.

**Subgroup** Assigns subgroup variables. To define subgroup levels as a combination of multiple columns, add multiple variables to the **Subgroup** zone. When a subgroup variable is assigned, each point on the control chart corresponds to a summary statistic for all of the points in the subgroup.

**Phase** Assigns phase variables. When a Phase variable is assigned, separate control limits are computed for each phase. See also “Filter the Control Chart by Another Variable” on page 75.
The initial Control Chart Builder window contains the following buttons:

**Undo**  Reverses the last change made to the window.

**Start Over**  Returns the window to the default condition, removing all data, and clearing all zones.

**Done**  Hides the buttons and the Select Columns box and removes all drop zone outlines. In this presentation-friendly format, you can copy the graph to other programs. To restore the window to the interactive mode, click the Control Chart Builder red triangle and select **Show Control Panel**.

**By**  Identifies the variable and produces a separate analysis for each value that appears in the column.

**Shewhart Variables/Shewhart Attribute/Rare Event**  Enables you to select Shewhart Variables, Shewhart Attribute, or Rare Event control chart types. If you select an Attribute chart type, an n Trials box and zone appear on the chart.

**n Trials**  (Available for Attribute charts.) Assigns a lot size for an attribute control chart.

**New Y Chart**  Produces a copy of the current chart for every column selected in the Select Columns box. The new charts use the selected columns in the Y role.

Once you drag variables to the chart, other buttons and options appear at left that enable you to show, hide or switch items on the chart (Figure 3.7). Many of these functions (Points, Limits, Warnings, etc.) are the same as the functions available when you right-click the chart. See “Options Panel and Right-Click Chart Options” on page 51. For information about warnings and rules, see “Tests” on page 55 and “Westgard Rules” on page 59.

**Three Way Control Chart**  Enables you to produce a three way control chart for variable chart types. The subgroup size must be greater than one. The plotting statistic is based on subgroup averages, within-subgroup variation, or between-subgroup variation. The default set of three includes a presummarized chart of the averages using Moving Range limits, a Moving Range chart and a Range chart.

**Event Chooser**  Allows the chart to respond in real time to selection changes. There are several standard groups of responses that are recognized and pre-scored (for example, pass/fail, yes/no, Likert Scales, conforming/non-conforming, and defective/non-defective). If you are analyzing results from a survey and want to focus solely on a specific sector of the results for one or more questions, you can make the selection on the screen. When you make the selection, the chart is scored again and replotted immediately. The levels selected in the Event Chooser are counted as events, and all other levels are counted as non-events.

The Event Chooser is available for attribute charts with response columns that have a modeling type of nominal or ordinal. If you want the Event Chooser to work on a numeric integer-valued nominal or ordinal response column, you must select the Use Event
Chooser option from the Control Chart Builder red triangle menu. The Event Chooser does not appear for response columns with a modeling type of continuous.

**Launch Windows for Specific Control Charts**

The options that you see in the launch windows vary depending on whether you are launching variable control charts or attribute control charts.

**Launch Windows for Variable Control Charts**

This section contains information about the launch windows for I/MR, XBar, Run, Levey Jennings, I/MR on Means, and Three Way Control Charts.

**Figure 3.5** Launch Window for Variable Control Charts

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y** Assigns the process variables.

**Subgroup** (Available only for XBar, Levey Jennings, I/MR on Means, and Three Way Control Charts.) Assigns the subgroup variables. When a subgroup variable is assigned, each point on the control chart corresponds to a summary statistic for all of the points in the subgroup.

**Phase** (Not available for Run Charts.) Assigns the phase variable. When a Phase variable is assigned, separate control limits are computed for each phase.

**By** Identifies a variable to produce a separate analysis for each value that appears in the column.
Launch Windows for Attribute Control Charts

This section contains information about the launch windows for NP, P, C, and U Control Charts.

Figure 3.6  Launch Window for Attribute Control Charts

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Y  Assigns the process variables.

Subgroup  Assigns the subgroup variables. When a subgroup variable is assigned, each point on the control chart corresponds to a summary statistic for all of the points in the subgroup.

n Trials  Assigns the subgroup sample size.

Phase  Assigns the phase variable. When a Phase variable is assigned, separate control limits are computed for each phase.

By  Identifies a variable to produce a separate analysis for each value that appears in the column.
Control Chart Builder Window

Use Control Chart Builder to construct control charts for process data. The analysis produces a chart that can be used to evaluate whether a process is in a state of statistical control. The report varies depending on which type of chart you select. Control charts update dynamically as data is added or changed in the data table. Figure 3.7 displays the Control Chart Builder window for the Bottle Tops.jmp sample data table.

To create the chart:

1. Select Help > Sample Data Library and open Quality Control/Bottle Tops.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Status to the Y zone.
4. Drag Sample to the Subgroup zone (at bottom).

You can drag other variables into the various zones to augment the analysis and use the Control Chart Builder Options to further examine the data. Some of the right-click chart options (for example, show or hide points, limits, warnings, and zones; select statistic and sigma options) also appear on the left hand side of the chart for easy access.

Control charts have the following characteristics:

- Each point plotted on the chart represents an individual process measurement or summary statistic. Subgroups should be chosen rationally, that is, they should be chosen to maximize the probability of seeing a true process signal between subgroups. Often, this
requires knowledge of the process to determine the most effective grouping strategy. See Wheeler (2004); Woodall and Adams (1998).

- The vertical axis of a control chart is scaled in the same units as the summary statistic.
- The horizontal axis of a control chart identifies the subgroup samples and is time ordered. Observing the process over time is important in assessing if the process is changing.

The green line is the center line, or the average of the data. The center line indicates the average (expected) value of the summary statistic when the process is in statistical control. Measurements should appear equally on both sides of the center line. If not, this is possible evidence that the process average is changing.

- The two red lines are the upper and lower control limits, labeled UCL and LCL. These limits give the range of variation to be expected in the summary statistic when the process is in statistical control. If the process is exhibiting only routine variation, then all the points should fall randomly in that range.

**Note:** To hide the lower control limits on dispersion, attribute, and rare event charts, deselect the Show Lower Limit option in the options panel. To change the default to always hide the lower control limits, deselect the Show Lower Control Limit preference in File > Preferences > Platforms > Control Chart Builder.

- A point outside the control limits signals the presence of a special cause of variation.

Options in the Control Chart Builder window create control charts that can be updated dynamically as samples are received and recorded or added to the data table. When a control chart signals abnormal variation, action should be taken to return the process to a state of statistical control if the process degraded. If the abnormal variation indicates an improvement in the process, the causes of the variation should be studied and implemented.

When you double-click the axes, the appropriate Axis Specification window appears for you to specify the format, axis values, number of ticks, gridline, reference lines, and other options to display.

---

**Control Chart Builder Options**

Control Chart Builder options appear in the red triangle menu or by right-clicking on a chart or axis. Some of the right-click chart options also appear on the bottom left hand side of the chart for easy access. You can also set preferences for many of the options in Control Chart Builder at File > Preferences > Platforms > Control Chart Builder.

- “Control Chart Builder Red Triangle Menu Options”
- “Options Panel and Right-Click Chart Options”
- “Control Chart Builder Right-Click Axis Options”
Control Chart Builder Red Triangle Menu Options

The Control Chart Builder red triangle menu contains the following options:

**Show Control Panel**  Shows or hides the following elements:
- buttons
- the Select Columns box
- the drop zone borders
- check boxes and drop-down menus

**Show Limit Summaries**  Shows or hides the Limit Summaries report. This report shows the control limits (LCL and UCL), the center line (Avg), the Points and Limits plotted, and the Sample Size for the chart. Sample size is not shown for rare event charts.

**Show Capability**  (Available only for Shewhart Variables charts that have specification limits.) Shows or hides the Process Capability Analysis report. Since the report is part of the Limit Summaries report, the Process Capability report appears only when the Show Limit Summaries option is selected. For more information, see “The Process Capability Report” on page 189. You can set preferences for many of the options in the Process Capability report in Control Chart Builder at File > Preferences > Platforms > Process Capability.

**Note:** Show Capability is not available if the response variable has no variation.

**Show Alarm Report**  Shows or hides a report that contains information about out of control samples. The report reflects failures for currently enabled tests in each chart and updates automatically as different tests are enabled and disabled and as data and row states change. A second table lists the currently enabled tests for each chart. The first table contains the following columns:

- **Position**  Indicates the numerical position of the chart, starting from the top of the report.
- **Total Samples Out of Control**  Counts the number of samples that failed at least one of the selected tests.
- **Alarm Rate**  The total number of samples out of control divided by the total number of nonmissing samples. This is also known as the Proportion Out of Control.

**Note:** The counts that contribute to the calculation of the alarm rate include excluded samples only if the Test Excluded Subgroups and the Show Excluded Region options are both selected.

**Show Limit Labels**  Shows or hides labels for the limits in each chart. The limits are shown inside the right frame of the chart.
**Show Sigma Report**  (Available only for Shewhart Variables charts.) Shows or hides the Process Sigma Report, which is a table of sigma values. The Process Sigma Report contains the overall sample size, number of subgroups, sample mean, overall sigma, within sigma, and stability index. For three way control charts, the between-sigma and between-and-within sigma values are also shown. If a phase variable is specified, a set of values is given for each phase.

**Note:** The Process Sigma Report appears only if the Limit Summaries report is turned on.

**Get Limits**  Retrieves the control limits that are stored in an open or saved data table.

**Show Excluded Region**  Shows (on) or removes (off) the regions of the chart where samples have been excluded. When entirely excluded subgroups are shown on the location chart, they appear as dimmed points to indicate that they are excluded.

**Caution:** The Show Excluded Region option impacts the chart. Excluded samples are removed from the calculation of control limits, whether this option is on or off. Excluded samples are included in alarm rate calculations only if the Test Excluded Subgroups and the Show Excluded Region options are both selected.

**Set Subgroup Size**  (Not available if a subgroup variable is specified.) Sets a subgroup size. Missing values are taken into account when computing limits and sigma.

**Note:** If the Set Subgroup Size option is used, the Show Excluded Region option is turned on automatically.

**Save Limits**  Saves the control limits in one of the following ways:

- **in Column**  Saves control limits as a column property in the existing data table for the response variable. If the limits are constant, LCL, Avg, and UCL values for each chart type in the report are saved. This option is not available with phase charts. In addition, the option has no effect if the sample sizes are not constant for each chart.

- **in New Table**  Saves the standard deviation and mean for each chart into a new data table. If the limits are constant, the LCL, Avg, UCL, and Sample Size for each chart are saved as well. If there are phases, a new set of values is saved for each phase. There is a row for each statistic and a column for each Y variable.

- **in New Tall Table**  (Not available for Rare Event, Attribute, or Phase charts.) Saves the standard deviation, mean, and Sigma for each chart into a new data table. If the limits are constant, the LCL, Avg, UCL, and Sample Size for each chart are saved as well. There is a row for each Y variable and a column for each statistic. A column for Sigma that can be used in the Process Screening platform is also saved.
**Save Summaries**  Creates a new data table containing such information as the sample label, sample sizes, statistic being plotted, center line, control limits, and any tests, warnings and failures. The specific statistics included in the table depend on the type of chart.

**Graph Spacing**  Sets the amount of space between the graphs.

**Include Missing Categories**  Enables the graph to collect rows with missing values in a categorical column, and displays the missing values on the graph as a separate category. If this option is disabled, all rows with a missing X value are removed from the calculations, in addition to being hidden from the graph.

This option is not available for continuous X variables or categorical Y variables because there is no compelling way to display the collected missing values on the relevant axes. By default, this option is enabled.

**Note:** If Include Missing Categories is enabled, capability analysis results in Control Chart Builder do not match those in the Process Capability platform if a categorical X variable has missing values.

**Use Event Chooser**  (Available only for attribute charts with numeric non-continuous Y variables.) Categorizes ordinal numeric data and offers individual numeric-level modeling selections.

**Alarm Script**  Enables you to write and run a script that indicates when the data fail special causes tests. See “Tests” on page 55. Results can be written to the log or spoken aloud, and there is an option to include an explanation of why the test failed. You can also send results to an email using the custom script option.

As an Alarm Script is invoked, the following variables are available, both in the issued script and in subsequent JSL scripts:

- `qc_col` is the name of the column
- `qc_test` is the test that failed
- `qc_sample` is the sample number
- `qc_phase` is the label of the phase during which the failure occurred

See the *Scripting Guide* for more information about writing custom Alarm Scripts.

**Note:** Alarm scripts are not available in reports that use the Local Data Filter.

**Sort by Row Order**  Sorts all subgroup and phase variables in the order in which the levels appear in the data table. This applies to all combinations of nested subgroup and phase variables.

**Test Excluded Subgroups**  (Available only if the Show Excluded Region option is selected.) Includes (on) or excludes (off) entirely excluded subgroups in the computation of tests.
When excluded subgroups are shown and the Text Excluded Subgroups option is not selected, the excluded subgroups are treated as missing values.

**Note:** For any test that relies on consecutive points (runs tests), an entirely excluded subgroup is treated as missing and counts of consecutive points are restarted.

**Control Chart Dialog**  (Available only if the control chart is launched through a Control Chart launch window.) Opens the Control Chart launch window with the original settings that were used to create the control chart.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

- Column Switcher is available only for a single Y variable having two or fewer associated charts. Based on the selected chart type, only columns that are appropriate for the Y role are included in the Column Switcher column list.
- In Control Chart Builder, the Automatic Recalc option is turned on by default and cannot be turned off.
- When using the local data filter, you can deselect the Show Excluded Region option for more focused exploration.

### Options Panel and Right-Click Chart Options

The following options appear on the left hand side of the Control Chart Builder report for easy access and when you right-click a chart.

**Points**  Provides the following options:

**Statistic**  Changes the statistic plotted on the chart. See “Statistic” on page 54.

**Individual Points**  Show or hides individual observations in a subgroup. Available only with a subgroup variable or Set Sample Size. This option is not available for Attribute chart types or Rare Event charts.
Box Plots  (Available only for Shewhart Variables charts.) Shows or hides box plots on the chart.

Show Connect Line  Shows connecting lines between the points.

Show Points  Shows or hides the points on the chart.

Limits  Provides the following options:

Sigma  Specifies the method of computing sigma. See “Sigma” on page 54.

Zones  (Available only for Variables and Attribute chart types.) Shows or hides the zones on the chart. There are three equal-width zones on either side of the mean. Zones are not drawn below the LCL or above the UCL. If the limits for a Variables chart are not centered around the mean, \( \min(Avg-LCL, UCL-Avg)/3 \) is used as the width of each zone. The zones for an Attributes chart use a width of \( (UCL-Avg)/3 \).

Shade Zones  Shows or hides shading zones by ranges. Zone C is shaded green, zones A and B are shaded yellow, and beyond zone A is shaded red.

Spec Limits  (Available only if the data table has a Spec Limits column property or if you specify Spec Limits using the Add Spec Limits option.) Shows or hides the specification limits on the chart. By default, the spec limits are shown if the Spec Limits column property has the Show as Graph Reference Lines option selected. See Using JMP for information about adding a Spec Limits column property.

Add Spec Limits  Enables you to enter specification limits.

Set Control Limits  Enables you to enter control limits for tests. After you click OK in the Set Control Limits window, the specified control limits are set uniformly across groups. Select this option again to remove the specified control limits.

Add Limits  Specifies additional control limits to be plotted on the chart. These limits are not used in tests.

Show Upper Limit  Shows or hides the upper control limit on the chart. If you hide the upper control limit on a chart, the Test Beyond Limits and Test 1 options do not flag points associated with the hidden upper control limit.

Show Lower Limit  Shows or hides the lower control limit on the chart. If you hide the lower control limit on a chart, the Test Beyond Limits and Test 1 options do not flag points associated with the hidden lower control limit.

Show Center Line  Shows or hides the center line on the chart.

Add Dispersion Chart  Adds a dispersion chart to the chart area. Change the chart type with the Points options. A dispersion chart illustrates the variation in the data by plotting one of
many forms of dispersion, including the range, standard deviation, or moving range. Available only for Variables chart types.

**Note:** You can customize the default dispersion chart type using the Dispersion Chart and Summarized Dispersion Chart preferences in File > Preferences > Platforms > Control Chart Builder.

**Set Subgroup Size**  Sets a subgroup size. Missing values are taken into account when computing limits and sigma.

**Warnings**  Provides the following options:

- **Customize Tests**  Enables you to design custom tests and select or deselect multiple tests at once. After the option is selected, the Customize Tests window appears for designing the tests. Select a test description, and enter the desired number (n) and label. You can save the settings to preferences and also restore the default settings. Available only for Variables and Attribute chart types.

- **Tests**  Enables you to select which statistical control tests to enable. For more information about tests, see “Tests” on page 55. Available only for Variables and Attribute chart types.

  **Note:** Hover over a flagged point on the chart to see a description of the test that failed.

- **Westgard Rules**  Specifies the set of Westgard statistical control tests that are enabled. Because Westgard rules are based on sigma and not the zones, they can be computed without regard to constant sample size. For more information about tests, see “Westgard Rules” on page 59. Available only for Variables and Attribute chart types.

- **Test Beyond Limits**  (Called Test 15 in JMP) Enables the test for any points beyond the control limits. These points are identified on the chart. This test works on all charts with limits, regardless of the sample size being equal.

  **Note:** If you hide the upper or lower control limits, the Test Beyond Limits option does not flag points that are beyond limits that are not shown on the control chart.

**Remove Graph**  Removes the control chart.

**Remove Location Chart**  (Available only if you right-click a location chart.) Removes the location chart from the report.

**Remove Dispersion Chart**  (Available only if you right-click a dispersion chart.) Removes the dispersion chart from the report.

**Note:** For a description of the Rows, Graph, Customize, and Edit menus, see *Using JMP*. 
Statistic

You can change the statistic represented by the points on the chart. The options available depend on the chart type selected.

For Variables chart types, you can change the statistic represented by the points on the chart using the following options:

**Individual**   Creates a chart where each point represents an individual value in the data table.

**Average**   Creates a chart where each point represents the average of the values in a subgroup.

**Range**   Creates a chart where each point represents the range of the values in a subgroup.

**Standard Deviation**   Creates a chart where each point represents the standard deviation of the values in a subgroup.

**Moving Range on Means**   Computes the difference in the range between two consecutive subgroup means.

**Moving Range on Std Dev**   Computes the difference in the range between two consecutive subgroup standard deviations.

**Moving Range**   Creates a chart where each point is the difference between two consecutive observations.

**Note:** The Average, Range, Standard Deviation, Moving Range on Means, and Moving Range on Std Dev methods appear only if a subgroup variable with a sample size greater than one is specified or a sample size is set.

For Attribute chart types, you can change the statistic represented by the points on the chart using the following options:

**Proportion**   Creates a chart where each point represents the proportion of items in subgroup samples.

**Count**   Creates a chart where each point represents the number of items in subgroup samples.

For Rare Event chart types, the statistic represented by the points on the chart uses the Count option.

Sigma

You can change the method for computing sigma for the chart. The options available depend on the chart type selected.
For Variables chart types, you can use the following options:

**Range**  Uses the range of the data in a subgroup to estimate sigma.

**Standard Deviation**  Uses the standard deviation of the data in a subgroup to estimate sigma.

**Moving Range**  Uses the moving ranges to estimate sigma. The moving range is the difference between two consecutive points.

**Median Moving Range**  Uses the median moving range to estimate sigma, rather than the average moving range.

**Levey-Jennings**  Uses the standard deviation of all the observations to estimate sigma. If your chart has phases, sigma is calculated for each phase separately.

For Attribute chart types, you can use the following options:

**Binomial**  Uses the binomial distribution model to estimate sigma. The model indicates the number of successes in a sequence of experiments, where each experiment yields success with some probability. Selecting Binomial yields either a P or NP chart.

**Poisson**  Uses the Poisson distribution model to estimate sigma. The model indicates the number of events and the time at which these events occur in a given time interval. Selecting Poisson yields either a C or U chart.

For Rare Event chart types, you can use the following options:

**Negative Binomial**  Uses the negative binomial distribution model to estimate sigma. The model indicates the number of successes in a sequence of trials before a specified number of failures occur. Selecting Negative Binomial yields a G chart.

**Weibull**  Uses the Weibull distribution model to estimate sigma. The model indicates the mean time between failures. Selecting Weibull yields a T chart.

**Tests**

The Warnings option in the pop-up menu or on the left hand side of the window displays a submenu for Tests selection. You can select one or more tests for special causes (Western Electric rules) from the menu. Nelson (1984) developed the numbering notation used to identify special tests on control charts. The tests work with both equal and unequal sample sizes.

If a selected test is positive for a particular sample, that point is labeled with the test number. When you select several tests for display and more than one test signals at a particular point, the label of the numerically lowest test specified appears beside the point. You can hover over a flagged point on the chart to see a description of the test that failed.
Tip: To add or remove several tests at once, select or deselect the tests in the Control Panel under **Warnings > Tests**.

Table 3.8 on page 57 lists and interprets the eight tests, and Figure 3.9 illustrates the tests. The following rules apply to each test:

- The area between the upper and lower limits is divided into six zones, each with a width of one standard deviation.
- The zones are labeled A, B, C, C, B, A with zones C nearest the center line.
- A point lies in Zone B or beyond if it lies beyond the line separating zones C and B. That is, if it is more than one standard deviation from the center line.
- Any point lying on a line separating two zones lines is considered belonging to the innermost zone. So, if a point lies on the line between Zone A and Zone B, the point is considered to be in Zone B.
- When a Phase variable is specified, the counts for each test are reset at the start of each phase.

Notes:

- Tests 1 through 8 apply to all Shewhart Variables chart types.
- Tests 1, 2, 5, and 6 apply to the upper and lower halves of the chart separately.
- Tests 3, 4, 7, and 8 apply to the whole chart.
- Once a runs test (one that is based on consecutive observations) is triggered, the counts do not reset to 0 when moving to the next sample.
- Runs tests handle excluded rows based on the setting of the Show Excluded Region and Test Excluded Subgroups options.
  - By default, both options are selected, and the excluded rows are included in the runs tests calculations.
  - If the Show Excluded Region option is selected and the Test Excluded Subgroups option is not selected, the excluded rows are treated as missing and the counts for the runs tests reset to 0 when moving to the next sample.
  - If the Show Excluded Region option is not selected, the excluded rows are treated as if they are deleted.
- Tests 5 through 8 are not available for attribute charts.

See Nelson (1984, 1985) for further recommendations on how to use these tests.
Table 3.8 Description and Interpretation of Tests for Special Causes

<table>
<thead>
<tr>
<th>Test 1</th>
<th>One point beyond Zone A (upper or lower)</th>
<th>Detects a shift in the mean, an increase in the standard deviation, or a single aberration in the process. For interpreting Test 1, any dispersion chart (R, S, or MR) can be used to rule out increases in variation. Note that if you hide the upper or lower control limits, the Test 1 option does not flag points that are associated with limits that are not shown on the control chart.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test 2</td>
<td>Nine points in a row in a single (upper or lower) side of Zone C or beyond</td>
<td>Detects a shift in the process mean.</td>
</tr>
<tr>
<td>Test 3</td>
<td>Six points in a row steadily increasing or decreasing (anywhere on the chart)</td>
<td>Detects a trend or drift in the process mean.</td>
</tr>
<tr>
<td>Test 4</td>
<td>Fourteen points in a row alternating up and down (anywhere on the chart)</td>
<td>Detects systematic effects such as two alternately used machines, vendors, or operators.</td>
</tr>
</tbody>
</table>
### Table 3.8 Description and Interpretation of Tests for Special Causes\(^a\) (Continued)

| Test 5 | Two out of three points in a row in or beyond Zone A and the point itself is in or beyond Zone A; the two points must be on the same side (upper or lower) | Detects a shift in the process average or increase in the standard deviation. Any two out of three points provide a positive test. |
| Test 6 | Four out of five points in a row in or beyond Zone B and the point itself is in or beyond Zone B; the four points must be on the same side (upper or lower) | Detects a shift in the process mean. Any four out of five points provide a positive test. |
| Test 7 | Fifteen points in a row in Zone C, above and below the center line | Detects stratification of subgroups when the observations in a single subgroup come from various sources with different means. Also detects a reduction in variation. |
| Test 8 | Eight points in a row on both sides of the center line with none in Zones C | Detects stratification of subgroups when the observations in one subgroup come from a single source, but subgroups come from different sources with different means. |

\(a\). Nelson (1984, 1985)
Westgard Rules

Westgard rules are implemented under the Westgard Rules submenu of the Warnings option when you right-click a chart or on the left hand side of the window. The different tests are abbreviated with the decision rule for the particular test. For example, 1 2s refers to a test where one point is two standard deviations away from the mean.

Notes:

- Once a runs test (one that is based on consecutive observations) is triggered, the counts do not reset to 0 when moving to the next sample.

- Runs tests handle excluded rows based on the setting of the Show Excluded Region and Test Excluded Subgroups options.
  - By default, both options are selected, and the excluded rows are included in the runs tests calculations.
  - If the Show Excluded Region option is selected and the Test Excluded Subgroups option is not selected, the excluded rows are treated as missing and the counts for the runs tests reset to 0 when moving to the next sample.
  - If the Show Excluded Region option is not selected, the excluded rows are treated as if they are deleted.

Rule 1 2S (called Test 9 in JMP) is commonly used with Levey-Jennings charts, where control limits are set 2 standard deviations away from the mean. The rule is triggered when any one point goes beyond these limits.

Rule 1 3S (called Test 10 in JMP) refers to a rule common to Levey-Jennings charts where the control limits are set 3 standard deviations away from the mean. The rule is triggered when any one point goes beyond these limits.

Rule 2 2S (called Test 11 in JMP) is triggered when two consecutive control measurements are farther than two standard deviations from the mean.
Rule R 4S (called Test 12 in JMP) is triggered when one measurement is greater than two standard deviations from the mean and the previous measurement is greater than two standard deviations from the mean in the opposite direction such that the difference is greater than 4 standard deviations.

Rule 4 1S (called Test 13 in JMP) is triggered when four consecutive measurements are more than one standard deviation from the mean.

Rule 10 X (called Test 14 in JMP) is triggered when ten consecutive points are on one side of the mean.

Control Chart Builder Right-Click Axis Options

Remove Graph  Removes the entire graph.

Remove  Removes a variable.

Note: If there is more than one chart type on the graph, a submenu listing the different charts is displayed. You can select which chart to remove.

For more information about the Axis Settings, Revert Axis, Add or Remove Axis Label, Save to Column Property, and Edit options, see Using JMP.
Work with Control Limits

Control limits are based on the performance of your process and tell you about the variability in your process. Upper control limits (UCLs), center lines, and lower control limits (LCLs) are calculated from the data when a control chart is created. You can use these calculated control limits to indicate when your process has changed.

It is important to note that control limits are different from specification limits, which are often used in capability analysis.

Table 3.9  Control Limits versus Specification Limits

<table>

</tbody>
</table>

Example of Control Limits

In this example, consider a company’s printing process. Variations can cause distortion in the line, including skew, thickness, and length problems. In this example, we will consider the length of the line. A line is considered good if it has a printed length of 16 cm +/- 0.2 cm. Any longer and the sentence might run off of the page. Any shorter and there would be a lot of wasted space on the page. For every print run, the first and last books are taken for measurement. The line lengths are measured on a specified page in the middle of each book.

You want to know: Is this process in control (stable)? Are we getting consistent print quality? What happens when we make improvements to the printing process? Does quality improve? To answer these questions, we need to create control charts and use control limits.

This example is in three parts. In most cases, you would start with Create the Baseline Control Chart, where you let JMP calculate the control limits for you. Then, to apply these control limits to new data, you would either Specify Control Limits or Specify Multiple Sets of Control Limits (for phase data).

Create the Baseline Control Chart

First, examine whether the existing process is in control. If it is, we can use the control limits created by JMP as our baseline or historical limits.

1. Select Help > Sample Data Library and open Quality Control/Line Length.jmp.
2. Select **Analyze > Quality and Process > Control Chart Builder**.

3. Drag Length to the \( Y \) zone.

   An Individual and Moving Range chart of Length appears. This chart is appropriate if you have no natural subgrouping in your data. However, in this example, there is a natural subgrouping, which is each print run.

4. Drag Run to the **Subgroup** zone (at bottom).

**Figure 3.10** XBar and R Chart of Line Length by Print Run

Three lines are drawn horizontally across the XBar and R charts. These are the calculated LCL (lower control limit), Avg (average) and UCL (upper control limit).

Ideally, we would like for all of our points to fall within the control limits, and we would like for the points to fall randomly within these limits. Looking at the graph, we see that no points fall outside of the control limits, and there does not appear to be a pattern to the points. To investigate further, perform Western Electric tests to check for patterns and trends that would cause these tests to fail. (The Western Electric tests are also referred to as Nelson tests.)

5. In the XBar chart, right-click and select **Warnings > Tests > All Tests**.

Notice that no points were circled or flagged. This means that our process is in control or stable.

If we had determined that our process was not in control, we would investigate out of control points or work to alter our process so that it is in control. For this example, since the process is already in control or stable, we can skip that step. Now, you can use these
control limits with new data. Proceed to “Specify Control Limits” on page 64, or “Specify Multiple Sets of Control Limits” on page 68 (to see an example with phase data).

Specify Control Limits

Since we established that the process is in control, we can use these historical limits with new data to see how the new data compares to the existing process. To use historical limits, we need to specify control limits instead of having JMP calculate them.

There are several ways to specify control limits in JMP:

- “Set Control Limits Option” on page 64
- “Add a Column Property” on page 65
- “Use the Get Limits Option” on page 66
- “Exclude Rows” on page 67

Set Control Limits Option

One simple way to specify control limits is to use the Set Control Limits option in Control Chart Builder.

1. Select Help > Sample Data Library and open Quality Control/New Length Data.jmp. This is the table that contains your new data.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Length to the Y zone.
4. Drag Run to the Subgroup zone (at bottom).
5. Right-click in the Average (XBar) chart and select Limits > Set Control Limits.
6. Enter these limits:
   - LCL - 15.90519
   - Avg - 15.99825
   - UCL - 16.09131
   These are the historical limits from the Average (XBar) chart in Figure 3.10.
7. Click OK.
8. Right-click in the Range (R) chart and select Limits > Set Control Limits.
9. Enter these limits:
   - LCL - 0
   - Avg - 0.0495
   - UCL - 0.161693
   These are the historical limits from the Range (R) chart in Figure 3.10.
10. Click **OK**.

**Figure 3.11** XBar and R Chart of Line Length with Historical Limits

Rather than calculating limits from the data, JMP used the historical control limits that you defined. In the Length Limit Summaries table, notice that the Limits Sigma now says User Defined. Many points now fall outside of the limits. Also, the averages are higher than those of the baseline process. This process appears different from the original process that we used to calculate the baseline control limits.

**Add a Column Property**

Another way to specify control limits is to add the Control Limits column property to a column in your new data table.

1. Select **Help > Sample Data Library** and open **Quality Control/New Length Data.jmp**. This is the table that contains your new data.
2. Select the Length column and click **Cols > Column Info**.
3. Click **Column Properties > Control Limits**.
4. XBar is selected, so enter these fixed limits for the Average (XBar) chart:
   - Avg - 15.99825
   - LCL - 15.90519
   - UCL - 16.09131

These are the historical limits from the Average (XBar) chart in Figure 3.10.
5. Click XBar > R. Enter these fixed limits for the Range (R) chart:
   - Avg - 0.0495
   - LCL - 0
   - UCL - 0.161693
   These are the historical limits from the Range (R) chart in Figure 3.10.
   Leave the value for Subgroup Size as missing. This value is not used in the Control Chart Builder platform.

6. Click OK.
   You have entered control limits for XBar and R charts for the Length column. Now you can create a control chart.

7. Select Analyze > Quality and Process > Control Chart Builder.

8. Drag Length to the Y zone.

9. Drag Run to the Subgroup zone (at bottom).

   The control chart is identical to Figure 3.11.

**Use the Get Limits Option**

The Get Limits method of specifying control limits is the most flexible. You should use this method in the following cases:

- If you have control limits for many different processes
- If you have different control limits for each phase (see “Specify Multiple Sets of Control Limits” on page 68)

To use the Get Limits method, you need a data table that defines your historical limits. For more information about how to create a limits table, see “Saving and Retrieving Limits” on page 347 in the “Legacy Control Charts” chapter.

**Note:** When no subgroup variable is specified, the Get Limits option uses the subgroup size (_Sample Size) from the limits table. Also, when the limits are missing in the file, JMP also looks for the sigma (_Std Dev). When no LCL or UCL are specified in the limits file (if both the average and sigma are found, and the subgroup size is constant), the option sets the limits based on the average, subgroup size, and sigma.

In this example, a limits data table has already been created.

1. Select Help > Sample Data Library and open Quality Control/New Length Data.jmp.
   This is the table that contains your new data.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag Length to the **Y** zone.
4. Drag Run to the **Subgroup** zone (at bottom).
5. Click the Control Chart Builder red triangle and select **Get Limits**.
6. Select **Other** and click **OK**.
7. Navigate and open the limits data table for this example, called Length Limits.jmp. By default, the file is located here:
   - On Windows: C:\Program Files\SAS\JMP\16\Samples\Data\Quality Control
   - On macOS: \Library\Application Support\JMP\16\Samples\Data\Quality Control

The control chart is identical to Figure 3.11.

**Exclude Rows**

Another way to specify control limits is to exclude rows in a data table. One advantage to this method is that you can see both the historical data and new data in the same graph. This can help to visualize and investigate differences when they occur between the data collection periods.

To use this method, you must meet the following criteria:

- New and old data must reside in the same data table.
- Historical data and new data must all have equal subgroup sizes.
- All new data must be excluded in the data table (using Rows > Exclude/Unexclude).

In this example, new data have already been excluded.

1. Select **Help > Sample Data Library** and open Quality Control/Combined.jmp.
   - This table contains old and new data, and the rows corresponding to the new data are excluded.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag Length to the **Y** zone.
4. Drag Run to the **Subgroup** zone (at bottom).
JMP uses only the unexcluded rows (historical data) to create the control limits. The new data (excluded data) are plotted on the graph (dimmed), but these data were not used in any of the calculations.

Specify Multiple Sets of Control Limits

In this example, you want to set different control limits for different phases of a process. The column property, set control limits, and excluded row state methods will not work in this situation because these methods are limited to only one set of control limits for the entire chart. For a control chart with phases, you need to use the get limits method.

In the printing company, the goal is to reduce the variability of the force needed to break the bond between paper and the book spine for three different sites. Each site has different machines, different operators, and is also located in different countries; therefore, each site has a unique set of historical limits. For all three sites, the company does the following:

1. Creates a baseline control chart based on the existing process data.
2. Changes the process, based on a designed experiment.
3. Gathers data from the new process.
4. Creates a new control chart based on the new process data.

The goal is to plot the new data on a control chart using historical limits from the old process. In this way, the printing company can compare the new process to the old process limits.
Create a Control Chart Based on Existing Process

1. Select **Help > Sample Data Library** and open *Quality Control/Phase Historical Data.jmp*. This table contains the existing process data for all three sites.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag **Force** to the **Y** zone.
4. Drag **Run** to the **Subgroup** zone (at bottom).
5. Drag **Site** to the **Phase** zone.

**Figure 3.13** Baseline Control Chart for Existing Data

Create a Control Chart Based on Updated Process

1. From the report in Figure 3.13, click the Control Chart Builder red triangle and select **Save Limits > in New Table**.
   This creates a limits table.
2. Save this new limits table to any location, so you can access it later.
3. Select **Help > Sample Data Library** and open *Quality Control/Phase New Data.jmp*. This data was collected from all three sites after the change was made to the process.
4. Select **Analyze > Quality and Process > Control Chart Builder**.
5. Drag **Force** to the **Y** zone.
6. Drag **Run** to the **Subgroup** zone (at bottom).
7. Drag **Site** to the **Phase** zone.
8. Click the Control Chart Builder red triangle and select **Get Limits**. Open the limits table that you saved in step 2.

This applies the historical limits to the new data in the Control Chart Builder report.

**Figure 3.14** Control Chart for New Data Based on Historical Limits

Now you can see how the new data (after the process change) compare with the historical process limits (before the process change). None of the points fall outside of the control limits for either the location or dispersion chart. The goal was to reduce variability. Looking at the moving range chart, you can see that most points fall below the average line. For sites 1 and 2, it is clear that the variability of force needed to break the bond between pages and the book spine has been decreased. The decrease at Site 3 is not as strong as at sites 1 and 2. The improvements to the printing process appear to have succeeded in reducing the variability.

---

**Excluded and Hidden Samples in Control Chart Builder**

The following bullets summarize the use of excluded and hidden samples in control chart builder:

- Excluded subgroups are not used in the calculations of control limits, and appear on the chart as dimmed points by default. If the Show Excluded Region option is not selected, the points for the excluded subgroups do not appear in the chart, are treated as missing in Tests for Special Causes, and are not included in the count of points for Tests for Special Causes.
• Hidden observations are used in the calculations of control limits, but do not appear in the chart.

• Rows that are both hidden and excluded are included in the count of points for Tests for Special Causes when the Test Excluded Subgroups option is selected. An excluded row can be labeled with a special cause flag. A hidden point cannot be labeled. If the flag for a Tests for Special Causes test is on a hidden point, it will not appear in the chart.

• For partially excluded subgroups, if one or more observations within a subgroup is excluded, and at least one observation within the subgroup is included, the excluded observation is not included in the calculations of either the point statistic or the limits.

• Checks for negative and non-integer data happen on the entire data (even excluded values).

• Tests apply to all excluded subgroups only when the Test Excluded Subgroups option is selected.

---

### Additional Examples of Control Chart Builder

**Note:** In this section, some examples show the Control Panel while others do not. To show or hide the Control Panel, select Show Control Panel from the Control Chart Builder red triangle menu.

- “Individual Measurement and Moving Range Charts Example”
- “XBar and R Chart Phase Example”
- “XBar and S Charts with Varying Subgroup Sizes Example”
- “Run Chart Example”
- “P chart Example”
- “NP chart Example”
- “C chart Example”
- “U chart Example”
- “G chart Example”
- “T chart Example”
- “Three Way Control Chart Example”
Individual Measurement and Moving Range Charts Example

The Pickles.jmp data in the Quality Control sample data folder contains the acid content for vats of pickles. Because the pickles are sensitive to acidity and produced in large vats, high acidity ruins an entire pickle vat. The acidity in four vats is measured each day at 1, 2, and 3 PM. The data table records day, time, and acidity measurements.

1. Select Help > Sample Data Library and open Quality Control/Pickles.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Acid to the Y role.
4. Click the Control Chart Builder red triangle and select Show Limit Labels.

This option labels the control limits and averages in both charts.

Figure 3.15 Individual Measurement and Moving Range Charts for Acid

The individual measurement and moving range charts monitor the acidity in each vat produced (subgroup of size 1). Vat 13 has an acidity above the upper control limit of 14.05.

You can also view a Median Moving Range chart. Continue with the following steps to change the charts to use median moving ranges.

5. In the Limits[1] outline, change the Sigma setting to Median Moving Range.
The limits in the individual measurement and median moving range charts use the median moving range as the sigma, rather than the average moving range. This results in slightly narrower control limits for Acid.

**XBar and R Chart Phase Example**

A manufacturer of medical tubing collected tube diameter data for a new prototype. The data was collected over the past 40 days of production. After the first 20 days (phase 1), some adjustments were made to the manufacturing equipment. Analyze the data to determine whether the past 20 days (phase 2) of production are in a state of control.

1. Select Help > Sample Data Library and open Quality Control/Diameter.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag DIAMETER to the Y role.
4. Drag DAY to the Subgroup role (at bottom).
Figure 3.17 Control Charts for Diameter

The first 20 days appear to have high variability, and in the Average chart, there are three observations that are outside of the control limits. An adjustment was made to the manufacturing equipment and new control limits were incorporated.

To compute separate control limits for each phase:

5. Drag Phase to the Phase role.

6. In the Average chart, right-click and select Warnings > Test Beyond Limits.

Including the Phase variable means that the control limits for phase 2 are based only on the data for phase 2. None of the phase 2 observations are outside the control limits. This is highlighted by including the zone shading on the chart. Therefore, you can conclude that the process is in control after the adjustments were made.

**Filter the Control Chart by Another Variable**

This data table, Diameter.jmp, contains a column for the operator of the machine for each sample. You can use the Local Data Filter with Control Chart Builder to show the data for a subset of operators.

8. Click the **Control Chart Builder** red triangle and deselect **Show Excluded Region**.

Turning off the Show Excluded Region option indicates that the subgroups that are excluded by settings in the Local Data Filter no longer appear on the horizontal axis of the control chart as you make selections in the Local Data Filter. As a result, you see only the portion of the data that are of interest.

9. Click the **Control Chart Builder** red triangle and select **Local Data Filter**.

10. In the Local Data Filter, click on OPERATOR and click the + button.

11. In the Local Data Filter, select the bar labeled RMM.
The XBar and R charts now show only the points for the RMM operator, as denoted by the Where() statement below the charts. The limits for both phases have been adjusted to reflect that the observations for the other three operators have been excluded.

XBar and S Charts with Varying Subgroup Sizes Example

This example uses the Coating.jmp data table. This quality characteristic of interest is the Weight 2 column.

1. Select Help > Sample Data Library and open Quality Control/Coating.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Weight 2 to the Y role.
4. Drag Sample to the Subgroup role (at bottom).
Weight 2 has several missing values in the data, so the chart has uneven limits. Although each sample has the same number of observations, samples 1, 3, 5, and 7 each have a missing value.

Instead of viewing a line connecting the averages of each sample, you can switch to viewing box plots at each sample.

5. In the Points[1] outline, deselect the Show Connected Line option.
6. In the Points[1] outline, select the Box Plots option.
Run Chart Example

Runs charts display a column of data as a connected series of points. This example is a Runs chart for the Close variable from Stock Averages.jmp in the Quality Control sample data folder.

1. Select Help > Sample Data Library and open Stock Averages.jmp.
2. Select Analyze > Quality and Process > Control Chart > Run Chart.
3. Select Close and click Y.
4. Click OK.
**P chart Example**

The Washers.jmp sample data contains defect data for two different lot sizes from the *ASTM Manual on Presentation of Data and Control Chart Analysis*, American Society for Testing and Materials (1976). To view the differences between constant and variable sample sizes, you can compare charts for Lot Size and Lot Size 2.

The Washers.jmp data in the Quality Control sample data folder contains defect counts of 15 lots of 400 galvanized washers. The washers were inspected for finish defects such as rough galvanization and exposed steel. If a washer contained a finish defect, it was deemed nonconforming or defective. Thus, the defect count represents how many washers were defective for each lot of size 400. Using the Washers.jmp data table, specify a sample size variable, which would allow for varying sample sizes. This data table contains all constant sample sizes.

1. Select **Help > Sample Data Library** and open Quality Control/Washers.jmp.
2. Select **Analyze > Quality and Process > Control Chart > P Control Chart**.
3. Select # defective and click Y.
4. Select Lot Size and click n Trials.
5. Click OK.
6. In the Limits outline, deselect the **Show Lower Limit** option.
This hides the lower limit, which is not of interest in this situation.

**Figure 3.23** P chart of # defective with sample size

To view the differences between constant and variable sample sizes, you can compare charts for Lot Size and Lot Size 2 by simply dragging the variables to the nTrials zone.

**NP chart Example**

The Bottle Tops.jmp sample data contains simulated data from a bottle top manufacturing process. Sample is the sample ID number for each bottle. Status indicates whether the bottle top conformed to the design standards. In the Phase column, the first phase represents the time before the process adjustment. The second phase represents the time after the process adjustment. Notes on changes in the process are also included.

1. Select **Help > Sample Data Library** and open Quality Control/Bottle Tops.jmp.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag Sample to the **Subgroup** role.
4. Drag Status to the **Y** role.
The original observations appear to have high variability and there are five observations (Samples 13, 15, 21, 22 and 23) that are outside of the upper control limit. Samples 15 and 23 note that new material and a new operator were introduced into the process, respectively. At the end of the phase, an adjustment was made to the manufacturing equipment. Therefore, the control limits for the entire series should not be used to assess the control during phase 2.

To compute separate control limits for each phase:

5. Drag Phase to the Phase zone.
Including the Phase variable means that the control limits for phase 2 are based only on the data for phase 2. None of the phase 2 observations are outside the control limits. Therefore, you can conclude that the process is in control after the adjustment.

**C chart Example**

The Cabinet Defects.jmp sample data table contains data concerning the various defects discovered while manufacturing cabinets over two time periods.

1. Select **Help > Sample Data Library** and open Quality Control/Cabinet Defects.jmp.
2. Select **Analyze > Quality and Process > Control Chart > C Control Chart**.
3. Select **Type of Defect** and click **Y**.
4. Select **Lot Number** and click **Subgroup**.
5. Select **Date** and click **Phase**.
6. Click **OK**.
Figure 3.26 C chart of Type of Defect with Phases

You can now view the results on the two different days. Both appear to be within limits. To examine other defect type behavior, select another defect type under the Event Chooser > Type of Defect and view the results as the limits are updated.

U chart Example

The Braces.jmp data in the Quality Control sample data folder records the defect count in boxes of automobile support braces. A box of braces is one inspection unit. The number of boxes inspected (per day) is the subgroup sample size, which can vary. The U chart in Figure 3.27 is monitoring the number of brace defects per subgroup sample size. The upper and lower bounds vary according to the number of units inspected.

1. Select Help > Sample Data Library and open Quality Control/Braces.jmp.
2. Select Analyze > Quality and Process > Control Chart > U Control Chart.
3. Select # defects and click Y.
4. Select Unit size and click n Trials.
5. Click OK.
**G chart Example**

A G chart is an effective way to understand whether rare events are occurring more frequently than expected and warrant an intervention. See “Rare Event Control Charts” on page 37.

The Adverse Reactions.jmp sample data table contains simulated data about adverse drug events (ADEs) reported by a group of hospital patients. An ADE is any type of injury or reaction the patient suffered after taking the drug. The date of the reaction and the number of days since the last reaction were recorded.

1. Select **Help > Sample Data Library** and open Quality Control/Adverse Reactions.jmp.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag Doses since Last ADE to the **Y** role.
4. Drag Date of ADE to the **Subgroup** role.
   An Individual & Moving Range chart of Doses since Last ADE appears.
5. In the drop-down list, select **Rare Event** instead of **Shewhart Variables**.
A G chart of Doses since Last ADE appears, showing that the number of doses given since the last event.

**Figure 3.28** G chart of Doses since Last ADE

---

**T chart Example**

T charts are used to measure the time that has elapsed since the last event. See “Rare Event Control Charts” on page 37.

The Fan Burnout.jmp sample data table contains simulated data for a fan manufacturing process. The first column identifies each fan that burned out. The second column identifies the number of hours between each burnout.

1. Select **Help > Sample Data Library** and open Quality Control/Fan Burnout.jmp.
2. Select **Analyze > Quality and Process > Control Chart Builder**.
3. Drag Hours between Burnouts to the **Y** role.
4. Drag Burnout to the **Subgroup** role.
5. In the drop-down list, select Rare Event instead of Shewhart Variables. A T chart of Hours between Burnouts appears.

6. Under Limits, change the Sigma from Negative Binomial to Weibull.
In the T chart, all points appear to be within the control limits. It is clear that the Individual & Moving Range chart was inappropriate for the analysis, as the limits were too narrow.

**Three Way Control Chart Example**

Three way control charts are useful when there is variation between batches and variation within batches.

1. Select **Help > Sample Data Library** and open Quality Control/Vial Fill Weights.jmp.
2. Select **Analyze > Quality and Process > Control Chart > Three Way Control Chart**.
3. Select Fill Weight and click **Y**.
4. Select Sample and click **Subgroup**.
5. Click **OK**.
Figure 3.31 Three Way Control Chart for Fill Weight

A Moving Range chart appears between the Range and Average charts. The limits on the Average (XBar) chart are now calculated using the moving range between each sample.
Statistical Details for Control Chart Builder

Notes:

- Control limits are calculated using a sigma multiplier, $K$, which is set to 3 by default. To change the default value of $K$, use the KSigma preference in File > Preferences > Platforms > Control Chart Builder.
- For sample sizes up to $n = 50$, JMP uses control chart constants $d_2(n)$ and $d_3(n)$ that are defined in Table 2 of Harter (1960). For samples with a sample size greater than 50, JMP uses the control chart constant values for sample size 50 in both the sigma and control limit calculations.

- “Control Limits for XBar and S Charts”
- “Control Limits for Individual Measurement and Moving Range Charts”
- “Control Limits for P and NP Charts”
- “Control Limits for U Charts and C Charts”
- “Levey-Jennings Charts”
- “Control Limits for G Charts”
- “Control Limits for T Charts”
- “Sigma Calculations for Three Way Control Charts”

Control Limits for XBar and R Charts

JMP generates control limits for XBar and R charts using the following formulas:

LCL for XBar chart = $X_{\bar{w}} - \frac{K\hat{\sigma}}{\sqrt{n_i}}$

UCL for XBar chart = $X_{\bar{w}} + \frac{K\hat{\sigma}}{\sqrt{n_i}}$

LCL for R chart = $\max\left(d_2(n_i)\hat{\sigma} - Kd_3(n_i)\hat{\sigma}, 0\right)$

UCL for R chart = $d_2(n_i)\hat{\sigma} + Kd_3(n_i)\hat{\sigma}$

Center line for R chart: By default, the center line for the $i^{th}$ subgroup (where $K$ is the sigma multiplier) indicates an estimate of the expected value of $R_i$. This value is computed as follows: $d_2(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of $\sigma$. 
The standard deviation for XBar and R charts is estimated using the following formula:

\[
\sigma = \frac{R_1}{d_2(n_1)} + \ldots + \frac{R_N}{d_2(n_N)} \frac{N}{N}
\]

where:

- \( \bar{X}_w \) = weighted average of subgroup means
- \( K \) = the sigma multiplier and is set to 3 by default
- \( \sigma \) = process standard deviation
- \( n_i \) = sample size of \( i^{th} \) subgroup
- \( d_2(n) \) is the expected value of the range of \( n \) independent normally distributed variables with unit standard deviation
- \( d_3(n) \) is the standard deviation of the range of \( n \) independent normally distributed variables with unit standard deviation
- \( R_i \) is the range of \( i^{th} \) subgroup
- \( N \) is the number of subgroups for which \( n_i \geq 2 \).

**Control Limits for XBar and S Charts**

JMP generates control limits for XBar and S charts using the following formulas:

- LCL for XBar chart = \( \bar{X}_w - \frac{K\hat{\sigma}}{\sqrt{n_i}} \)
- UCL for XBar chart = \( \bar{X}_w + \frac{K\hat{\sigma}}{\sqrt{n_i}} \)
- LCL for S chart = \( \max\left(c_4(n_i)\hat{\sigma} - Kc_5(n_i)\hat{\sigma}, 0\right) \)
- UCL for S chart = \( c_4(n_i)\hat{\sigma} + Kc_5(n_i)\hat{\sigma} \)

Center line for S chart: By default, the center line for the \( i^{th} \) subgroup (where \( K \) is the sigma multiplier) indicates an estimate of the expected value of \( s_i \). This value is computed as \( c_4(n_i)\hat{\sigma} \), where \( \hat{\sigma} \) is an estimate of \( \sigma \).
The estimate for the standard deviation for XBar and S charts is:

\[
\hat{\sigma} = \frac{s_1}{c_4(n_1)} + \ldots + \frac{s_N}{c_4(n_N)}
\]

where:
- $\bar{X}_w$ = weighted average of subgroup means
- $K$ = the sigma multiplier and is set to 3 by default
- $\sigma$ = process standard deviation
- $n_i$ = sample size of $i^{th}$ subgroup
- $c_4(n)$ is the expected value of the standard deviation of $n$ independent normally distributed variables with unit standard deviation
- $c_5(n)$ is the standard error of the standard deviation of $n$ independent normally distributed variables with unit standard deviation
- $N$ is the number of subgroups for which $n_i \geq 2$
- $s_i$ is the sample standard deviation of the $i^{th}$ subgroup

Control Limits for Individual Measurement and Moving Range Charts

Control limits for Individual Measurement charts are computed as follows:
- LCL for Individual Measurement Chart = $\bar{X} - K\hat{\sigma}$
- UCL for Individual Measurement Chart = $\bar{X} + K\hat{\sigma}$

Control limits for Individual Measurement charts with sigma estimated by the median moving range are computed as follows:
- LCL for Individual Measurement Chart = $\bar{X} - K\hat{\sigma}_{MMR}$
- UCL for Individual Measurement Chart = $\bar{X} + K\hat{\sigma}_{MMR}$

Control limits for Moving Range charts are computed as follows:
- LCL for Moving Range Chart = $\max\{d_2(n)\hat{\sigma} - Kd_3(n)\hat{\sigma}, 0\}$
- UCL for Moving Range Chart = $d_2(n)\hat{\sigma} + Kd_3(n)\hat{\sigma}$
Control limits for Median Moving Range charts are computed as follows:

\[
\text{LCL}_{\text{MMR}} = \max(0, \text{MMR} - K d_3(n) \hat{\sigma}_{\text{MMR}})
\]

\[
\text{UCL}_{\text{MMR}} = \text{MMR} + K d_3(n) \hat{\sigma}_{\text{MMR}}
\]

The standard deviation for Individual Measurement and Moving Range charts is estimated as follows:

\[
\hat{\sigma} = \frac{\overline{MR}}{d_2(n)}
\]

The standard deviation for Individual Measurement and Moving Range charts when using the median is estimated as follows:

\[
\hat{\sigma}_{\text{MMR}} = \frac{\text{MMR}}{0.954}
\]

where:

\(
\overline{X} = \text{the mean of the individual measurements}
\)

\(
K = \text{the sigma multiplier and is set to 3 by default}
\)

\(
\overline{MR} = \text{the mean of the nonmissing moving ranges computed as } (\overline{MR}_2+\overline{MR}_3+\ldots+\overline{MR}_N)/(N-1)
\)

where \(\overline{MR}_i = |x_i - x_{i-1}|\).

\(\text{MMR} = \text{the median of the nonmissing moving ranges}
\)

\(\hat{\sigma} = \text{the process standard deviation}
\)

\(d_2(n) = \text{expected value of the range of } n \text{ independent normally distributed variables with unit standard deviation.}
\)

\(d_3(n) = \text{standard deviation of the range of } n \text{ independent normally distributed variables with unit standard deviation}
\)

**Note:** Moving Range charts in Control Chart Builder use a range span of \(n=2\).

### Control Limits for P and NP Charts

The lower and upper control limits, LCL, and UCL, respectively, are computed using the following formulas:

\[
P \text{ chart LCL} = \max(\hat{p} - K \sqrt{\hat{p}(1-\hat{p})/n_i}, 0)
\]

\[
P \text{ chart UCL} = \min(\hat{p} + K \sqrt{\hat{p}(1-\hat{p})/n_i}, 1)
\]

\[
\text{NP chart LCL} = \max(n_i \hat{p} - K \sqrt{n_i \hat{p}(1-\hat{p})}, 0)
\]
NP chart UCL = \min(n_i\bar{p} + K\sqrt{n_i\bar{p}(1-\bar{p})}, n_i)

where:

\bar{p} is the average proportion of nonconforming items taken across subgroups

\bar{p} = \frac{n_1p_1 + \ldots + n_Np_N}{n_1 + \ldots + n_N} = \frac{X_1 + \ldots + X_N}{n_1 + \ldots + n_N}

n_i is the number of items in the \(i^{th}\) subgroup

K is the sigma multiplier and is set to 3 by default

Control Limits for U Charts and C Charts

The lower and upper control limits, LCL, and UCL, are computed using the following formulas:

U chart LCL = \max(\bar{u} - K\sqrt{\bar{u}/n_i}, 0)

U chart UCL = \bar{u} + K\sqrt{\bar{u}/n_i}

C chart LCL = \max(n_i\bar{u} - K\sqrt{n_i\bar{u}}, 0)

C chart UCL = n_i\bar{u} + K\sqrt{n_i\bar{u}}

The limits vary with \(n_i\).

\(u_i\) is the number of nonconformities per unit in the \(i^{th}\) subgroup. In general, \(u_i = c_i/n_i\).

K is the sigma multiplier and is set to 3 by default

\(c_i\) is the total number of nonconformities in the \(i^{th}\) subgroup

\(n_i\) is the number of inspection units in the \(i^{th}\) subgroup

\(\bar{u}\) is the average number of nonconformities per unit taken across subgroups. The quantity \(\bar{u}\) is computed as a weighted average

\bar{u} = \frac{n_1u_1 + \ldots + n_Nu_N}{n_1 + \ldots + n_N} = \frac{c_1 + \ldots + c_N}{n_1 + \ldots + n_N}

N is the number of subgroups
Levey-Jennings Charts

Levey-Jennings charts show a process mean with control limits based on a long-term sigma. The control limits are placed at \( K \)\(^*\)s distance from the center line, where \( K = 3 \) by default.

The standard deviation, \( s \), for the Levey-Jennings chart is calculated the same way standard deviation is in the Distribution platform.

\[
s = \sqrt{\frac{\sum_{i=1}^{N} (y_i - \bar{y})^2}{N-1}}
\]

See Levey and Jennings (1950); Westgard (2002).

Control Limits for G Charts

The negative binomial distribution is an extension of the geometric (Poisson) distribution and allows for over-dispersion relative to the Poisson. The negative binomial distribution can be used to construct both exact and approximate control limits for count data. Approximate control limits can be obtained based on a chi-square approximation to the negative binomial. All data is used as individual observations regardless of subgroup size.

Let \( X \) have a negative binomial distribution with parameters \((\mu, k)\). Then:

\[
P(X \leq r) \sim P\left( \chi^2_v \leq \frac{2r + 1}{1 + \mu k} \right)
\]

where:

\( \chi^2_v \) is a chi-square variate with \( v = 2\mu/(1+\mu k) \) degrees of freedom.

Based on this approximation, approximate upper and lower control limits can be determined. For a nominal level \( \alpha \) Type 1 error probability in one direction, an approximate upper control limit is a limit \( UCL \) such that the following equation is true:

\[
P(X > UCL) = 1 - P\left( \chi^2_v \leq \frac{2UCL + 1}{1 + \mu k} \right) = \alpha
\]

Likewise, an approximate lower control limit, \( LCL \), is a limit such that the following equation is true:

\[
P(X < LCL) = 1 - P\left( \chi^2_v \geq \frac{2LCL + 1}{1 + \mu k} \right) = \alpha
\]
Thus, an approximate level lower and upper control limits, LCL and UCL, respectively, are computed using the following formulas:

\[
\text{UCL} = \frac{\chi^2_{v, 1 - \alpha} (1 + \mu k) - 1}{2}
\]

\[
\text{LCL} = \max\left\{0, \frac{\chi^2_{v, \alpha} (1 + \mu k) - 1}{2}\right\}
\]

where:

\(\chi^2_{v, 1 - \alpha}(\chi^2_{v, \alpha})\) is the upper (lower) percentile of the chi-square distribution with \(v = 2\mu/(1+\mu k)\) degrees of freedom. Negative lower control limits can be set to zero.

For more information about the negative binomial control limits, see Hoffman (2003).

**Control Limits for T Charts**

The estimates of the shape and scale parameters are calculated from the data and used to obtain the percentiles of the Weibull distribution.

**Note:** Subgroups with a response value of zero are given a weight of zero when estimating the Weibull distribution parameters.

Define the following quantities:

- \(p_1 = \text{normalDist}(-K)\) for Normal (0,1)
- \(p_2 = \text{normalDist}(0)\) for Normal (0,1)
- \(p_3 = \text{normalDist}(K)\) for Normal (0,1)

Then the limits are calculated using the following formulas:

\(\text{LCL} = \text{Weibull Quantile} (p_1, \beta, \alpha)\)
\(\text{CL} = \text{Weibull Quantile} (p_2, \beta, \alpha)\)
\(\text{UCL} = \text{Weibull Quantile} (p_3, \beta, \alpha)\)

where:

- \(\beta\) is the shape parameter and \(\alpha\) is the scale parameter for the Weibull Quantile function
- \(K\) is the sigma multiplier and is set to 3 by default

For more information about the Weibull Quantile function, see Help > Scripting Index.
Sigma Calculations for Three Way Control Charts

Within Sigma Based on Average of Ranges

The within sigma estimate for three way control charts that is estimated using the average of ranges can be used for the Individual on Means, Moving Range on Means and R chart.

\[ \hat{\sigma}_{\text{within}} = \frac{R_1}{d_2(n_1)} + \cdots + \frac{R_N}{d_2(n_N)} \]

The formula uses the following notation:

- \( R_i \) = range of \( i^{\text{th}} \) subgroup
- \( n_i \) = sample size of \( i^{\text{th}} \) subgroup
- \( d_2(n_i) \) = expected value of the range of \( n_i \) independent normally distributed variables with unit standard deviation
- \( N \) = number of subgroups for which \( n_i \geq 2 \)

Within Sigma Based on Average of Unbiased Standard Deviations

The within sigma estimate for three way control charts that is estimated using the average of unbiased standard deviations can be used for the Individual on Means, Moving Range on Means, and S chart.

\[ \hat{\sigma}_{\text{within}} = \frac{s_1}{c_4(n_1)} + \cdots + \frac{s_N}{c_4(n_N)} \]

The formula uses the following notation:

- \( s_i \) = sample standard deviation of the \( i^{\text{th}} \) subgroup
- \( n_i \) = sample size of \( i^{\text{th}} \) subgroup
- \( c_4(n_i) \) = expected value of the standard deviation of \( n_i \) independent normally distributed variables with unit standard deviation
- \( N \) = number of subgroups for which \( n_i \geq 2 \)
Between Sigma

The between sigma estimate for three way control charts is estimated using the moving range of subgroup means.

\[
\hat{\sigma}_{\text{between}} = \sqrt{\frac{(\overline{MR})^2}{d_2(2)^2} - \frac{\hat{\sigma}^2_{\text{within}}}{H}}
\]

The formula uses the following notation:

- \(\overline{MR}\) = the mean of the nonmissing moving ranges computed as \((MR_2+MR_3+...+MR_N)/(N-1)\) where \(MR_i = |y_i - y_{i-1}|\).
- \(d_2(2)\) = expected value of the range of two independent normally distributed variables with unit standard deviation.
- \(H = \frac{N}{1/n_1 + 1/n_2 + ... + 1/n_N}\), the harmonic mean of subgroup sample sizes.

**Note:** If between Sigma is estimated as a negative value, it is set to 0.

Between-and-Within Sigma

The between-and-within sigma estimate for three way control charts is estimated using a combination of the within sigma and between sigma estimates.

\[
\hat{\sigma}_{\text{between-and-within}} = \sqrt{\hat{\sigma}_{\text{within}}^2 + \hat{\sigma}_{\text{between}}^2}
\]
The Measurement Systems Analysis (MSA) platform assesses the precision, consistency, and bias of a measurement system. Before you can study the process itself, you need to make sure that you can accurately and precisely measure the process. If most of the variation that you see comes from the measuring process itself, then you are not reliably learning about the process. Use MSA to find out how your measurement system is performing.

This chapter covers the EMP method. The Gauge R&R method is described in the “Variability Gauge Charts” chapter on page 127.

Overview of Measurement Systems Analysis

The EMP (Evaluating the Measurement Process) method in the Measurement Systems Analysis platform is largely based on the methods presented in Donald J. Wheeler’s book EMP III Using Imperfect Data (2006). The EMP method provides visual information and results that are easy to interpret and helps you improve your measurement system to its full potential.

The Gauge R&R method analyzes how much of the variability is due to operator variation (reproducibility) and measurement variation (repeatability). Gauge R&R is available for many combinations of crossed and nested models, regardless of whether the model is balanced. See the “Variability Gauge Charts” chapter on page 127.

Within the Six Sigma DMAIC methodology, MSA (Measurement System Analysis) addresses the Measure phase and process behavior charts (or control charts) address the Control phase. MSA helps you predict and characterize future outcomes. You can use the information gleaned from MSA to help you interpret and configure your process behavior charts.

For more information about Control Charts, see the “Control Chart Builder” on page 29.

Example of Measurement Systems Analysis

In this example, three operators measured the same five parts. See how the measurement system is performing, based on how much variation is found in the measurements.

1. Select Help > Sample Data Library and open Variability Data/Gasket.jmp.
3. Assign Y to the Y, Response role.
4. Assign Part to the Part, Sample ID role.
5. Assign Operator to the X, Grouping role.
   Notice that the MSA Method is set to EMP, the Chart Dispersion Type is set to Range, and the Model Type is set to Crossed.
6. Click OK.
Figure 4.2 MSA Initial Report

The Average Chart shows the average measurements for each operator and part combination. In this example, the means of the part measurements are generally beyond the control limits. This is a desirable outcome, because it indicates that you can detect part-to-part variation.

The Range Chart shows the variability for each operator and part combination. In this example, the ranges are within the control limits. This is a desirable outcome, because it indicates that the operators are measuring parts in the same way and with similar variation.

The color coding for each part is shown in the legend below the charts.

7. Click the red triangle next to Measurement Systems Analysis for Y and select **Parallelism Plots**.
**Figure 4.3** Parallelism Plot for Operator and Part

The Parallelism Plots chart shows the average measurements for each part by operator. Because the lines are generally parallel and there is no major crossing, you conclude that there is no interaction between operators and parts.

**Tip:** Interactions indicate a serious issue that requires further investigation.

8. Click the red triangle next to Measurement Systems Analysis for Y and select EMP Results.

* Probability of warning for a 3 standard error shift within 10 subgroups using Wheeler’s tests, which correspond to Nelson’s tests 1, 2, 5, and 6.
The EMP Results report computes several statistics to help you assess and classify your measurement system. The Intraclass Correlation indicates the proportion of the total variation that you can attribute to the part.

From the EMP Results report, you can conclude the following:

- The Intraclass Correlation values are close to 1, indicating that most of the variation is coming from the part instead of the measurement system.
- The classification is First Class, meaning that the strength of the process signal is weakened by less than 11%.
- There is at least a 99% chance of detecting a warning using Test 1 only.
- There is 100% chance of detecting a warning using Tests 1-4.

**Note:** For more information about tests and detecting process shifts, see “Shift Detection Profiler” on page 112.

There is no interaction between operators and parts, and there is very little variation in your measurements (the classification is First Class). Therefore, you conclude that the measurement system is performing quite well.
Launch the Measurement Systems Analysis Platform

Figure 4.5 The Measurement Systems Analysis Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The Measurement Systems Analysis window contains the following features:

Select Columns Lists all of the variables in your current data table. Move a selected column into a role.

MSA Method Select the method to use: EMP (Evaluating the Measurement Process) or Gauge R&R. This chapter covers the EMP method. For more information about the Gauge R&R method, see the “Variability Gauge Charts” chapter on page 127.

Chart Dispersion Type Designates the type of chart for showing variation. Select the Range option or the Standard Deviation option.
**Note:** For the EMP method, the chart dispersion type determines how the statistics in the EMP Results report are calculated. If the **Range** option is selected, and you have a one factor or a two factor, balanced, crossed model, the statistics in this report are based on ranges. Otherwise, the statistics in this report are based on standard deviations.

**Model Type**  Designates the model type:

- **Main**  Variables with nominal or ordinal modeling types are treated as main effects.
- **Crossed**  The model is crossed when every level of every factor occurs with every level of every other factor.
- **Crossed with Two Factor Interactions**  The model is crossed when each level of two factors occurs with every level of the other factor.
- **Nested**  The model is nested when all levels of a factor appear within only a single level of any other factor.
- **Cross then Nested (3 Factors Only)**  The factors are crossed and then nested for 3 factors.
- **Nested then Crossed (3 Factors Only)**  The factors are nested and then crossed for 3 factors.

**Options**  Contains the following options:

- **Analysis Settings**  Sets the REML maximum iterations and convergence.
- **Specify Alpha**  Specifies the 1-alpha confidence level.

**Y, Response**  The column of measurements.

**Part, Sample, ID**  The column designating the part or unit.

**X, Grouping**  The column(s) representing grouping variables.

**By**  Identifies a column that creates a report consisting of separate analyses for each level of the variable.

**Data Format**

To use the Measurement Systems Analysis platform, all response measurements must be in a single response column. Sometimes, responses are recorded in multiple columns, where each row is a level of a design factor and each column is a level of a different design factor. Data that are in this format must be stacked before running the Measurement Systems Analysis platform. See *Using JMP*. 
Measurement Systems Analysis Platform Options

Platform options appear within the red triangle menu next to Measurement Systems Analysis. Selecting an option creates the respective graph or report in the MSA report window. Deselecting an option removes the graph or report. Choose from the following options:

**Average Chart**  
A plot of the average measurement values for each combination of the part and X variables. The Average Chart helps you detect product variation despite measurement variation. In an Average Chart, out of control data is desirable because it detects part-to-part variation. See “Average Chart” on page 109.

**Range Chart**  
A plot of the variability statistic for each combination of the part and X variables. Appears only if you selected Range as the Chart Dispersion Type in the launch window. The Range Chart helps you check for consistency within subgroups. In a Range Chart, data within limits is desirable, indicating homogeneity in your error. See “Range Chart or Standard Deviation Chart” on page 109.

**Std Dev Chart**  
A plot of the standard deviation statistic for each combination of the part and X variables. Appears only if you selected Standard Deviation as the Chart Dispersion Type in the launch window. The Standard Deviation Chart helps you check for consistency within subgroups. In a Standard Deviation Chart, data within limits is desirable, indicating homogeneity in your error. See “Range Chart or Standard Deviation Chart” on page 109.

**Parallelism Plots**  
An overlay plot that reflects the average measurement values for each part. If the lines are relatively not parallel or crossing, there might be an interaction between the part and X variables.

**Tip:** Interactions indicate a serious issue that requires further investigation. For example, interactions between parts and operators mean that operators are measuring different parts differently, on average. Therefore, measurement variability is not predictable. This issue requires further investigation to find out why the operators do not have the same pattern or profile over the parts.

**EMP Results**  
A report that computes several statistics to help you assess and classify your measurement system. See “EMP Results” on page 110.

**Effective Resolution**  
A report containing results for the resolution of a measurement system. See “Effective Resolution” on page 111.

**Bias Comparison**  
An Analysis of Means chart for testing if the X variables have different averages. See “Bias Comparison” on page 117.
**Test-Retest Error Comparison**  An Analysis of Means for Variances or Analysis of Means Ranges chart for testing if any of the groups have different test-retest error levels. See “Test-Retest Error Comparison” on page 118.

**Shift Detection Profiler**  An interactive set of charts that you can adjust to see the probabilities of getting warnings on your process behavior chart. See “Shift Detection Profiler” on page 112.

**Variance Components**  A report containing the estimates of the variance components for the given model. The calculations in this report are based on variances, not ranges. Balanced data uses the EMS method. Unbalanced data uses the REML method.

**Note:** This report is similar to the Variance Components report in the Variability Chart platform, except that it does not compute Bayesian variance component estimates. See “Variance Components” on page 137 in the “Variability Gauge Charts” chapter.

**EMP Gauge R&R Results**  A report that partitions the variability in the measurements into part variation and measurement system variation. The calculations in this report are based on variances, not ranges. Because negative variance components are set to zero, values of zero could indicate outliers in your results.

**Note:** This report is similar to the Gauge R&R report in the Variability Chart platform. However, by default, the calculation for Reproducibility does not include interactions. To specify that interactions be included in the Reproducibility calculation, select the Include Interactions in Reproducibility platform preference. This preference is located in File > Preferences > Platforms > EMP Measurement Systems Analysis. For more information about Gauge R&R studies, see “About the Gauge R&R Method” on page 139 in the “Variability Gauge Charts” chapter.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Average Chart

The red triangle menu next to Average Chart contains the following options:

Show Grand Mean  Draws the overall mean of the $Y$ variable on the chart.

Show Connected Means  Draws lines connecting all of the average measurement values.

Show Control Limits  Draws lines representing the Upper Control Limit (UCL) and the Lower Control Limit (LCL) and labels those values. The control limits for the Average Chart use the same calculations as an XBar control chart. See “Control Limits for XBar and R Charts” on page 89 in the “Control Chart Builder” chapter.

Show Control Limits Shading  Adds shading between the UCL and LCL.

Show Separators  Draws vertical lines to delineate between the $X$ variables.

Show Data  Adds the data points to the chart.

Note: You can replace variables in the Average Chart in one of two ways: swap existing variables by dragging and dropping a variable from one axis to the other axis; or, click a variable in the Columns panel of the associated data table and drag it onto an axis.

Range Chart or Standard Deviation Chart

The red triangle menu next to Range Chart or Standard Deviation Chart contains the following options:

Show Average Dispersion  Draws the average range or standard deviation on the chart.

Show Connected Points  Draws lines connecting all of the ranges or standard deviations.

Show Control Limits  Draws lines representing the Upper Control Limit (UCL) and the Lower Control Limit (LCL) and labels those values. For more information about the calculations of the limits used in the Range Chart, see “Control Limits for XBar and R Charts” on page 89 in the “Control Chart Builder” chapter. For more information about the calculations of the limits used in the Standard Deviation Chart, see “Control Limits for XBar and S Charts” on page 90 in the “Control Chart Builder” chapter.

Show Control Limits Shading  Adds shading between the UCL and LCL.

Show Separators  Draws vertical lines to delineate between the $X$ variables.
Note: You can replace variables in the Range or Standard Deviation Charts in one of two ways: swap existing variables by dragging and dropping a variable from one axis to the other axis; or, click a variable in the Columns panel of the associated data table and drag it onto an axis.

EMP Results

Note: The statistics in this report are based on ranges in the following instances: if you selected EMP as the MSA Method and Range as the Chart Dispersion Type, and you have a one factor or a two factor, balanced, crossed model. Otherwise, the statistics in this report are based on variances.

The EMP Results report computes several statistics to help you assess and classify your measurement system. Using this report, you can determine the following:

- How your process chart is affected.
- Which tests to set.
- How much the process signal is attenuated.
- How much the bias factors are affecting your system and reducing your potential intraclass correlation coefficient.

The EMP Results report contains the following calculations:

**Test-Retest Error**  Indicates measurement variation or repeatability (also known as within error or pure error).

**Degrees of Freedom**  Indicates the amount of information used to estimate the within error.

**Probable Error**  The median error for a single measurement. Indicates the resolution quality of your measurement and helps you decide how many digits to use when recording measurements. See “Effective Resolution” on page 111.

**Intraclass Correlation**  Indicates the proportion of the total variation that you can attribute to the part. If you have very little measurement variation, this number is closer to 1.

- **Intraclass Correlation (no bias)**  Does not take bias or interaction factors into account when calculating the results.

- **Intraclass Correlation (with bias)**  Takes the bias factors (such as operator, instrument, and so on) into account when calculating the results.

- **Intraclass Correlation (with bias and interaction)**  Takes the bias and interaction factors into account when calculating the results. This calculation appears only if the model is crossed and uses standard deviation instead of range.
Bias Impact  The amount by which the bias factors reduce the Intraclass Correlation.

Bias and Interaction Impact  The amount by which the bias and interaction factors reduce the Intraclass Correlation. This calculation appears only if the model is crossed and uses standard deviation instead of range.

Classes of Process Monitors

In order to understand the System and Classification parameters, you must first understand the Monitor Classification Legend.

Figure 4.6 Monitor Classification Legend

This legend describes the following classifications: First, Second, Third, and Fourth Class. Each classification indicates the following:

- the corresponding Intraclass Correlation values
- the amount of process signal attenuation (decrease)
- the chance of detecting a 3 standard error shift within 10 subgroups, using Wheeler’s test one or all four tests

Wheeler (2006) identifies four detection tests known as the Western Electric Zone Tests. Within the Shift Detection Profiler, there are eight tests that you can select from. The tests that correspond to the Wheeler tests are the first, second, fifth, and sixth tests.

Tip: To prevent the legend from appearing, deselect Show Monitor Classification Legend in the EMP Measurement Systems Analysis platform preferences.

Effective Resolution

The Effective Resolution report helps you determine how well your measurement increments are working. You might find that you need to add or drop digits when recording your measurements, or your current increments might be effective as is. Note the following:

- The Probable Error calculates the median error of a measurement.
• The Current Measurement Increment reflects how many digits you are currently rounding to and is taken from the data as the nearest power of ten. This number is compared to the Smallest Effective Increment, Lower Bound Increment, and Largest Effective Increment. Based on that comparison, a recommendation is made.

• Large measurement increments have less uncertainty in the last digit, but large median errors. Small measurement increments have small median errors, but more uncertainty in the last digit.

**Shift Detection Profiler**

Use the Shift Detection Profiler to assess the sensitivity of the control chart that you use to monitor your process. The Shift Detection Profiler estimates the probability of detecting shifts in the product mean or product standard deviation. The control chart limits include sources of measurement error variation. Based on these limits, the Shift Detection Profiler estimates the Probability of Warning. This is the probability that a control chart monitoring the process mean signals a warning over the next \( k \) subgroups.

You can set the subgroup size that you want to use for your control chart. Note the following:

• If the Subgroup Size equals one, the control chart is an Individual Measurement chart.

• If the Subgroup Size exceeds one, the control chart is an XBar-chart.

You can explore the effect of Subgroup Size on the control chart’s sensitivity. You can also explore the benefits of reducing bias and test-retest error.

Figure 4.7 shows the Shift Detection Profiler report for the Gasket.jmp sample data table, found in the Variability Data folder.
Figure 4.7 Shift Detection Profiler for Gasket.jmp

Probability of Warning

The Probability of Warning is the probability of detecting a change in the process. A change is defined by the Part Mean Shift and the Part Std Dev settings in the Shift Detection Profiler. The probability calculation assumes that the tests selected in the Customize and Select Tests outline are applied to the Number of Subgroups specified in the Profiler.

The control limits for the Individual Measurement chart (Subgroup Size = 1) and the XBar-chart (Subgroup Size > 1) are based on the In-Control Chart Sigma. The In-Control Sigma takes into account the bias factor (reproducibility) variation and the test-retest (repeatability) variation. These are initially set to the values obtained from your MSA study. The In-Control Chart Sigma also incorporates the In-Control Part Std Dev. Both of these values appear beneath the profiler, along with the False Alarm Probability, which is based on the In-Control Chart Sigma.
In-Control Part Std Dev  The standard deviation for the true part values, exclusive of measurement errors, for the stable process. The default value for In-Control Part Std Dev is the standard deviation of the part component estimated by the MSA analysis and found in the Variance Components report.

Often, parts for an MSA study are chosen to have specific properties and do not necessarily reflect the part-to-part variation seen in production. For this reason, you can specify the in-control part standard deviation by selecting **Change In-Control Part Std Dev** from the Shift Detection Profiler red triangle menu.

In-Control Chart Sigma  The value of sigma used to compute control limits. This value is computed using the In-Control Part Std Dev, the Bias Factors Std Dev, and Test-Retest Std Dev specified in the Shift Detection Profiler, and the Subgroup Size. The reproducibility factors are assumed to be constant within a subgroup.

For a subgroup of size $n$, control limits are set at the following values:

$$\pm 3(\text{In-Control Chart Sigma})/\sqrt{n}$$

It follows that the In-Control Chart Sigma is the square root of the sum of the squares of the following terms:

- In-Control Part Std Dev
- Bias Factors Std Dev, as specified in the Shift Detection Profiler, multiplied by $\sqrt{n}$
- Test-Retest Std Dev, as specified in the Shift Detection Profiler

The Bias Factors Std Dev is multiplied by $\sqrt{n}$ to account for the assumption that the reproducibility factors are constant within a subgroup.

JMP updates the In-Control Chart Sigma when you change the In-Control Part Std Dev, the Bias Factors Std Dev, the Test-Retest Std Dev, or the Subgroup Size.

False Alarm Probability  The probability that the control chart tests signal a warning when no change in the part mean or standard deviation has occurred. JMP updates the False Alarm Probability when you change the Number of Subgroups or the tests in Customize and Select Tests.

For more information about the Variance Components report, see “Variance Components” on page 137 in the “Variability Gauge Charts” chapter.

**Shift Detection Profiler Settings**

**Number of Subgroups**  The number of subgroups over which the probability of a warning is computed. If the number of subgroups is set to $k$, the profiler gives the probability that the control chart signals at least one warning based on these $k$ subgroups. The Number of Subgroups is set to 10 by default. Drag the vertical line in the plot to change the Number of Subgroups.
**Part Mean Shift**  The shift in the part mean. By default, the profiler is set to detect a 1 sigma shift. The initial value is the standard deviation of the part component estimated by the MSA analysis and found in the Variance Components report. Drag the vertical line in the plot or click the value beneath the plot to change the Part Mean Shift.

**Part Std Dev**  The standard deviation for the true part values, exclusive of measurement errors. The initial value for Part Std Dev is the standard deviation of the part component estimated by the MSA analysis and is found in the Variance Components report. Drag the vertical line in the plot or click the value beneath the plot to change the Part Std Dev.

**Bias Factors Std Dev**  The standard deviation of factors related to reproducibility. Bias factors include operator and instrument. The bias factor variation does not include part and repeatability (within) variation. The initial value is derived using the reproducibility and interaction variance components estimated by the MSA analysis and is found in the Variance Components report. Drag the vertical line in the plot or click the value beneath the plot to change the Bias Factors Std Dev.

**Test-Retest Std Dev**  The standard deviation of the test-retest, or repeatability, variation in the model. The initial value is the standard deviation of the Within component estimated by the MSA analysis and is found in the Variance Components report. Drag the vertical line in the plot or click the value beneath the plot to change the Test-Retest Std Dev.

**Subgroup Size**  The sample size used for each subgroup. This is set to 1 by default. You can increase the sample size to investigate improvement in control chart performance. Increasing the sample size from 1 demonstrates what happens when you move from an Individual Measurement chart to an XBar-chart. Drag the vertical line in the plot to change the Subgroup Size.

### Shift Detection Profiler Options

The red triangle menu for the Shift Detection Profiler provides several options. Only one option is described here.

**Change In-Control Part Std Dev**  Specify a value for the part standard deviation for the stable process. The in-control part standard deviation should reflect the variation of the true part values, exclusive of measurement errors. Enter a new value and click OK.

The In-Control Part Std Dev is originally set to the standard deviation of the part component estimated by the MSA analysis, found in the Variance Components report.

This option is useful if the parts chosen for the EMP study were not a random sample from the process.

**Reset Factor Grid**  Displays a window for each factor allowing you to enter a specific value for the factor’s current setting, to lock that setting, and to control aspects of the grid. See *Profilers*. 
Factor Settings  Submenu that consists of the following options:

- **Remember Settings**: Adds an outline node to the report that accumulates the values of the current settings each time the Remember Settings command is invoked. Each remembered setting is preceded by a radio button that is used to reset to those settings. There are options to remove selected settings or all settings in the Remember Settings red triangle menu.

- **Copy Settings Script**: Copies the current Profiler’s settings to the clipboard.

- **Paste Settings Script**: Pastes the Profiler settings from the clipboard to a Profiler in another report.

- **Set Script**: Sets a script that is called each time a factor changes. The set script receives a list of arguments of the form:

\{\text{factor1} = n1, \text{factor2} = n2, \ldots\}

For example, to write this list to the log, first define a function:

ProfileCallbackLog = Function({arg},show(arg));

Then enter ProfileCallbackLog in the Set Script dialog.

Similar functions convert the factor values to global values:

ProfileCallbackAssign = Function({arg},evalList(arg));

Or access the values one at a time:

ProfileCallbackAccess = Function({arg},f1=arg["factor1"];f2=arg["factor2"]);

**Shift Detection Profiler Legend**

This panel gives a brief description of four of the Shift Detection Profiler settings. See “Shift Detection Profiler Settings” on page 114.

**Tip**: To prevent the legend from appearing, deselect Show Shift Detection Profiler Legend in the EMP Measurement Systems Analysis platform preferences.

**Customize and Select Tests**

In the Customize and Select Tests panel, select and customize the tests that you want to apply to the $k$ subgroups in your control chart. The eight tests are based on Nelson (1984). For more information about the tests, see “Tests” on page 55 in the “Control Chart Builder” chapter.
Chapter 4  
Quality and Process Methods  
Measurement Systems Analysis  
Platform Options

The Shift Detection Profiler calculations take these tests into account. The Probability of Warning and False Alarm Probability values increase as you add more tests. Because the calculations are based on a quasi-random simulation, there might be a slight delay as the profiler is updated.

The Customize and Select Tests panel has the following options:

**Restore Default Settings**  If no settings have been saved to preferences, this option resets the selected tests to the first test only. The values of $n$ are also reset to the values described in “Tests” on page 55 in the “Control Chart Builder” chapter. If settings have been saved to preferences, this option resets the selected tests and the values of $n$ to those specified in the preferences.

**Note:** You can access preferences for control chart tests by selecting File > Preferences > Platforms > Control Chart Builder. Custom Tests 1 through 8 correspond to the eight tests shown in Customize and Select Tests.

**Save Settings to Preferences**  Saves the selected tests and the values of $n$ for use in future analyses. These preferences are added to the Control Chart Builder platform preferences.

### Bias Comparison

The **Bias Comparison** option creates an Analysis of Means chart. This chart shows the mean values for each level of the grouping variables and compares them with the overall mean. You can use this chart to see whether an operator is measuring parts too high or too low, on average.

The red triangle menu next to Analysis of Means contains the following options:

**Set Alpha Level**  Select an option from the most common alpha levels or specify any level using the **Other** selection. Changing the alpha level modifies the upper and lower decision limits.

**Show Summary Report**  Shows a report containing group means and decision limits, and reports if the group mean is above the upper decision limit or below the lower decision limit.

**Display Options**  Include the following options:

**Show Decision Limits**  Draws lines representing the Upper Decision Limit (UDL) and the Lower Decision Limit (LDL) and defines those values.

**Show Decision Limit Shading**  Adds shading between the UDL and the LDL.

**Show Center Line**  Draws the center line statistic that represents the average.

**Point Options**  Changes the chart display to needles, connected points, or points.
Test-Retest Error Comparison

The **Test-Retest Error Comparison** option creates a type of Analysis of Means for Variances or Analysis of Means Ranges chart. This chart shows if there are differences in the test-retest error between operators. For example, you can use this chart to see whether there is an inconsistency in how each operator is measuring. The Analysis of Mean Ranges chart is displayed when ranges are used for variance components.

- For information about the options in the red triangle menu next to Operator Variance Test, see “Bias Comparison” on page 117.
- For more information about Analysis of Means for Variances charts, see “Variance Components” on page 137 in the “Variability Gauge Charts” chapter.

Additional Example of Measurement Systems Analysis

In this example, three operators have measured a single characteristic twice on each of six wafers. Perform a detailed analysis to find out how well the measurement system is performing.

**Perform the Initial Analysis**

1. Select **Help > Sample Data Library** and open Variability Data/Wafer.jmp.
2. Select **Analyze > Quality and Process > Measurement Systems Analysis**.
3. Assign **Y** to the **Y, Response** role.
4. Assign **Wafer** to the **Part, Sample ID** role.
5. Assign **Operator** to the **X, Grouping** role.
   - Notice that the **MSA Method** is set to **EMP**, the **Chart Dispersion Type** is set to **Range**, and the **Model Type** is set to **Crossed**.
6. Click **OK**.
Figure 4.8 Average and Range Charts

The Average Chart shows that some of the average part measurements fall beyond the control limits. This is desirable, indicating measurable part-to-part variation.

The Range Chart shows no points that fall beyond the control limits. This is desirable, indicating that the operator measurements are consistent within part.

Examine Interactions

Take a closer look for interactions between operators and parts. Click the red triangle next to Measurement Systems Analysis for Y and select Parallelism Plots.
Figure 4.9 Parallelism Plot

Looking at the parallelism plot by operator, you can see that the lines are relatively parallel and that there is only some minor crossing.

Examine Operator Consistency

Take a closer look at the variance between operators. Click the red triangle next to Measurement Systems Analysis for Y and select Test-Retest Error Comparison.

Figure 4.10 Test-Retest Error Comparison

Looking at the Test-Retest Error Comparison, you can see that none of the operators have a test-retest error that is significantly different from the overall test-retest error. The operators appear to be measuring consistently.
Just to be sure, you decide to look at the Bias Comparison chart, which indicates whether an operator is measuring parts too high or too low. Click the red triangle next to Measurement Systems Analysis for Y and select **Bias Comparison**.

**Figure 4.11** Bias Comparison

Looking at the Bias Comparison chart, you make the following observations:

- Operator A and Operator B have detectable measurement bias, as they are significantly different from the overall average.
- Operator A is significantly biased low.
- Operator B is significantly biased high.
- Operator C is not significantly different from the overall average.

**Classify Your Measurement System**

Examine the EMP Results report to classify your measurement system and look for opportunities for improvement. Click the red triangle next to Measurement Systems Analysis for Y and select **EMP Results**.
Figure 4.12 EMP Results

The classification is Second Class, which means that there is a better than 88% chance of detecting a three standard error shift within ten subgroups, using Test one only. You notice that the bias factors have an 11% impact on the Intraclass Correlation. In other words, if you could eliminate the bias factors, your Intraclass Correlation coefficient would improve by 11%.

Explore the Ability of a Control Chart to Detect Process Changes

Use the Shift Detection Profiler to explore the probability that a control chart will be able to detect a change in your process. Click the red triangle next to Measurement Systems Analysis for Y and select **Shift Detection Profiler**.
By default, the only test selected is for a point beyond the 3 sigma limits. Also note that the default Subgroup Size is 1, indicating that you are using an Individual Measurement chart.

Explore your ability to detect a shift in the mean of two part standard deviations in the 10 subgroups following the shift. Click the **Part Mean Shift** value of 2.1701 and change it to 4.34 (2.17 multiplied by 2). The probability of detecting a shift of twice the part standard deviation is 56.9%.

Next, see how eliminating bias affects your ability to detect the shift of two part standard deviations. Change the **Bias Factors Std Dev** value from 1.1256 to 0. The probability of detecting the shift increases to 67.8%.

Finally, add more tests to see how your ability to detect the two part standard deviation shift changes. In addition to the first test, select the second, fifth, and sixth tests (Wheeler’s Rules 4, 2, and 3). With these four tests and no bias variation, your probability of detecting the shift is 99.9%.

You can also explore the effect of using a control chart based on larger subgroup sizes. For subgroup sizes of two or more, the control chart is an XBar-chart. Change the **Bias Factors Std Dev** value back to 1.1256 and deselect all but the first test. Set the **Subgroup Size** in the profiler to 4. The probability of detecting the two part standard deviation shift is 98.5%.
Examine Measurement Increments

Finally, see how well your measurement increments are working. Click the red triangle next to Measurement Systems Analysis for Y and select **Effective Resolution**.

![Effective Resolution](image)

The Current Measurement Increment of 0.01 is below the Lower Bound Increment of 0.09, indicating that you should adjust your future measurements to record one less digit.

### Statistical Details for Measurement Systems Analysis

For more information about the calculations of the limits used in the Range Chart, see “Control Limits for XBar and R Charts” on page 89 in the “Control Chart Builder” chapter. For more information about the calculations of the limits used in the Standard Deviation Chart, see “Control Limits for XBar and S Charts” on page 90 in the “Control Chart Builder” chapter.

### Computation of Intraclass Correlation and Probable Error

Intraclass Correlation without bias is computed as follows:

$$ r_{pe} = \frac{\hat{\sigma}_p^2}{\hat{\sigma}_p^2 + \hat{\sigma}_{pe}^2} $$

Intraclass Correlation with bias is computed as follows:

$$ r_b = \frac{\hat{\sigma}_p^2}{\hat{\sigma}_p^2 + \hat{\sigma}_b^2 + \hat{\sigma}_{pe}^2} $$
Intraclass Correlation with bias and interaction factors is computed as follows:

\[ r_{int} = \frac{\hat{\sigma}_p^2}{\hat{\sigma}_p^2 + \hat{\sigma}_b^2 + \hat{\sigma}_{int}^2 + \hat{\sigma}_{pe}^2} \]

Probable Error is computed as follows:

\[ Z_{0.75} \times \hat{\sigma}_{pe} \]

Note the following:

\( \hat{\sigma}_{pe}^2 = \) variance estimate for pure error
\( \hat{\sigma}_p^2 = \) variance estimate for product
\( \hat{\sigma}_b^2 = \) variance estimate for bias factors
\( \hat{\sigma}_{int}^2 = \) variance estimate for interaction factors
\( Z_{0.75} = \) the 75% quantile of standard normal distribution
Variability gauge charts analyze continuous measurements and can reveal how your measurement system is performing. You can also perform a gauge study to see measures of variation in your data.

**Tip:** This chapter covers only variability charts. For more information about attribute charts, see the “Attribute Gauge Charts” chapter on page 155.

Overview of Variability Charts

Tip: The traditional name for a variability chart is a *multi vari* chart, but because that name is not well known, the more generic term variability chart is used instead.

Just as a control chart shows variation across time in a process, a variability chart shows the same type of variation across categories such as parts, operators, repetitions, and instruments. A variability chart plots the data and means for each level of grouping factors, with all plots side by side. Along with the data, you can view the mean, range, and standard deviation of the data in each category, seeing how they change across the categories. The report options are based on the assumption that the primary interest is how the mean and variance change across the categories.

Variability charts are commonly used for measurement systems analysis such as Gauge R&R. This analysis examines how much of the variability is due to operator variation (reproducibility) and measurement variation (repeatability). Gauge R&R is available for many combinations of crossed and nested models, regardless of whether the model is balanced.
Example of a Variability Chart

Suppose that you have data containing part measurements. Three operators, Cindy, George, and Tom, each took measurements of 10 parts. They measured each part three times, making a total of 90 observations. You want to identify the variation between operators.

1. Select Help > Sample Data Library and open Variability Data/2 Factors Crossed.jmp.
2. Select Analyze > Quality and Process > Variability / Attribute Gauge Chart.
3. For Chart Type, select Variability.
5. Select Operator and click X, Grouping.
6. Select part# and click Part, Sample ID.
7. Click OK.
8. Click the Variability Gauge red triangle and select Show Group Means and Connect Cell Means.

Figure 5.2 Example of a Variability Chart
Looking at the Std Dev chart, you can see that Cindy and George have more variation in their measurements than Tom, who appears to be measuring parts the most consistently. George seems to have the most variation in his measurements, so he might be measuring parts the most inconsistently.

**Launch the Variability/Attribute Gauge Chart Platform**

Launch the Variability/Attribute Gauge Chart platform by selecting **Analyze > Quality and Process > Variability/Attribute Gauge Chart**. Set the **Chart Type** to **Variability**.

**Figure 5.3 The Variability/Attribute Gauge Chart Launch Window**

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Chart Type** Choose between a variability gauge analysis (for a continuous response) or an attribute gauge analysis (for a categorical response, usually “pass” or “fail”).

**Note:** The content in this chapter covers only the **Variability** chart type. For more information about the **Attribute** chart type, see the “**Attribute Gauge Charts**” chapter on page 155.

**Model Type** Choose the model type (**Main Effect**, **Crossed**, **Nested**, and so on). See “**Statistical Details for Variance Components**” on page 151.

**Analysis Settings** Specify the method for computing variance components. See “**Analysis Settings**” on page 138.
Specify Alpha Specify the alpha level used by the platform.

Y, Response Specify the measurement column. Specifying more than one Y column produces a separate variability chart for each response.

Standard Specify a standard or reference column that contains the “true” or known values for the measured part. Including this column enables the Bias and Linearity Study options. These options perform analysis on the differences between the observed measurement and the reference or standard value. See “Bias Report” on page 144 and “Linearity Study” on page 144.

X, Grouping Specify the classification columns that group the measurements. If the factors form a nested hierarchy, specify the higher terms first. If you are doing a gauge study, specify the operator first and then the part.

Freq Identifies the data table column whose values assign a frequency to each row. Can be useful when you have summarized data.

Part, Sample ID Identifies the part or sample that is being measured.

By Identifies a column that creates a report consisting of separate analyses for each level of the variable.

Data Format

To use the Variability Chart platform, all response measurements must be in a single response column. Sometimes, responses are recorded in multiple columns, where each row is a level of a design factor and each column is a level of a different design factor. Data that are in this format must be stacked before running the Variability Chart platform. See Using JMP.

The Variability Gauge Chart

The variability chart and the standard deviation chart show patterns of variation. You can use these charts to identify possible groups of variation (within subgroups, between subgroups, over time). If you notice that any of these sources of variation are large, you can then work to reduce the variation for that source.

Follow the instructions in “Example of a Variability Chart” on page 130 to produce the results shown in Figure 5.4.
**Figure 5.4 Variability Gauge Chart**

The charts show the response on the $y$-axis and a multilevel, categorized $x$-axis.

In Figure 5.4, the Measurement chart shows the range of measurements for each operator by part. Each measurement appears on the chart. Maximum and minimum bars indicate the range of values for each cell, and a cell means bar indicates the median value for each combination of values. The Std Dev chart plots the standard deviation of the measurements taken on each part by operator.

You can add features to the charts, as illustrated in Figure 5.4. See “Variability Gauge Platform Options” on page 134.

To replace variables in charts, do one of the following:

- Swap existing variables by dragging a variable from one axis label to the other axis label. When you drag a variable over a chart or click an axis label, the axis labels are highlighted. This indicates where to drop the variable.
- Click a variable in the Columns panel of the associated data table and drag it onto an axis label.

In other platforms, rows that are excluded in the associated data table still appear on the charts or plots. However, in variability charts, excluded rows do not appear on the charts.
Variability Gauge Platform Options

Use the red triangle options to modify the appearance of the chart, perform Gauge R&R analysis, and compute variance components.

**Note:** Figure 5.4 illustrates some of these options.

**Tip:** To set the default behavior of these options, select File > Preferences > Platforms > Variability Chart.

**Vertical Charts**  Changes the layout to horizontal or vertical.

**Variability Chart**  Shows or hides the variability chart.

**Show Points**  Shows or hides the points for individual rows.

**Show Range Bars**  Shows or hides the bars indicating the minimum and the maximum value of each cell.

**Show Cell Means**  Shows or hides the mean mark for each cell.

**Connect Cell Means**  Connects or disconnects cell means within a group of cells.

**Show Separators**  Shows or hides the separator lines between levels of the X, Grouping variables.

**Show Group Means**  (Available only if you have two or more X, Grouping variables or one X, Grouping variable and one Part, Sample ID variable.) Shows or hides the mean for groups of cells, represented by a horizontal solid line. A window appears, prompting you to select one of the grouping variables.

**Show Grand Mean**  Shows or hides the overall mean, represented by a gray dotted line across the entire graph.

**Show Grand Median**  Shows or hides the overall median, represented by a blue dotted line across the entire graph.

**Show Box Plots**  Shows or hides box plots.

**Mean Diamonds**  Shows or hides mean diamonds. The confidence intervals use the within-group standard deviation for each cell.

**XBar Control Limits**  Shows or hides lines at the UCL and LCL on the variability chart. For more information about the calculations of these limits, see “Statistical Details for Control Chart Builder” on page 89 in the “Control Chart Builder” chapter.
**Points Jittered**  Adds some random noise to the plotted points so that coincident points do not plot on top of one another.

**Show Standard Mean**  (Available only if you have specified a **Standard** variable.) Shows or hides the mean of the standard column.

**Variability Summary Report**  Shows or hides a report that gives the mean, standard deviation, coefficient of variation (CV), standard error of the mean, lower and upper confidence intervals, and the minimum, maximum, and number of observations.

**Std Dev Chart**  Shows or hides a separate graph that shows cell standard deviations across category cells.

**Mean of Std Dev**  Shows or hides a line at the mean standard deviation on the Std Dev chart.

**S Control Limits**  Shows or hides lines showing the LCL and UCL in the Std Dev chart. For more information about the calculations of these limits, see “Statistical Details for Control Chart Builder” on page 89 in the “Control Chart Builder” chapter.

**Group Means of Std Dev**  Shows or hides the mean lines on the Std Dev chart.

**Heterogeneity of Variance Tests**  Performs a test for comparing variances across groups. See “Heterogeneity of Variance Tests” on page 136.

**Variance Components**  Estimates the variance components for a specific model. Variance components are computed for these models: main effects, crossed, nested, crossed then nested (three factors only), and nested then crossed (three factors only). See “Variance Components” on page 137.

**Gauge Studies**  Contains the following options:

- **Gauge R&R**  Interprets the first factors as grouping columns and the last factor as Part, and creates a gauge R&R report using the estimated variance components. (Note that there is also a Part field in the launch window). See “Gauge R&R Option” on page 140.

- **Discrimination Ratio**  Characterizes the relative usefulness of a given measurement for a specific product. It compares the total variance of the measurement with the variance of the measurement error. See “Discrimination Ratio” on page 143.

- **Misclassification Probabilities**  Shows probabilities for rejecting good parts and accepting bad parts. See “Misclassification Probabilities” on page 143.

- **Bias Report**  Shows the average difference between the observed values and the standard. A graph of the average biases and a summary table appears. This option is available only when you specify a Standard variable in the launch window. See “Bias Report” on page 144.
**Linearity Study**  Performs a regression using the standard values as the X variable and the bias as the Y variable. This analysis examines the relationship between bias and the size of the part. Ideally, you want the slope to equal 0. A nonzero slope indicates that your gauge performs differently with different sized parts. This option is available only when you specify a Standard variable in the launch window. See “Linearity Study” on page 144.

**Gauge R&R Plots**  Shows or hides Mean Plots (the mean response by each main effect in the model) and Std Dev plots. If the model is purely nested, the graphs appear with a nesting structure. If the model is purely crossed, interaction graphs appear. Otherwise, the graphs plot independently at each effect. For the standard deviation plots, the red lines connect $\sqrt{\text{mean weighted variance}}$ for each effect.

**AIAG Labels**  Enables you to specify that quality statistics should be labeled in accordance with the AIAG standard, which is used extensively in automotive analyses.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

### Heterogeneity of Variance Tests

**Note:** See “Example of the Heterogeneity of Variance Test” on page 145.

The **Heterogeneity of Variance Tests** option performs a test for comparing variances across groups. The test is an Analysis of Means for Variances (ANOMV) based method. This method indicates whether any of the group standard deviations are different from the square root of the average group variance.
To be robust against non-normal data, the method uses a permutation simulation to compute decision limits. For more information about this method, see Wludyka and Sa (2004). Because the method uses simulations, the decision limits can be slightly different each time. To obtain the same results each time, press Ctrl+Shift, select the option, and then specify the same random seed.

The red triangle menus for the test reports contain the following options:

- **Set Alpha Level**   Sets the alpha level for the test.
- **Show Summary Report**   Shows or hides a summary report for the test. The values in the report are the same values that are shown in the plot.
- **Display Options**   Shows or hides the decision limits, shading, center line, and needles.

### Variance Components

The **Variance Components** option models the variation from measurement to measurement. The response is assumed to be a constant mean plus random effects associated with various levels of the classification.

**Note:** Once you select the **Variance Components** option, if you did not select the **Model Type** in the launch window (if you selected **Decide Later**), you are prompted to select the model type. For more information about model types, see “Launch the Variability/Attribute Gauge Chart Platform” on page 131.

**Figure 5.5** Example of the Variance Components Report

![Analysis of Variance](image)

![Variance Components](image)

The Analysis of Variance report appears only if the EMS method of variance component estimation is used. This report shows the significance of each effect in the model.

The Variance Components report shows the estimates themselves. See “Statistical Details for Variance Components” on page 151.
Analysis Settings

From the launch window, click **Analysis Settings** to choose the method for computing variance components.

**Figure 5.6 Analysis Settings Window**

![Analysis Settings Window]

**Choose best analysis (EMS, REML, or Bayesian)** Chooses the best analysis from EMS, REML, or Bayesian, using the following logic:

- If the data are balanced, and if no variance components are negative, the EMS (expected mean squares) method is used to estimate the variance components.
- If the data are unbalanced, the REML (restricted maximum likelihood) method is used, unless a variance component is estimated to be negative, then the Bayesian method is used.
- If any variance component is estimated to be negative using the EMS method, the Bayesian method is used.
- If there is confounding in the variance components, then the bounded REML method is used, and any negative variance component estimates are set to zero.

**Choose best analysis (EMS or REML)** Chooses the best analysis from EMS or REML, using the same logic as the **Choose best analysis (EMS, REML, or Bayesian)** option. However, this option never uses the Bayesian method, even for negative variance components. The bounded REML method is used and any negative variance component is forced to be 0.

**Use REML analysis** Uses the bounded REML method, even if the data are balanced. The bounded REML method can handle unbalanced data and forces any negative variance component to be 0.

**Use Bayesian analysis** Uses the Bayesian method. The Bayesian method can handle unbalanced data and forces all variances components to be positive and nonzero. If there is confounding in the variance components, then the bounded REML method is used, and any negative variance component estimates are set to zero. The method implemented in JMP computes the posterior means using a modified version of Jeffreys’ prior. See Portnoy (1971) and Sahai (1974).
**Maximum Iterations** (Applicable only for the REML method.) For difficult problems, you might want to increase the number of iterations. Increasing this value means that JMP will try more times to find a solution in the optimization phase.

**Convergence Limit** (Applicable only for the REML method.) For problems where you want greater precision, you might want to change the convergence limit to be smaller. Decreasing this value means that JMP will find the solution to a higher level of accuracy in the optimization phase. However, this can increase the time taken to find a solution. Providing a larger convergence value returns quicker results, but is less precise.

**Number of Iteration Abscissas** (Applicable only for the Bayesian method.) For greater accuracy, you might want to increase the number of iteration abscissas. However, this can increase the time taken to find a solution. Providing a smaller number returns quicker results, but is less precise.

**Maximum Number of Function Evaluations** (Applicable only for the Bayesian method.) For greater accuracy, you might want to increase the maximum number of function evaluations. However, this can increase the time taken to find a solution. Providing a smaller number returns quicker results, but is less precise.

---

**About the Gauge R&R Method**

The Gauge R&R method analyzes how much of the variability in your measurement system is due to operator variation (reproducibility) and measurement variation (repeatability). Gauge R&R studies are available for many combinations of crossed and nested models, regardless of whether the model is balanced.

**Tip:** Alternatively, you can use the EMP method to assess your measurement system. See the “Measurement Systems Analysis” chapter on page 99.

Before performing a Gauge R&R study, you collect a random sample of parts over the entire range of part sizes from your process. Select several operators at random to measure each part several times. The variation is then attributed to the following sources:

- The *process variation*, from one part to another. This is the ultimate variation that you want to be studying if your measurements are reliable.
- The variability inherent in making multiple measurements, that is, *repeatability*. In Table 5.1 on page 140, this is called the *within variation*.
- The variability due to having different operators measure parts—that is, *reproducibility*.

A Gauge R&R analysis then reports the variation in terms of repeatability and reproducibility.
A Shewhart control chart can identify processes that are going out of control over time. A variability chart can also help identify operators, instruments, or part sources that are systematically different in mean or variance.

### Table 5.1 Definition of Terms and Sums in Gauge R&R Analysis

<table>
<thead>
<tr>
<th>Variances Sums</th>
<th>Term and Abbreviation</th>
<th>Alternate Term</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

A Shewhart control chart can identify processes that are going out of control over time. A variability chart can also help identify operators, instruments, or part sources that are systematically different in mean or variance.

### Gauge R&R Option

The **Gauge R&R** option shows measures of variation interpreted for a gauge study of operators and parts.

Once you select the **Gauge R&R** option, if you have not already selected the model type, you are prompted to do so. Then, modify the Gauge R&R specifications.

**Note:** The Platform preferences for Variability include the Gauge R&R Specification Dialog option. The preference is selected by default. Deselect the preference to use the spec limits that are defined in the data table.
Chapter 5
Quality and Process Methods

Variability Gauge Charts
Variability Gauge Platform Options

Enter/Verify Gauge R&R Specifications

The Enter/Verify Gauge R&R Specifications window contains these options:

**Choose tolerance entry method**  Choose how to enter the tolerance:

- Select **Tolerance Interval** to enter the tolerance directly, where tolerance = USL – LSL.
- Select **LSL and/or USL** to enter the specification limits and then have JMP calculate the tolerance.

**K, Sigma Multiplier**  K is a constant value that you choose to multiply with sigma. For example, you might type 6 so that you are looking at 6*sigma or a 6 sigma process.

**Tip:** Modify the default value of **K** by selecting **File > Preferences > Platforms > Variability Chart**.

**Tolerance Interval, USL-LSL**  Enter the tolerance for the process, which is the difference between the upper specification limits and the lower specification limits.

**Spec Limits**  Enter upper and lower specification limits. See *Using JMP*.

**Historical Mean**  Computes the tolerance range for one-sided specification limits, either USL-Historical Mean or Historical Mean-LSL. If you do not enter a historical mean, the grand mean is used.

**Historical Sigma**  Enter a value that describes the variation (you might have this value from history or past experience).
### The Gauge R&R Report

**Figure 5.7** Example of the Gauge R&R Report

<table>
<thead>
<tr>
<th>Measurement Source</th>

<th>Variation (S/StdDev)</th>
<th>which is k*sort of</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operator (p)</td>
<td>0.59194535</td>
<td>V(Operator)</td>
</tr>
<tr>
<td>Part (p)</td>
<td>0.44905246</td>
<td>V(Operator*p)</td>
</tr>
<tr>
<td>Total Variation</td>
<td>1.20194535</td>
<td>V(Within) + V(Operator) + V(Operator*p) + V(p)</td>
</tr>
</tbody>
</table>

Note: To generate the reduced Gauge R&R report, select **File > Preferences > Platforms > Variability Chart > Reduced Gauge R&R Report**.

In this example, the values in the Variation column are the square roots of sums of variance components scaled by the value of $k$ (6 in this example).

Table 5.2 shows guidelines for measurement variation, as suggested by Barrentine (1991).

<table>
<thead>
<tr>
<th>Acceptable Percent Measurement Variation</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 10%</td>
<td>excellent</td>
</tr>
<tr>
<td>11% to 20%</td>
<td>adequate</td>
</tr>
<tr>
<td>21% to 30%</td>
<td>marginally acceptable</td>
</tr>
<tr>
<td>&gt; 30%</td>
<td>unacceptable</td>
</tr>
</tbody>
</table>

Note the following:

- If you have provided a **Tolerance Interval** in the Enter/Verify Gauge R&R Specifications window, a % of Tolerance column appears in the Gauge R&R report. This column is computed as $100\times\text{Variation/Tolerance}$. Also, a Precision-to-Tolerance ratio appears at the
bottom of the report. This ratio represents the proportion of the tolerance or capability interval that is lost due to gauge variability.

- If you have provided a Historical Sigma in the Enter/Verify Gauge R&R Specifications window, a % Process column appears in the Gauge R&R report. This column is defined as 100*(Variation/(K*Historical Sigma)).
- The Number of Distinct Categories (NDC) is defined as (1.41*(PV/RR)), rounded down to the nearest integer.

**Discrimination Ratio**

The discrimination ratio characterizes the relative usefulness of a given measurement for a specific product. Generally, when the discrimination ratio is less than 2, the measurement cannot detect product variation, implying that the measurement process needs improvement. A discrimination ratio greater than 4 adequately detects unacceptable product variation, implying that the production process needs improvement.

See “Statistical Details for the Discrimination Ratio” on page 152.

**Misclassification Probabilities**

Due to measurement variation, good parts can be rejected and bad parts can be accepted. This is called misclassification. Misclassification rates decrease as measurement variability decreases. When you select the Misclassification Probabilities option, you are prompted to select the model type and enter specification limits if you have not already done so.

**Figure 5.8 Example of the Misclassification Probabilities Report**

<table>
<thead>
<tr>
<th>Description</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>P(Good part is falsely rejected)</td>
<td>0.0802</td>
</tr>
<tr>
<td>P(Bad part is falsely accepted)</td>
<td>0.2787</td>
</tr>
<tr>
<td>P(Part is good and is rejected)</td>
<td>0.0735</td>
</tr>
<tr>
<td>P(Part is bad and is accepted)</td>
<td>0.0235</td>
</tr>
<tr>
<td>P(Part is good)</td>
<td>0.9157</td>
</tr>
</tbody>
</table>

The misclassification probabilities are based on the joint probability function of Y, the measured value of the part, and X, the true value of the part. The joint probability density function used is a bivariate normal distribution. To understand the descriptions, define the following probabilities:

\[
\delta = P[(LSL \leq X \leq USL) \text{ and } (Y < LSL \text{ or } Y > USL)] \\
\beta = P[(X < LSL \text{ or } X > USL) \text{ and } (LSL \leq Y \leq USL)] \\
\pi = P(LSL \leq X \leq USL)
\]
Descriptions

\[ P(\text{Good part is falsely rejected}) \]  
The conditional probability that a part is rejected given that it is a good part, or \( \delta/\pi \).

\[ P(\text{Bad part is falsely accepted}) \]  
The conditional probability that a part is accepted given that it is a bad part, or \( \beta/(1-\pi) \).

\[ P(\text{Part is good and is rejected}) \]  
The joint probability that a part is good and that it is rejected, or \( \delta \).

\[ P(\text{Part is bad and is accepted}) \]  
The joint probability that a part is bad and that it is accepted, or \( \beta \).

\[ P(\text{Part is good}) \]  
The probability that a part is good, or \( \pi \).

For more information, see “Statistical Details for the Misclassification Probabilities” on page 153 as well as Burdick et al. (2005).

Bias Report

The Bias Report shows a graph for Overall Measurement Bias with a summary table and a graph for Measurement Bias by Standard with a summary table. The average bias, or the differences between the observed values and the standard values, appears for each level of the X variable. A t test for the bias is also given.

The Bias Report option is available only when a Standard variable is provided in the launch window.

The Measurement Bias Report red triangle menu contains the following options:

Confidence Intervals  Calculates confidence intervals for the average bias for each part and places marks on the Measurement Bias Report by Standard plot.

Measurement Error Graphs  Produces a graph of Measurement Error versus all grouping columns together. There are also graphs of Measurement Error by each grouping column separately.

Linearity Study

The Linearity Study performs a regression analysis using the standard variable as the X variable and the bias as the Y variable. This analysis examines the relationship between bias and the size of the part. Ideally, you want to find a slope of zero. If the slope is significantly different from zero, you can conclude that there is a significant relationship between the size of the part or variable measured as a standard and the ability to measure.
The **Linearity Study** option is available only when a **Standard** variable is provided in the launch window.

The report shows the following information:

- Bias summary statistics for each standard.
- An ANOVA table that tests if the slope of the line is equal to zero.
- The line parameters, including tests for the slope (linearity) and intercept (bias). The test for the intercept is useful only if the test on the slope fails to reject the hypothesis of slope = 0.
- The equation of the line appears directly beneath the graph.

The Linearity Study red triangle menu contains the following options:

**Set Alpha Level**  Changes the alpha level that is used in the bias confidence intervals.

**Linearity by Groups**  Produces separate linearity plots for each level of the **X, Grouping** variables that you specified in the launch window.

### Additional Examples of Variability Charts

- “Example of the Heterogeneity of Variance Test”
- “Example of the Bias Report Option”

### Example of the Heterogeneity of Variance Test

Suppose that you have data containing part measurements. Three operators (Cindy, George, and Tom) each took measurements of 10 parts. They measured each part three times, making a total of 90 observations. You want to examine the following:

- whether the variance of measurements for each operator are the same or different
- whether the variance for each part is the same or different
- whether the variance for each Operator*part combination is the same or different

Ideally, you want all of the variances for each of the groups to be considered the same statistically.

1. Select **Help > Sample Data Library** and open **Variability Data/2 Factors Crossed.jmp**.
2. Select **Analyze > Quality and Process > Variability / Attribute Gauge Chart**.
3. Select **Measurement** and click **Y, Response**.
4. Select **Operator** and click **X, Grouping**.
5. Select part# and click **Part, Sample ID**.
6. Click **OK**.
7. Click the Variability Gauge red triangle and select **Heterogeneity of Variance Tests**.
8. Select **Crossed**.
9. Click **OK**.
Figure 5.9 Heterogeneity of Variances Tests Report

Note: Because the method uses simulations, the decision limits can be slightly different each time.
In the Operator Variance test, all three levels exceed the upper and lower decision limits. From this, you conclude that each operator has a different variability from the square root of the average group variance. You might want to examine why the variation between each operator is different.

For the part# Variance test and the interaction (Operator*part#) Variance test, none of the levels exceed the decision limits. From this, you conclude that the variances are not statistically different from the square root of the average group variance. Each part has a similar variance to the other parts, and each Operator*part# combination has similar variance to the other Operator*part# combinations.

**Example of the Bias Report Option**

**Note:** These data come from the Automotive Industry Action Group (2002).

Assume that as a plant supervisor, you are introducing a new measurement system into your process. As part of the Production Part Approval Process (PPAP), the bias and linearity of the measurement system needs to be evaluated. Five parts were chosen throughout the operating range of the measurement system, based on documented process variation. Each part was measured by layout inspection to determine its reference value. Each part was then measured twelve times by the lead operator. The parts were selected at random during the day. In this example, you want to examine the overall bias and the individual measurement bias (by standard).

1. Select **Help > Sample Data Library** and open Variability Data/MSALinearity.jmp.
2. Select **Analyze > Quality and Process > Variability / Attribute Gauge Chart**.
3. Select **Response** and click **Y, Response**.
4. Select **Standard** and click **Standard**.
5. Select **Part** and click **X, Grouping**.
6. Click **OK**.
7. Click the Variability Gauge red triangle and select **Gauge Studies > Bias Report**.
The bias (Response minus Standard) is calculated for every measurement. The Overall Measurement Bias Report shows a histogram of the bias and a t test to see whether the average bias is equal to 0. You can see that the Average Bias is not zero, it is -0.0533. However, zero is contained within the confidence interval (-0.1152, 0.0085), which means that the Average Bias is not significantly different from 0. Using a significance level of 0.05, you can see that the p-value is greater than 0.05, which also shows that the Average Bias is not significantly different from 0.

The Measurement Bias Report by Standard shows average bias values for each part. The bias averages are plotted on the graph along with the actual bias values for every part, so that you can see the spread. In this example, part number 1 (with a standard value of 2) is biased high and parts 4 and 5 (with standard values of 8 and 10) are biased low.

**Tip:** To see confidence intervals for the bias, right-click in the table and select **Columns > Lower 95% and Upper 95%**.
Example of a Linearity Study

Using the same data and scenario as the Bias Report option, you can now examine the linearity to determine whether there is a significant relationship between the size of the parts and the operator’s ability to measure them.

1. Select Help > Sample Data Library and open Variability Data/MSALinearity.jmp.
2. Select Analyze > Quality and Process > Variability / Attribute Gauge Chart.
5. Select Part and click X, Grouping.
6. Click OK.
7. Click the Variability Gauge red triangle and select Gauge Studies > Linearity Study.
8. In the window that prompts you to Specify Process Variation, type 14.9286.

The value 14.9286 is 6 times the standard deviation of the response, 2.488105.

Note the following:

- The slope is -0.131667. This value appears as part of the equation below the graph, and also in the third table.
- The p-value associated with the test on the slope is quite small, <.0001. The t test for the slope is testing whether the bias changes with the standard value.
Because the $p$-value is small, you can conclude that there is a significant linear relationship between the size of the parts and the operator’s ability to measure them. You can also see this in the graph. If the part or standard value is small, the bias is high, and vice versa.

## Statistical Details for Variability Charts

- “Statistical Details for Variance Components”
- “Statistical Details for the Discrimination Ratio”
- “Statistical Details for the Misclassification Probabilities”

### Statistical Details for Variance Components

The exact model type that you choose depends on how the data was collected. For example, are the operators measuring the same parts (in which case you have a crossed design) or are they measuring different parts (in which case you have a nested design)? To illustrate, in a model where $B$ is nested within $A$, multiple measurements are nested within both $B$ and $A$, and there are $na \cdot nb \cdot nw$ measurements, the following statements hold:

- $na$ random effects are due to $A$
- $na \cdot nb$ random effects due to each $nb$ $B$ levels within $A$
- $na \cdot nb \cdot nw$ random effects due to each $nw$ levels within $B$ within $A$:

$$y_{ijk} = u + Za_i + Zb_{ij} + Zw_{ijk}.$$  

The $Z$s are the random effects for each level of the classification. Each $Z$ is assumed to have a mean of zero and to be independent from all other random terms. The variance of the response $y$ is the sum of the variances due to each $z$ component:

$$\text{Var}(y_{ijk}) = \text{Var}(Za_i) + \text{Var}(Zb_{ij}) + \text{Var}(Zw_{ijk}).$$

Table 5.3 shows the supported models and what the effects in the model would be.

**Statistical Details for the Discrimination Ratio**

The discrimination ratio compares the total variance of the measurement, \( M \), with the variance of the measurement error, \( E \). The discrimination ratio is computed for all main effects, including nested main effects. The discrimination ratio, \( D \), is computed as follows:

\[
D = \sqrt{2\left(\frac{P}{T-P}\right) + 1}
\]

where:

\( P \) = estimated variance for a factor

\( T \) = estimated total variance
Statistical Details for the Misclassification Probabilities

This section describes the computations for the probabilities in the Misclassification Probabilities report. The misclassification probabilities are based on the joint probability function of $Y$, the measured value of the part, and $X$, the true value of the part. The joint probability distribution function $F_{YX}(y, x)$ uses a bivariate normal distribution with mean vector $[\mu, \mu]$ and the following covariance matrix:

$$
\begin{bmatrix}
\gamma_P + \gamma_M & \gamma_P \\
\gamma_P & \gamma_P
\end{bmatrix}
$$

where $\gamma_P$ is the part-to-part variation, $\gamma_M$ is the measurement variation, and $\mu$ is the grand mean. These quantities can be found or derived from quantities in the report window. Specifically, $\gamma_P + \gamma_M$ is equal to the square of Total Variation (TV) divided by 6: $(TV/6)^2$ and $\gamma_P$ is equal to the square of Part Variation (PV) divided by 6: $(PV/6)^2$. The correlation $\rho_{YX}$ between $Y$ and $X$ is defined as the square root of $\gamma_P/(\gamma_P + \gamma_M)$.

Next, define the following probabilities:

$$
\delta = P[(LSL \leq X \leq USL) \text{ and } (Y < LSL \text{ or } Y > USL)]
$$

$$
\beta = P[(X < LSL \text{ or } X > USL) \text{ and } (LSL \leq Y \leq USL)]
$$

$$
\pi = P(LSL \leq X \leq USL)
$$

These probabilities can be expressed in terms of the joint probability distribution function $F_{YX}(y, x)$ and the marginal probability distribution functions for $Y$ and $X$: $F_Y(y)$ and $F_X(x)$:

$$
\delta = F_{YX}(LSL, USL) - F_{YX}(LSL, LSL) - F_{YX}(USL, USL) + F_{YX}(USL, LSL) + F_X(USL) - F_X(LSL)
$$

$$
\beta = F_{YX}(USL, LSL) - F_{YX}(LSL, LSL) - F_{YX}(USL, USL) + F_{YX}(LSL, USL) + F_Y(USL) - F_Y(LSL)
$$

$$
\pi = F_X(USL) - F_X(LSL)
$$

$P$(Good part is falsely rejected) = $\delta/\pi$
$P$(Bad part is falsely accepted) = $\beta/(1-\pi)$
$P$(Part is good and is rejected) = $\delta$
$P$(Part is bad and is accepted) = $\beta$
$P$(Part is good) = $\pi$
Attribute Gauge Charts
Evaluate a Categorical Measurement Process Using Agreement Measures

Attribute charts analyze categorical measurements and can help show you measures of agreement across responses, such as raters. In attribute data, the variable of interest has a finite number of categories. Typically, data has only two possible results, such as pass or fail. You can examine aspects such as how effective raters were at classifying a part, how much they agreed with each other, and how much they agreed with themselves over the course of several ratings.

Tip: This chapter covers only attribute charts. For more information about variability charts, see the “Variability Gauge Charts” chapter on page 127.

Overview of Attribute Gauge Charts

Before you create an attribute gauge chart, your data should be formatted using the following guidelines:

- In order to compare agreement among raters, each rater in the data table must be in a separate column. These columns are then assigned to the Y, Response role in the launch window. In Figure 6.2, each rater (A, B, and C) is in a separate column.
- Responses in the different columns can be character (pass or fail) or numeric (0 or 1). In Figure 6.2, rater responses are numeric (0 for pass, 1 for fail). All response columns must have the same data type.
- Any other variables of interest that you might want to use as X, Grouping variables should appear stacked in one column each (see the Part column in Figure 6.2). You can also define a Standard column, which produces reports that compare raters with the standard. The Standard column and response columns must have the same data type.

Figure 6.2 Attribute Gauge Data

Example of an Attribute Gauge Chart

Suppose that you have data containing pass or fail ratings for parts. Three raters, identified as A, B, and C, each noted a 0 (pass) or a 1 (fail) for 50 parts, three times each. You want to examine how effective the raters were in correctly classifying the parts, and how well the raters agreed with each other and with themselves over the course of the ratings.

1. Select Help > Sample Data Library and open Attribute Gauge.jmp.
2. Select Analyze > Quality and Process > Variability / Attribute Gauge Chart.
3. For Chart Type, select Attribute.
4. Select A, B, and C and click **Y, Response**.
5. Select Standard and click **Standard**.
6. Select Part and click **X, Grouping**.
7. Click **OK**.

**Figure 6.3** Example of an Attribute Chart

The first chart (Part) shows how well the raters agreed with each other for each part. For example, here you can see that the percent agreement dropped for part 6, 12, 14, 21, 22, and so on. These parts might have been more difficult to categorize.

The second chart (Rater) shows each rater’s agreement with him or herself and the other raters for a given part, summed up over all of the parts. In this example, it looks like the performance of the raters is relatively similar. Rater C had the lowest agreement, but the difference is not major (about 89% instead of 91%).

8. Open the Effectiveness Report and scroll down to the Conformance Report.
   You can see that 0 = non-conform (fail) and a 1 = conform (pass). However in this data, it is exactly the opposite: 0 is a pass and 1 is a fail. Reverse this setting.
9. Click the Conformance Report red triangle and select **Change Conforming Category**.
Launch the Variability/Attribute Gauge Chart Platform

Launch the Variability/Attribute Gauge Chart platform by selecting **Analyze > Quality and Process > Variability/Attribute Gauge Chart**. Set the **Chart Type** to **Attribute**.

**Figure 6.4** The Variability/Attribute Gauge Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Chart Type** Choose between a variability gauge analysis (for a continuous response) or an attribute gauge analysis (for a categorical response, usually “pass” or “fail”).

**Note:** The content in this chapter covers only the **Attribute** chart type. For more information about the **Variability** chart type, see the “**Variability Gauge Charts**” chapter on page 127.

**Specify Alpha** Specify the alpha level used by the platform.

**Y, Response** Specify the columns of ratings given by each rater. You must specify more than one rating column.

**Standard** Specify a standard or reference column that contains the “true” or known values for the part. In the report window, an Effectiveness Report and an additional section in the Agreement Comparisons report appear, which compare the raters with the standard.

**X, Grouping** Specify the classification columns that group the measurements. If the factors form a nested hierarchy, specify the higher terms first.

**Freq** Identifies the data table column whose values assign a frequency to each row. Can be useful when you have summarized data.
By Identifies a column that creates a report consisting of separate analyses for each level of the variable.

The Attribute Gauge Chart and Reports

Attribute gauge chart plots the percent Agreement, which is a measurement of rater agreement for every part in the study. The agreement for each part is calculated by comparing the ratings for every pair of raters for all ratings of that part. See “Statistical Details for Attribute Gauge Charts” on page 165.

Follow the instructions in “Example of an Attribute Gauge Chart” on page 157 to produce the results shown in Figure 6.5.

Figure 6.5 Attribute Gauge Chart

The first chart in Figure 6.5 uses all X grouping variables (in this case, the Part) on the x-axis. The second chart uses all Y variables on the x-axis (typically, and in this case, the Rater).

- In the first graph, you can look for parts with a low percent Agreement value, and investigate to determine why raters do not agree about the measurement of that particular part.
• In the second graph, you can look for raters with a low percent Agreement value, and investigate to determine why they do not agree with the other raters or with themselves. For information about additional options, see “Attribute Gauge Platform Options” on page 164.

**Agreement Reports**

**Note:** The Kappa value is a statistic that expresses agreement. The closer the Kappa value is to 1, the more agreement there is. A Kappa value closer to 0 indicates less agreement.

The Agreement Report shows agreement summarized for each rater and overall agreement. This report is a numeric form of the data presented in the second chart in the Attribute Gauge Chart report (Figure 6.5).

The Agreement Comparisons report shows each rater compared with all other raters, using Kappa statistics. The rater is compared with the standard only if you have specified a Standard variable in the launch window.

The Agreement within Raters report shows the number of items that were inspected. The confidence intervals are score confidence intervals, as suggested by Agresti and Coull (1998). The Number Matched is the sum of the number of items inspected, where the rater agreed with him or herself on each inspection of an individual item. The Rater Score is the Number Matched divided by the Number Inspected.

The Agreement across Categories report shows the agreement in classification over that which would be expected by chance. It assesses the agreement between a fixed number of raters when classifying items.
**Figure 6.6 Agreement Reports**

The Effectiveness Report appears only if you have specified a Standard variable in the launch window. For a description of a Standard variable, see “Launch the Variability/Attribute Gauge Chart Platform” on page 159. This report compares every rater with the standard.
The Agreement Counts table shows cell counts on the number correct and incorrect for every level of the standard. In Figure 6.7, the standard variable has two levels, 0 and 1. Rater A had 45 correct responses and 3 incorrect responses for level 0, and 97 correct responses and 5 incorrect responses for level 1.

Effectiveness is defined as the number of correct decisions divided by the total number of opportunities for a decision. For example, say that rater A sampled every part three times. On the sixth part, one of the decisions did not agree (for example, pass, pass, fail). The other two decisions would still be counted as correct decisions. This definition of effectiveness is different from the MSA 3rd edition. According to MSA, all three opportunities for rater A on part six would be counted as incorrect. Including all of the inspections separately gives you more information about the overall inspection process.

In the Effectiveness table, 95% confidence intervals are given about the effectiveness. These are score confidence intervals. It has been demonstrated that score confidence intervals provide increased coverage probability, particularly where observations lie near the boundaries. See Agresti and Coull (1998).

The Misclassifications table shows the incorrect labeling. The rows represent the levels of the standard or accepted reference value. The columns contain the levels given by the raters.
Conformance Report

The Conformance Report shows the probability of false alarms and the probability of misses. The Conformance Report appears only when the rating has two levels (such as pass or fail, or 0 or 1).

The following descriptions apply:

**False Alarm** The part is determined to be non-conforming, when it actually is conforming.

**Miss** The part is determined to be conforming, when it actually is not conforming.

\[ P(\text{False Alarms}) \] The number of parts that have been incorrectly judged to be nonconforming divided by the total number of parts that are judged to be conforming.

\[ P(\text{Miss}) \] The number of parts that have been incorrectly judged to be conforming divided by the total number of parts that are actually nonconforming.

The Conformance Report red triangle menu contains the following options:

**Change Conforming Category** Reverses the response category that is considered conforming.

**Calculate Escape Rate** Calculates the Escape Rate, which is the probability that a non-conforming part is produced and not detected. The Escape Rate is calculated as the probability that the process will produce a non-conforming part times the probability of a miss. You specify the probability that the process will produce a non-conforming part, also called the Probability of Nonconformance.

**Note:** Missing values are treated as a separate category in this platform. To avoid this separate category, exclude rows of missing values in the data table.

Attribute Gauge Platform Options

The Attribute Gauge red triangle menu contains the following options:

**Attribute Gauge Charts** Shows or hides the gauge attribute chart and the efficiency chart.

**Show Agreement Points** Shows or hides the agreement points on the charts.

**Connect Agreement Points** Connects the agreement points in the charts.

**Agreement by Rater Confid Intervals** Shows or hides the agreement by rater confidence intervals on the efficiency chart.
Show Agreement Group Means  Shows or hides the agreement group means on the gauge attribute chart. This option is available when you specify more than one X, Grouping variable.

Show Agreement Grand Mean  Shows or hides the overall agreement mean on the gauge attribute chart.

Show Effectiveness Points  Shows or hides the effectiveness points on the charts.

Connect Effectiveness Points  Draws lines between the effectiveness points in the charts.

Effectiveness by Rater Confid Intervals  Shows or hides confidence intervals on the second chart in the Attribute Gauge Chart report (Figure 6.5).

Effectiveness Report  Shows or hides the Effectiveness report. This report compares every rater with the standard, using the Kappa statistic.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Statistical Details for Attribute Gauge Charts

For the first chart in Figure 6.5 that plots all X, Grouping variables on the x-axis, the percent Agreement is calculated as follows:

\[
\text{% Agreement for part } i = \frac{\sum_{l=1}^{k} \left( \frac{\text{number of responses for level } l}{2} \right)}{\sum_{l=1}^{k} \left( \frac{N_l}{2} \right)}
\]
For the second chart in Figure 6.5 that plots all \( Y, \text{Response} \) variables on the \( x \)-axis, the percent Agreement is calculated as follows:

\[
\text{% Agreement for rater } k = \frac{n \left( \sum_{i=1}^{n} \sum_{j=1}^{r_i} \frac{N_i - j}{N_i} \right)}{n \left( \sum_{i=1}^{n} \sum_{j=1}^{r_i} \frac{N_i - j}{N_i} \right)}
\]

Note the following:

- \( n \) = number of parts (grouping variables)
- \( r_i \) = number of reps for part \( i \) (\( i = 1, \ldots, n \))
- \( m \) = number of raters
- \( k \) = number of levels
- \( N_i = m \times r_i \). Number of ratings on part \( i \) (\( i = 1, \ldots, n \)). This includes responses for all raters, and repeat ratings on a part. For example, if part \( i \) is measured 3 times by each of 3 raters, then \( N_i \) is \( 3 \times 3 = 9 \).

For example, consider the following table of data for three raters, each having three replicates for one part.

**Table 6.1** Three Replicates for Raters A, B, and C

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Using this table, you can make these calculations:

\[
\text{% Agreement} = \frac{\left( \binom{4}{2} + \binom{5}{2} \right)}{\binom{9}{2}} = \frac{16}{36} = 0.444
\]

\[
\text{% Agreement [rater A]} = \text{percent Agreement [rater B]} = \frac{4 + 3 + 3}{8 + 7 + 6} = \frac{10}{21} = 0.476 \text{ and}
\]

\[
\text{% Agreement [rater C]} = \frac{4 + 3 + 2}{8 + 7 + 6} = \frac{9}{21} = 0.4286
\]
Statistical Details for the Agreement Report

The simple Kappa coefficient is a measure of inter-rater agreement.

\[
\hat{\kappa} = \frac{P_0 - P_e}{1 - P_e}
\]

where:

\[
P_0 = \sum_i p_{ii}
\]

and:

\[
P_e = \sum_i p_{i}.p_.i
\]

If you view the two response variables as two independent ratings of the \(n\) parts, the Kappa coefficient equals +1 when there is complete agreement of the raters. When the observed agreement exceeds chance agreement, the Kappa coefficient is positive, and its magnitude reflects the strength of agreement. Although unusual in practice, Kappa is negative when the observed agreement is less than the chance agreement. The minimum value of Kappa is between -1 and 0, depending on the marginal proportions.

Estimate the asymptotic variance of the simple Kappa coefficient with the following equation:

\[
\text{var} = \frac{A + B - C}{(1 - P_e)^2 n}
\]

where:

\[
A = \sum_i p_{ii} \left[1 - (p_{i.} + p_{.i})(1 - \hat{\kappa})\right]
\]

\[
B = (1 - \hat{\kappa})^2 \sum_{i \neq j} \sum p_{ij}(p_{i.} + p_{.j})^2
\]

and:

\[
C = \left[\hat{\kappa} - P_e(1 - \hat{\kappa})\right]^2
\]

The Kappas are plotted and the standard errors are also given.

Note: The Kappa statistics in the Attribute Chart platform are shown even when the levels of the variables are unbalanced.
Categorical Kappa statistics (Fleiss 1981) are found in the Agreement Across Categories report.

Given the following assumptions:

- \( n \) = number of parts (grouping variables)
- \( m \) = number of raters
- \( k \) = number of levels
- \( r_i \) = number of reps for part \( i \) (\( i = 1, \ldots, n \))
- \( N_i = m \times r_i \). Number of ratings on part \( i \) (\( i = 1, 2, \ldots, n \)). This includes responses for all raters, and repeat ratings on a part. For example, if part \( i \) is measured 3 times by each of 2 raters, then \( N_i \) is \( 3 \times 2 = 6 \).
- \( x_{ij} \) = number of ratings on part \( i \) (\( i = 1, 2, \ldots, n \)) into level \( j \) (\( j = 1, 2, \ldots, k \))

The individual category Kappa is defined as follows:

\[
\hat{\kappa}_j = 1 - \frac{\sum_{i=1}^{n} x_{ij}(N_i - x_{ij})}{\left(\bar{p}_j\bar{q}_j\right) \sum_{i=1}^{n} N_i(N_i - 1)}
\]

where

\[
\bar{p}_j = \frac{\sum_{i=1}^{n} x_{ij}}{n} \quad \bar{q}_j = 1 - \bar{p}_j
\]

The overall Kappa is defined as follows:

\[
\hat{\kappa} = \frac{\sum_{j=1}^{k} \bar{q}_j\bar{p}_j\hat{\kappa}_j}{\sum_{j=1}^{k} \bar{p}_j\bar{q}_j}
\]

The variance of \( \hat{\kappa}_j \) and \( \hat{\kappa} \) are calculated as follows:

\[
\text{var}(\hat{\kappa}_j) = \frac{2}{nN(N-1)}
\]

\[
\text{var}(\hat{\kappa}) = \frac{2}{\left(\sum_{j=1}^{k} \bar{p}_j\bar{q}_j\right) nN(N-1)} \times \left[ \left(\sum_{j=1}^{k} \bar{p}_j\bar{q}_j\right)^2 - \sum_{j=1}^{k} \bar{p}_j\bar{q}_j(\bar{q}_j - \bar{p}_j)^2 \right]
\]

The standard errors of \( \hat{\kappa}_j \) and \( \hat{\kappa} \) are shown only when there are an equal number of ratings per part (for example, \( N_i = N \) for all \( i = 1, \ldots, n \)).
Process capability analysis, used in process control, measures how well a process is performing compared to given specification limits. A good process is one that is stable and consistently produces product that is well within specification limits. A capability index is a measure that relates process performance, summarized by process centering and variability, to specification limits.

Graphical tools such as a goal plot and box plots give you quick visual ways of identifying which process or product characteristics are within specifications. Individual detail reports display a capability report for each variable in the analysis. The analysis enables you to identify variation relative to the specifications or requirements; this enables you to achieve increasingly higher conformance values.

You can specify subgroups to compare the overall variation of the process to the within subgroup variation. You can compute capability indices for processes that produce measurements that follow various distributions. For data that follow none of the specified distributions, you can compute nonparametric capability indices.

Overview of the Process Capability Platform

The Process Capability platform provides the tools needed to measure the compliance of a process to given specifications. By default, JMP shows a Goal Plot, Capability Box Plots, and a Capability Index Plot for the variables that you fit with normal distributions. Capability indices for nonnormal variables are plotted on the Capability Index Plot. You can add normalized box plots, summary reports, and individual detail reports for the variables in your analysis.

You can supply specification limits in several ways:

- in the data table, using a column property
- by requesting the Spec Limits Dialog in the launch window
- by loading the limits from a specification limits data table
- using the Manage Spec Limits utility (Analyze > Quality and Process > Manage Spec Limits)

You can specify two-sided, one-sided, or asymmetric specification limits.

**Note:** The Process Capability platform expands significantly on the Capability analyses that are available through Analyze > Distribution and through Analyze > Quality and Process > Control Chart.

**Capability Indices**

A capability index is a ratio that relates the ability of a process to produce product that meets specification limits. The index relates estimates of the mean and standard deviation of the quality characteristic to the specification limits. Within estimates of capability are based on an estimate of the standard deviation constructed from within-subgroup variation. Overall estimates of capability use an estimate of standard deviation constructed from all of the process data. See “Capability Indices for Normal Distributions” on page 234 and “Variation Statistics” on page 228.

Estimates of the mean or standard deviation are well-defined only if the processes related to centering or spread are *stable*. Therefore, interpretation of within capability indices requires that process spread is stable. Interpretation of overall capability indices requires that both process centering and spread are stable.

Capability indices constructed from small samples can be highly variable. The Process Capability platform provides confidence intervals for most capability indices. Use these to determine the range of potential values for your quality characteristic’s actual capability.
Note: When confidence intervals are not provided (for example, for nonnormal distributions) you can use the Simulate feature to construct confidence intervals. For an example, see “Simulation of Confidence Limits for a Nonnormal Process Ppk” on page 221.

Guidelines for values of capability indices can be found in Montgomery (2013). The minimum recommended value is 1.33. Six Sigma initiatives aim for much higher capability levels that correspond to extremely low rates of defective parts per million.

**Capability Indices for Nonnormal Processes**

The Process Capability platform constructs capability indices for process measurements with the following distributions: Normal, Beta, Exponential, Gamma, Johnson, Lognormal, Mixture of 2 Normals, Mixture of 3 Normals, SHASH, and Weibull. A Best Fit option determines the best fit among these distributions and provides capability indices for this fit. The platform also provides a Nonparametric fit option that gives nonparametric estimates of capability.

For the nonnormal methods, estimates are constructed using two approaches: the ISO/Quantile method (Percentiles) and the Bothe/Z-scores method (Z-Score). For more information about these methods, see “Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods” on page 240.

Note: Process Capability analysis for individual responses is accessible through Analyze > Quality and Process > Control Chart Builder. However, nonnormal distributions are available only in the Process Capability platform.

**Overall and Within Estimates of Sigma**

Most capability indices in the Process Capability platform can be computed based on estimates of the overall (long-term) variation and the within-subgroup (short-term) variation. If the process is stable, these two measures of variation should yield similar results since the overall and within subgroup variation should be similar. The normalized box plots and summary tables can be calculated using either the overall or the within-subgroup variation. See “Additional Examples of the Process Capability Platform” on page 213 for examples of capability indices computed for stable and unstable processes.

You can specify subgroups for estimating within-subgroup variation in the launch window. You can specify a column that defines subgroups or you can select a constant subgroup size. For each of these methods, you can choose to estimate the process variation using the average of the unbiased standard deviations or using the average of the ranges. If you do not specify subgroups, the Process Capability platform constructs a within-subgroup estimate of the process variation using a moving range of subgroups of size two. Finally, you can specify a historical sigma to be used as an estimate of the process standard deviation.
Capability Index Notation

The Process Capability platform provides two sets of capability indices. See “Capability Indices for Normal Distributions” on page 234 for more information about the calculation of the capability indices.

- Cpk, Cpl, Cpu, Cp, and Cpm. These indices are based on a within-subgroup (short-term) estimate of the process standard deviation.
- Ppk, Ppl, Ppu, Pp, and Cpm. These indices are based on an overall (long-term) estimate of the process standard deviation. Note that the process standard deviation does not exist if the process is not stable. See Montgomery (2013).

The Process Capability platform uses the appropriate AIAG notation for capability indices: Ppk labeling denotes an index constructed from an overall variation estimate and Cpk denotes an index constructed from a within-subgroup variation estimate.

**Note:** The AIAG (Ppk) Labeling platform preference is selected by default. You can change the reporting to use Cp notation only by deselecting this preference under Process Capability.

For more information about process capability analysis, see Montgomery (2013) and Wheeler (2004).

Example of the Process Capability Platform with Normal Variables

This example uses the Semiconductor Capability.jmp sample data table. The variables represent standard measurements that a semiconductor manufacturer might make on a wafer as it is being processed. Specification limits for the variables have been entered in the data table through the Column Properties > Spec Limits property.

1. Select Help > Sample Data Library and open Semiconductor Capability.jmp.
3. Click the white triangle next to Processes to view all of the continuous variables.
4. Select PNP1, PNP2, NPN2, PNP3, IVP1, PNP4, NPN3, and IVP2, and click Y, Process.
5. Click OK.
6. Click the Goal Plot red triangle and select Label Overall Sigma Points.
7. Click the Capability Index Plot red triangle and select Label Overall Sigma Points.
Figure 7.2  Example Results for Semiconductor Capability.jmp

The Goal Plot shows the spec-normalized mean shift on the $x$-axis and the spec-normalized standard deviation on the $y$-axis for each variable. The triangular region defined by the red lines in the bottom center of the plot is the goal triangle. It defines a region of capability index values. You can adjust the goal triangle using the Ppk slider to the right of the plot. When the slider is set to 1, note that PNP1, PNP3, IVP1, and IVP2 are outside of the goal triangle and possibly out of specification.

The Capability Box Plots report shows a box plot for each variable in the analysis. The values for each column are centered by their target value and scaled by the specification range. In this example, all process variables have both upper and lower specification limits, and these are symmetric about the target value. It follows that the solid green line shows where the target should be and the dashed lines represent the specification limits.
It appears that the majority of points for IVP1 are above its upper specification limit (USL), and the majority of points for IVP2 are less than its target. PNP2 seems to be on target with all data values inside the specification limits.

The Capability Index Plot plots the Ppk values for each variable. Four variables come from very capable processes, with Ppk values of 2 or more. Four variables have Ppk values below 1.

Example of the Process Capability Platform with Nonnormal Variables

The Process Measurements.jmp data table contains measurements made on seven different processes used to construct a product. For each process, specification limits are saved as column properties. You begin by examining the distributions of your process data. You see that the distributions are not normal. Then you use the nonnormal capability features of the Process Capability platform to compute capability indices.

View the Distributions
2. Select Analyze > Distribution.
3. Select all seven columns from the Select Columns list and click Y, Columns.
4. Check the box next to Histograms Only.
5. Click OK.

For most processes, the histograms show evidence that the theoretical distribution of measurements is skewed and does not follow a normal distribution. Therefore, for each process, you find the best fitting distributions among all of the available parametric distributions.

Perform a Capability Analysis
2. Select all seven columns from the Columns list and click Y, Process.
3. Select all seven columns in the Y, Process list.
4. Open the Distribution Options panel and select Best Fit from the Distribution list.
5. Click Set Process Distribution.

The suffix &Dist(Best Fit) is added to each variable name in the Y, Process list. The Best Fit option specifies that the best-fitting parametric distribution should be fit to each variable. The available parametric distributions are Normal, Beta, Exponential, Gamma, Johnson,
Lognormal, Mixture of 2 Normals, Mixture of 3 Normals, SHASH, and Weibull (Figure 7.3).

6. Open the **Nonnormal Distribution Options** outline. Note that the Nonnormal Capability Indices Method is set to **Percentiles**, the Johnson Distribution Fitting Method is set to **Quantile Matching**, and the Distribution Comparison Criterion is set to **AICc**.

**Figure 7.3 Completed Launch Window**

The Quantile Matching method is the default method used for fitting Johnson distributions because of its stability and speed as compared to Maximum Likelihood. Note that Maximum Likelihood is used in the Distribution platform.

7. Click **OK**.

8. Click the Goal Plot red triangle and select **Label Overall Sigma Points**.

9. Click the Capability Index Plot red triangle and select **Label Overall Sigma Points**.
Figure 7.4 Initial Report with Variables Labeled

Note: Click a label in the plot and drag it to make the plot more interpretable. Click the right side frame of the Capability Index Plot and drag it to the right to make the labels easier to distinguish.

The Goal Plot shows only one point and it corresponds to Process 7. The Capability Box Plots report shows a single box plot for Process 7. This is because the best fit for Process 7 is a normal distribution.

10. To the right of the Capability Index Plot, set the Ppk value to 2.
The Capability Index Plot shows Ppk values for all seven processes. Only two processes, Process 2 and Process 7, have capability values that exceed 2. Note that the best fitting nonnormal distributions are shown in parentheses to the right of the variable names in the Capability Index Plot. The best fitting distribution for Process 7 is not shown because it is a normal distribution.

11. Click the Process Capability red triangle and select Individual Detail Reports.

Because you requested Best Fit in the launch window, the Compare Distributions option has been selected from each distribution’s red triangle menu.

Figure 7.5 Individual Detail Report for Process 4

The title of the report for Process 4 indicates that the capability calculations are based on a lognormal fit. All of the check boxes in the Compare Distributions report, except the boxes
for Nonparametric and Beta, are checked, indicating that these nine distributions are fit. (This is because you requested a Best Fit in the launch window.) The button that is selected in the Selected column indicates that the Lognormal distribution is the distribution that is used in the remainder of the Process 4(Lognormal) Capability report to estimate capability and nonconformance.

The Compare Distributions report enables you to compare the nine distributional fits. The Histogram - Compare Distributions report gives a visual assessment of the fit and the Comparison Details report shows fit statistics for the selected distributions. Both the plot and the fit statistics indicate that the lognormal distribution gives the best fit among the selected distributions.

The Individual Detail Report information that is shown by default includes a histogram showing the estimated best-fit distribution, a summary of the process information, capability indices based on an overall estimate of sigma, parameter estimates for the fitted lognormal distribution, and observed and expected nonconformance levels.
Chapter 7
Quality and Process Methods

Launch the Process Capability Platform

Launch the Process Capability Platform by selecting Analyze > Quality and Process > Process Capability. In Figure 7.6, which uses the Semiconductor Capability.jmp data table, all outlines and panels have been opened.

**Figure 7.6 Process Capability Launch Window**

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Process Capability launch window contains the following outlines and options:

- “Process Selection” on page 182
- “Process Subgrouping” on page 182
• “Moving Range Options” on page 183
• “Historical Information” on page 184
• “Distribution Options” on page 184
• “Other Specifications” on page 185

After you click OK in the launch window, the Spec Limits window appears unless one of the following occurs:

• All of the columns contain specification limits.
• You selected No (skip columns with no spec limits) on the launch window.

The Spec Limits window also appears if you select Yes on the launch window. Otherwise, the Process Capability report window appears.

**Process Selection**

Select the process variables to include in the capability analysis.

**Y, Process**  Assigns the variables that you want to analyze.

**Notes:**

• The Transform menu is not available for the Select Column list in the Process Capability launch window. Right-click a column heading in the data table and select New Formula Column to create a transform column for use in Process Capability. See Using JMP for more information about creating new formula columns.

• Reference columns for virtually joined tables are not available in the Process Capability platform.

**Process Subgrouping**

This group of options enables you to assign each variable in the Y, Process list a subgroup ID column or a constant subgroup size.

**Create Subgroups Using an ID Column**

1. Select a variable or variables in the Y, Process list.
2. Select Subgroup ID Column from the Subgroup with options.
3. Select a subgroup ID column in the Select Columns list.
4. Click Nest Subgroup ID Column.

The subgroup ID column appears in brackets to the right of the variable names in the Y, Process list.
Create Subgroups Using a Constant Subgroup Size

1. Select a variable or variables in the Y, Process list.
2. Select **Constant Subgroup Size** from the **Subgroup with** options.
3. Enter the subgroup size next to **Set Constant Subgroup Size**.
4. Click **Subgroup by Size**.

The subgroup size appears in brackets to the right of the variable names in the Y, Process list.

**Nest Subgroup ID Column**  (Available when you select Subgroup ID Column.) Assigns a column that you select from the Select Columns list to define the subgroups for the selected Y, Process columns.

**Subgroup by Size**  (Available when you select Constant Subgroup Size.) Assigns the subgroup size that you specify in the Set Constant Subgroup Size box to define the subgroups for the selected Y, Process columns.

**Set Constant Subgroup Size**  (Available when you select Constant Subgroup Size.) Specify the constant subgroup size for the selected Y, Process columns. You need to assign this value using Subgroup by Size.

**Within-Subgroup Variation Statistic**  (Available when Process Subgrouping is used.) Specifies if the within-subgroup estimate of standard deviation is calculated using standard deviations or ranges.

**Calculate Between-and-Within Capability**  (Available when Process Subgrouping is used.) Specifies that the between-and-within subgroup estimate of the standard deviation should be used in the capability analysis.

Moving Range Options

Use this outline to specify which moving range statistic is used in the within sigma estimate when subgrouping is not used.

**Note:** When you specify subgrouping and click **Calculate Between-and-Within Capability**, use the Moving Range Options outline to specify which moving range statistic is used in the between sigma estimate.

**Average of Moving Range**  Uses the mean of the moving ranges to estimate sigma. The moving range is the difference between two consecutive points.

**Median of Moving Range**  Uses the median of the moving ranges to estimate sigma.
Historical Information

Use this outline to assign historically accepted values of the standard deviation to variables in the Y, Process list.

1. Select a variable or variables in the Y, Process list.
2. Enter a value next to Set Historical Sigma.
3. Select Use Historical Sigma to assign that value to the selected variables.

The specified value appears in parentheses in the expression “&Sigma()” to the right of the variable names in the Y, Process list.

Note: If you set a historical sigma, then subgroup assignments for the selected process variable are no longer relevant and are removed.

Distribution Options

Unless otherwise specified, all Y, Process variables are analyzed using the assumption that they follow a normal distribution. Use the Distribution Options outline to assign other distributions or calculation methods to variables in the Y, Process list and to specify options related to nonnormal calculations.

- The available distributions are the Normal, Beta, Exponential, Gamma, Johnson, Lognormal, Mixture of 2 Normals, Mixture of 3 Normals, SHASH, and Weibull distributions. Except for Johnson distributions, maximum likelihood estimation is used to fit distributions. See “Johnson Distribution Fit Method” on page 185.
- The Best Fit option determines the best fit among the available distributions and applies this fit.
- The Nonparametric option fits a distribution using kernel density estimation.

For more options related to nonnormal fits, see “Nonnormal Distribution Options” on page 185.

Specify a Distribution

1. Select a variable or variables in the Y, Process list.
2. Select a distribution from the Distribution list.
3. Select Set Process Distribution to assign that distribution to the selected variables.

The specified distribution appears in parentheses in the expression “&Dist()” to the right of the variable names in the Y, Process list.
Note: If you select a distribution other than Normal, you cannot assign a Subgroup ID column or a Historical Sigma. These selections are not supported by the methods used to calculate nonnormal capability indices. See “Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods” on page 240.

Nonnormal Distribution Options

Nonnormal Capability Indices Method  Specifies the method used to compute capability indices for nonnormal distributions. See “Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods” on page 240.

Johnson Distribution Fit Method  Specifies the method used to find the best-fitting Johnson distribution. Before estimating the parameters, the best-fitting family of distributions is determined from among the Johnson Su, Sb, and Sl families. The procedure described in Slifker and Shapiro (1980) is used to find the best-fitting family.

Quantile Matching  The default method. It is more stable and faster than Maximum Likelihood. Quantile Matching Parameter estimates, assuming the best-fitting family, are obtained using a quantile-matching approach. See Slifker and Shapiro (1980).

Maximum Likelihood  Parameters for the best-fitting family are determined using maximum likelihood.

Distribution Comparison Criterion  (Available when a Best Fit Distribution is selected.) Specify the criterion that you want to use in determining a Best Fit. This criterion also determines the ordering of distributions in the Comparison Details report. See “Order by Comparison Criterion” on page 208.

Other Specifications

By  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Specify Alpha Level  Specifies the significance level for confidence limits.

Show Spec Limits Dialog  Specifies how to handle columns that do not have specification limits.
Note: It is good practice to ensure that specification limits for all process variables are specified as Spec Limits column properties or to load specification limits from a Limits Data table (see “Limits Data Table” on page 187). Otherwise, you can specify limits interactively in the Spec Limits window that appears after you click OK in the launch window (unless you select No (skip columns with no spec limits) on the launch window).

**Entering Specification Limits**

The lower specification limit (LSL), upper specification limit (USL), and target define the lower bound, upper bound, and target value for a quality process.

There are several ways to enter specification limits:

- Enter limits in the Spec Limits window after selecting columns in the launch window. See “Spec Limits Window” on page 186.
- Import limits from a JMP data table (known as a Limits Table). See “Limits Data Table” on page 187.
- Enter limits as Spec Limits column properties in the data table. See “Spec Limits Column Property” on page 189.
- If you are creating a Process Capability report by running a JSL script, enter limits in the script. See “The Process Capability Report” on page 189.

Only one specification limit is required for a selected column. If only the USL is specified, the box plots and Goal Plot point are colored blue. If only the LSL is specified, the box plots and Goal Plot point are colored red.

**Spec Limits Window**

After you click OK on the launch window, the Spec Limits window appears if any of the columns do not contain limits and you did not select No (skip columns with no spec limits) on the launch window. The Spec Limits window also appears if you select Yes on the launch window. Figure 7.7 shows the Spec Limits window for the Cities.jmp sample data table after selecting OZONE, CO, SO2, and NO as process variables in the launch window. Enter the known specification limits and click OK to view the Process Capability report.

You can specify process importance values for each column. Process importance values provide a mechanism to sort processes in the order that you prefer. Process importance values are used to size markers in many of the graphs in the Process Capability report.
If you select the Show Limits option for a process and then save the specification limits to a column property, the Show as Graph Reference Lines option is selected in the saved Spec Limits column property. If you select the Show Limits option for a process and then save the specification limits to a new table, the Show Limits column in the new table contains a 1 for the process. The **Select All Show Limits** button selects the Show Limits option for all processes.

**Figure 7.7** Spec Limits Window for Cities.jmp

### Limits Data Table

You can also specify a limits data table with the **Load spec limits from data table** option from the Spec Limits window. Click the **Select Data Table** button and then select the appropriate data table that contains the specification limits for the analysis. After you select the appropriate limits table, the values populate the window. Click **OK** to view the Process Capability report.

A limits data table can be in two different formats: **tall** or **wide**. A tall limits data table has one column for the responses and the limits key words are the other columns. A wide limits data table has a column for each response with one column to label the limits keys. Either of these formats can be read using the **Load spec limits from data table** option.

- A tall table contains four or five columns and has one row for each process. The first column has a character data type and contains the names of the columns analyzed in the Process Capability platform. The next three columns need to be named LSL, Target, and USL. These column names can also be preceded by an underscore character. The optional final column named Show Limits specifies if the specification limits are shown as reference lines in select analysis plots.
Figure 7.8  Example of a Tall Specification Limits Table

• A wide table contains three rows and one column for each column analyzed in the Process Capability platform plus a _LimitsKey column. In the _LimitsKey column, the three rows need to contain the identifiers _LSL, _Target, and _USL.

Figure 7.9  Example of a Wide Specification Limits Table

The easiest way to create a limits data table is to save results computed by the Process Capability platform. The Save options in the Process Capability red triangle menu enable you to save limits from the sample values. After entering or loading the specification limits, you can do the following:

• Select **Save > Save Spec Limits as Column Properties** to save the limits as Spec Limits column properties to the columns in the data table.

• Select **Save > Save Distributions as Column Properties** to save the distributions used in calculating capability as Process Capability Distribution column properties to the columns in the data table.

• Select **Save > Save Spec Limits to New Table** to save the limits to a new tall specification limits data table. If you have selected at least one nonnormal distribution, a column called Distribution that contains the specified distributions is also added to the limits data table.

See “Process Capability Platform Options” on page 197.
Spec Limits Column Property

When you perform a capability analysis, you can use Column Properties > Spec Limits to save specification limits as a column property. The Spec Limits property applies only to numeric columns.

Some processes have one-sided specifications. Some have no target. You can enter any of these that apply: a lower specification limit, an upper specification limit, a target value, or a process importance value.

Figure 7.10 displays the Spec Limits section of the Column Properties window for OZONE in the sample data table Cities.jmp.

Figure 7.10 Spec Limits Section of the Column Properties Window

Tip: Saving specification limits as a column property ensures consistency when you repeat an analysis.

The Process Capability Report

By default, the Process Capability platform provides the following reports:

- “Goal Plot” on page 190 (provided only if at least one variable is fit with a normal distribution and shows only points for variables fit with normal distributions)
• “Capability Box Plots” on page 193 (provided only if at least one variable is fit with a normal distribution and shows only box plots for variables fit with normal distributions)
• “Capability Index Plot” on page 195

Figure 7.2 on page 174 shows an example of a default Process Capability report.

Using the Process Capability red triangle menu, you can add individual detail reports, normalized box plots, and summary reports. The red triangle menu also has options for identifying out-of-spec values in your data table, creating a summary data table, changing the display order of analyzed columns, and saving out spec limits. These options are described in “Process Capability Platform Options” on page 197.

You can change the default report at File > Preferences > Platforms > Process Capability. You can also make changes to the appearance of reports produced by options by selecting the relevant Process Capability topic at File > Preferences > Platforms.

Goal Plot

The Goal Plot shows, for each variable, the spec-normalized mean shift on the x-axis, and the spec-normalized standard deviation on the y-axis. It is useful for getting a quick, summary view of how the variables are conforming to specification limits. By default, the Goal Plot shows only those points for each column that are calculated using the overall sigma. Hover over each point to view the variable name and the sigma method used to calculate the point. See “Goal Plot” on page 232 for more information about the calculation of the coordinates for the Goal Plot.

Note: Process variables with distributions other than Normal are not plotted on the Goal Plot.

Goal Plot Points

Points on the Goal Plot correspond to columns, not rows. Selecting a point in the Goal Plot selects the corresponding column in the data table. If process importance values are specified, the goal plot points are sized by importance.

Hover over a point in the Goal Plot to view a control chart for that process. Click the control chart to launch Control Chart Builder with the corresponding control chart and capability report.

Note: A control chart is not available for a process if the unbiased pooled standard deviation is chosen as the within-group variation statistic for that process.
The points on the Goal Plot are also linked to the rows of the Goal Plot Summary Table, where each row corresponds to a column. You can select a point in the Goal Plot, right-click, and apply row states. These row states are applied to the rows of the Goal Plot Summary Table. Row states that you apply in the Goal Plot Summary Table are reflected in the Goal Plot. To see this table, select Make Goal Plot Summary Table from the Process Capability red triangle menu. See “Make Goal Plot Summary Table” on page 212.

**Tip:** If you hide a point in the Goal Plot, you can show the point again by changing the corresponding row state in the Goal Plot Summary Table.

**Goal Plot Triangle**

The goal plot triangle appears in the center of the bottom of the Goal Plot. The slider to the right of the plot enables you to adjust the size of goal triangle in the plot.

By default, the Ppk slider and the value beneath it are set to Ppk = 1. This approximates a non-conformance rate of 0.0027, if the distribution is normal. The goal triangle represents the Ppk shown in the box. To change the Ppk value, move the slider or enter a number in the box.

JMP gives the Goal Plot in terms of Ppk values by default. You can change this preference at File > Preferences > Platforms > Process Capability. When the AIAG (Ppk) Labeling preference is unchecked, all of the Ppk labeling is changed to Cpk labeling, including the label of the slider to the right of the goal plot.

**Goal Plot Options**

The Goal Plot red triangle menu has the following options:

- **Show Within Sigma Points**  Shows or hides the points calculated using the within sigma estimate.

- **Show Within or Between-and-Within Sigma Points** (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.)  Shows or hides the points calculated using the within sigma estimate or, if specified, the between-and-within sigma estimate.

- **Show Overall Sigma Points**  Shows or hides the points calculated using the overall sigma estimate.

- **Shade Levels**  Shows or hides the Ppk level shading (Figure 7.11). When you select Shade Levels, shaded areas appear in the plot. The shaded areas depend on the relationship between \( p \) and Ppk, with \( p \) representing the value shown in the box beneath Ppk:
  
  - Points in the red area have \( \text{Ppk} < p \).
  - Points in the yellow area have \( p < \text{Ppk} < 2p \).
– Points in the green area have $2\sigma < Ppk$.

**Label Within Sigma Points**  Shows or hides labels for points calculated using the within sigma estimate.

**Label Within or Between-and-Within Sigma Points**  (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides labels for points calculated using the within sigma estimate or, if specified, the between-and-within sigma estimate.

**Label Overall Sigma Points**  Shows or hides labels for points calculated using the overall sigma estimate.

**Defect Rate Contour**  Shows or hides a contour representing a specified defect rate.

Figure 7.11 shows the Goal Plot for the entire data set for the Semiconductor Capability.jmp sample data table after selecting Shade Levels and Show Within Sigma Points from the Goal Plot red triangle menu.

**Figure 7.11** Goal Plot

---

**One-Sided or Missing Specification Limits**

When there is only one specification limit for a column, markers and colors are used in the following ways:

- If only the upper specification limit (USL) is specified, the point on the Goal Plot is represented by a right-pointing triangle and is colored blue.
• If only the lower specification limit (LSL) is specified, the point on the Goal Plot is represented by a left-pointing triangle and is colored red.
• If at least one process has only an upper specification limit, the right half of the goal triangle is blue.
• If at least one process has only a lower specification limit, the left half of the goal triangle is red.

Processes with only an upper specification limit are represented by blue and should be compared to the blue (right) side of the goal triangle. Processes with only a lower specification limit are represented by red and should be compared to the red (left) side of the goal triangle. For more information about how the coordinates of points are calculated, see “Goal Plot” on page 232.

**Capability Box Plots**

The Capability Box Plots show a box plot for each variable selected in the analysis. The values for each column are centered by their target value and scaled by the difference between the specification limits. If the target is not centered between the specification limits, the values are scaled by twice the minimum difference between the target and specification limits. For each process column $Y_j$ (see “Notation for Goal Plots and Capability Box Plots” on page 231 for a description of the notation):

$$Z_{ij} = \frac{Y_{ij} - T_j}{2 \times \min(T_j - LSL_j, USL_j - T_j)}$$

For a process with a one-sided specification, see “One-Sided or Missing Specification Limits” on page 192. For the situation where no target is specified, see “Capability Box Plots for Processes with Missing Targets” on page 233.

**Note:** Process variables with distributions other than Normal are not plotted on the Capability Box Plot.

Figure 7.11 shows a Capability Box Plots report for eight variables in the Semiconductor Capability.jmp sample data table.
The plot displays dotted green lines drawn at ±0.5.

- For a process with a target that is centered between its specification limits, the dotted green lines represent the standardized specification limits.
- For a process with a target that is not centered between its specification limits, one of the dotted green lines represents the standardized specification limit for the limit closer to the target. The other dotted green line represents the same distance in the opposite direction.

This plot is useful for comparing variables with respect to their specification limits. For example, in Figure 7.12, the majority of points for IVP1 are above its USL, and the majority of its points for IVP2 are less than its target. PNP2 seems to be on target with all data points in the specification limits.

**One-Sided or Missing Specification Limits**

When there is only one specification limit for a column, colors are used in the following ways:

- If only the upper specification limit (USL) is specified, the box plot is colored blue.
- If only the lower specification limit (LSL) is specified, the box plot is colored red.
- If at least one process has only an upper specification limit, the dotted line at 0.5 is blue.
- If at least one process has only a lower specification limit, the dotted line at -0.5 is red.
Suppose that only the lower specification limit is specified and that the process target is specified. The capability box plot is based on the following values for the transformed observations. See “Notation for Goal Plots and Capability Box Plots” on page 231 for a description of the notation:

\[ Z_{ij} = \frac{Y_{ij} - T_j}{2(T_j - \text{LSL}_j)} \]

Suppose that only the upper specification limit is specified and that the process target is specified. The capability box plot is based on the following values for the transformed observations:

\[ Z_{ij} = \frac{Y_{ij} - T_j}{2(\text{USL}_j - T_j)} \]

For more information about how missing targets are handled with one-sided specification limits, see “Single Specification Limit and No Target” on page 234.

### Capability Index Plot

The Capability Index Plot shows Ppk values for all variables that you entered as Y, Process. Each variable name appears on the horizontal axis and the Ppk values appear on the vertical axis. If you fit a nonnormal distribution, the fitted distribution name appears in the plot as a parenthetical suffix to the variable name. If process importance values are specified, the points on the capability index plot are sized by importance. A horizontal line is placed at the Ppk value that is specified by the slider to the right of the plot.

Hover over a point in the Capability Index Plot to view a control chart for that process. Click the control chart to launch Control Chart Builder with the corresponding control chart and capability report.

**Note:** A control chart is not available for a process if the unbiased pooled standard deviation is chosen as the within-group variation statistic for that process.

Figure 7.13 shows a Capability Index Plot report for the Process Measurements.jmp sample data table. Seven of the variables are fit with nonnormal distributions. Process 7 is fit with a normal distribution. Points have been labeled using the Label Overall Sigma Points option that is available in the Capability Index Plot red triangle menu.
Figure 7.13 Capability Index Plot with Nonnormal Distributions

Capability Index Plot Options

The Capability Index Plot red triangle menu has the following options:

**Show Within Sigma Points**  Shows or hides the points calculated using the within sigma estimate.

**Show Within or Between-and-Within Sigma Points**  (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides the points calculated using the within sigma estimate or, if specified, the between-and-within sigma estimate.

**Show Overall Sigma Points**  Shows or hides the points calculated using the overall sigma estimate.

**Shade Levels**  Shows or hides the Ppk level shading. When you select Shade Levels, shaded areas appear in the plot. The shaded areas depend on the relationship between $p$ and Ppk, with $p$ representing the value shown in the box beneath Ppk:

- Points in the red area have $Ppk < p$.
- Points in the yellow area have $p < Ppk < 2p$.
- Points in the green area have $2p < Ppk$. 
**Process Capability Platform Options**

The Process Capability red triangle menu contains the following options:

**Individual Detail Reports**  Shows or hides individual detail reports for each variable in the analysis. See “Individual Detail Reports” on page 200.

**Goal Plot**  Shows or hides a goal plot for the data. The Goal Plot shows the spec-normalized mean shift on the x-axis and the spec-normalized standard deviation on the y-axis for each variable. See “Goal Plot” on page 190. (Only variables for which you specify normal distributions are shown on the plot.)

**Capability Box Plots**  Shows or hides a capability box plot for each variable in the analysis. The values for each column are centered by their target value and scaled by twice the minimum difference between the target value and the specification limits. See “Capability Box Plots” on page 193. (Box plots are shown only for variables for which you specify normal distributions.)

**Normalized Box Plots**  Provides two options for plots that show normalized box plots for each process variable. Each column is standardized by subtracting its mean and dividing by an estimate of the column’s standard deviation. The box plot is constructed using quantiles for the standardized values. See “Normalized Box Plots” on page 208. (Normalized box plots are shown only for variables for which you specify normal distributions.)

**Within Sigma Normalized Box Plots**  Shows or hides a plot called Within Sigma Normalized Box Plots. The box plots are constructed using the within-subgroup estimate of standard deviation.
Within or Between-and-Within Sigma Normalized Box Plots  (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides a plot called Within or Between-and-Within Normalized Box Plots. The box plots are constructed using the within group estimate of the standard deviation or, if specified, the between-and-within estimate.

Overall Sigma Normalized Box Plots  Shows or hides a plot called Overall Sigma Normalized Box Plots. The box plots are constructed using the overall estimate of standard deviation.

Capability Index Plot  Shows overall Ppk values for all variables that you entered as Y, Process. See “Capability Index Plot” on page 195.

Process Performance Plot  Shows or hides a four-quadrant plot of capability versus stability. Each process that has at least one specification limit is represented by a point. See “Process Performance Plot” on page 209.

Summary Reports  Provides two options for summary reports of capability indices. See “Summary Reports” on page 211.

Within Sigma Summary Report  Shows or hides a summary report of capability indices calculated using the within-subgroup estimate of standard deviation. (Results are available only for variables with specified normal distributions.)

Within or Between-and-Within Sigma Summary Report  (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides a summary report of capability indices calculated using the within group estimate of the standard deviation or, if specified, the between-and-within group estimate.

Overall Sigma Summary Report  Shows or hides a summary report of capability indices calculated using the overall estimate of standard deviation.

Action Options

The following red triangle menu options perform actions:

Out of Spec Values  Provides options for the cells in the data table containing values that are out of spec.

Select Out of Spec Values  Selects all rows and columns in the data table that contain at least one value that does not fall within the specification limits.

Color Out of Spec Values  Colors the cells in the data table that correspond to values that are out of spec. The cell is colored blue if the value is above the USL and red if the value is below the LSL.
**Tip:** To remove colors in specific cells, select all cells of interest. Right-click in one of the cells and select Clear Color. To remove colors in all cells, deselect Color Out of Spec Values.

**Make Goal Plot Summary Table**  Creates a summary table for the points plotted in the Goal Plot. This table includes the variable’s name, its spec-normalized mean shift, and its spec-normalized standard deviation. Each variable has two rows in this table: one for each sigma type (within and overall). See “Make Goal Plot Summary Table” on page 212.

**Order By**  Reorders the box plots, summary reports, and individual detail reports. You can reorder by Initial Order, Reverse Initial Order, Within Sigma Cpk Ascending, Within or Between-and-Within Sigma Cpk Ascending, Within Sigma Cpk Descending, Within or Between-and-Within Sigma Cpk Descending, Overall Sigma Ppk Ascending, or Overall Sigma Ppk Descending. The options that order by Within Sigma reorder plot elements only for variables with specified normal distributions.

**Note:** The options to order by Within or Between-and-Within Sigma are available only if Calculate Between-and-Within Capability is selected for at least one process in the launch window.

**Save**  Provides options for saving specification limits and distributions.

**Save Spec Limits as Column Properties**  Saves the specification limits to a column property for each variable in the analysis. If no Spec Limits column property is present, the column property is created. If a Spec Limits column property is present, the values in the column property are overwritten. See “Spec Limits Column Property” on page 189.

**Save Distributions as Column Properties**  Saves the distribution used in calculating capability as a Process Capability Distribution column property. See *Using JMP*.

If a column contains the Distribution property specifying a nonnormal distribution and no Process Capability Distribution property, then the Process Capability platform applies a nonnormal fit. The Process Capability platform uses the distribution specified in the Distribution column property, or a Johnson fit if that distribution is not supported in Process Capability. If a column contains the Process Capability Distribution property, then the Process Capability platform uses the distribution specified in the Process Capability Distribution column property.

**Note:** If you want to use a specific distribution in the Process Capability platform, save it as a Process Capability Distribution column property.

**Save Spec Limits to New Table**  Saves the specification limits and the setting for Show Limits for each process to a limits data table in tall format. See “Limits Data Table” on page 187.
Relaunch Dialog  Opens the platform launch window and recalls the settings used to create the report.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Individual Detail Reports

The Individual Detail Reports option displays a capability report for each variable in the analysis.

Normal Distributions

Figure 7.14 shows the Individual Detail Report for PNP1 from the Semiconductor Capability.jmp sample data table as described in “Example of the Process Capability Platform with Normal Variables” on page 173.
The Individual Details report for a variable with a normal distribution shows a histogram, process summary details, and capability and nonconformance statistics. The histogram shows the distribution of the values, the lower and upper specification limits and the process target (if they are specified), and one or two curves showing the assumed distribution. The histogram in Figure 7.14 shows two normal curves, one based on the overall estimate of standard deviation and the other based on the within-subgroup estimate.

When you fit your process with a normal distribution, the Process Summary includes the Stability Index, which is a measure of stability of the process. The stability index is defined as follows:

\[
\text{Stability Index} = \frac{\text{Overall Sigma}}{\text{Within Sigma}}
\]

If Calculate Between-and-Within Capability is specified for a process in the launch window, the stability index for that process is defined as follows:

\[
\text{Stability Index} = \frac{\text{Overall Sigma}}{\text{Between-and-Within Sigma}}
\]

A stable process has stability index near one. Higher values indicate less stability.
**Note:** You can change the preferences for stability assessment type in File > Preferences > Platforms > Process Capability. This changes the stability assessment type used through the Process Capability platform.

### Nonnormal Distributions

**Note:** Capability indices based on within-subgroup variation and stability indices are not available for processes for which you have specified nonnormal distributions.

Figure 7.15 shows the Individual Detail Report for Process 1 from the Process Measurements.jmp sample data table as described in “Example of the Process Capability Platform with Nonnormal Variables” on page 175.

**Figure 7.15** Individual Detail Report for Process 1

The report opens with a note summarizing the Nonnormal Distribution Options that you selected in the launch window.
The Individual Details report for a variable with a nonnormal distribution shows a histogram, process summary details, and capability and nonconformance statistics. The histogram shows the distribution of the values, the lower and upper specification limits and the process target (if they are specified). A curve showing the fitted distribution is superimposed on the histogram. If you selected a Nonparametric distribution, the curve shown in the histogram is the nonparametric density.

The report also shows a Parameter Estimates report if you selected a nonnormal parametric distribution or a Nonparametric Density report if you selected a Nonparametric fit. See “Parameter Estimates” on page 205 and “Nonparametric Density” on page 206.

**Individual Detail Report Options**

The outline title for each variable in the Individual Detail Reports section is of the form <Variable Name> Capability. However, if you request nonnormal capability, the relevant distribution name is shown parenthetically in the outline title.

Each Capability report has a red triangle menu with the following options:

**Compare Distributions**  Shows or hides the control panel for comparing distributions for the process. See “Compare Distributions” on page 206.

**Process Summary**  Shows or hides the summary statistics for the variable, including the overall sigma estimate, and, if you have specified a normal distribution, the within sigma estimate and the stability index. If you have specified Calculate Between-and-Within Capability for at least one process in the launch window, estimates for the between sigma and the between-and-within sigma are also included.

**Histogram**  Shows or hides the histogram of the values of the variable. The histogram report includes a red triangle menu that controls the following features of the histogram:

**Show Spec Limits**  Shows or hides vertical red lines on the histogram at the specification limits for the process.

**Show Target**  Shows or hides a vertical green line on the histogram at the process target.

**Show Within Sigma Density**  Shows or hides an approximating normal density function on the histogram with mean given by the sample mean and standard deviation given by the within estimate of sigma.

**Show Between-and-Within Sigma Density**  (Available only when Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides an approximating normal density function on the histogram with mean given by the sample mean and standard deviation given by the between-and-within estimate of sigma.
**Show Overall Sigma Density**  Shows or hides an approximating normal density function on the histogram with mean given by the sample mean and standard deviation given by the overall estimate of sigma.

**Show Count Axis**  Shows or hides an additional axis to the right of the histogram plot showing the count of observations.

**Show Density Axis**  Shows or hides an additional axis to the right of the histogram plot showing the density.

**Capability Indices**  Controls display of the following capability index reports:

**Within Sigma Capability**  (Available when distribution is Normal.) Shows or hides capability indices (and confidence intervals) based on the within (short-term) sigma.

**Between-and-Within Sigma Capability**  (Available only when distribution is Normal and Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides capability indices based on the between-and-within sigma.

**Within Sigma Z Benchmark**  (Available when distribution is Normal.) Shows or hides Z benchmark indices based on the within (short-term) sigma.

**Between-and-Within Sigma Z Benchmark**  (Available only when distribution is Normal and Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides Z benchmark indices based on the between-and-within sigma.

**Within Sigma Target Index**  (Available when distribution is Normal.) Shows or hides an estimate of the target index that is based on the within (short-term) sigma.

**Between-and-Within Sigma Target Index**  (Available only when distribution is Normal and Calculate Between-and-Within Capability is selected for at least one process in the launch window.) Shows or hides an estimate of the target index that is based on the between-and-within sigma.

**Overall Sigma Capability**  Shows or hides capability indices (and confidence intervals) based on the overall (long-term) sigma.

**Overall Sigma Z Benchmark**  (Available when distribution is Normal.) Shows or hides Z benchmark indices based on the overall (long-term) sigma.

**Note:** By default, the confidence intervals for the capability indices are constructed based on $\alpha = 0.05$. To change the default confidence level, select File > Preferences > Platforms > Process Capability.
Nonconformance  Shows or hides the observed and expected percentages of observations below the LSL, above the USL, and outside of the specification limits. The Nonconformance table contains hidden columns for observed and expected PPM and counts.

Interactive Capability Plot  Shows or hides the Interactive Capability Plot. The Interactive Capability Plot enables you to change the value of one or more summary statistics and see how the changes affect the capability analysis. There are Original and New reports that show the original and new summary statistics, capability indices, and expected PPM. Use the slider controls or text boxes to change the spec limits, mean, and overall sigma from the original values. You can also use the Mean Shift box to shift the mean by a factor of the original sigma. The Interactive Capability Plot report has the following red triangle menu options:

- **Capability**  Shows or hides the capability indices in the Original and New reports.
- **Expected PPM**  Shows or hides the expected PPM values in the Original and New reports.
- **Revert to Original Values**  Reverts the interactive capability plot and the summary values in the New report back to the original values.
- **Save New Spec Limits as a Column Property**  Saves the new specification limits as a Spec Limits column property to the column in the original data table.

**Note:** The analysis is not rerun with the new specification limits unless the Auto Recalc option is turned on.

Parameter Estimates  (Available when a distribution other than Normal or Nonparametric is selected.) Shows or hides the Parameter Estimates report, which gives estimates for the parameters of the selected distribution.

The estimates for all except the Johnson family distributions are obtained using maximum likelihood. For more information about Johnson family fits, see “Johnson Distribution Fit Method” on page 185.

The parameters and probability density functions for the normal, beta, exponential, gamma, Johnson, lognormal, and Weibull distributions are described in “Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods” on page 240. These are the same parameterizations used in the Distribution platform, with the exception that Process Capability does not support threshold parameters. See Basic Analysis.

Fix Parameters  (Available when a distribution other than Normal or Nonparametric is selected.) Displays a window that enables you to fix one or more parameter values in a nonnormal distribution. Enter a value in the User-defined Value column for the parameters that you would like to fix. Once you click OK, the omitted parameter values
are re-estimated given the fixed parameter values. The re-estimated parameter values appear in the Parameter Estimates report, along with a column indicating which parameters are fixed.

**Nonparametric Density**  (Available when Nonparametric is selected as the distribution.)

Shows or hides the Nonparametric Density report, which gives the *kernel bandwidth* used in fitting the nonparametric distribution. The kernel bandwidth is given by the following, where \( n \) is the number of observations and \( S \) is the uncorrected sample standard deviation:

\[
\text{bandwidth} = \frac{0.9S}{n^{1/5}}
\]

**Compare Distributions**

The Compare Distributions report enables you to compare and apply various distributional fits. Note the following:

- Your selected distribution is indicated in the Selected column.
- The report initially shows fit statistics for your Selected distribution and other fitted distributions in the Comparison Details report. If you selected Best Fit, the Comparison Details report initially shows statistics for all parametric fits.
- Check the distributions in the Distribution list that you want to compare.
  - The probability density function for the best fitting distribution in each family that you select is superimposed on the histogram in the Histogram - Compare Distributions report.
  - If the distribution is parametric, a row for that family containing fit results is added to the Comparison Details report.
  - If Nonparametric is checked in the Distribution list, the Nonparametric Density report, showing the automatically selected kernel bandwidth, is added to the Compare Distributions report. See “Nonparametric Density” on page 206.
  - You can change your selected distribution by selecting its radio button under Selected. The capability report is updated to show results for the selected distribution.

Figure 7.16 shows the Compare Distributions report for Process 1 in the Process Measurements.jmp sample data table. The Selected distribution, which is Lognormal, is being compared to a Normal distribution. The Comparison Details report shows fit statistics for both distributions.

To obtain probability plots, click the Compare Distributions red triangle and select Probability Plots. The points in the probability plot for the normal distribution in Figure 7.16 do not follow the line closely. This indicates a poor fit.
Figure 7.16 Compare Distributions with Probability Plot for Normal

Compare Distributions Options

The Compare Distributions red triangle menu contains the following options:

Comparison Details  For each distribution, gives AICc, BIC, and -2Loglikelihood values. See Fitting Linear Models. (Not available for a Nonparametric fit.)

Comparison Histogram  Shows or hides the Histogram report.

Probability Plots  Shows or hides a report that displays probability plots for each parametric distribution that you fit (Figure 7.16). An observation’s horizontal coordinate is its observed data value. An observation’s vertical coordinate is the value of the quantile of the
fitted distribution for the observation’s rank. For the normal distribution, the overall estimate of sigma is used in determining the fitted distribution.

The red triangle menus associated with each Probability Plot contain the following options.

**Simultaneous Empirical Confidence Limits**  Shows or hides confidence limits that have a simultaneous 95% confidence level of containing the true probability function, given that the data come from the selected parametric family. These limits have the same estimated precision at all points. Use them to determine whether the selected parametric distribution fits the data well. See Nair (1984) and Meeker and Escobar (1998).

**Simultaneous Empirical Confidence Limits Shading**  Shows or hides shading of the region between the Simultaneous Empirical Confidence Limits.

**Parametric Fit Line**  Shows or hides the line that shows the predicted probabilities for the observations based on the fitted distribution.

**Parametric Fit Confidence Limits Shading**  Shows or hides shading of the region between parametric fit confidence intervals. The parametric fit confidence limits have confidence level \((1 - \alpha)\), where \(\alpha\) is the value that you specify in the launch window. (Available only when the parametric fit confidence limits are meaningful and when it is possible to calculate them.)

When possible, the intervals are computed by expressing the parametric distribution \(F\) as a location-scale family, so that \(F(y) = G(z)\), where \(z = (y - \mu)/\sigma\). The approximate standard error of the fitted location-scale component at a point is computed using the delta method. Using the standard error estimate, a Wald confidence interval for \(z\) is computed for each point. The confidence interval for the cumulative distribution function \(F\) is obtained by transforming the Wald interval using \(G\). Note that, in some cases, special accommodations are required to provide appropriate intervals near the endpoints of the interval of process measurements.

**Order by Comparison Criterion**  Orders the distributions in the Comparison Details report according to the criterion that you select. The default ordering is by AICc, unless you selected another criterion in the Distribution Comparison Criterion panel in the launch window.

**Normalized Box Plots**

The Normalized Box Plots options show or hide box plots that have been normalized using the specified sigma in the title. When drawing normalized box plots, JMP standardizes each column by subtracting the mean and dividing by the standard deviation. The box plots are formed for each column using these standardized values.
Figure 7.17  Within Sigma Normalized Box Plot

Figure 7.17 shows the Within Sigma Normalized Box Plot for a selection of the process variables in the Semiconductor Capability.jmp sample data table using wafer as a subgroup variable.

The green vertical lines represent the specification limits for each variable normalized by the mean and standard deviation of each variable. The gray dotted vertical lines are drawn at ±0.5, since the data is standardized to a standard deviation of 1.

**Process Performance Plot**

The Process Performance Plot option shows or hides a four-quadrant plot of capability versus stability. Each process that has specification limits is represented by a point. If process importance values are specified, the points are sized by importance. The horizontal coordinate of each point equals the stability index of the process and the vertical coordinate of each point equals the overall Ppk capability of the process. The plot is divided into four shaded quadrants based on the following default boundaries:

- A stability index that exceeds 1.25 indicates that the process is unstable.
- A Ppk that is smaller than 1.0 indicates that the process is not capable.
Additionally, there is a red line on the graph that indicates where the Cpk value is 1. The boundaries that define the four quadrants can be adjusted using the Ppk and Stability Index slider controls to the right of the plot. You can also set preferences for your desired Capability and Stability boundaries, as well as stability assessment type in File > Preferences > Platforms > Process Performance Plot and File > Preferences > Platforms > Process Capability.

The legend contains descriptions of the shaded regions. If any of the processes are missing a lower or upper specification limit, the legend also shows the markers used for those processes. If the markers do not appear in the legend, then all of the processes in the plot contain both lower and upper specification limits. See “One-Sided or Missing Specification Limits” on page 192.

Hover over a point in the Process Performance Plot to view a control chart for that process. Click the control chart to launch Control Chart Builder with the corresponding control chart and capability report.

**Note:** A control chart is not available for a process if the unbiased pooled standard deviation is selected as the within-group variation statistic for that process.

The Process Performance Plot red triangle menu contains the following option:

- **Label Points** Shows or hides labels for each point in the Process Performance Plot.

- **Show Within Cpk Curve** Shows or hides the within Cpk curve in the Process Performance Plot.
Figure 7.18  Process Performance Plot

Figure 7.18 shows the Process Performance Plot for a selection of the process variables in the Semiconductor Capability.jmp sample data table using wafer as a subgroup variable.

Summary Reports

The Summary Report options show or hide a table that contains the following statistics for each variable: LSL, Target, USL, Sample Mean, various Sigma estimates, Stability Index, Cpk, Cpl, Cpu, Cp, Cpm, and Nonconformance statistics. If there is at least one nonmissing process importance value, an Importance column is also included in the Summary Report. These statistics are calculated using the sigma estimate specified in the report title. The columns for Stability Index, Cpk, Cpl, Cpu, and Cp are colored as green, yellow, and red to indicate adequate, marginal, and poor stability or capability. This color coding scheme matches what you would see in the Process Performance graph.

Note: You can change the preferences for stability assessment type in File > Preferences > Platforms > Process Capability. This changes the stability assessment type used through the Process Capability platform.

Figure 7.19 shows a subset of columns for both summary reports as described in “Example of the Process Capability Platform with Normal Variables” on page 173. The following optional columns are available for this report:

- Confidence intervals for Cpk, Cpl, Cpu, CP, and Cpm
Process Capability Platform Options Quality and Process Methods

- Expected and observed PPM statistics (outside, below LSL, above USL)

**Note:** The expected PPM statistics are the percentages you would expect to see based on the distribution chosen. By default, the distribution is normal. The observed PPM statistics are the percentages based on the actual data.

- Sample standard deviation
- The sample size (N), the minimum, and the maximum.
- Target Index

**Note:** Target Index is only available in the Within Sigma Capability Summary report.

To reveal these optional columns, right-click the report and select the column names from the Columns submenu.

Note that the report (based on overall sigma) shows the overall capability indices Ppk, Ppl, Ppu, and Pp instead of the within capability indices Cpk, Cpl, Cpu, and Cp. The labeling of the overall capability indices depends on the setting of the AIAG (Ppk) Labeling preference.

**Figure 7.19** Within Sigma and Overall Sigma Capability Summary Reports

### Make Goal Plot Summary Table

The Make Goal Plot Summary Table option produces a summary data table that includes each variable’s name, its spec-normalized mean shift (Spec-Standardized Mean), and its spec-normalized standard deviation (Spec-Standardized Std Dev). For each variable, there is a row for each of the sigma types.
**Note:** If a variable is fit with a distribution other than normal, the name of the fitted distribution is appended parenthetically to the variable name. The Spec-Standardized Mean and Spec-Standardized Std Dev values are not provided for nonnormal variables.

The points in the Goal Plot are linked to the rows in the Goal Plot Summary Table. If you apply row states to a point in the Goal Plot, you can change the corresponding row states in the Goal Plot Summary Table. Conversely, if you apply row states in the Goal Plot Summary Table, they are reflected on the Goal Plot.

Figure 7.20 shows the Goal Plot Summary Table for the Semiconductor Capability jmp sample data table as described in “Example of the Process Capability Platform with Normal Variables” on page 173.

**Additional Examples of the Process Capability Platform**

- “Process Capability for a Stable Process”
- “Process Capability for an Unstable Process”
- “Simulation of Confidence Limits for a Nonnormal Process Ppk”
Process Capability for a Stable Process

In this example, you verify the assumptions that enable you to estimate PPM defective rates based on a capability analysis. You access Process Capability through Control Chart Builder and then directly. The data consist of 22 subgroups of size five. There are six missing readings, with three in each of two consecutive subgroups.

Process Capability through Control Chart Builder

You can use Control Chart Builder to check process stability and the normality assumption for your process characteristic. You can also obtain Process Capability information directly within Control Chart Builder.

1. Select Help > Sample Data Library and open Quality Control/Clips2.jmp.
2. Select Analyze > Quality and Process > Control Chart Builder.
3. Drag Date to the Subgroup zone.
4. Drag Gap to the Y zone.

Figure 7.21 XBar and R Control Chart for Gap

The control chart indicates that Gap is stable over time. Because Gap has the Spec Limits column property, a Process Capability Analysis report appears to the right of the control chart.
The histogram and fitted normal blue curve suggest that the distribution of \( \text{Gap} \) is approximately normal. Although the process is stable, the distribution of \( \text{Gap} \) is shifted to the right of the specification range.

The Process Summary report shows the specification limits that are saved to the Spec Limits column property. It also shows that the estimate of sigma calculated from within-subgroup variation (Within Sigma) does not differ greatly from the overall estimate given by the sample standard deviation (Overall Sigma). Consequently, the Stability Index is near one (0.979268). This is expected because the process is stable.

5. Right-click in the body of the Nonconformance report and select Expected Within PPM from the Columns submenu.

The Cpk value calculated using subgroup variation is 0.966, indicating that the process is not very capable. The Cpl value suggests good performance, but this is because the process is shifted away from the lower specification limit. Defective parts generally result from large values of \( \text{Gap} \).

Note that the confidence interval for Cpk is wide; it ranges from 0.805 to 1.128. This occurs even though there are 104 observations. Capability indices are surprisingly variable, due to the fact that they are ratios. It is easy to reach incorrect conclusions based on the point estimate of a capability index.
The estimates of out-of-specification product given in the Nonconformance report provide a direct measure of process performance. The PPM values in the Nonconformance report indicate that $Gap$ hardly ever falls below the lower specification limit (1.4 parts per million). However, the number of parts for which $Gap$ falls above the upper specification limit is 1869.0 parts per million.

For an uncentered process, the $C_p$ value indicates potential capability if the process were adjusted to be centered. If this process were adjusted to be centered at the target value of 14.8, then its capability would be 1.264, with a confidence interval from 1.071 to 1.457.

**Process Capability Platform**

Now that you have verified stability and normality for $Gap$, you can obtain additional information in the Process Capability platform.

1. Select **Analyze > Quality and Process > Process Capability**.
2. Select $Gap$ and click **Y, Process**.
3. Open the **Process Subgrouping** outline.
4. Select **Date** in the Select Columns list and **Gap** in the Roles list.
5. Click **Nest Subgroup ID Column**.
   
   By default, the Within-Subgroup Variation Statistic selection is set to Average of Unbiased Standard Deviations. In the Control Chart Builder example (“Process Capability through Control Chart Builder” on page 214), subgroup ranges were used.
6. Click **OK**.
Figure 7.24 Goal Plot and Box Plot for Gap

The Goal Plot shows the Ppk index for Gap as being essentially equal to 1. The box plot shows that most values fall within specifications, but the preponderance of data values are shifted to the right within the specification range.

7. Click the Process Capability red triangle and select Individual Detail Reports.

The report is the one obtained using Control Chart Builder, except that the Within Sigma is based on average standard deviations rather than average ranges. See “Histogram in Process Capability Analysis for Gap” on page 215 and “Capability Indices and Nonconformance Report” on page 215.

Process Capability for an Unstable Process

This example shows a case where the overall variation differs from the within variation because the process is not stable. It uses the Coating.jmp data table from the Quality Control folder of Sample Data (taken from the ASTM Manual on Presentation of Data and Control Chart Analysis). The process variable of interest is the Weight column, grouped into subgroups by the Sample column.
Process Capability Platform

1. Select Help > Sample Data Library and open Quality Control/Coating.jmp.
4. Open the Process Subgrouping outline.
5. Select Sample in the Select Columns list on the left.
6. Select Weight in the Cast Selected Columns into Roles list on the right.
7. Click Nest Subgroup ID Column.
8. Click OK.
9. Enter 16 for LSL, 20 for Target, and 24 for USL in the Spec Limits window.
10. Click OK.
11. Click the Goal Plot red triangle and select Show Within Sigma Points.
12. Click the Process Capability red triangle and select Individual Detail Reports.
Figure 7.25  Process Capability Report for Coating.jmp Data
Figure 7.25 shows the resulting Process Capability report. The Goal Plot shows two points that represent the mean shift and standard deviation standardized to the specification limits. There is a legend next to the Goal Plot that identifies the two points. The Overall Sigma point is calculated using the overall sample standard deviation. The Within Sigma point is calculated using a within-subgroup estimate of the standard deviation.

The point calculated using Overall Sigma is outside the goal triangle corresponding to a Ppk of 1. This indicates that the variable Weight results in non-conforming product.

However, the point calculated using Within Sigma is inside the goal triangle. This indicates that, if the process were stable, Weight values would have a high probability of falling within the specification limits.

**Control Chart to Assess Stability**

Use Control Chart Builder to determine whether the Weight measurements are stable.

1. Select Help > Sample Data Library and open Quality Control/Coating.jmp.
1. Select Analyze > Quality and Process > Control Chart Builder.
2. Drag Sample to the Subgroup zone.
3. Drag Weight to the Y zone.

**Figure 7.26** XBar and R Chart for Weight
The control chart indicates that the Weight measurements are unstable. The process is affected by special causes and is unpredictable. This makes the interpretation of capability indices and nonconformance estimates highly questionable. Even estimates based on Overall Sigma are questionable, because the process is not predictable.

The histogram in Figure 7.25 shows the distribution of the Weight values with normal density curves using both sigma estimates superimposed over the histogram. The normal curve that uses the Overall Sigma estimate is flatter and wider than the normal curve that uses the Within Sigma estimate. This normal curve is more dispersed because the estimate of Overall Sigma is inflated by the special causes that make the process unstable. If the process were stable, the narrower normal curve would reflect process behavior.

You can also compare the Cpk estimate (1.142) to the Ppk estimate (0.814). The fact that Ppk is much smaller than Cpk is additional evidence that this is an unpredictable process. The Cpk estimate is a forecast of the capability that you would achieve by bringing the process to a stable state.

Note: The Individual Detail Reports Cutoff preference determines whether the Individual Reports appear by default. If the preference is enabled, the Individual Reports appear by default if the number of process variables is less than or equal to the number specified in the preference. You can change this preference in Preferences > Platforms > Process Capability.

Simulation of Confidence Limits for a Nonnormal Process Ppk

In this example, you first perform a capability analysis for the three nonnormal variables in Tablet Measurements.jmp. You then use Simulate to find confidence limits for the nonconformance percentage for the variable Purity.

Nonnormal Capability Analysis

If you prefer not to follow the steps below, you can obtain the results in this section by running the Process Capability table script in Tablet Measurements.jmp.

1. Select Help > Sample Data Library and open Tablet Measurements.jmp.
4. Select Weight, Thickness, and Purity in the Cast Selected Columns into Roles list on the right.
5. Open the Distribution Options outline.
6. From the Distribution list, select Best Fit.
7. Click Set Process Distribution.
The &Dist(Best Fit) suffix is added to each column name in the list on the right.

8. Click OK.

A Capability Index Plot appears, showing the Ppk values. Note that only the Thickness variable appears above the line that denotes Ppk = 1. Purity is nearly on the line. Although the number of measurements, 250, seems large, the estimated Ppk value is still quite variable. For this reason, you construct a confidence interval for the true Purity Ppk value.

**Note:** Because a Goal Plot is not shown, you can conclude that a normal distribution fit was not the best fit for any of the three variables.

9. Click the Process Capability red triangle and select Individual Detail Reports.

The best fits are different for each process.

- Weight: Lognormal
- Thickness: SHASH
- Purity: Weibull

**Construct the Simulation Column**

To use the Simulate utility to estimate Ppk confidence limits, you need to construct a simulation formula that reflects the fitted Weibull distribution. If you prefer not to follow the steps below, you can obtain the results in this section by running the Add Simulation Column table script.

2. Figure 7.27  Weibull Parameter Estimates for Purity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Estimate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale</td>
<td>99.918709</td>
</tr>
<tr>
<td>Shape</td>
<td>1589.7168</td>
</tr>
</tbody>
</table>

These are the parameter estimates for the best fitting distribution, which is Weibull.

2. In the Tablet Measurements.jmp sample data table, select Cols > New Columns.

3. Next to Column Name, enter Simulated Purity.

4. From the Column Properties list, select Formula.

5. In the formula editor, select Random > Random Weibull.

6. The placeholder for beta is selected. Click the insertion element (^).
7. In the Process Capability report, under Purity (Weibull) Capability, right-click in the Parameter Estimates report table and select **Make into Data Table**.

8. Copy the entry in Row 2 in the *Estimate* column (1589.7167836).

9. In the formula editor window, select the placeholder for **beta** in the Random Weibull formula and paste 1589.7167836 into the placeholder for **beta**.

10. In the data table that you created from the Parameter Estimates report, copy the entry in Row 1 in the *Estimate* column (99.918708989).

11. In the formula editor window, select the placeholder for **alpha** in the Random Weibull formula and paste 99.918708989 into the placeholder for **alpha**.

12. Click **OK** in the formula editor window.

13. In the Tablet Measurements.jmp data table, right-click the Simulated Purity column and select **Column Properties > Spec Limits**.

15. Click **OK** in the New Column window.
The Simulated Purity column contains a formula that simulates values from the best-fitting distribution.

**Simulate Confidence Intervals for Purity Ppk and Expected Percent Nonconforming**

When you use Simulate, the entire analysis is run the number of times that you specify. To shorten the computing time, you can minimize the computational burden by running only the required analysis. In this example, because you are interested only in Purity with a fitted Weibull distribution, you perform only this analysis before running Simulate.

**Note:** If you do not care about computing time, you can use the same report you created in the previous section and start with step 7.

1. In the Process Capability report, click the Process Capability red triangle and select **Relaunch Dialog**.
2. (Optional) Close the Process Capability report.
3. In the launch window, from the **Cast Selected Columns into Roles** list, select **Weight&Dist(Lognormal)** and **Thickness&Dist(SHASH)**.
4. Click **Remove**.
5. Click **OK**.
6. Click the Process Capability red triangle and select **Individual Detail Reports**.
   Both Ppk and Ppl values are provided, but they are identical because Purity has only a lower specification limit.
7. In the Overall Sigma Capability report, right-click the **Estimate** column and select **Simulate**.
   In the **Column to Switch Out** list, make sure Purity is selected. In the **Column to Switch In** list, make sure Simulated Purity is selected.
8. Next to **Number of Samples**, type **500**.
   **Note:** The next step is not required. However, it ensures that you obtain exactly the simulated values shown in this example.
9. (Optional) Next to **Random Seed**, type **12345**.
10. Click **OK**.

The calculation might take several seconds. A data table entitled Process Capability Simulate Results (Estimate) appears. The Ppk and Ppl columns in this table each contain 500 values calculated based on the Simulated Purity formula. The first row, which is excluded, contains the values for Purity obtained in your original analysis. Because Purity has only a lower specification limit, the Ppk values are identical to the Ppl values.
11. In the Process Capability Simulate Results (Estimate) data table, click the green triangle next to the **Distribution** script.

**Figure 7.30** Distribution of Simulated Ppk Values for Purity

![Distribution Chart](image)

**Note:** Your values may vary slightly from what is shown, depending on the decimal precision of the parameters in the Simulated Purity column formula.

Two Distribution reports are shown, one for Ppk and one for Ppl. But Purity has only a lower specification limit, so that the Ppk and Ppl values are identical. For this reason, the Distribution reports are identical.
The Simulation Results report shows that a 95% confidence interval for Ppk is 0.909 to 1.145. The bias corrected 95% confidence interval for Ppk is 0.899 to 1.124. Both confidence intervals indicate that the true Ppk value could be above 1.0, which would place Purity above the Ppk = 1 line in the Capability Index Plot you constructed in “Nonnormal Capability Analysis” on page 221.

12. In the Process Capability report, right-click the Expected Overall % column in the Nonconformance report and select Simulate.

In the Column to Switch Out list, make sure Purity is selected. In the Column to Switch In list, make sure Simulated Purity is selected.

13. Next to Number of Samples, enter 500.

14. (Optional) Next to Random Seed, enter 12345.

15. Click OK.

The calculation might take several seconds. A data table entitled Process Capability Simulate Results (Expected Overall %) appears. Because Purity has only a lower specification limit, the Below LSL values are identical to the Total Outside values.

16. In the Process Capability Simulate Results (Expected Overall %) data table, click the green triangle next to the Distribution script.
Figure 7.31 Distribution of Simulated Total Outside Values for Purity

Note: Your values may vary slightly from what is shown, depending on the decimal precision of the parameters in the Simulated Purity column formula.

Again, two identical Distribution reports appear. The Simulation Results report shows that a 95% confidence interval for the Expected Overall % nonconforming is 0.055 to 0.238. The bias corrected confidence interval is 0.062 to 0.253.
Statistical Details for the Process Capability Platform

- “Variation Statistics”
- “Notation for Goal Plots and Capability Box Plots”
- “Goal Plot”
- “Capability Box Plots for Processes with Missing Targets”
- “Capability Indices for Normal Distributions”
- “Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods”
- “Parameterizations for Distributions”

Variation Statistics

Denote the standard deviation of the process by $\sigma$. The Process Capability platform provides two types of capability indices. The Ppk indices are based on an estimate of $\sigma$ that uses all of the data in a way that does not depend on subgroups. This overall estimate can reflect special cause as well as common cause variation. The Cpk indices are based on an estimate that attempts to capture only common cause variation. The Cpk indices are constructed using within-subgroup or between-and-within-subgroup estimates of $\sigma$. In this way, they attempt to reflect the true process standard deviation. When a process is not stable, the different estimates of $\sigma$ can differ markedly.

Overall Sigma

The overall sigma does not depend on subgroups. The overall estimate of $\sigma$ is calculated as follows:

$$\hat{\sigma} = \sqrt{\frac{1}{N-1} \sum_{i=1}^{N} (y_i - \bar{y})^2}$$

The formula uses the following notation:

$N$ = number of nonmissing values in the entire data set

$y_i$ = value of the $i^{th}$ observation

$\bar{y}$ = mean of nonmissing values in the entire data set

**Caution:** When the process is stable, the Overall Sigma estimates the process standard deviation. If the process is not stable, the overall estimate of $\sigma$ is of questionable value, since the process standard deviation is unknown.
Estimates of Sigma Based on Within-Subgroup Variation

An estimate of $\sigma$ that is based on within-subgroup variation can be constructed in one of the following ways:

- Within sigma estimated by average of ranges
- Within sigma estimated by average of unbiased standard deviations
- Within sigma estimated by moving range
- Within sigma estimated by unbiased pooled standard deviation

If you specify a subgroup ID column or a constant subgroup size on the launch window, you can specify your preferred within-subgroup variation statistic. See “Launch the Process Capability Platform” on page 181. If you do not specify a subgroup ID column, a constant subgroup size, or a historical sigma, JMP estimates the within sigma using the third method (moving range of subgroups of size two).

Within Sigma Based on Average of Ranges

Within sigma estimated by the average of ranges is the same as the estimate of the standard deviation of an XBar and R chart:

$$\hat{\sigma} = \frac{\frac{R_1}{d_2(n_1)} + \ldots + \frac{R_N}{d_2(n_N)}}{N}$$

The formula uses the following notation:

$R_i =$ range of $i^{th}$ subgroup

$n_i =$ sample size of $i^{th}$ subgroup

$d_2(n_i) =$ expected value of the range of $n_i$ independent normally distributed variables with unit standard deviation

$N =$ number of subgroups for which $n_i \geq 2$

Within Sigma Based on Average of Unbiased Standard Deviations

Within sigma estimated by the average of unbiased standard deviations is the same as the estimate for the standard deviation in an XBar and S chart:

$$\hat{\sigma} = \frac{\frac{s_1}{c_4(n_1)} + \ldots + \frac{s_N}{c_4(n_N)}}{N}$$

The formula uses the following notation:

$n_i =$ sample size of $i^{th}$ subgroup
\[ c_4(n_i) = \text{expected value of the standard deviation of } n_i \text{ independent normally distributed variables with unit standard deviation} \]
\[ N = \text{number of subgroups for which } n_i \geq 2 \]
\[ s_i = \text{sample standard deviation of the } i^{th} \text{ subgroup} \]

**Within Sigma Based on Average Moving Range**

Within sigma estimated by *average moving range* is the same as the estimate for the standard deviation for Individual Measurement and Moving Range charts:

\[ \hat{\sigma} = \frac{\overline{MR}}{d_2(2)} \]

The formula uses the following notation:

\[ \overline{MR} = \text{the mean of the nonmissing moving ranges computed as } (MR_2 + MR_3 + \ldots + MR_N)/(N-1) \]
\[ d_2(2) = \text{expected value of the range of two independent normally distributed variables with unit standard deviation.} \]

**Within Sigma Based on Median Moving Range**

Within sigma estimated by median moving range:

\[ \hat{\sigma} = \frac{MMR}{0.954} \]

The formula uses the following notation:

\[ MMR = \text{the median of the nonmissing moving ranges computed as Median(MR}_2, MR_3, \ldots, MR_N) \text{ where } MR_i = |y_i - y_{i-1}|. \]

**Within Sigma Based on Unbiased Pooled Standard Deviation**

Within sigma estimated by the *unbiased pooled standard deviation*:

\[ \hat{\sigma} = \sqrt{\frac{(n_1 - 1)s_1^2 + \ldots + (n_N - 1)s_N^2}{c_4(n)\sqrt{n_1 + \ldots + n_2 - N}}} \]

The formula uses the following notation:

\[ n_i = \text{sample size of } i^{th} \text{ subgroup} \]
\[ n = n_1 + \ldots + n_N, \text{ the total sample size} \]
\[ c_4(n) = \text{expected value of the standard deviation of } n \text{ independent normally distributed variables with unit standard deviation} \]
variables with unit standard deviation
N = number of subgroups for which \( n_i \geq 2 \)
\( s_i \) = sample standard deviation of the \( i^{th} \) subgroup

**Estimate of Sigma Based on Between Group Variation**

**Between Sigma Based on Moving Range**

The estimate of \( \sigma \) that is based on between-subgroup variation is estimated by the moving range of subgroup means:

\[
\hat{\sigma} = \sqrt{\frac{\overline{MR}}{d_2(2)}} - \hat{\sigma}^2_{\text{Within}} \frac{H}{H}
\]

The formula uses the following notation:

\( \overline{MR} \) = the mean of the nonmissing moving ranges computed as \( (MR_2+MR_3+...+MR_N)/(N-1) \) where \( MR_i = |y_i - y_{i-1}| \).
\( d_2(2) \) = expected value of the range of two independent normally distributed variables with unit standard deviation.
\( \hat{\sigma}^2_{\text{within}} \) = the specified within sigma estimate.
\( H = \frac{N}{\frac{1}{n_1} + \frac{1}{n_2} + \ldots + \frac{1}{n_N}} \), the harmonic mean of subgroup sample sizes.

**Estimate of Sigma Based on Between and Within Group Variation**

**Between-and-Within Sigma**

The estimate of sigma that is based on the combined between and within group variation is defined as follows:

\[
\hat{\sigma} = \sqrt{\frac{\hat{\sigma}^2_{\text{within}} + \hat{\sigma}^2_{\text{between}}}{2}}
\]

**Notation for Goal Plots and Capability Box Plots**

The formulas for the Goal Plot and Capability Box Plots use the following notation:

\( Y_{ij} \) = \( i^{th} \) observation for process \( j \).
\( \bar{Y}_j = \text{mean of the observations on process } j \)

\[ \text{SD}(Y_j) = \text{standard deviation of the observations on process } j \]

\( T_j = \text{target value for process } j \)

\( \text{LSL}_j = \text{lower specification limit for process } j \)

\( \text{USL}_j = \text{upper specification limit for process } j \)

**Goal Plot**

This section provides details about the calculation of the mean shift and standard deviation standardized to specification quantities plotted in the Goal Plot. This section uses the notation defined in “Notation for Goal Plots and Capability Box Plots” on page 231.

The mean shift and the standard deviation standardized to the specification limits for the \( j \)th column are defined as follows:

\[
\text{Spec-Standardized Mean} = \frac{\bar{Y}_j - T_j}{2 \times \min(T_j - \text{LSL}_j, \text{USL}_j - T_j)}
\]

\[
\text{Spec-Standardized Std Dev} = \frac{\text{SD}(Y_j)}{2 \times \min(T_j - \text{LSL}_j, \text{USL}_j - T_j)}
\]

**Note:** If either \( \text{LSL}_j \) or \( \text{USL}_j \) is missing, twice the distance from the target to the nonmissing specification limit is used in the denominators of the Goal Plot coordinates.

**Goal Plot Points for Processes with Missing Targets**

Suppose that the process has both a lower and an upper specification limit but no target. Then the formulas given in “Goal Plot” on page 232 are used, replacing \( T_j \) with the midpoint of the two specification limits.

Suppose that the process has only one specification limit and no target. To obtain \((x,y)\) coordinates for a point on the Goal Plot, the capability indices of the process are used. (See “Capability Indices for Normal Distributions” on page 234 for definitions in terms of the theoretical mean and standard deviation.) For sample observations, the following relationships hold:

\[
C_{pu} = \frac{\text{USL}_j - \bar{Y}_j}{3\text{SD}(Y_j)}
\]

\[
C_{pl} = \frac{\bar{Y}_j - \text{LSL}_j}{3\text{SD}(Y_j)}
\]
If a process has two specification limits and a target at the midpoint of the limits, then the \((x,y)\) coordinates for the point on the Goal Plot satisfy these relationships:

\[
C_{pu} = (0.5 - x)/3y \\
C_{pl} = (0.5 + x)/3y
\]

To obtain coordinates when there is only one specification limit and no target, these relationships are used. To identify a unique point requires an assumption about the slope of the line from the origin on which the points fall. A slope of 0.5 is assumed for the case of an upper specification limit and of -0.5 for a lower specification limit. When capability values are equal to one and the Ppk slider for the goal plot triangle is set to 1, these slopes place the points on the goal plot triangle lines.

Consider the case of only an upper specification limit and no target. Using the assumption that the \((x,y)\) coordinates fall on a line from the origin with slope 0.5, solving for \(x\) and \(y\) gives the following coordinates:

\[
x = 1/(3C_{pu} + 2) \\
y = 1/(6C_{pu} + 4)
\]

Consider the case of only a lower specification limit and no target. Using the assumption that the \((x,y)\) coordinates fall on a line from the origin with slope -0.5, solving for \(x\) and \(y\) gives the following coordinates:

\[
x = -1/(3C_{pl} + 2) \\
y = 1/(6C_{pl} + 4)
\]

**Note:** If either \(C_{pu}\) or \(C_{pl}\) is less than -0.6, then it is set to -0.6 in the formulas above. At the value -2/3, the denominator for \(x\) assumes the value 0. Bounding the capability values at -0.6 prevents the denominator from assuming the value 0 or switching signs.

**Capability Box Plots for Processes with Missing Targets**

A column with no target can have both upper and lower specification limits, or only a single specification limit. This section uses the notation defined in “Notation for Goal Plots and Capability Box Plots” on page 231.
Two Specification Limits and No Target

When no target is specified for the \( j \)th column, the capability box plot is based on the following values for the transformed observations:

\[
Z_{ij} = \frac{Y_{ij} - (\text{LSL}_j + \text{USL}_j)/2}{\text{USL}_j - \text{LSL}_j}
\]

Single Specification Limit and No Target

Suppose that only the lower specification limit is specified. (The case where only the upper specification limit is specified in a similar way.)

When no target is specified for the \( j \)th column, the capability box plot is based on the following values for the transformed observations:

\[
Z_{ij} = \frac{Y_{ij} - \overline{Y}_j}{2(\overline{Y}_j - \text{LSL}_j)}
\]

**Note:** When a column has only one specification limit and no target value, and the sample mean falls outside the specification interval, no capability box plot for that column is plotted.

Capability Indices for Normal Distributions

This section provides details about the calculation of capability indices for normal data.

For a process characteristic with mean \( \mu \) and standard deviation \( \sigma \), the population-based capability indices are defined as follows. For sample observations, the parameters are replaced by their estimates:

\[
\begin{align*}
\text{Cp} &= \frac{\text{USL} - \text{LSL}}{6\sigma} \\
\text{Cpl} &= \frac{\mu - \text{LSL}}{3\sigma} \\
\text{Cpu} &= \frac{\text{USL} - \mu}{3\sigma} \\
\text{Cpk} &= \min(\text{Cpl}, \text{Cpu}) \\
\text{Cpm} &= \frac{\min(T - \text{LSL}, \text{USL} - T)}{3\sigma \sqrt{1 + \left(\frac{T - \mu}{\sigma}\right)^2}} \\
\text{Target Index} &= 3(\text{Cp} - \text{Cpk})
\end{align*}
\]
The formulas use the following notation:

\[ LSL = \text{Lower specification limit} \]

\[ USL = \text{Upper specification limit} \]

\[ T = \text{Target value} \]

For estimates of Within Sigma capability, \( \sigma \) is estimated using the subgrouping method that you specified. For estimates of Overall Sigma capability, \( \sigma \) is estimated using the sample standard deviation. If either of the specification limits is missing, the capability indices containing the missing specification limit are reported as missing.

**Note:** With the default AIAG (Ppk) Labeling, the indices based on Overall Sigma are denoted by Pp, Ppl, Ppu, and Ppk. The labeling for the index Cpm does not change when Overall Sigma is used. The formulas in this section are defined using Cp labels.

### Confidence Intervals for Capability Indices

Confidence intervals for capability indices are available only for processes with normal distributions. Confidence intervals are calculated for both Within and Overall Sigma capability and are shown in the Individuals Detail Reports.

**Cp**

The 100(1 - \( \alpha \))% confidence interval for Cp is calculated as follows:

\[
\left( \hat{Cp} \frac{2}{\chi_{\alpha/2, df}^2}, \hat{Cp} \frac{2}{\chi_{1-\alpha/2, df}^2} \right)
\]

where

\( \hat{Cp} \) is the estimated value for Cp

\( \chi_{\alpha/2, df}^2 \) is the \((\alpha/2)\)th quantile of a chi-square distribution with \( df \) degrees of freedom

\( df \) is the degrees of freedom

\( N \) is the number of observations

\( m \) is the number of subgroups

For Overall Sigma capability, the degrees of freedom is equal to \( N - 1 \).

For Within Sigma capability, the degrees of freedom depends on the subgrouping and the within sigma estimation method.
• For Within Sigma capability with unbalanced subgroups, the degrees of freedom calculation is the same regardless of the within sigma estimation method. The degrees of freedom is equal to \( N - m \).

• For Within Sigma capability with balanced subgroups of size \( n = \frac{N}{m} \), the degrees of freedom calculation depends on the within sigma estimation method.

  – When Within Sigma is estimated by the average of the unbiased standard deviations, the degrees of freedom is equal to \( f^* (N - m) \). The scale factor \( f \), which varies between 0.875 and 1, is defined as follows:

    \[
    f = \frac{1}{2(n - 1)} \left( \frac{n - 1}{2} \left( \frac{\Gamma\left(\frac{n - 1}{2}\right)}{\Gamma\left(\frac{n}{2}\right)} \right)^2 - 1 \right)
    \]

    where \( \Gamma(n) \) is the gamma function evaluated at \( n \).

    For more information, see Bissell (1990).

  – When Within Sigma is estimated by the average of ranges, the degrees of freedom is calculated as \( df = \frac{1}{A} - \frac{3}{16} A + \frac{3}{64} A^2 + 0.25 \). \( A \) is defined as follows:

    \[
    A = \frac{2d_3(n)^2}{m \cdot d_2(n)^2}
    \]

    \( d_2(n) \) is the expected value of the range of \( n \) independent normally distributed variables with unit standard deviation

    \( d_3(n) \) is the standard deviation of the range of \( n \) independent normally distributed variables with unit standard deviation

    For more information, see David (1951).

  – When Within Sigma is estimated by the unbiased pooled standard deviations, the degrees of freedom is equal to \( N - m \).

• For Within Sigma capability with no subgroups, the degrees of freedom calculation depends on the within sigma estimation method.

  – When Within Sigma is estimated by the average moving ranges, the degrees of freedom is calculated as \( 0.62 \times (N - 1) \).

  – When Within Sigma is estimated by the median moving ranges, the degrees of freedom is calculated as \( 0.32 \times (N - 1) \).

    For more information, see Wheeler (2004, p. 82).
Cpk

The 100(1 - α)% confidence interval for Cpk is calculated as follows:

\[
\left( \hat{C}_{pk} \left[ 1 - \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \sqrt{\frac{1}{9N\hat{C}_{pk}^2} + \frac{1}{2df}} \right] , \hat{C}_{pk} \left[ 1 + \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \sqrt{\frac{1}{9N\hat{C}_{pk}^2} + \frac{1}{2df}} \right] \right)
\]

where

\( \hat{C}_{pk} \) is the estimated value for Cpk

\( \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \) is the \((1 - \alpha/2)\)th quantile of a standard normal distribution

\( df \) is the degrees of freedom

\( N \) is the number of observations

\( m \) is the number of subgroups

For Overall Sigma capability, the degrees of freedom is equal to \( N - 1 \).

For Within Sigma capability, the degrees of freedom depends on the subgrouping and the within sigma estimation method.

- For Within Sigma capability with unbalanced subgroups, the degrees of freedom calculation is the same regardless of the within sigma estimation method. The degrees of freedom is equal to \( N - m \).

- For Within Sigma capability with balanced subgroups of size \( n = N/m \), the degrees of freedom calculation depends on the within sigma estimation method.
  - When Within Sigma is estimated by the average of the unbiased standard deviations, the degrees of freedom is equal to \( f^* (N - m) \). The scale factor \( f \), which varies between 0.875 and 1, is defined as follows:

\[
f = \frac{1}{2(n - 1) \left( \frac{(n - 1)}{2} \left( \frac{\Gamma \left( \frac{n - 1}{2} \right)}{\Gamma \left( \frac{n}{2} \right)} \right)^2 - 1 \right)}
\]

where \( \Gamma(n) \) is the gamma function evaluated at \( n \).

For more information, see Bissell (1990).

- When Within Sigma is estimated by the average of ranges, the degrees of freedom is calculated as \( df = 1/A - (3/16) * A + (3/64) * A^2 + 0.25 \). \( A \) is defined as follows:

\[
A = \frac{2d_3(n)^2}{m \cdot d_3(n)^2}
\]
\( d_2(n) \) is the expected value of the range of \( n \) independent normally distributed variables with unit standard deviation.

\( d_3(n) \) is the standard deviation of the range of \( n \) independent normally distributed variables with unit standard deviation.

For more information, see David (1951).

- When Within Sigma is estimated by the unbiased pooled standard deviations, the degrees of freedom is equal to \( N - m \).

- For Within Sigma capability with no subgroups, the degrees of freedom calculation depends on the within sigma estimation method.
  - When Within Sigma is estimated by the average moving ranges, the degrees of freedom is calculated as \( 0.62 \times (N - 1) \).
  - When Within Sigma is estimated by the median moving ranges, the degrees of freedom is calculated as \( 0.32 \times (N - 1) \).

For more information, see Wheeler (2004, p. 82).

\textbf{Cpm}

\textbf{Note:} The confidence interval for Cpm is computed only when the target value is centered between the lower and upper specification limits.

The 100(1 - \( \alpha \))% confidence interval for Cpm is calculated as follows:

\[
\left( \hat{C}_{pm} - \frac{2}{\gamma} \chi_{\alpha/2, \gamma}, \hat{C}_{pm} + \frac{2}{\gamma} \chi_{1 - \alpha/2, \gamma} \right)
\]

where

\( \hat{C}_{pm} \) is the estimated value for Cpm.

\( \chi_{\alpha/2, \gamma} \) is the \( (\alpha/2) \)th quantile of a chi-square distribution with \( \gamma \) degrees of freedom.

\[
\gamma = \frac{N \left( 1 + \left( \frac{\bar{x} - T}{s} \right)^2 \right)^2}{1 + 2 \left( \frac{\bar{x} - T}{s} \right)^2}
\]

\( N \) is the number of observations.

\( \bar{x} \) is the mean of the observations.

\( T \) is the target value.

\( s \) is the sigma estimate.
For Overall Sigma capability, $s$ is the Overall Sigma estimate. For Within Sigma capability, $s$ is replaced by the Within Sigma estimate.

**Tip:** For more information on confidence intervals for $C_p$, $C_{pk}$, and $C_{pm}$, see Pearn and Kotz (2006).

### Cpl and Cpu

Lower and upper confidence limits for $C_{pl}$ and $C_{pu}$ are computed using the method of Chou et al. (1990).

The $100(1 - \alpha)\%$ confidence limits for $C_{pl}$ (denoted by $CPL_L$ and $CPL_U$) satisfy the following equations:

\[
\Pr\left[t_{n-1} (\delta_L) \geq 3\hat{C}_{pl} / \sqrt{n}\right] = \frac{\alpha}{2} \quad \text{where} \quad \delta_L = 3CPL_L / \sqrt{n}
\]

\[
\Pr\left[t_{n-1} (\delta_U) \leq 3\hat{C}_{pl} / \sqrt{n}\right] = \frac{\alpha}{2} \quad \text{where} \quad \delta_U = 3CPL_U / \sqrt{n}
\]

where

- $t_{n-1}(\delta)$ has a non-central $t$-distribution with $n - 1$ degrees of freedom and noncentrality parameter $\delta$
- $\hat{C}_{pl}$ is the estimated value for $C_{pl}$

The $100(1 - \alpha)\%$ confidence limits for $C_{pu}$ (denoted by $CPU_L$ and $CPU_U$) satisfy the following equations:

\[
\Pr\left[t_{n-1} (\delta_L) \geq 3\hat{C}_{pu} / \sqrt{n}\right] = \frac{\alpha}{2} \quad \text{where} \quad \delta_L = 3CPU_L / \sqrt{n}
\]

\[
\Pr\left[t_{n-1} (\delta_U) \leq 3\hat{C}_{pu} / \sqrt{n}\right] = \frac{\alpha}{2} \quad \text{where} \quad \delta_U = 3CPU_U / \sqrt{n}
\]

where

- $t_{n-1}(\delta)$ has a non-central $t$-distribution with $n - 1$ degrees of freedom and noncentrality parameter $\delta$
- $\hat{C}_{pu}$ is the estimated value for $C_{pu}$
Capability Indices for Nonnormal Distributions: Percentile and Z-Score Methods

This section describes how capability indices are calculated for nonnormal distributions. Two methods are described: the Percentile (also known as ISO/Quantile) method and the Z-Score (also known as Bothe/Z-scores) method. When you select a distribution for a nonnormal process variable, you can fit a parametric distribution or a nonparametric distribution. You can use either the Percentile or the Z-Score methods to calculate capability indices for the process variable of interest. However, unless you have a very large amount of data, a nonparametric fit might not accurately reflect behavior in the tails of the distribution.

**Note:** For both the Percentile and the Z-Score methods, if the data are normally distributed, the capability formulas reduce to the formulas for normality-based capability indices.

The descriptions of the two methods use the following notation:

\[ LSL = \text{Lower specification limit} \]
\[ USL = \text{Upper specification limit} \]
\[ T = \text{Target value} \]

**Percentile (ISO/Quantile) Method**

The percentile method replaces the mean in the standard capability formulas with the median of the fitted distribution and the 6\( \sigma \) range of values with the corresponding percentile range. The method is described in AIAG (2005).

Denote the \( \alpha^{100} \)th percentile of the fitted distribution by \( P_\alpha \). Then Percentile method capability indices are defined as follows:

\[
P_{pk} = \min\left( \frac{P_{0.5} - LSL}{P_{0.5} - P_{0.00135}}, \frac{USL - P_{0.5}}{P_{0.99865} - P_{0.5}} \right)
\]

\[
P_{pl} = \frac{P_{0.5} - LSL}{P_{0.5} - P_{0.00135}}
\]

\[
P_{pu} = \frac{USL - P_{0.5}}{P_{0.99865} - P_{0.5}}
\]

\[
P_{p} = \frac{USL - LSL}{P_{0.99865} - P_{0.00135}}
\]
Z-Score (Bothe/Z-Scores) Method

The Z-Score method transforms the specification limits to values that have the same probabilities on a standard normal scale. It computes capability measures that correspond to a normal distribution with the same risk levels as the fitted nonnormal distribution.

Let $F$ denote the fitted distribution for a process variable with lower and upper specification limits given by LSL and USL. Equivalent standard normal specification limits are defined as follows:

\[
\begin{align*}
LSL_F &= \Phi^{-1}(F(LSL)) \\
USL_F &= \Phi^{-1}(F(USL))
\end{align*}
\]

Then the Z-Score method capability indices are defined as follows:

\[
\begin{align*}
P_{pk} &= \min(-LSL_F/3, USL_F/3) \\
P_{pl} &= -LSL_F/3 \\
P_{pu} &= USL_F/3 \\
P_p &= (USL_F - LSL_F)/6
\end{align*}
\]

**Note:** Because $C_{pm}$ is a target-based measure, it cannot be calculated using the Z-Scores method.

**Note:** For very capable data, $F(LSL)$ or $F(USL)$ can be so close to zero or one, respectively, that $LSL_F$ or $USL_F$ cannot be computed. In these cases, JMP automatically switches from the Z-Score method to the Percentile method by default. This gives more meaningful capability indices. To turn off this default setting, select File > Preferences > Platforms > Process Capability.
Parameterizations for Distributions

This section gives the density functions $f$ for the distributions used in the Process Capability platform. It also gives expected values and variances for all but the Johnson and SHASH distributions.

**Normal**

$$f(x|\mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left[-\frac{1}{2\sigma^2}(x-\mu)^2\right], \ -\infty < x < \infty, \ -\infty < \mu < \infty, \ \sigma > 0$$

$E(X) = \mu$  
$\text{Var}(X) = \sigma^2$

**Beta**

$$f(x|\alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}, \ 0 \leq x \leq 1, \ \alpha > 0, \ \beta > 0$$

$E(X) = \frac{\alpha}{\alpha + \beta}$  
$\text{Var}(X) = \frac{\alpha \beta}{(\alpha + \beta)^2 (\alpha + \beta + 1)}$

where $B(\cdot)$ is the Beta function.

**Exponential**

$$f(x|\sigma) = \frac{1}{\sigma} \exp(-x/\sigma), \ x > 0, \ \sigma > 0$$

$E(X) = \sigma$  
$\text{Var}(X) = \sigma^2$

**Gamma**

$$f(x|\alpha, \sigma) = \frac{1}{\Gamma(\alpha)\sigma^\alpha} x^{\alpha-1} \exp(-x/\sigma), \ x > 0, \ \alpha > 0, \ \sigma > 0$$

$E(X) = \alpha \sigma$  
$\text{Var}(X) = \alpha \sigma^2$

where $\Gamma(\cdot)$ is the gamma function.
Chapter 7
Quality and Process Methods

Process Capability

Statistical Details for the Process Capability Platform

Johnson

Johnson Su

\[ f(x | \gamma, \delta, \sigma, \theta) = \frac{\delta}{\sigma} \left[ 1 + \left( \frac{x - \theta}{\sigma} \right)^2 \right]^{-1/2} \phi \left[ \gamma + \delta \sinh^{-1} \left( \frac{x - \theta}{\sigma} \right) \right], -\infty < x, \theta, \gamma < \infty, \theta > 0, \delta > 0 \]

Johnson Sb

\[ f(x | \gamma, \delta, \sigma, \theta) = \phi \left[ \gamma + \delta \ln \left( \frac{x - \theta}{\sigma - (x - \theta)} \right) \right] \left( \frac{\delta \sigma}{(x - \theta)(\sigma - (x - \theta))} \right), \theta < x < \theta + \sigma, \sigma > 0 \]

Johnson Sl

\[ f(x | \gamma, \delta, \sigma, \theta) = \frac{\delta}{x - \theta} \phi \left[ \gamma + \delta \ln \left( \frac{x - \theta}{\sigma} \right) \right], x > 0 \text{ if } \sigma = 1, x < 0 \text{ if } \sigma = -1 \]

where \( \phi(\cdot) \) is the standard normal probability density function.

Lognormal

\[ f(x | \mu, \sigma) = \frac{\exp \left[ -(\log(x) - \mu)^2 \right]}{\sigma \sqrt{2\pi x}}, x > 0, -\infty < \mu < \infty, \sigma > 0 \]

\[ E(X) = \exp(\mu + \sigma^2/2) \]

\[ \text{Var}(X) = \exp(2(\mu + \sigma^2)) - \exp(2\mu + \sigma^2) \]

Mixture of Normals

The Mixture of 2 Normals and Mixture of 3 Normals options for Distribution share the following parameterization:

\[ f(x | \mu_i, \sigma_i, \pi_i) = \sum_{i=1}^{k} \pi_i \phi \left( \frac{x - \mu_i}{\sigma_i} \right) \]

\[ E(X) = \sum_{i=1}^{k} \pi_i \mu_i \]

\[ \text{Var}(X) = \sum_{i=1}^{k} \pi_i (\mu_i^2 + \sigma_i^2) - \left( \sum_{i=1}^{k} \pi_i \mu_i \right)^2 \]
where \( \mu_i, \sigma_i, \text{ and } \pi_i \) are the respective mean, standard deviation, and proportion for the \( i^{th} \) group, and \( \phi(\cdot) \) is the standard normal probability density function. For the Mixture of 2 Normals, \( k \) is equal to 2. For the Mixture of 3 Normals distribution, \( k \) is equal to 3. A separate mean, standard deviation, and proportion of the whole is estimated for each group in the mixture.

**SHASH**

\[
f(x|\gamma, \delta, \sigma, \theta) = \frac{\delta \cosh(w)}{\sqrt{\sigma^2 + (x - \theta)^2}} \phi[\sinh(w)], \quad -\infty < \gamma, x, \theta < \infty, \; 0 < \delta, 0 < \sigma \]

where

\( \phi(\cdot) \) is the standard normal pdf

\[
w = \gamma + \delta \sinh^{-1}\left(\frac{x - \theta}{\sigma}\right) \]

**Note:** When \( \gamma = 0 \) and \( \delta = 1 \), the SHASH distribution is equivalent to the normal distribution with location \( \theta \) and scale \( \sigma \).

**Weibull**

\[
f(x|\alpha, \beta) = \frac{\beta}{\alpha^\beta} x^{\beta - 1} \exp\left[-\left(\frac{x}{\alpha}\right)^\beta\right], \quad \alpha > 0, \; \beta > 0 \]

\[
E(X) = \alpha \Gamma\left(1 + \frac{1}{\beta}\right) \]

\[
Var(X) = \alpha^2 \left[\Gamma\left(1 + \frac{2}{\beta}\right) - \Gamma^2\left(1 + \frac{1}{\beta}\right)\right], \]

where \( \Gamma(\cdot) \) is the gamma function.
CUSUM Control Charts

Create Tabular CUSUM Control Charts with Decision Limits

Cumulative Sum (CUSUM) control charts enable you to detect small shifts in a process. They are useful in detecting shifts that occur over time, such as a gradual drift, and that are not necessarily accompanied by a sudden shift. The CUSUM Control Chart platform creates a CUSUM chart with decision limits, similar to a Shewhart chart. This chart is also called a tabular CUSUM chart. To create a V-mask cumulative sum control chart, see “V-Mask CUSUM Control Charts” on page 330.

The CUSUM Control Chart platform also provides information about average run length (ARL). The average run length is the average number of samples or observations that can be expected to occur before an out-of-control signal occurs. You can use the average run length to assess the performance of a CUSUM chart, given specific parameters and assuming constant variance.

Overview of the CUSUM Control Chart Platform

A tabular CUSUM chart consists of two one-sided decision limits charts superimposed on one chart. The chart contains decision limits that signal when the process is out of control and places a shift line on the chart where the shift is suspected to have occurred. To use the CUSUM Control Chart platform, you must determine the smallest change in the mean that you consider important. You can view the CUSUM control chart in standard deviation units or in data units. For more information about tabular CUSUM charts, see Woodall and Adams (1998) and Montgomery (2013).

Another form of a cumulative sum control chart is the V-mask chart. To create a V-mask CUSUM chart, see “V-Mask CUSUM Control Charts” on page 330.

**Note:** The summary results in the CUSUM Control Chart platform do not always match the summary results in the V-mask CUSUM platform. Specifically, the summary results for a two-sided V-mask CUSUM chart do not match those from a CUSUM Control Chart with both Upper Side and Lower Side options selected. However, the one-sided summary reports from the CUSUM Control Chart platform and the V-mask CUSUM platform do match.

Example of CUSUM Control Chart

You want to detect small shifts in the temperature of an engine. The data table contains temperature measurements from the engine thermostat.

1. Select **Help > Sample Data Library** and open Quality Control/Engine Temperature Sensor.jmp.
2. Select **Analyze > Quality and Process > Control Chart > CUSUM Control Chart.**
3. Select **Y** and click **Y.**
4. Click **OK.**
5. In the Target box, type 100.
6. In the Sigma box, type 10.
The vertical line on the CUSUM Chart indicates that a shift in the temperature measurements started around sample 26.

**Note:** You can compare this result to the Individual Moving Range control chart by running the IMR Chart table script in Engine Temperature Sensor.jmp. The IMR chart does not trigger any of the Nelson tests.

**Example of a One-Sided CUSUM Control Chart**

Continuing the previous example, suppose that you care only about increasing temperature changes. To change the CUSUM control chart in Figure 8.2 to a one-sided chart, deselect the Lower Side check box. When you do that, the points for the negative cumulative sums are removed from the chart. You are left with a CUSUM control chart that contains only the positive cumulative sum points.
Launch the CUSUM Control Chart Platform

Launch the CUSUM Control Chart platform by selecting Analyze > Quality and Process > Control Chart > CUSUM Control Chart.

Figure 8.4 The CUSUM Control Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The CUSUM Control Chart platform launch window contains the following options:

**Y** Identifies the variables that you want to chart.

**Note:** The rows of the data table must be sorted in the order in which the observations were collected.
X Identifies a subgroup variable. The horizontal axis of the CUSUM chart is labeled by the subgroup variable. If a value of this column is present more than once, the average response at each X value is plotted on the CUSUM chart.

By Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Show Excluded Region (Applicable only when an X variable is specified.) Specifies that subgroups that are entirely excluded are shown on the horizontal axis in the CUSUM control chart.

Data Units Specifies that data units be used in the report rather than standard deviation units. By default, the chart and parameters are shown in standard deviation units. However, if you select the Data Units option in the launch window, the chart and parameters are shown in the units of the data column that is being analyzed.

When you use standard deviation units, values for the $h$ and $k$ parameters do not depend on the process standard deviation. This can be an advantage.

The CUSUM Control Chart Platform Report

By default, the CUSUM Control Chart platform produces a report that contains a parameter control panel and a CUSUM chart.

Figure 8.5 CUSUM Control Chart Report

Note: A $k$ of 0.5, together with a Sigma of 10, indicates a minimum detectable change of $2 \times k \times \text{Sigma} = 10$ (Deg C), centered around the Target.
Control Panel for CUSUM Control Chart

The Control Panel report contains the current values for the chart parameters. The current values are in boxes that enable you to update the parameter values. There are also boxes for Upper Side and Lower Side. If you have specified the Data Units option in the launch window, this setting is denoted in the Control Panel below the check boxes.

The following options appear in the Control Panel report:

**Target**  The known value of the mean. This is the value of the center line in the chart. By default, this parameter is set to the Target value in the Spec Limits column property for the Y column. If the Y column does not have a Target value in the Spec Limits column property, this parameter is set to the overall average of the Y column.

**Note:** To use the overall average of the Y column as the value of the center line even if the Y column has a Target value in the Spec Limits column property, select the Use Process Mean for Center Line platform preference. This preference is located in File > Preferences > Platforms > CUSUM Control Chart.

**Sigma**  The known value of the standard deviation. By default, this parameter is set to the average moving range of the Y column. If there is an X variable, the Sigma parameter is set to the average moving range of the summary data.

**Head Start**  The value of the cumulative sums before the first sample. Starting the cumulative sums at a nonzero value increases the sensitivity of the CUSUM chart near the beginning of the samples. This parameter is also known as the fast initial response (FIR) value. By default, this parameter is set to 0.

**h or H**  The value of the parameter that defines the limits. If the Data Units option was not selected in the launch window, this is the h parameter. If the Data Units option was selected in the launch window, this is the H parameter. Note that H is equal to h times Sigma. By default, h is equal to 5 and H is equal to 5 times Sigma.

**k or K**  The value of the parameter that defines the smallest change in the mean that is valuable to detect. If the Data Units option was not selected in the launch window, this is the k parameter. If the Data Units option was selected in the launch window, this is the K parameter. Note that K is equal to k times Sigma. By default, k is equal to 0.5 and K is equal to one half of Sigma.

**Upper Side**  Shows or hides the positive values for the cumulative sum on the chart. These values are the $C^+$ values.

**Lower Side**  Shows or hides the negative values for the cumulative sum on the chart. These values are the $C^-$ values.
Using Data Units  The presence of this text indicates that the Data Units option was selected in the launch window and that the values in the CUSUM chart are centered but not standardized.

CUSUM Chart

The CUSUM Chart report contains the cumulative sum control chart with decision limits that are determined by the current values of the chart parameters. The samples (or subgroups if you specified an X variable) are denoted on the horizontal axis. The vertical axis denotes centered values of the positive and negative values for the cumulative sum. If the Data Units option was not selected in the launch window, the vertical axis denotes cumulative sums for standardized response values. If the Data Units option was selected in the launch window, the vertical axis denotes cumulative sums for unstandardized response values.

CUSUM Control Chart Platform Options

The CUSUM Control Chart red triangle menu contains the following options:

Show Limits  Shows or hides the upper and lower decision limits in the CUSUM Chart.

Show Center Line  Shows or hides the center line in the CUSUM Chart.

Show Shift Lines  (Available only when there is a shift detected in the data.) Shows or hides the vertical lines in the CUSUM Chart that designate shifts. Shift lines are drawn at the start of a shift.

- A positive shift occurs when the value of \( C^+ \) exceeds the upper limit on the chart. The start of the shift is defined as the first point after the most recent zero value for \( C^+ \).
- A negative shift occurs when the value of \( C^- \) falls below the lower limit on the chart. The start of the shift is defined as the first point after the most recent zero value for \( C^- \).

Show ARL  Shows or hides the Average Run Length (ARL) report. See “Average Run Length (ARL) Report” on page 256.

ARL Profiler  Shows or hides a profiler of average run length versus the parameters \( h \) and \( k \). If you have specified the Data Units option in the launch window, the profiler plots average run length versus the parameters \( H \) and \( K \).

The average run length (ARL) for a specified shift is the average number of runs expected before an out-of-control signal occurs. For example, the ARL at 0 represents the average
number of runs expected before a false-alarm signal occurs when the process is in control. When the process is in control, the shift size is 0.

The ARL Profiler enables you to explore how various settings of the parameters affect the performance of the corresponding CUSUM chart. As the parameters in the Control Panel report are updated, the ARL Profiler is updated as well. An ideal CUSUM chart has a high ARL(0) value and a low ARL(Δ) value, where Δ is the size shift that is of interest.

The ARL Profiler depends on the settings of the Upper Side and Lower Side options in the Control Panel report:

– If both the Upper Side and Lower Side options are selected, the profiler represents the average run length for crossing either the upper or lower decision limits on the CUSUM chart.

– If only the Upper Side option is selected, the profiler represents the average run length for the upper decision limit on the CUSUM chart.

– If only the Lower Side option is selected, the profiler represents the average run length for the lower decision limit on the CUSUM chart.

For more information about the options in the red triangle menu next to ARL Profiler, see Profilers.

Control Panel  Shows or hides a report of the current values of the parameters. This report enables you to change the parameter values as well as the sidedness of the CUSUM chart.

Parameters Report  Shows or hides a report of the current values of the parameters.

Test Beyond Limits  Shows or hides a red circle around any point that is above the upper limit or below the lower limit in the CUSUM chart.

Save Summaries  Creates a new data table that contains statistics for each subgroup in the CUSUM chart. The following statistics are saved to the new data table: the subgroup number and size, the subgroup sample mean, an indicator of shift starts, a value that indicates each interval between shift starts, the upper and lower cumulative sums and corresponding consecutive run counts, and the LCL and UCL values.

Tune Chart  Shows or hides a control that enables you to set an acceptable range for the Y variable. Adjust the minimum and maximum values of the acceptable range and click Done. At this point, the CUSUM chart updates based on a new value of the k parameter.

– If you specified the Data Units option in the launch window, the imputed k parameter is the average of the minimum and maximum values divided by the Sigma parameter.
– If the Data Units option is not specified, the imputed K parameter is the average of the minimum and maximum values.

Setting the acceptable range for the Y variable enables you to set the practical significance of the CUSUM chart. This is particularly helpful when the testing interval is more frequent, which can result in a much shorter practical average run length.

**Reset to Defaults**  Resets all parameters back to their default values.

**Alarm Script**  Enables you to write and run a script that indicates when the data fail special causes tests. Results can be written to the log or spoken aloud, and there is an option to include an explanation of why the test failed. You can also send results to an email using the custom script option.

As an Alarm Script is invoked, the following variables are available, both in the issued script and in subsequent JSL scripts:

- `qc_col` is the name of the column
- `qc_test` is the test that failed
- `qc_sample` is the sample number

**Tip:** After an alarm script is specified, the alarm script is invoked when the Test Beyond Limits option is turned on.

See the *Scripting Guide* for more information about writing custom Alarm Scripts.

See *Using JMP* for more information about the following options:

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

### Average Run Length (ARL) Report

The Average Run Length (ARL) report contains a table and a graph of ARL values. The average run length (ARL) for a specified shift is the average number of runs expected before an out-of-control signal occurs. For example, the ARL at 0 represents the average number of runs expected before seeing a false-alarm signal when the process is in control. When the process is in control, the shift size is 0.
The table and graph in the ARL report enable you to explore how various settings of the parameters affect the performance of the corresponding CUSUM chart. As the $h$ and $k$ parameters in the Control Panel report are updated, the ARL report is updated as well. An ideal CUSUM chart has a high ARL(0) value and a low ARL($\Delta$) value, where $\Delta$ is the size shift that is of interest.

The Average Run Length (ARL) report depends on the settings of the Upper Side and Lower Side options in the Control Panel report. If only one option is selected, the ARL report uses calculations for the corresponding one-sided CUSUM chart. If both options are selected, the ARL report uses calculations for the two-sided CUSUM chart. Note that the two-sided ARL values are related to the positive and negative one-sided ARL values by the following equation:

$$\frac{1}{\text{ARL}} = \frac{1}{\text{Positive ARL}} + \frac{1}{\text{Negative ARL}}$$

**ARL Table**

The ARL Table shows the average run length for shifts ($\Delta$) between zero and three at 0.25 increments. If the Data Units option is specified, the shift is represented by $2*K/\sigma^2$. If the Data Units option is not specified, the shift is represented by $2*k/\sigma$.

**ARL Graph**

The ARL Graph shows the average run length for shifts ($\Delta$) between 0 and 3. This graph contains the same data points as the ARL Table to the left of the ARL Graph.

---

### Additional Example of CUSUM Control Charts

- “Example of the Data Units Option in a CUSUM Control Chart”
- “Example of CUSUM Chart with Subgroups”

#### Example of the Data Units Option in a CUSUM Control Chart

This example uses the Data Units option and reproduces the analysis in “Example of CUSUM Control Chart” on page 249. You want to detect small shifts in the temperature of an engine. The data table contains temperature measurements from the engine thermostat.

1. Select **Help > Sample Data Library** and open Quality Control/Engine Temperature Sensor.jmp.
2. Select **Analyze > Quality and Process > Control Chart > CUSUM Control Chart**.
3. Select Y and click **Y**.
4. Select the box next to Data Units.
5. Click OK.
6. In the Target box, type 100.
7. In the Sigma box, type 10.

   Note that the options below Head Start are H and K, instead of h and k. These parameters are now specified in units of the data column, rather than in standard deviation units.

**Figure 8.6 CUSUM Control Chart Report**

![CUSUM Control Chart Report](image)

Like in the example using sigma units, the vertical line on the CUSUM Chart indicates that a shift in the temperature measurements started around sample 26.

**Example of CUSUM Chart with Subgroups**

A machine fills 8-ounce cans of two-cycle engine oil additive. The filling process is believed to be in statistical control. The process is set so that the average weight of a filled can ($\mu_0$) is 8.10 ounces. Previous analysis shows that the standard deviation of fill weights ($\sigma_0$) is 0.05 ounces.

Subgroup samples of four cans are selected and weighed every hour for twelve hours. Each observation in the Oil1 Cusum.jmp data table contains one value of weight and its associated value of hour. The observations are sorted so that the values of hour are in increasing order. You want to be able to detect a $2\sigma$ shift in the process.

1. Select Help > Sample Data Library and open Quality Control/Oil1 Cusum.jmp.
2. Select Analyze > Quality and Process > Control Chart > CUSUM Control Chart.
3. Select weight and click Y.
4. Select hour and click X.
5. Click **OK**.

6. In the Target box, type 8.1.
   This is the target mean for the process.

7. In the Sigma box, type 0.05.
   This is the known standard deviation for the process.

8. In the h box, type 2.
   This defines the decision limits to be 2 standard deviations in each direction.

**Figure 8.7 CUSUM Control Chart with Subgroups**

The CUSUM Chart does not show any points outside of the upper or lower decision limits. There is no evidence that a shift in the process has occurred.

**Note:** Montgomery (2013) states that “only if there is some significant economy of scale or some other valid reason for taking samples of size greater than one should subgroups of size greater than one be used with the CUSUM.” The use of rational subgroups in the tabular CUSUM chart does not always improve the performance of the chart.
Statistical Details for the CUSUM Control Chart Platform

- “Statistical Details for CUSUM Control Chart Construction”
- “Statistical Details for Shift Detection”
- “Statistical Details for Average Run Length”

Statistical Details for CUSUM Control Chart Construction

This section defines the statistics that are used in the construction of the CUSUM Chart. Some of these statistics are also saved in the data table that is created by the Save Summaries command.

One-Sided Upper and Lower Cumulative Sums

The definitions of $C^+$ and $C^-$ depend on the setting of the Data Units option.

**Note:** In the Save Summaries data table, $C^+$ and $C^-$ are labeled Upper Cumulative Sum and Lower Cumulative Sum, respectively.

Cumulative Sums in Standardized Units

If the Data Units option is not selected, $C^+$ and $C^-$ for each step are defined as follows:

$$C^+_i = \max\left(0, \frac{x_i - T}{\sigma} - k + C^+_i-1\right)$$

$$C^-_i = \min\left(0, \frac{x_i - T}{\sigma} + k + C^-_i-1\right)$$

where:

- $x_i$ is the value of the response at the $i^{th}$ step
- $T$ is the target of the process
- $\sigma$ is the standard deviation of the process
- $k$ is the reference value, in units of standard deviations

If a value is specified for Head Start, that value is used as the initial $C^+$ value and the negative of that value is used as the initial $C^-$ value. Otherwise, the initial values of $C^+$ and $C^-$ are zero.
Cumulative Sums in Data Units

If the Data Units option is selected, $C^+_i$ and $C^-_i$ for each step are defined as follows:

\[ C^+_i = \max(0, (x_i - T) - K + C^+_{i-1}) \]
\[ C^-_i = \min(0, (x_i - T) + K + C^-_{i-1}) \]

where:

- $x_i$ is the value of the response at the $i^{th}$ step
- $T$ is the target of the process
- $\sigma$ is the standard deviation of the process
- $K$ is the reference value, in units of the data

If a value is specified for Head Start, that value is used as the initial $C^+_1$ value and the negative of that value is used as the initial $C^-_1$ value. Otherwise, the initial values of $C^+_1$ and $C^-_1$ are zero.

Counters for Positive and Negative Runs

$N^+_i$ at each step is the number of steps since the most recent zero value for $C^+_i$. $N^-_i$ at each step is the number of steps since the most recent zero value for $C^-_i$.

**Note:** In the Save Summaries data table, $N^+_i$ and $N^-_i$ are labeled Positive Runs and Negative Runs, respectively.

Statistical Details for Shift Detection

A positive shift occurs when the value of $C^+_i$ exceeds the upper limit on the chart. The start of the shift is defined as the first point after the most recent zero value for $C^+_i$.

A negative shift occurs when the value of $C^-_i$ exceeds the lower limit on the chart. The start of the shift is defined as the first point after the most recent zero value for $C^-_i$.

Statistical Details for Average Run Length

The one-sided average run length (ARL) values are calculated using the integral equation method (with 24 Gaussian points) described by Goel and Wu (1971). If the Head Start value is greater than 0, the values are calculated according to the method in Appendix A.1 of Lucas and Crosier (1982).
Note that the two-sided ARL values are related to the positive and negative one-sided ARL values by the following equation:

\[
\frac{1}{\text{ARL}} = \frac{1}{\text{Positive ARL}} + \frac{1}{\text{Negative ARL}}
\]

Lucas and Crosier (1982) describe the properties of a Head Start value for CUSUM charts in which the initial CUSUM \( S_0 \) is set to a nonzero value. This is sometimes referred to as a fast initial response (FIR) feature. Average run length calculations given by them show that the FIR feature has little effect when the process is in control and that it leads to a faster response to an initial out-of-control condition than a standard CUSUM chart.
Exponentially weighted moving average (EWMA) charts can be used to detect small shifts in a process. Each point on an Exponentially Weighted Moving Average (EWMA) chart is the weighted average of all the previous subgroup means, including the mean of the present subgroup sample. The weights decrease exponentially going backward in time.

Statistical Details for the EWMA Control Chart Platform ............................... 274
Overview of the EWMA Control Chart Platform

Exponentially weighted moving average (EWMA) charts can be used to detect small shifts in a process. Each point on an Exponentially Weighted Moving Average (EWMA) chart is the weighted average of all the previous subgroup means, including the mean of the present subgroup sample. The weights decrease exponentially going backward in time. For more information about exponentially weighted moving average charts, see Montgomery (2013).

The EWMA Control Chart platform pairs an EWMA chart with an X chart and a residual chart. If you do not specify a Subgroup variable, the X chart is an individual measurements chart. If you specify a Subgroup variable and at least one subgroup size is greater than 1, the X chart is an XBar chart.

Example of the EWMA Control Chart Platform

In the sample data table Clips1.jmp, the measure of interest is the gap between the ends of manufactured metal clips. To monitor the process for a change in the average gap, subgroup samples of five clips are selected daily.

1. Select Help > Sample Data Library and open Quality Control/Clips1.jmp.
2. Select Analyze > Quality and Process > Control Chart > EWMA Control Chart.
3. Select Gap and click Y.
4. Select Sample and click Subgroup.
5. Click OK.
Purple vertical lines in the EWMA chart denote shifts. Shift starts are detected at samples 4 and 17.
Launch the EWMA Control Chart Platform

Launch the EWMA Control Chart platform by selecting Analyze > Quality and Process > Control Chart > EWMA Control Chart.

Figure 9.3 EWMA Control Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The EWMA Control Chart platform launch window contains the following options:

**Y** Identifies the variables that you want to chart.

**Note:** If you do not specify a Subgroup variable, the rows of the data table must be sorted in the order in which the observations were collected.

**Subgroup** Identifies a subgroup variable. The horizontal axis of the EWMA chart is labeled by the subgroup variable.

**By** Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

**Center Data** Specifies that the data are centered by subtracting the target from each observation.

**Show Excluded Region** (Applicable only when a Subgroup variable is specified.) Specifies that subgroups that are entirely excluded in the data table are shown in the EWMA control chart.
The EWMA Control Chart Platform Report

By default, the EWMA Control Chart platform produces a report that contains a parameter control panel, an EWMA chart, an X chart, and a residuals chart.

**Figure 9.4** EWMA Control Chart Report

![ EWMA Control Chart Report ]

**Control Panel for EWMA Control Chart**

The Control Panel contains the current values for the chart parameters. The current values are in boxes that enable you to update the parameter values.
The following options appear in the Control Panel:

**Target**  The known value of the mean. This is the value of the center line in the chart. By default, this parameter is set to the Target value in the Spec Limits column property for the Y column. If the Y column does not have a Target value in the Spec Limits column property, this parameter is set to the overall average of the Y column.

The Target value cannot be edited in these situations:

- If you specified the Center Data option in the launch window.
- If the Y variable has a Spec Limits column property that contains a value for Target. However, you can select the Use Overall Mean for Target option in the red triangle menu to switch between the Target value in the Spec Limits column property and the overall mean of the Y variable.

**Sigma**  The known value of the standard deviation. By default, this parameter is set to the average moving range of the Y column. If there is a Subgroup variable, the Sigma parameter is set to the average of the moving ranges of the subgroup means.

**Note:** The default Sigma value calculation does not include excluded rows.

**Lambda**  The value of the smoothing constant for weighting prior samples. By default, this parameter is set to 0.2.

**Using Centered Data**  The presence of this text indicates that the Centered Data option was selected in the launch window and that the values in the EWMA chart and X chart are centered around the Target value.

**EWMA Chart Report**

The EWMA Chart report contains three charts: an EWMA chart, an X chart, and a residuals chart.

**EWMA Chart**

The EWMA chart is an exponentially weighted moving average (EWMA) chart with decision limits that are determined by the current values of the chart parameters. The samples (or subgroups if you specified a Subgroup variable) are denoted on the horizontal axis. The vertical axis denotes the exponentially weighted moving average. If you specified the Center Data option in the launch window, the vertical axis denotes the exponentially weighted moving average with the target value subtracted from it. Each sample or subgroup has a single point on the chart. There is one additional point that is a forecast point, which is shown in blue.
**Note:** If the last sample (or subgroup) is both hidden and excluded, the line connecting the last sample (or subgroup) to the forecast point is not drawn.

### X Chart

The X chart is an individual measurements chart of the values (or an XBar chart of the mean values if you specified a Subgroup variable with at least one subgroup size greater than 1). The samples (or subgroups if you specified a Subgroup variable with at least one subgroup size greater than 1) are denoted on the horizontal axis. The vertical axis denotes the measurements (or subgroup means). If you selected the Center Data option in the launch window, the vertical axis denotes the measurements (or subgroup means) with the target value subtracted from it. Each sample or subgroup has a single point on the chart. For more information about the limits on the X chart, see “Statistical Details for Control Chart Builder” on page 89 in the “Control Chart Builder” chapter.

### Residuals Chart

The residuals chart is a chart of the differences between the sample values (or subgroup means if you specified a Subgroup variable) and the EWMA value for the previous sample (or subgroup). This chart enables you to visually check for autocorrelation. The $i^{th}$ residual is calculated as $r_i = X_i - EWMA_{i-1}$ where $X_i$ denotes the $i^{th}$ sample value (or subgroup mean) and $EWMA_{i-1}$ denotes the $(i-1)^{th}$ EWMA value. The limits on the residuals chart are $\pm 3 \times ResidSigma$, where $ResidSigma$ is the standard deviation of the residuals.

### The EWMA Control Chart Platform Options

The EWMA Control Chart red triangle menu contains the following options:

- **Show Limits**  Shows or hides the upper and lower decision limits in the EWMA chart, X chart, and residuals chart.

- **Show Center Line**  Shows or hides the center line in the EWMA chart, X chart, and residuals chart.

- **Show Shift Lines**  Shows or hides the vertical lines in the EWMA chart that designate shifts. Shift lines are drawn at the start of a shift. A shift start is defined as the first point after the EWMA value crosses the center line in a particular direction.
  - A positive shift occurs when the EWMA value exceeds the upper limit on the chart. The start of the shift is defined as the first point after the most recent EWMA value below the Target line.
– A negative shift occurs when the EWMA value falls below the lower limit on the chart. The start of the shift is defined as the first point after the most recent EWMA value above the Target line.

**Test Beyond Limits**  Shows or hides a red circle around any point that is above the upper limit or below the lower limit in the EWMA and XBar charts.

**Show ARL**  Shows or hides the Average Run Length (ARL) report. See “Average Run Length (ARL) Report for EWMA Control Charts” on page 273.

**Control Panel**  Shows or hides a report of the current values of the parameters. This report enables you to change the parameter values in the EWMA chart.

**Parameters Report**  Shows or hides a report of the current values of the parameters.

**Constant Limits**  Specifies that the EWMA chart limits are calculated using an asymptotic expression so that the limits on the EWMA chart are constant.

**Caution:** The Constant Limits option has no effect when the sample sizes are not equal across subgroups.

**Save Summaries**  Creates a new data table that contains statistics for each subgroup in the EWMA chart. The following statistics are saved to the new data table: the subgroup number, the subgroup label, the subgroup size, the subgroup mean, an indicator of shift starts, a value that indicates each interval between shift starts, the exponentially weighted moving average of each subgroup, the number of positive and negative consecutive run counts, and the LCL and UCL values. The forecast value is saved in the last row of the summary table.

**Reset to Defaults**  Resets all parameters back to their default values. If a Lambda value has been specified in the Lambda platform preference, the Lambda value is reset to the value specified in the platform preference.

**Note:** When the Y variable has a Spec Limits column property that contains a value for Target, the Reset to Defaults option sets the Target to the Target value in the Spec Limits column property.

**Restart EWMA After Empty Subgroup**  Specifies how calculations for the moving average and limits are handled when there are empty subgroups. A subgroup can be empty if all the observations for the subgroup are missing values or are in excluded rows. If this option is selected, the calculations restart in the first nonmissing subgroup that follows an empty subgroup. The restart of the calculations resets the moving average to the overall mean. If this option is not selected, the EWMA calculations continue with the most recent nonmissing subgroup moving average.
**Use Overall Mean for Target**  (Available only when the Y variable has a Spec Limits column property that contains a value for Target.) Sets the Target in the EWMA chart to the overall mean of the Y variable. If this option is not selected, the Target in the EWMA chart is set to the Target value in the Spec Limits column property.

**Overlay Charts**  Specifies whether the individual location values are overlaid on the EWMA chart. When this option is selected, the Location chart is no longer shown. Instead, the points from the Location chart appear on the EWMA chart as unconnected gray Xs. The limits from the Location chart do not appear on the EWMA chart, unless the Show X Limits on Overlay Charts option is selected.

**Show X Limits on Overlay Charts**  (Available only when the Overlay Charts option is selected.) Shows or hides the limits from the Location chart on the EWMA chart when the Overlay Charts option is selected. When the Location chart limits are shown on the EWMA chart, they appear as dashed lines.

**Note:** The Tests Beyond Limits option is applied to the Location chart values in the Overlay Chart only when the Show X Limits on Overlay Charts option is selected.

**Lambda Slider**  Shows or hides a slider control that enables you to change the value of the Lambda parameter interactively.

**Show X Chart**  Shows or hides the Location chart below the EWMA chart.

**Note:** When the Overlay Charts option is selected, the Show X Chart option shows or hides the individual location values and limits that are overlaid on the EWMA chart.

**Show Residuals Chart**  Shows or hides a chart of residuals.

**Alarm Script**  Enables you to write and run a script that indicates when the data fail special causes tests. Results can be written to the log or spoken aloud, and there is an option to include an explanation of why the test failed. You can also send results to an email using the custom script option.

As an Alarm Script is invoked, the following variables are available, both in the issued script and in subsequent JSL scripts:

- `qc_col` is the name of the column
- `qc_test` is the test that failed
- `qc_sample` is the sample number

**Tip:** After an alarm script is specified, the alarm script is invoked when the Test Beyond Limits option is turned on.

See the *Scripting Guide* for more information about writing custom Alarm Scripts.
See *Using JMP* for more information about the following options:

**Redo** Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script** Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script** Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

### Average Run Length (ARL) Report for EWMA Control Charts

The Average Run Length (ARL) report contains a table and a graph of ARL values. The average run length (ARL) for a specified shift is the average number of runs expected before an out-of-control signal occurs. For example, the ARL at 0 represents the average number of runs expected before seeing a false-alarm signal when the process is in control. When the process is in control, the shift size is 0.

The table and graph in the ARL report enable you to explore how various settings of the Lambda parameter affect the performance of the corresponding EWMA chart. The table and graph also enable you to compare the performance of the EWMA chart with a Shewhart chart, such as the X chart in the EWMA Chart report. The Shewhart ARL column is equivalent to the EWMA ARL column when Lambda is set to 1.

The value of EWMA ARL at 0 depends on the setting of the Constant Limits option:

- If the Constant Limits option is selected, the process is assumed to have been in control long enough that the effect of the starting value is negligible. In this case, also referred to as a *steady state* of the EWMA chart, the value of EWMA ARL(0) is calculated using the method described in Crowder (1987).
- If the Constant Limits option is not selected, the value of EWMA ARL(0) is calculated using the method described in Knoth (2004). This situation is also referred to as a *zero state* of the EWMA chart.

### ARL Report

The ARL Report shows the average run length for shifts (Δ) between zero and three at 0.25 increments. The shift is represented by $2^k/\Sigma$, where $k$ is the sigma multiplier used by control charts. This table contains ARL values for the EWMA chart as well as a Shewhart chart.
ARL Graph

The ARL Graph shows the average run length for shifts (Δ) between 0 and 3. This graph contains the same data points as the ARL Table to the left of the ARL Graph. The solid line corresponds to the EWMA ARL values, and the dashed line corresponds to the Shewhart ARL values.

Statistical Details for the EWMA Control Chart Platform

This section defines the statistics that are used in the construction of the EWMA chart. Some of these statistics are also saved in the data table that is created by the Save Summaries command.

The $i^{th}$ point on the EWMA chart is calculated as follows:

$$EWMA_i = \lambda X_i + (1 - \lambda)EWMA_{i-1}$$

where:

$\lambda$ = Lambda parameter

$X_i = i^{th}$ sample value (or subgroup mean)

$EWMA_{i-1} = (i-1)^{th}$ EWMA value

When $i = 1$, define $EWMA_0$ as the Target value.

Note: When the Restart EWMA after Empty Subgroup option is selected, the $EWMA_{i-1}$ value following an empty subgroup is the Target value. When the Restart EWMA after Empty Subgroups option is not selected, the $EWMA_{i-1}$ value following an empty subgroup is the EWMA value for the most recent non-empty subgroup.

The computation of the control limits on the EWMA chart is determined by the setting of the Constant Limits option.

EWMA Limits

When the Constant Limits option is not selected and the subgroup sizes are not equal, the EWMA control limits are computed as follows:

$$LCL = T - K\sigma\lambda \left[ \sum_{j=1}^{i} \frac{(1-\lambda)^{2(i-j)}}{n_j} \right]$$
UCL = \( T + K\sigma \lambda \sum_{j=1}^{i} \frac{(1-\lambda)^{2(i-j)}}{n_j} \)

where:

- \( T \) = Target value
- \( K \) = the sigma multiplier and is set to 3 by default
- \( \sigma \) = Sigma value
- \( i \) = the number of the sample (or subgroup)
- \( n_i \) = the size of subgroup \( i \)

When the Constant Limits option is not selected and the subgroup sizes are equal, the formulas for the EWMA control limits simplify as follows:

LCL = \( T - K\sigma \frac{\lambda}{\sqrt{n(2-\lambda)}}[1 - (1-\lambda)^{2i}] \)

UCL = \( T + K\sigma \frac{\lambda}{\sqrt{n(2-\lambda)}}[1 - (1-\lambda)^{2i}] \)

where:

- \( T \) = Target value
- \( K \) = the sigma multiplier and is set to 3 by default
- \( \sigma \) = Sigma value
- \( i \) = the number of the sample (or subgroup)
- \( n \) = the size of each subgroup (or 1 if no subgroup is specified)

**Constant Limits**

When the Constant Limits option is selected, the EWMA control limits are computed as follows:

LCL = \( T - K\sigma \frac{\lambda}{\sqrt{n(2-\lambda)}} \)

UCL = \( T + K\sigma \frac{\lambda}{\sqrt{n(2-\lambda)}} \)

where:

- \( T \) = Target value
- \( K \) = the sigma multiplier and is set to 3 by default
- \( \sigma \) = Sigma value
- \( n \) = the subgroup size (or 1 if no subgroup is specified)
For more information about constructing exponentially weighted moving average charts, see Montgomery (2013).
Multivariate control charts are used to monitor two or more interrelated process variables. Where univariate control charts are used to monitor a single independent process characteristic, multivariate control charts are necessary when process variables are correlated. The Multivariate Control Chart platform enables you to build Hotelling $T^2$ charts. You can use the platform to determine whether a process is stable as well as to monitor a process as new data are collected.

For monitoring and diagnosing complex processes, see the “Model Driven Multivariate Control Charts” chapter on page 303.

Overview of Multivariate Control Charts

Multivariate control charts are used to monitor two or more interrelated process variables. Where univariate control charts are used to monitor a single independent process characteristic, multivariate control charts are necessary when process variables are correlated. A Hotelling $T^2$ chart, or just $T^2$ chart for short, is one type of multivariate control chart. A $T^2$ chart can detect shifts in the mean or the relationship between several interrelated variables. The observations can either be individual observations of the process variables or they can be grouped into rational subgroups.

You can construct a multivariate control chart using current or historical data. The control chart is said to be a Phase I chart if it is constructed using current data; the control chart is said to be a Phase II chart if it is constructed using target statistics from a historical data set. In Phase I, you check that the process is stable and establish a historical data set from which to calculate target statistics for the process. In Phase II, the multivariate control chart uses the target statistics from Phase I in order to monitor new process observations.

To construct a Phase II multivariate control chart, first identify a period of time during which the process is stable and capable.

1. Develop a Phase I control chart to verify that the process is stable over this period.
   The data used in Phase I provides a historical data set.
2. Save the target statistics for this historical data set.
3. Monitor the on-going process using a Phase II control chart based on the target statistics that were saved in step 2.

Example of a Multivariate Control Chart

This example illustrates constructing a control chart for data that are not sub-grouped. The data are measurements on a steam turbine engine. For an example that uses sub-grouped data, “Example of Monitoring a Process Using Sub-Grouped Data” on page 287.

Step 1: Determine Whether the Process Is Stable

1. Select Help > Sample Data Library and open Quality Control/Steam Turbine Historical.jmp.
2. Select Analyze > Quality and Process > Control Chart > Multivariate Control Chart.
3. Select all of the columns and click Y, Columns.
4. Click OK.
The process seems to be in reasonable statistical control, because there is only one out-of-control point. Therefore, it is appropriate to create targets based on this data.

**Step 2: Save Target Statistics**

1. Click the red triangle next to Multivariate Control Chart and select **Save Target Statistics**. This creates a new data table containing target statistics for the process.

2. Save the new data table as **Steam Turbine Targets.jmp**.

Now that target statistics have been established, create the multivariate control chart that monitors the process.

**Step 3: Monitor the Process**

1. Select **Help > Sample Data Library** and open **Quality Control/Steam Turbine Current.jmp**.
This sample data table contains recent observations from the process.

2. Select **Analyze > Quality and Process > Control Chart > Multivariate Control Chart**.

3. Select all of the columns and click **Y, Columns**.

4. Click **Get Targets**.

5. Open the Steam Turbine Targets.jmp table that you saved.

6. Click **OK**.

The default alpha level is set to 0.05. Change it to 0.001.

7. Click the red triangle next to Multivariate Control Chart and select **Set Alpha Level > Other**.

8. Type 0.001 and click **OK**.

**Figure 10.4** Steam Turbine Control Chart

Figure 10.4 shows out-of-control conditions occurring at observations 2, 3, 4, 5, and 8. This result implies that these observations do not conform to the historical data from Steam Turbine Historical.jmp, and that the process should be further investigated. To find an assignable cause, you might want to examine individual univariate control charts or perform another univariate procedure.
Launch the Multivariate Control Chart Platform

Launch the Multivariate Control Chart platform by selecting **Analyze > Quality And Process > Control Chart > Multivariate Control Chart**.

**Figure 10.5** The Multivariate Control Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Multivariate Control Chart platform launch window contains the following options:

**Y, Columns** Specify the columns to be analyzed.

**Subgroup** Enter a column with sub-grouped data. Hierarchically, this group is nested within **Group**.

**Group** Enter a column that specifies group membership at the highest hierarchical level.

**Weight** Identifies the data table column whose variables assign weight (such as importance or influence) to the data.

**Freq** Identifies the data table column whose values assign a frequency to each row. Can be useful when your data table contains summarized data.

**By** Identifies a column that creates a report consisting of separate analyses for each level of the variable.

**Get Targets** Click to select a JMP table that contains historical targets for the process.

The Multivariate Control Chart

Use the multivariate control chart to quickly identify shifts in your process and to monitor your process for special cause indications.
Follow the instructions in “Example of a Multivariate Control Chart” on page 279 to produce the results shown in Figure 10.6.

**Figure 10.6 Multivariate Control Chart**

<table>
<thead>
<tr>
<th>T Square with All Principal Components</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Graph" /></td>
</tr>
</tbody>
</table>

**Tip:** For information about additional options, see “Multivariate Control Chart Platform Options” on page 284.

The multivariate control chart plots Hotelling’s $T^2$ statistic. The calculation for the control limit differs based on whether targets have been specified. To understand how the $T^2$ statistic and the UCL (Upper Control Limit) are calculated, see “Statistical Details for Multivariate Control Charts” on page 293. For more information about control limits, see Tracy et al. (1992).
In this example, the Principal Components reports for both data sets indicate that the first
eigenvalue, corresponding to the first principal component, explains about 95% of the total
variation in the variables. The values in both Eigenvectors tables indicate that the first
principal component is driven primarily by the variables Fuel and Steam Flow. You can use
this information to construct a potentially more sensitive control chart based only on this first
component. For more information about the Principal Components reports, see “Principal
Components” on page 286.

Multivariate Control Chart Platform Options

The Multivariate Control Chart red triangle menu contains the following options:

- **T Square Chart**: Shows the $T^2$ chart. Hotelling’s $T^2$ chart is a multivariate extension of the
  XBar chart that takes correlation into account.

- **T Square Partitioned**: Constructs multivariate control charts based on the principal
  components of Y. Specify the number of major principal components for $T^2$. See “T Square
  Partitioned” on page 285.

- **Set Alpha Level**: Set the $\alpha$ level used to calculate the control limit. The default is $\alpha=0.05$.

- **Show Covariance**: Shows the Pooled Covariance report. Covariance is a measure of the
  linear relationship between two variables.

- **Show Correlation**: Shows the Pooled Correlation report.

- **Show Inverse Covariance**: Shows the Pooled Inverse Covariance report. If the inverse
  covariance is singular, a generalized inverse of the covariance matrix is reported.

- **Show Inverse Correlation**: Shows the Pooled Inverse Correlation report. If the inverse
  correlation is singular, a generalized inverse of the correlation matrix is reported.

- **Show Means**: Shows the Group Means report, which contains the means for each group.

- **Save T Square**: Creates a new column in the data table containing $T^2$ values.

- **Save T Square Formula**: Creates a new column in the data table. Stores a formula in the
  column that calculates the $T^2$ values.

- **Save Target Statistics**: Creates a new data table containing target statistics for the process.
  Target statistics include: sample size, the number of samples, mean, standard deviation,
  and any correlations.

- **Change Point Detection** (Not available for sub-grouped data.) Shows a Change Point
  Detection plot of test statistics by row number and indicates the row number where the
  change point appears. See “Change Point Detection” on page 286.
**Principal Components**  Shows reports showing eigenvalues and their corresponding eigenvectors. Principal components help you understand which of the many variables you might be monitoring are primarily responsible for the variation in your process. See “Principal Components” on page 286.

**Save Principal Components**  Creates new columns in the data table that contain the scaled principal components.

**T Square Partitioned**

If you are monitoring a large number of correlated process characteristics, you can use the T Square Partitioned option to construct a control chart based on principal components. If a small number of principal components explains a large portion of the variation in your measurements, then a multivariate control chart based on these big components might be more sensitive than a chart based on your original, higher-dimensional data.

The T Square Partitioned option is also useful when your covariance matrix is ill-conditioned. When this is the case, components with small eigenvalues, explaining very little variation, can have a large, and misleading, impact on $T^2$. It is useful to separate out these less important components when studying process behavior.

Once you select the T Square Partitioned option, you need to decide how many major principal components to use.

The option creates two multivariate control charts: T Square with Big Principal Components and T Square with Small Principal Components. Suppose that you enter $r$ as the number of major components when you first select the option. The chart with Big Principal Components is based on the $r$ principal components corresponding to the $r$ largest eigenvalues. These are the $r$ components that explain the largest amount of variation, as shown in the Percent and Cum Percent columns in the Principal Components: on Covariances reports. The chart with Small Principal Components is based on the remaining principal components.

For a given subgroup, its $T^2$ value in the Big Principal Components chart and its $T^2$ value in the Small Principal Components chart sum to its overall $T^2$ statistic presented in the $T^2$ with All Principal Components report. For more information about how the partitioned $T^2$ values are calculated, see Kourti and MacGregor (1996).

**Tip:** Consider using the Model Driven Multivariate Control Chart platform for decomposition of the $T^2$ statistic. See the “Model Driven Multivariate Control Charts” chapter on page 303.
Change Point Detection

When the data set consists of multivariate individual observations, a control chart can be developed to detect a shift in the mean vector, the covariance matrix, or both. This method partitions the data and calculates likelihood ratio test statistics for a shift. The statistic that is plotted on the control chart is an observation’s likelihood ratio test statistic divided by the product of the following:

- Its approximate expected value assuming no shift.
- An approximate value for an upper control limit.

Division by the approximate upper control limit allows the points to be plotted against an effective upper control limit of 1. A Change Point Detection plot readily shows the change point for a shift occurring at the maximized value of the control chart statistic. The Change Point Detection implementation in JMP is based on Sullivan and Woodall (2000) and is described in “Statistical Details for Change Point Detection” on page 298.

**Note:** The Change Point Detection method is designed to show a single shift in the data. Detect multiple shifts by recursive application of this method.

Note the following about the Change Point Detection plot:

- Values above 1.0 indicate a possible shift in the data.
- Control chart statistics for the Change Point Detection plot are obtained by dividing the likelihood ratio statistic of interest (either a mean vector or a covariance matrix) by a normalizing factor.
- The change point of the data occurs for the observation having the maximum test statistic value for the Change Point Detection plot.

Note the following about the scatterplot matrix:

- This plot shows the shift in the sample mean vector.
- In the “Example of Change Point Detection” on page 292, data are divided into two groups. The first 24 observations are classified as the first group. The remaining observations are classified as the second group.

Principal Components

The Principal Components report contain the following information:

**Eigenvalue**  Eigenvalues for the covariance matrix.

**Percent**  Percent variation explained by the corresponding eigenvector. Also shows an accompanying bar chart.
Cum Percent  Cumulative percent variation explained by eigenvectors corresponding to the eigenvalues.

ChiSquare  Provides a test of whether the correlation remaining in the data is of a random nature. This is a Bartlett test of sphericity. When this test rejects the null hypothesis, this implies that there is structure remaining in the data that is associated with this eigenvalue.

DF  Degrees of freedom associated with the Chi-square test.

Prob > ChiSq  $p$-value for the test.

Eigenvectors  Table of eigenvectors corresponding to the eigenvalues. Note that each eigenvector is divided by the square root of its corresponding eigenvalue.

For more information about principal components, see *Multivariate Methods*.

### Additional Examples of Multivariate Control Charts

- “Example of Monitoring a Process Using Sub-Grouped Data”
- “Example of T Square Partitioned”
- “Example of Change Point Detection”

### Example of Monitoring a Process Using Sub-Grouped Data

The workflow for monitoring a multivariate process with sub-grouped data is similar to the one for individual data. See “Example of a Multivariate Control Chart” on page 279. You create an initial control chart to save target statistics and then use these targets to monitor the process.

#### Step 1: Determine Whether the Process Is Stable

1. Select Help > Sample Data Library and open Quality Control/Aluminum Pins Historical.jmp.
2. Select Analyze > Quality and Process > Control Chart > Multivariate Control Chart.
4. Select subgroup and click Subgroup.
5. Click OK.
The process appears to be in statistical control, making it appropriate to create targets using this data.

**Step 2: Save Target Statistics**

1. Click the red triangle next to Multivariate Control Chart and select **Save Target Statistics**. This creates a new data table containing target statistics for the process.
2. Save the new data table as Aluminum Pins Targets.jmp. Now that target statistics have been established, create the multivariate control chart for process monitoring.

**Step 3: Monitor the Process**

1. Select **Help > Sample Data Library** and open Quality Control/Aluminum Pins Current.jmp. This sample data table contains recent observations from the process.
2. Select **Analyze > Quality and Process > Control Chart > Multivariate Control Chart**.
3. Select all of the Diameter and Length columns and click **Y, Columns**.
4. Select subgroup and click **Subgroup**.
5. Click **Get Targets**.
6. Open the Aluminum Pins Targets.jmp table that you saved.
7. Click **OK**.
8. Click the red triangle next to Multivariate Control Chart and select **Show Means**. The Show Means option gives the means for each subgroup. You can then observe which groups are most dissimilar from each other.
Figure 10.8 shows indications of instability at subgroups 4-7, 9-11, 18, and 20. This result implies that these observations do not conform to the historical data from Aluminum Pins Historical.jmp, and that the process should be further investigated. To determine why the process was out of control at these points, you might want to examine individual univariate control charts or perform another univariate procedure.
An alternative method to monitoring this process is based on the big principal components. In this example, for the historical data, the first three principal components account for about 98% of the variation. Based on this, you might construct a chart for the first three principal components. Then you would monitor current data using those three components. The control limits for the chart used in monitoring the process should be based on the corresponding chart for the historical data.

Example of T Square Partitioned

Use T Square Partitioned to separate out the more important components from the less important components when studying process behavior. In this example, the coating on each of 50 bars was measured at 12 uniformly spaced locations across the bar. You want to examine the variation in the measurements and determine whether the causes of variation need to be investigated further.

1. Select Help > Sample Data Library and open Quality Control/Thickness.jmp.
2. Select Analyze > Quality and Process > Control Chart > Multivariate Control Chart.
3. Select all of the Thickness columns and click Y, Columns.
4. Click OK.
   The current alpha level is set to 0.05, which corresponds to a 5% false alarm rate. You want to set the false alarm rate to 1%.
5. To change the alpha level, click the red triangle next to Multivariate Control Chart, select Set Alpha Level, and choose 0.01.
The overall control chart in Figure 10.9 suggests that special causes affected bars 1, 2, 4, 5, and 22. Looking at the Principal Components report, you can see that almost 95% of the variation in the 12 thickness measurements is explained by the first principal component. You want to study the variation associated with this principal component further.

6. Click the red triangle Multivariate Control Chart and select **T Square Partitioned**.
7. Accept the default value of 1 principal component by clicking **OK**.
In contrast to the Principal Components report, the T Square with Big Principal Components chart, which reflects variation for only the first component, shows no evidence of special causes. The T Square with Small Principal Components chart shows that the special cause indications reside in the remaining smaller components. These smaller components do not explain much variation, and likely represent random noise. Therefore, you might conclude that the variation in the thickness measurements is not a major cause for concern.

**Example of Change Point Detection**

Use change point detection to find the point at which a shift occurs in your data.

1. Select Help > Sample Data Library and open Quality Control/Gravel.jmp.
2. Select Analyze > Quality and Process > Control Chart > Multivariate Control Chart.
3. Select Large and Medium and click Y, Columns.
4. Click OK.
5. Click the red triangle next to Multivariate Control Chart and select **Change Point Detection**.

**Figure 10.11** Change Point Detection for Gravel.jmp

Tip: You might need to drag the axes to see the density ellipses for the two groups, depending on your data.

In the Change Point Detection plot, values above 1.0 indicate a possible shift in the data. At least one shift is apparent; the change point occurs at observation 24 and the shift occurs immediately after observation 24. The 95% prediction regions for the two groups have approximately the same size, shape, and orientation, visually indicating that the sample covariance matrices are similar.

**Statistical Details for Multivariate Control Charts**

- “Statistical Details for Individual Observations”
- “Statistical Details for Observations in Rational Subgroups”
- “Statistical Details for Change Point Detection”
Statistical Details for Individual Observations

Consider measurements that are not sub-grouped, that is, where the natural subgroup size is \( n = 1 \). Denote the number of observations by \( m \) and the number of variables measured by \( p \). A \( T^2 \) statistic is calculated and plotted for each observation. The calculation of the \( T^2 \) statistic and upper control limit (UCL) depends on the source of the target statistics. In a Phase I chart, the limits are based on the same data that is being plotted on the control chart. In a Phase II chart, the limits are based on target statistics that were calculated from a historical data set. For more information about \( T^2 \) statistic and control limit calculations for Hotelling \( T^2 \) control charts, see Montgomery (2013).

Calculations for Phase I Control Charts

In Phase I control charts, the \( T^2 \) statistic for the \( i^{th} \) observation is defined as follows:

\[
T_i^2 = (Y_i - \bar{Y})S^{-1}(Y_i - \bar{Y})
\]

where:

- \( Y_i \) is the column vector of \( p \) measurements for the \( i^{th} \) observation
- \( \bar{Y} \) is the column vector of sample means of the \( p \) variables
- \( S^{-1} \) is the inverse of the sample covariance matrix

The \( T_i^2 \) value for each of the \( i \) observations are the points plotted on the multivariate control chart.

When computing Phase I control limits, the UCL is based on the beta distribution. Specifically, the upper control limit (UCL) is defined as follows:

\[
UCL = \frac{(m-1)^2}{m} \beta \left[ 1 - \alpha, \frac{p}{2}, \frac{m-p-1}{2} \right]
\]

where:

- \( p \) = number of variables
- \( m \) = number of observations

\( \beta \left[ 1 - \alpha, \frac{p}{2}, \frac{m-p-1}{2} \right] = (1-\alpha)^{th} \) quantile of a Beta \( \left( \frac{p}{2}, \frac{m-p-1}{2} \right) \) distribution
Chapter 10
Multivariate Control Charts

Quality and Process Methods Statistical Details for Multivariate Control Charts

295

Calculations for Phase II Control Charts

In Phase II control charts, define the historical data set as \( X \). Then the \( T^2 \) statistic for the \( i \)th observation is defined as follows:

\[
T_i^2 = (Y_i - \overline{X})S_X^{-1}(Y_i - \overline{X})
\]

where:
- \( Y_i \) is the column vector of \( p \) measurements for the \( i \)th observation
- \( \overline{X} \) is the column vector of sample means of the \( p \) variables, calculated from the historical data set
- \( S_X^{-1} \) is the inverse of the sample covariance matrix, calculated from the historical data set

The \( T_i^2 \) value for each of the \( i \) observations are the points plotted on the multivariate control chart.

When computing Phase II control limits, new observations are independent of the historical data set. In this case, the upper control limit (UCL) is a function of the \( F \) distribution and partially depends on the number of observations in the historical data set from which the targets are calculated. The UCL is defined as follows:

\[
UCL = \begin{cases} 
\frac{p(m+1)(m-1)}{m(m-p)} F_{[1-\alpha, p, m-p]} & \text{if } m \leq 100 \\
\frac{p(m-1)}{m-p} F_{[1-\alpha, p, m-p]} & \text{if } m > 100
\end{cases}
\]

where:
- \( p \) = number of variables
- \( m \) = number of observations in the historical data set
- \( F_{[1-\alpha, p, m-p]} = (1-\alpha) \text{th quantile of an } F(p, m-p) \text{ distribution} \)

Statistical Details for Observations in Rational Subgroups

Consider the case where \( p \) variables are monitored and \( m \) subgroups of size \( n > 1 \) are obtained. A \( T^2 \) statistic is calculated and plotted for each subgroup. The calculation of the \( T^2 \) statistic and upper control limit (UCL) depends on the source of the target statistics. In a Phase I chart, the limits are based on the same data that is being plotted on the control chart. In a Phase II chart, the limits are based on target statistics that were calculated from a historical data set. For more information about \( T^2 \) statistic and control limit calculations for Hotelling \( T^2 \) control charts, see Montgomery (2013).
Calculations for Phase I Control Charts

For Phase I control charts, the $T^2$ statistic for the $j^{th}$ subgroup is defined as follows:

$$T_j^2 = (\bar{Y}_j - \bar{Y})S_p^{-1}(\bar{Y}_j - \bar{Y})$$

where:

- $\bar{Y}_j$ is the mean of the $n$ column vectors of $p$ measurements for the $j^{th}$ subgroup
- $\bar{Y} = \frac{1}{m} \sum_{j=1}^{m} \bar{Y}_j$ is the mean of the subgroup means
- $S_j$ is the sample covariance matrix for the $n$ observations in the $j^{th}$ subgroup
- $S_p = \frac{1}{m} \sum_{j=1}^{m} S_j$ is the pooled covariance matrix, calculated as the mean of the within-subgroup covariance matrices

The Phase I upper control limit (UCL) is defined as follows:

$$UCL = \frac{p(m-1)(n-1)}{mn-m-p+1} F_{1-\alpha, p, mn-m-p+1}$$

where:

- $p =$ number of variables
- $n =$ sample size for each subgroup
- $m =$ number of subgroups
- $F_{1-\alpha, p, mn-m-p+1} =$ $(1-\alpha)^{th}$ quantile of an $F(p, mn-m-p+1)$ distribution

Calculations for Phase II Control Charts

In Phase II control charts, define the historical data set from which the target statistics are calculated as $X$. Then the $T^2$ statistic for the $j^{th}$ subgroup is defined as follows:

$$T_j^2 = (\bar{Y}_j - \bar{X})S_p^{-1}(\bar{Y}_j - \bar{X})$$

where:

- $\bar{Y}_j$ is the mean of the $n$ column vectors of $p$ measurements for the $j^{th}$ subgroup
- $\bar{X}_k$ is the mean of the $n$ column vectors of $p$ measurements for the $k^{th}$ subgroup from the historical data set
\[ \overline{X} = \frac{1}{m} \sum_{k=1}^{m} \overline{X}_k \] is the overall mean of the observations

\( S_k \) is the sample covariance matrix for the \( n \) observations in the \( k^{th} \) subgroup from the historical data set

\[ S_p = \frac{1}{m} \sum_{k=1}^{m} S_k \] is the pooled covariance matrix, calculated as the mean of the within-subgroup covariance matrices

The Phase II upper control limit (UCL) is defined as follows:

\[ UCL = \frac{p(m+1)(n-1)}{mn - m - p + 1} F_{[1-\alpha, p, mn - m - p + 1]} \]

where:

\( p \) = number of variables

\( n \) = subgroup sample size

\( m \) = number of subgroups in the historical data set

\[ F_{[1-\alpha, p, mn - m - p + 1]} = (1-\alpha)^{th} \text{ quantile of an } F(p, mn - m - p + 1) \text{ distribution} \]

**Additivity of Test Statistics for Observations in Rational Subgroups**

When a sample of \( mn \) independent normal observations is grouped into \( m \) rational subgroups each of size \( n \), define \( T^2_M \) as the distance between the mean \( \overline{Y}_j \) of the \( j^{th} \) subgroup and the target value. \( T^2_M \) is equivalent to \( T^2 \) in the previous sections for observations in rational subgroups.) You can also calculate \( T^2 \) statistics related to the internal variability in each subgroup and the overall variability around the target value. The components of the \( T^2 \) statistic are additive, much like sums of squares. Specifically, the following relationship is true for each of the \( m \) subgroups:

\[ T^2_{A_j} = T^2_{M_j} + T^2_{D_j} \]

In all of the following definitions, \( S_p \) is defined as it is in the previous sections, depending on whether the control chart is a Phase I or a Phase II control chart. Also, define \( \mu \) as \( \overline{Y} \) for Phase I control charts and as \( \overline{X} \) for Phase II control charts.

The distance from the target value for the \( j^{th} \) subgroup is defined as follows:

\[ T^2_{M_j} = n(\overline{Y}_j - \mu)S_p^{-1}(\overline{Y}_j - \mu) \]
The internal variability for the \( j \)th subgroup is defined as follows:

\[
T_{Dj}^2 = \sum_{i=1}^{n} (Y_{ji} - \bar{Y}_j)^\prime S_p^{-1} (Y_{ji} - \bar{Y}_j)
\]

where \( Y_{ji} \) is the \( i \)th column vector of \( p \) measurements for the \( j \)th subgroup.

The overall variability for the \( j \)th subgroup is defined as follows:

\[
T_{Aj}^2 = \sum_{i=1}^{n} (Y_{ji} - \mu)^\prime S_p^{-1} (Y_{ji} - \mu)
\]

where \( Y_{ji} \) is the \( i \)th column vector of \( p \) measurements for the \( j \)th subgroup.

**Note:** When you select the **Save T Square** or **Save T Square Formula** options from the Multivariate Control Chart red triangle menu, the three values saved in each row correspond to one value of \( i \) in the three definitions above.

### Statistical Details for Change Point Detection

This discussion follows the development in Sullivan and Woodall (2000).

**Assumptions**

Denote a multivariate distribution of dimension \( p \) with mean vector \( \mu_i \) and covariance matrix \( \Sigma_i \) by \( N_p(\mu_i, \Sigma_i) \). Suppose that the \( x_i \) are \( m \) (where \( m > p \)) independent observations from such a distribution:

\[
x_i \sim N_p(\mu_i, \Sigma_i), \quad i = 1, \ldots, m
\]

If the process is stable, the means \( \mu_i \) and the covariance matrices \( \Sigma_i \) equal a common value so that the \( x_i \) have a \( N_p(\mu, \Sigma) \) distribution.

Suppose that a single change occurs in either the mean vector or the covariance matrix, or both, between the \( m_1 \) and \( m_1+1 \) observations. Then the following conditions hold:

- Observations 1 through \( m_1 \) have the same mean vector and the same covariance matrix \( (\mu_a, \Sigma_a) \).
- Observations \( m_1 + 1 \) to \( m \) have the same mean vector and covariance matrix \( (\mu_b, \Sigma_b) \).
- One of the following occurs:
  - If the change affects the mean, \( \mu_a \neq \mu_b \).
  - If the change affects the covariance matrix, \( \Sigma_a \neq \Sigma_b \).
  - If the change affects both the mean and the covariance matrix, \( \mu_a \neq \mu_b \) and \( \Sigma_a \neq \Sigma_b \).
Overview

A likelihood ratio test approach is used to identify changes in one or both of the mean vector and covariance matrix. The likelihood ratio test statistic is used to compute a control chart statistic that has an approximate upper control limit of 1. The control chart statistic is plotted for all possible \( m_1 \) values. If any observation’s control chart statistic exceeds the upper control limit of 1, this is an indication that a shift occurred. Assuming that exactly one shift occurs, that shift is considered to begin immediately after the observation with the maximum control chart statistic value.

Likelihood Ratio Test Statistic

The maximum value of twice the log-likelihood function for the first \( m_1 \) observations is defined as follows:

\[
l_1 = -m_1 k_1 \log(2\pi) - m_1 \log \left( |S_1|_{k_1} \right) - m_1 k_1
\]

The equation for \( l_1 \) uses the following notation:

- \( S_1 \) is the maximum likelihood estimate of the covariance matrix for the first \( m_1 \) observations.
- \( k_1 = \text{Min}[p,m_1-1] \) is the rank of the \( p \times p \) matrix \( S_1 \).
- The notation \( |S_1|_{k_1} \) denotes the generalized determinant of the matrix \( S_1 \), which is defined as the product of its \( k_1 \) positive eigenvalues \( \lambda_j \):

\[
|S_1|_{k_1} = \prod_{j=1}^{k_1} \lambda_j
\]

The generalized determinant is equal to the ordinary determinant when \( S_1 \) has full rank.

Denote the maximum of twice the log-likelihood function for the subsequent \( m_2 = m - m_1 \) observations by \( l_2 \), and the maximum of twice the log-likelihood function for all \( m \) observations by \( l_0 \). Both \( l_2 \) and \( l_0 \) are given by expressions similar to that given for \( l_1 \).

The likelihood ratio test statistic compares the sum \( l_1 + l_2 \) to \( l_0 \). The sum \( l_1 + l_2 \) is twice the log-likelihood that assumes a possible shift at \( m_1 \). The value \( l_0 \) is twice the log-likelihood that assumes no shift. If \( l_0 \) is substantially smaller than \( l_1 + l_2 \), the process is assumed to be unstable.
The likelihood ratio test statistic for a test of whether a change begins at observation $m_1 + 1$ is defined as follows:

$$
\text{lrt}[m_1] = (l_1 + l_2 - l_0) \\
= (m_1(p - k_1) + m_2(p - k_2))(1 + \log(2\pi)) + m \log(|S|) - m_1 \log(|S_{1k_1}|) - m_2 \log(|S_{2k_2}|)
$$

The distribution of the likelihood ratio test statistic is asymptotically chi-square distributed with $p(p + 3)/2$ degrees of freedom. Large log-likelihood ratio values indicate that the process is unstable.

### The Control Chart Statistic

Simulations indicate that the expected value of $\text{lrt}[m_1]$ varies based on the observation’s location in the series, and, in particular, depends on $p$ and $m$. See Sullivan and Woodall (2000).

Approximating formulas for the expected value of $\text{lrt}[m_1]$ are derived by simulation. To reduce the dependence of the expected value on $p$, $\text{lrt}[m_1]$ is divided by its asymptotic expected value, $p(p + 3)/2$.

The formulas for the approximated expected value of $\text{lrt}[m_1]$ divided by $p(p+3)/2$ are defined as follows:

$$
\text{ev}[m,p,m_1] = \begin{cases} 
 a_p + m_1 b_p' & \text{if } m_1 < p + 1 \\
 a_p + (m - m_1) b_p' & \text{if } m - m_1 < p + 1 \\
 1 + \frac{m - 2p - 1}{(m_1 - p)(m - p - m_1)} & \text{otherwise}
\end{cases}
$$

where

$$
a_p = \frac{0.08684(p - 14.69)(p - 2.036)}{(p - 2)}
$$

and

$$
b_p = \frac{0.1228(p - 1.839)}{(p - 2)}
$$

For $p = 2$, the value of $\text{ev}[m,p,m_1]$ when $m_1$ or $m_2 = 2$ is 1.3505.

**Note:** The formulas above are not accurate for $p > 12$ or $m < (2p + 4)$. In such cases, simulation should be used to obtain approximate expected values.
An approximate upper control limit that yields a false out-of-control signal with probability approximately 0.05, assuming that the process is stable, is calculated as follows:

\[
UCL[m,p] \approx (3.338 - 2.115\log[p] + 0.8819(\log[p])^2 - 0.1382(\log[p])^3 ) \\
+ (0.6389 - 0.3518\log[p] + 0.01784(\log[p])^3 )\log[m].
\]

Note that this formula depends on \( m \) and \( p \).

The control chart statistic is defined to be twice the log of the likelihood ratio test statistic divided by \( p(p + 3) \), divided by its approximate expected value, and also divided by the approximate value of the control limit. Because of the division by the approximate value of the UCL, the control chart statistic can be plotted against an upper control limit of 1. The approximate control chart statistic is calculated as follows:

\[
\hat{y}[m_1] = \frac{2\text{lrt}[m_1]}{p(p + 3)\text{(ev}[m_1]\text{UCL}[m,p])}
\]
Model-driven multivariate control charts are used to monitor parameters for multiple processes in a single control chart. The Model Driven Multivariate Control Chart (MDMVCC) platform enables you to build a control chart based on principal components or partial least squares models. For a set of continuous variables, the MDMVCC platform uses principal components to build the control chart. For saved principal components or partial least squares score functions, the MDMVCC platform builds a control chart based on the provided models. Use the MDMVCC platform to interactively explore and understand the underlying components that lead to out-of-control signals.

Overview of Model Driven Multivariate Control Charts

The Model Driven Multivariate Control Chart (MDMVCC) platform has two primary functions: monitoring and diagnosing.

- Use multivariate control charts to monitor a multivariate process.
- You can interactively drill down to investigate the contributions of individual variables to the overall signal to diagnosis the process.

For more information about multivariate control charts, see Kourti and MacGregor (1996).

Example of Model Driven Multivariate Control Charts

This example uses the Steam Turbine Historical.jmp sample data table that contains process variables from a steam turbine system. You want to build a control chart for the six monitored variables.

1. Select Help > Sample Data Library and open Quality Control/Steam Turbine Historical.jmp.
2. Select Analyze > Quality and Process > Model Driven Multivariate Control Chart.
3. Select all six columns, click Process, and click OK.

Figure 11.2  Steam Turbine Report

Note that the process shifts after sample 16.
4. Select the sample 17 data point. Right-click and select **Rows > Row Label**.

5. Hover over the sample 17 data point to view the $T^2$ contribution proportion plot for that point. Click on the plot to open the plot in the report window.

**Figure 11.3** Contribution Proportion Plot for Sample 17

Note that Cool Temp contributes 40% of the $T^2$ value. The Cool Temp bar is green indicating that sample 17 is within the univariate control limits for Cool Temp. Steam Flow and MW each contribute about 20% of the $T^2$ value. They are both red, which indicates that sample 17 is outside of the univariate control limits for each variable. Steam Temp has a zero contribution to the $T^2$ value. In this example, you found variables where the multivariate out-of-control sample could be traced to an out-of-control univariate variable. However, that is not always the case. In multivariate process control you may observe an out-of-control point on the $T^2$ chart but find that the sample is in-control at the univariate level for all variables.

6. Hover over the Steam Flow bar in the contribution proportion plot to see a univariate control chart for Steam Flow. Click on the chart to open in a new report window.
Figure 11.4 Individual Chart for Steam Flow

The individual chart indicates that the steam flow might have experienced an upset around sample 17.

7. In the PCA Model Driven Multivariate Control Chart report window, Click the $T^2$ for 3 Principal Components red triangle and select Contribution Proportion Heat Map.

Figure 11.5 Contribution Proportion Heat Map
The contribution proportion heat map shows that there is a shift in the contribution proportions for rows 16, 17, and 18 and again at row 23 as compared to other rows. Generally, Steam Temp, Cool Temp, and Pressure contribute the most to the $T^2$ value for each row.

**Launch the Model Driven Multivariate Control Chart Platform**

Launch the Model Driven Multivariate Control Chart (MDMVCC) platform by selecting **Analyze > Quality and Process > Model Driven Multivariate Control Chart**.

**Figure 11.6** The Model Driven Multivariate Control Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Model Driven Multivariate Control Chart platform launch window contains the following options:

**Process** Assigns the process columns. See "Data Format" on page 309.

**Time ID** Assigns a column that is used to identify samples. If no Time ID is assigned, the row number identifies the observations. If the Time ID column is a time, the time identifies each sample. Otherwise, the numeric value of the Time ID identifies each sample.

**By** Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the By variables.

**Historical Data End at Row** Specifies a row number to indicate where historical data end. This enables you to calculate chart limits based on historical data. Both historical and current data are plotted on the charts. Historical data are also known as Phase I data, and current data are also known as Phase II data.
Data Format

The MDMVCC platform accepts data in the following three allowable data formats:

**Raw Data**  Use continuous process data to build a control chart that is based on the principal components of the data. The default dimension of the control chart is based on the number of principal components that account for 85% of the process variation. This number is based on the cumulative percent of the principal component eigenvalues.

**Principal Components**  Use principal component columns that were previously saved from a principal component analysis (PCA). The default dimension of the control chart is the number of components specified as process variables.

**Partial Least Squares Score Data**  Use score columns that were previously saved from a partial least squares (PLS) analysis to build a control chart that is based on the score columns. The default dimension of the control chart is the number of scores specified as process variables.

**Notes:**
- PCA or PLS models built with a frequency or weight column are not supported.
- PCA or PLS models built with historical data must use the same number of historical data rows as specified in the MDMVCC launch window.
- PCA models built from within the Multivariate platform are not supported.
The Model Driven Multivariate Control Chart Report

The initial Model Driven Multivariate Control Chart Report shows a $T^2$ control chart. The hover labels on the chart are themselves charts. Click the hover label charts to open larger versions of the charts. Depending on the chart, they open in a separate report window or in the Diagnosis the Process section of the MDMVCC report. You can use the graphlets to interactively drill down into the data.

**Figure 11.7** MDMVCC Report with a Hover Graphlet

---

Model Driven Multivariate Control Chart Platform Options

**Show History Summary Statistics**  Shows or hides summary statistics for rows designated as historical data or all rows if historical data rows are not specified. Summary statistics include univariate means and standard deviations for process variables. For PCA-based charts, the eigenvalues and eigenvectors are displayed. For charts based on PLS scores, the standard deviation of scores and the score loadings are displayed.

**Monitor the Process**

**Show Monitoring Plots**  Shows or hides the selected process monitoring plots.

**Set Component**  Enables you to set the number of components for the $T^2$, DModX, or SPE plots. The number of components can range from one up to the number of valid eigenvectors for PCA driven analysis or from one up to the number of PLS model factors for PLS driven analysis.

**Set $\alpha$ Level**  Enables you to adjust the alpha level that is used for all control chart limits.
Chapter 11
Model Driven Multivariate Control Charts

Quality and Process Methods
Model Driven Multivariate Control Chart Platform Options

**T² Plot**  Shows or hides a $T^2$ plot. The $T^2$ statistic is a summary of multivariate variation that measures how far away an observation is from the center of a PCA or PLS model.

**Normalized DModX Plot**  Shows or hides a plot of the normalized DModX values. DModX measures the distance of each observation to the PCA or PLS model. A high DModX value indicates an observation that deviates from the underlying correlation structure of the data.

**Squared Prediction Error Plot**  Shows or hides the squared prediction error (SPE) plot. SPE measures the sum of squared of the residuals from the PCA or PLS model. A high SPE value indicates an observation that deviates from the underlying correlation structure of the data.

**Score Plot**  Shows or hides a score plot of principal components or partial least squares factors. See “Score Plot” on page 313.

**Diagnose the Process**  (Available when at least one diagnostic plot is active.) Shows or hides diagnostic plots.

See *Using JMP* for more information about the following options:

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

**Plot Options**

The following options apply to the $T^2$, Normalized DModX, Squared Prediction Error, and Score Plots. The plots, when selected, appear in the Diagnosis the Process section of the report window.

**Show Limit Summaries**  (Not available for the Score Plot.) Shows or hides control chart limits and summary data in a report table below the chart.

**Contribution Heat Map**  Shows or hides a heat map that is colored by the variable contributions of each observation.

**Contribution Proportion Heat Map**  Shows or hides a heat map that is colored by the variable contributions expressed as proportions of the overall value of each observation.
**Contribution Plot for Selected Samples**  (Available only when one or more points are selected.) Shows or hides a bar chart of the individual component contributions to the overall value for each selected sample.

**Contribution Proportion Plot for Selected Samples**  (Available only when one or more points are selected.) Shows or hides a bar chart of the individual component contributions expressed as proportions of contribution of the overall value for each selected sample.

**Mean Contribution Proportion Plot for Selected Samples**  (Available only when two or more points are selected.) Shows or hides a bar chart of the average of the individual component contributions to the overall value for each selected sample.

**Note:** Contribution plot bars are colored red when the value or mean value is beyond 3 sigma of the mean and green otherwise.

The following options are available for contribution plots:

- **Sort Bars**  Enables you to sort the bars from largest to smallest contribution or from largest to smallest average contribution for multiple plots.

- **Label Bars**  Enables you to label the bars by the value, the column name, or to remove labels (No Label).

- **Control Charts for Selected Items**  Shows a control chart for the selected columns.

- **Scatterplot Matrix**  (Available when two or more bars are selected.) Shows a scatterplot matrix for the selected variables.

- **Remove Plot**  Removes the plot from the report window.

**Normalized Score Plot for Selected Samples**  (Available only for a Score Plot when one or more points are selected.) Shows or hides a bar chart of normalized scores for each sample selected.

**Score Ellipse Coverage**  (Available only for Score Plots with two components.) Adds an ellipse with the specified coverage to the score plot. The ellipse is based on historical data. When both Phase I and Phase II data are present, there is an ellipse for each phase and the Phase II ellipse is dashed.

**Connect Points**  (Available only for Score Plots.) Connects data points in the score plot.

**Show Loadings**  (Available only for Score Plots.) Shows the PCA loadings on the score plot using biplot arrows.

**Save Columns**  For each plot there are three options to save values to the data table:

- **Save Values**  Saves values ($T^2$, Normalized DModX, SPE, or scores) to a new data table column.
Save Contributions  Saves contributions to new data table columns.

Save Contribution Proportions  Saves contribution proportions to new data table columns.

Score Plot

The Score Plot displays a plot of principal components or partial least squares factors. Use the controls below the plot to change the components shown in the Score Plot.

Use the buttons to the right of the plot to assign and compare the relative contributions between two groups of points. Relative contributions show how two or more samples differ from each other. Relative contributions show what changes in the underlying process variables contribute to differences in groups of samples. One use is to investigate the differences between an in-control sample and an out-of-control sample.

Group A is the reference group and Group B the comparator group. Each group can consist of one or more points. To assign the reference group, select one or more points and then click Group A. To assign the comparator group, select one or more points and then click Group B. To display the Relative Score Contribution Plot, click Compare.

Figure 11.8  Score Plot with Relative Contribution Plot for Row 17 Relative to Row 24

Additional Examples of the Model Driven Multivariate Control Chart Platform

- “Example of an MDMVCC with Historical Data”
- “Example of an MDMVCC with a PLS Model”
Example of an MDMVCC with Historical Data

This example demonstrates the use of historical data to set the monitoring limits for current data.

1. Select Help > Sample Data Library and open Quality Control/Flight Delays.jmp.
2. Select Analyze > Quality and Process > Model Driven Multivariate Control Chart.
3. Select the AA through WN and click Process.
4. Select Flight Date and click Time ID.
5. Enter 16 for Historical Data End at Row.
6. Click OK.

Figure 11.9  $T^2$ Chart for Historical and Current Data

Note that there are two sets of limits. One set applies to the historical data. A second set of limits applies to the current data. For more information about how the historical data is used to calculate the two sets of limits, see “Limits” on page 318.

Tip: Turn on Automatic Recalc to enable the chart to automatically update as you add additional observations to the data table. The Automatic Recalc option is under redo when you click the PCA Model Driven Multivariate Control Chart red triangle.
Example of an MDMVCC with a PLS Model

This example demonstrates the use of a PLS model for monitoring a multivariate process. Consider a process with 14 inputs and 5 quality variables. You have a PLS model that explains the process and you want to use this model to monitor the process for deviations.

1. Select **Help > Sample Data Library** and open Polyethylene Process.jmp.
   
   This data table contains 14 process variables and 5 quality or output variables. The first 100 rows are historical data used to build a PLS model to describe the process. These rows are colored blue. The remaining 239 rows are data collected since the model was built.

   The partial least squares model finds 4 score functions that describe the process. These functions are saved to the data table in columns X Score 1 Formula to X Score 4 Formula. To build the PLS model, use the table script *Set current data as excluded* to exclude the 239 rows of data collected after the historical data. Then use the *Fit Partial Least Squares* table script to build the PLS model to relate the quality variable to the process variables.

2. Select **Analyze > Quality and Process > Model Driven Multivariate Control Chart**.

3. Select the X Score 1 Formula through X Score 4 Formula and click **Process**.

4. Set the **Historical Data End at Row** to 100.

5. Click **OK**.

**Figure 11.10** $T^2$ Chart

The blue data points represent the historical data. The black data points are data points collected after the control chart was established. The process experienced an upset that begins around sample number 326.

6. Hover over the sample data points that are above the upper control limit to view contribution plots.
7. Select the first cluster of data points above the upper control limit. Click the $T^2$ for 4 Factors red triangle and select **Mean Contribution Proportion Plot for Selected Samples**.

8. Click the red triangle next to T2 Mean Contribution Proportion Plot for Selected Samples and select **Sort Bars**.

**Figure 11.11** Mean Contribution Proportion Plot

Notice that the contributions plot is in terms of the PLS model input variables. It appears that $z_2$ and $T_{max2}$ are causing the process upset. $T_{max2}$ and $z_2$ are related. $T_{max2}$ is a reactor temperature and $z_2$ is the location of the $T_{max2}$ temperature.

**Note:** The descriptions of the factors are recorded in the Notes column property.

---

**Statistical Details for the Model Driven Multivariate Control Chart Platform**

**Monitoring Statistics**

$T^2$

The $T^2_i$ value for each of the $i$ observations is plotted on the $T^2$ control chart. For historical and current data, the $T^2$ values for a PCA or PLS model with $k$ components are defined as:

$$T^2_i = t_i T S_k^{-1} t_i$$

where:
\( t_i \) = the vector of \( k \) scores for the \( i^{th} \) observation

\( S_k \) = the diagonal sample covariance matrix of the \( k \) scores for historical observations

For PCA models, \( S_k \) is the diagonal eigenvalue matrix.

The mean of each of the \( k \) historical score vectors is 0 when the data is centered during the data preprocessing step. This step occurs in PCA on correlations or covariances and in PLS with centering. For preprocessing options where \( X \) is not centered, the data is assumed to have been centered by the user, so the mean of each of the \( k \) score vectors is 0. For more information about Hotelling’s \( T^2 \), see Montgomery (2013).

**SPE**

For both PCA and PLS models, the preprocessed \( X \) matrix can be decomposed as:

\[
X = T_k P_k^T + E
\]

where \( T_k = (t_1, \ldots, t_k) \) is the \( k \) dimensional score matrix and \( P_k = (p_1, \ldots, p_k) \) is a matrix with the first \( k \) eigenvectors for PCA models or the loading matrix for PLS models. The squared prediction error of this PCA or PLS model is used for the SPE control chart.

The \( SPE_i \) value for each of the \( i \) observations is plotted on the SPE control chart. The squared prediction error is defined as:

\[
SPE_i = e_i^T e_i = \sum_{j=1}^{p} e_{ij}^2
\]

where

\( e_i \) = the residual vector for observation \( i \)

\( p \) = number of variables

**DModX**

The \( DModX_i \) value for each of the \( i \) observations is plotted on the DModX control chart. The normalized distance to model (DModX) is defined as:

\[
DModX_i = \frac{\left( \sum_{i=1}^{n} SPE_i \right) / (df_2)}{\left( \sum_{i=1}^{n} SPE_i \right) / (df_2)} = \frac{\sum_{i=1}^{p} e_{ij}^2 / (df_1)}{\sum_{i=1}^{p} e_{ij}^2 / (df_2)} = \sum_{i=1}^{p} e_{ij}^2 / (df_2)
\]

where
Model Driven Multivariate Control Charts

Chapter 11

Statistical Details for the Model Driven Multivariate Control Chart Platform Quality and Process Methods

\[ e_{ij} = \text{the residual for observation } i \text{ and variable } j \]

\[ df_1 = p-k \]

\[ df_2 = (n-k-1)(p-k) \text{ if the data is centered and } (n-k)(p-k) \text{ if the data is not centered} \]

\[ n = \text{number of historical data observations} \]

\[ k = \text{number of PCA/PLS components} \]

\[ p = \text{number of variables} \]

**Note:** \( DM_{odX_i} \) is equal to \( SPE_i \) scaled by \( 1/d \).

**Limits**

All data are treated as historical data when the number of historical rows is not specified in the launch window. See “Launch the Model Driven Multivariate Control Chart Platform” on page 308.

**\( T^2 \)**

The upper control limit (UCL) for historical data is based on the Beta distribution and defined as:

\[ UCL = \frac{(n-1)^2}{n} \beta \left[ 1 - \alpha; \frac{k}{2}, \frac{n-k-1}{2} \right] \]

where:

\[ n = \text{number of historical data observations} \]

\[ k = \text{number of PCA or PLS components} \]

\[ \beta \left[ 1 - \alpha; \frac{k}{2}, \frac{n-k-1}{2} \right] = (1-\alpha)^{th} \text{ quantile of a Beta } \left[ \frac{k}{2}, \frac{n-k-1}{2} \right] \text{ distribution.} \]

The UCL for current data is based on the \( F \) distribution and defined as:

\[ UCL = \frac{k(n+1)(n-1)}{n(n-k)} F[1 - \alpha;k;(n-k)] \]

where:

\[ n = \text{number of historical data observations} \]

\[ k = \text{number of PCA or PLS components} \]

\[ F(1-\alpha; k; n-k) = (1-\alpha)^{th} \text{ quantile of an } F(k; n-k) \text{ distribution.} \]
**DModX**

For PCA and PLS models, the UCL is based on the $F$ distribution. The DModX UCL for PCA models is defined as:

$$UCL = F[1 - \alpha; df_1; df_2]$$

where:

$$df_1 = p - k$$

$$df_2 = (n-k-1)(p-k)$$ if the data is centered and $$(n-k)(p-k)$$ if the data is not centered

$n$ = number of historical data observations

$k$ = number of PCA components

$p$ = number of variables

$$F(1 - \alpha; n-p-1; p-k) = (1 - \alpha)^{th}$$ quantile of a $F(n-p-1; p-k)$ distribution.

The DModX UCL for PLS models is defined as:

$$UCL = F[1 - \alpha; h; nh]$$

where:

$$h = \left(\frac{\hat{\mu}^2_{SPE}}{\hat{\sigma}^2_{SPE}}\right)$$

$\hat{\mu}_{SPE}$ = historical sample mean of SPE

$\hat{\sigma}^2_{SPE}$ = historical sample variance of SPE

$n$ = number of historical data observations

$$F(1 - \alpha; h; nh) = (1 - \alpha)^{th}$$ quantile of an $F(h; nh)$ distribution.

**SPE**

The SPE UCL for PCA models is defined as:

$$UCL = \theta_1 \left[ 1 - \frac{\theta_2 h_0 (1 - h_0)}{\theta_1^2} + \frac{z_{1 - \alpha}(2\theta_2 h_0^2)^{1/2}}{\theta_1} \right]^{1/h_0}$$

where:
\[ h_0 = 1 - 201 \frac{\theta_3}{\theta_2^2} \]

\[ \theta_1 = \sum_{a=1}^{k} \lambda_a \]

\[ \theta_2 = \sum_{a=1}^{k} \lambda_a^2 \]

\[ \theta_3 = \sum_{a=1}^{k} \lambda_a^3 \]

\( \lambda_a \) = the \( a \)th eigenvalue

\( k \) = number of PCA components

\( z_{1-\alpha} \) = \((1-\alpha)\)th quantile of the standard normal distribution

For more information about SPE control limits for PCA models, see Jackson and Mudholkar (1979).

For PLS models, the UCL is based on the chi-square distribution and defined as:

\[ UCL = g \chi^2_{1-\alpha; h} \]

where

\[ g = \frac{\hat{\sigma}^2_{SPE}}{2 \hat{\mu}_{SPE}} \]

\[ h = \frac{2 \hat{\mu}^2_{SPE}}{\hat{\sigma}^2_{SPE}} \]

\[ \hat{\mu}_{SPE} \] = historical sample mean of SPE

\[ \hat{\sigma}^2_{SPE} \] = historical sample variance of SPE

\[ \chi^2(1-\alpha; h) \] = \((1-\alpha)\)th quantile of an \( \chi^2(h) \) distribution

The \( g \) and \( h \) parameters are estimated by the method of moments. For more information about SPE control limits for PLS models, see Nomikos (1995).
Contributions

$T^2$

The $T^2$ contributions for a PCA or PLS model with $p$ variables and $k$ components are calculated as:

$$T^2_i = t_i' S_k^{-1} t_i$$

$$= \sum_{a=1}^{k} \frac{t_{ia}^2}{s_a}$$

$$= \sum_{a=1}^{k} \frac{t_{ia}^2}{s_a} \sum_{j=1}^{p} r_{ja} x_{ij}$$

$$= \sum_{j=1}^{p} \left( \sum_{a=1}^{k} \frac{t_{ia}^2}{s_a} r_{ja} x_{ij} \right)$$

where:

$t_i =$ the vector of $k$ scores for the $i^{th}$ observation

$S_k =$ the diagonal sample covariance matrix of the $k$ scores for historical observations. For PCA models, $S_k$ is the diagonal eigenvalue matrix.

$s_a =$ the $a^{th}$ diagonal element of $S_k$

$r_{ja} =$ the $j^{th}$ element of the $a^{th}$ eigenvector for PCA models and the $a^{th}$ column of the $R_k$ loading matrix for PLS models. $R_k$ is the matrix used to relate the score matrix, $T_k$ to the $X$ matrix, such that $T_k=XR_k$.

$x_{ij} =$ the value of the $j^{th}$ variable for the $i^{th}$ observation.

**Note:** The $p$ terms in the last sum are the variable contributions.

The contribution of each variable is the sum of its contribution to each score, weighted by the normalized score value. A variable is considered to have a large contribution to $T^2_i$ if there is a large normalized score value, and the variable contribution is large.

$$\sum_{j=1}^{p} Cont(T^2_j) = T^2$$

the contribution proportion of variable $j$ is defined as:
Note: When computing $T^2$ contribution proportions, JMP zeros out negative contributions. Negative contributions are possible due to the interaction of variables during the projection of $X$ in PCA and PLS models. The negative contributions are zeroed in order to identify the variable contributions that represent a large proportion of the total positive contributions.

For more information about PCA contributions and negative contributions, see Kourti and MacGregor (1996). For more information about PLS contributions, see Li et al. (2009).

**DModX**

For PCA and PLS models, the contribution of variable $j$ to DModX$_i$ is defined as:

$$Cont(DModX_i)_j = \frac{e_{ij}}{d}$$

Note that since

$$DModX_i = \sum_{j=1}^{p} \frac{e_{ij}^2}{d}$$

the contribution proportion of variable $j$ is defined as:

$$ContProp(DModX_i)_j = \frac{e_{ij}^2/d}{DModX_i}$$

**SPE**

For PCA and PLS models, the contribution of variable $j$ to SPE$_i$ is defined as:

$$Cont(SPE_i)_j = e_{ij}$$

Note that since

$$SPE_i = \sum_{j=1}^{p} e_{ij}^2$$

the contribution proportion of variable $j$ is defined as:
Score Contributions

The score contribution computation is the same as $T^2$ contributions but are computed only for the dimensions selected in the score plot.

Score Plot Group Comparisons

For the score plot group comparisons, the relative score contribution for variable $j$ is the difference between the average contribution in group B and the average contribution in group A:

$$
\sum_{i \in B} \frac{\text{Cont}(T^*_i)\_j}{n_b} - \sum_{i \in A} \frac{\text{Cont}(T^*_i)\_j}{n_a}
$$

where

- $T^*_i$ = the $i^{th}$ row of the score matrix with columns corresponding to the dimensions shown in the score plot.
- $A$ = the set of observations in group A
- $B$ = the set of observations in group B
- $n_a$ = the number of observations in group A
- $n_b$ = the number of observations in group B.

Score Plot Loadings

The loadings shown on the score plot are based on PCA eigenvectors or PLS X score loadings (R matrix). These loadings are scaled by the maximum absolute value of scores. The scaling is performed in order to graph the loadings on the score plot. The loadings illustrate each variable’s approximate influence on each score.
A control chart is a graphical and analytic tool for monitoring process variation. The natural variation in a process can be quantified using a set of control limits. Control limits help distinguish common-cause variation from special-cause variation. Typically, action is taken to identify and eliminate special-cause variation. It is also important to quantify the common-cause variation in a process, as this determines the capability of a process.

The legacy control chart platforms in JMP provide a variety of control charts, as well as runs charts, V-Mask CUSUM charts, and weighted moving average charts. To support process improvement initiatives, most of the control chart options display separate control charts for different phases of a project on the same chart.

Example of a Legacy Control Chart

This example uses the Coating.jmp sample data table in the Quality Control sample data folder (taken from the ASTM Manual on Presentation of Data and Control Chart Analysis). The quality characteristic of interest is the Weight column. A subgroup sample of four is chosen.

1. Select Help > Sample Data Library and open Quality Control/Coating.jmp.
2. Select Analyze > Quality And Process > Legacy Control Charts > XBar.
   
   Note the selected chart types of XBar and R.
4. Select Sample and click Sample Label.
5. Click OK.

Figure 12.2 Variables Charts for Coating Data

An XBar chart and an R chart for the process are shown in Figure 12.2. Sample six indicates that the process is not in statistical control. To check the sample values, click the sample six summary point on either control chart. The corresponding rows highlight in the data table.
Note: If an S chart is chosen with the XBar chart, then the limits for the XBar chart are based on the standard deviation. Otherwise, the limits for the XBar chart are based on the range.

Legacy Control Chart Types

Legacy control charts are broadly classified into two categories:

- **Control Charts for Variables** — IR, XBar, Runs Chart, Levey-Jennings, Presummarize, CUSUM, UWMA, and EWMA.
- **Control Charts for Attributes** — P, NP, C, and U.

Control Charts for Variables

Control charts for variables are classified according to the subgroup summary statistic plotted on the chart:

- The IR selection provides additional chart types:
  - Individual Measurement charts display individual measurements. These charts are appropriate when only one measurement is available for each subgroup sample.
  - Moving Range charts display moving ranges of two or more successive measurements. See “Moving Range (Average) Charts” on page 329.
- XBar charts display subgroup means (averages). This selection provides additional chart types:
  - R charts display subgroup ranges (maximum – minimum).
  - S charts display subgroup standard deviations.

For quality characteristics measured on a continuous scale, a typical analysis shows both the process mean and its variability with a mean chart aligned above its corresponding R or S chart.

- Runs Chart displays data as a connected series of points. Runs charts can also plot the group means when the Sample Label role is used, either on the window or through a script.
- Levey-Jennings charts show a process mean with control limits based on a long-term sigma. The control limits are placed at 3σ distance from the center line. The standard deviation, s, for the Levey-Jennings chart is calculated the same way standard deviation is in the Distribution platform.
- Presummarize charts display subgroup means and standard deviations. See “Presummarize Charts” on page 329.
• **CUSUM** charts show cumulative sums of subgroup or individual measurements from a target value. See “V-Mask CUSUM Control Charts” on page 330.

• UWMA charts show a uniformly weighted moving average of a specified number of measurements. See “Uniformly Weighted Moving Average Charts” on page 330.

• EWMA charts show an exponentially weighted moving average of all measurements with a specified weight. See “Exponentially Weighted Moving Average Charts” on page 331.

**Moving Range (Average) Charts**

In a Moving Average chart, the quantities that are averaged can be individual observations instead of subgroup means. However, a Moving Average chart for individual measurements is not the same as a control chart for individual measurements or moving ranges with individual measurements plotted.

Moving Range (Average) charts display moving ranges of two or more successive measurements. Moving ranges are computed for the number of consecutive measurements that you enter in the **Range Span** box. The default range span is 2. Because moving ranges are correlated, these charts should be interpreted with care.

A Median Moving Range chart is also available. If you choose a Median Moving Range chart and an Individual Measurement chart, the limits on the Individual Measurement chart use the Median Moving Range as the sigma, rather than the Average Moving Range.

**Presummarize Charts**

If your data consist of repeated measurements of the same process unit, you can combine these into one measurement for the unit. Pre-summarizing is not recommended unless the data have repeated measurements on each process or measurement unit.

Presummarize summarizes the process column into sample means or standard deviations, based either on the sample size or sample label chosen. Then it charts the summarized data based on the options chosen in the launch window. You can also append a capability analysis by checking the appropriate box in the launch window.

The **Presummarize** launch window has the following options for chart types:

• Individual on Group Means
• Individual on Group Std Devs
• Moving Range on Group Means
• Moving Range on Group Std Devs
• Median Moving Range on Group Means
• Median Moving Range on Group Std Devs

There is also an option for setting the range span that is used for the moving range chart types.
V-Mask CUSUM Control Charts

V-Mask Cumulative Sum (CUSUM) control charts show cumulative sums of subgroup or individual measurements from a target value. V-Mask CUSUM charts can help you decide whether a process is in a state of statistical control by detecting small, sustained shifts in the process mean. In comparison, standard Shewhart control charts can detect sudden and large changes in measurement, such as a two or three sigma shift, but they are less effective at spotting smaller changes, such as a one sigma shift.

The CUSUM menu selection has options for V-mask cumulative sum charts. In addition to KSigma, you also specify:

- The vertical distance $h$ between the origin for the V-mask and the upper or lower arm of the V-mask for a two-sided chart. For a one-sided chart, $H$ is the decision interval. Choose $H$ as a multiple of the standard error.
- The reference value $k$, where $k$ is greater than zero.

Another form of a cumulative sum control chart is the tabular CUSUM chart. To create a tabular CUSUM chart, see the “CUSUM Control Charts” chapter on page 247. The tabular CUSUM chart is recommended over the V-mask chart for a variety of reasons, including the following:

- The V-mask must be moved with each observation, not simply placed on the last observation.
- The cumulative sums in the V-mask procedure can end up a long way from the center of the graph, even for an on-target process.

**Caution:** Montgomery (2013) strongly “advises against using the V-mask procedure.”

Uniformly Weighted Moving Average Charts

Each point on a Uniformly Weighted Moving Average (UWMA) chart is the average of the $w$ most recent subgroup means, including the present subgroup mean. When you obtain a new subgroup sample, the next moving average is computed by dropping the oldest of the previous $w$ subgroup means and including the newest subgroup mean. The constant, $w$, is called the *span* of the moving average.

In addition to KSigma and Alpha, in the UWMA launch window you also specify:

- The Moving Average Span, or $w$, which indicates how many subgroups to include to form the moving average. The larger the Moving Average Span ($w$), the smoother the UWMA line, and the less it reflects the magnitude of shifts. This means that larger values of $w$ guard against smaller shifts. See “Control Limits for UWMA Charts” on page 368.
Exponentially Weighted Moving Average Charts

Each point on an Exponentially Weighted Moving Average (EWMA) chart is the weighted average of all the previous subgroup means, including the mean of the present subgroup sample. The weights decrease exponentially going backward in time.

**Note:** An Exponentially Weighted Moving Average (EWMA) chart can also be called a Geometric Moving Average (GMA) chart.

In addition to KSigma and Alpha, in the EWMA launch window you also specify:

- A Weight parameter, which is the weight \((0 < \text{weight} \leq 1)\) assigned to the present subgroup sample mean. Small values of Weight are used to guard against small shifts. See “Control Limits for EWMA Charts” on page 368.

**Tip:** See “EWMA Control Charts” chapter on page 263 for the newer EWMA Control Charts platform.

Control Charts for Attributes

In the previous types of charts, measurement data was the process variable. This type of data is often continuous, and the charts are based on theory for continuous data. Another type of data is count data, where the variable of interest is a discrete count of the number of defects or blemishes per subgroup. For discrete count data, attribute charts are applicable, as they are based on binomial and Poisson models. Because the counts are measured per subgroup, it is important when comparing charts to determine whether you have a similar number of items in the subgroups between the charts. Attribute charts, like variables charts, are classified according to the subgroup sample statistic plotted on the chart.

Determining Which Attribute Chart to Use

Each item is judged as either conforming or non-conforming:

- **p-chart** Shows the *proportion* of defective items.
- **np-chart** Shows the *number* of defective items.

The number of defects is counted for each item:

- **c-chart** Shows the *number* of defects.
- **u-chart** Shows the *proportion* of defects.
For attribute charts, specify the column containing the defect count or defective proportion as the Process variable. The data are interpreted as counts, unless the column contains non-integer values between 0 and 1.

- **P charts** display the proportion of nonconforming (defective) items in subgroup samples, which can vary in size. Since each subgroup for a P chart consists of $N_i$ items, and an item is judged as either conforming or nonconforming, the maximum number of nonconforming items in a subgroup is $N_i$.

- **NP charts** display the number of nonconforming (defective) items in subgroup samples. Because each subgroup for an NP chart consists of $N_i$ items, and an item is judged as either conforming or nonconforming, the maximum number of nonconforming items in subgroup $i$ is $N_i$.

**Note:** To use the Sigma column property for P or NP charts, the value needs to be equal to the proportion. JMP calculates the sigma as a function of the proportion and the sample sizes.

- **C charts** display the number of nonconformities (defects) in a subgroup sample that usually, but does not necessarily, consists of one inspection unit.

**Caution:** For a C chart, if you do not specify a Sample Size or Constant Size, then the Sample Label is used as the sample size.

- **U charts** display the proportion of nonconformities (defects) in each subgroup sample that can have a varying number of inspection units.

**Caution:** For a U chart, if you do not specify a Unit Size or Constant Size, then the Sample Label is used as the unit size.

## Launch a Legacy Control Chart Platform

When you launch a legacy control chart platform by selecting **Analyze > Quality And Process > Legacy Control Charts**, a launch window similar to Figure 12.3 appears. The specific controls vary depending on which type of chart you select. Initially, the window shows the following types of information:

- **Process Information** for measurement variable selection
- Chart type information (for more information, see “Legacy Control Chart Types” on page 328)
- “Limits Specifications” on page 336
- “Specified Statistics” on page 337
Figure 12.3 XBar Control Chart Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Process Information

The launch window displays a list of columns in the current data table. Here, you specify the variables to be analyzed and the subgroup sample size.

Process

The Process role selects variables for charting:

- For variables charts, specify measurements as the process.
- For attribute charts, specify the defect count or defective proportion as the process. The data are interpreted as counts, unless it contains non-integer values between 0 and 1.

Note: The rows of the data table must be sorted in the order in which the observations were collected. Even if there is a Sample Label variable specified, you still must sort the observations accordingly.
Sample Label

The **Sample Label** role enables you to specify a variable whose values label the horizontal axis and can also identify unequal subgroup sizes. If you do not specify a sample label variable, the samples are identified by their subgroup sample number.

- If the sample subgroups are the same size, select the **Sample Size Constant** option and enter the size in the text box. If you entered a Sample Label variable, its values are used to label the horizontal axis. The sample size is used in the calculation of the limits regardless of whether the samples have missing values.
- If the sample subgroups have an unequal number of rows or have missing values and you have a column identifying each sample, select the **Sample Grouped by Sample Label** option and enter the sample identifying column as the sample label.

For attribute charts (P, NP, C, and U charts), this variable is the subgroup sample size. Additional options appear on the launch window, including **Sample Size**, **Constant Size**, or **Unit Size**, depending on your selection. In variables charts, it identifies the sample. When the chart type is **IR**, a **Range Span** text box appears. The *range span* specifies the number of consecutive measurements from which the moving ranges are computed.

**Notes:**

- The rows of the data table must be sorted in the order in which the observations were collected. Even if there is a **Sample Label** variable specified, you still must sort the observations accordingly.
- The non-integer part of the value for **Constant Size** is truncated. If you have a constant non-integer subgroup sample size, you must specify a column of constant values.
The illustration in Figure 12.4 shows an XBar chart for a process with unequal subgroup sample sizes, using the Coating.jmp sample data from the Quality Control sample data folder.

**Figure 12.4** Variables Charts with Unequal Subgroup Sample Sizes

### Phase

The **Phase** role enables you to specify a column identifying different phases, or sections. A *phase* is a group of consecutive observations in the data table. For example, phases might correspond to time periods during which a new process is brought into production and then put through successive changes. Phases generate, for each level of the specified Phase variable, a new sigma, set of limits, zones, and resulting tests.

On the window for XBar, R, S, IR, P, NP, C, U, Presummarize, and Levey-Jennings charts, a **Phase** variable button appears. If a phase variable is specified, the phase variable is examined, row by row, to identify to which phase each row belongs. Saving to a limits file reveals the sigma and specific limits calculated for each phase.

### By

The **By** role identifies a variable to produce a separate analysis for each value that appears in the column.
Limits Specifications

You can specify computations for control limits by entering a value for \( k \) (K Sigma), or by entering a probability for \( \alpha \) (Alpha), or by retrieving a limits value from the process columns' properties or a previously created Limits Table. Limits Tables and the Get Limits button are discussed in the section “Saving and Retrieving Limits” on page 347. There must be a specification of either K Sigma or Alpha. The window default for K Sigma is 3.

**KSigma**

The KSigma parameter option enables specification of control limits in terms of a multiple of the sample standard error. KSigma specifies control limits at \( k \) sample standard errors above and below the expected value, which shows as the center line. To specify \( k \), the number of sigmas, click the radio button for KSigma and enter a positive \( k \) value into the text box. The usual choice for \( k \) is 3, which is three standard deviations. The examples shown in Figure 12.5 compare the XBar chart for the Coating.jmp data with control lines drawn with KSigma = 3 and KSigma = 4.

**Figure 12.5** K Sigma =3 (left) and K Sigma=4 (right) Control Limits

**Alpha**

The Alpha parameter option specifies control limits (also called probability limits) in terms of the probability \( \alpha \) that a single subgroup statistic exceeds its control limits, assuming that the process is in control. To specify alpha, click the Alpha radio button and enter the desired probability. Reasonable choices for \( \alpha \) are 0.01 or 0.001. For XBar charts under the assumption of normality and known in-control parameters, the Alpha value equivalent to a KSigma of 3 is 0.0027.
Specified Statistics

After specifying a process variable, if you click the Specify Stats (when available) button on a Control Chart launch window, a tab with editable fields is appended to the bottom of the window. This lets you enter historical statistics (that is, statistics obtained from historical data) for the process variable. The Control Chart platform uses those entries to construct control charts. The example here shows 1 as the standard deviation of the process variable and 20 as the mean measurement.

Figure 12.6 Example of Specify Stats

Note: When the mean is user-specified, it is labeled in the plot as $\mu_0$.

If you check the Capability option on a Control Chart launch window (Figure 12.3), a window appears as the platform is launched asking for specification limits. The standard deviation for the control chart selected is sent to the window and appears as a Specified Sigma value, which is the default option. After entering the specification limits and clicking OK, capability output appears in the same window next to the control chart. For information about how the capability indices are computed, see “Capability Indices for Normal Distributions” on page 234 in the “Process Capability” chapter.
Legacy Control Chart Reports

The analysis produces a chart that can be used to determine whether a process is in a state of statistical control. The report varies depending on the type of chart that you select. Figure 12.7 displays the parts of a simple control chart. Control charts update dynamically as data is added or changed in the data table.

**Figure 12.7** Example of a Control Chart

![Diagram of a control chart](image)

**Note:** Any rows that are excluded in the data table are also hidden in Runs charts, P charts, U charts, and C charts.

Control charts have the following characteristics:

- Each point plotted on the chart represents an individual process measurement or summary statistic. In Figure 12.7, the points represent the average for a sample of measurements.

  Subgroups should be chosen *rationally*, that is, they should be chosen to maximize the probability of seeing a true process change *between* subgroups. Often, this requires knowledge of the process to determine the most effective grouping strategy. See Wheeler (2004); Woodall and Adams (1998).

- The vertical axis of a control chart is scaled in the same units as the summary statistic.

- The horizontal axis of a control chart identifies the subgroup samples and is time ordered. Observing the process over time is important in assessing if the process is changing.

- The green line is the center line, or the average of the data. The center line indicates the average (expected) value of the summary statistic when the process is in statistical control. Measurements should appear equally on both sides of the center line. If not, this is possible evidence that the process average is changing.

- The two red lines are the upper and lower control limits, labeled UCL and LCL. These limits give the range of variation to be expected in the summary statistic when the process is in statistical control. If the process is exhibiting only routine variation, then all the points...
should fall randomly in that range. In Figure 12.7, one measurement is above the upper control limit. This is evidence that the measurement could have been influenced by a special cause, or is possibly a defect.

- A point outside the control limits (or the V-mask of a CUSUM chart) signals the presence of a special cause of variation.

Options within each platform create control charts that can be updated dynamically as samples are received and recorded or added to the data table.

When a control chart signals abnormal variation, action should be taken to return the process to a state of statistical control if the process degraded. If the abnormal variation indicates an improvement in the process, the causes of the variation should be studied and implemented.

When you double-click the horizontal or vertical axis, the appropriate Axis Specification window appears for you to specify the format, axis values, number of ticks, gridline, reference lines, and other options to display on the axis.

For example, the Pickles.jmp data lists measurements taken each day for three days. In Figure 12.8, by default, the horizontal axis is labeled at every other tick. Sometimes this gives redundant labels, as shown to the left in Figure 12.8. If you specify a label at an increment of eight, the horizontal axis is labeled once for each day, as shown in the chart on the right.

**Figure 12.8** Example of Labeled x Axis Tick Marks

![Chart Image]

**Tip:** For information about warnings and rules, see “Tests” on page 55 and “Westgard Rules” on page 59 in the “Control Chart Builder” chapter of this guide.
Interpret a Two-Sided V-Mask CUSUM Chart

Note: See also “V-Mask CUSUM Chart Example” on page 354.

To interpret a two-sided CUSUM chart, compare the points with limits that compose a V-mask. A V-mask is a shape in the form of a V on its side that is superimposed on the graph of the cumulative sums. The V-mask is formed by plotting V-shaped limits. The origin of a V-mask is the most recently plotted point, and the arms extended backward on the horizontal axis, as in Figure 12.9. As data are collected, the cumulative sum sequence is updated and the origin is relocated at the newest point.

Figure 12.9 V-Mask for a Two-Sided CUSUM Chart

Shifts in the process mean are visually easy to detect on a CUSUM chart because they produce a change in the slope of the plotted points. The point where the slope changes is the point where the shift occurs. A condition is out-of-control if one or more of the points previously plotted crosses the upper or lower arm of the V-mask. Points crossing the lower arm signal an increasing process mean, and points crossing the upper arm signal a downward shift.
There are important differences between CUSUM charts and Shewhart charts:

- A Shewhart control chart plots points based on information from a single subgroup sample. In CUSUM charts, each point is based on information from all samples taken up to and including the current subgroup.
- On a Shewhart control chart, horizontal control limits define whether a point signals an out-of-control condition. On a CUSUM chart, the limits can be either in the form of a V-mask or a horizontal decision interval.
- The control limits on a Shewhart control chart are commonly specified as $3\sigma$ limits. On a CUSUM chart, the limits are determined from average run length.

A CUSUM chart is more efficient for detecting small shifts in the process mean. Lucas (1976) states that a V-mask detects a $1\sigma$ shift about four times as fast as a Shewhart control chart.

**Interpret a One-Sided CUSUM Chart**

Use a one-sided CUSUM chart to identify data approaching or exceeding the side of interest.

Figure 12.10 Example of a One-Sided CUSUM Chart

The *decision interval* or horizontal line is set at the H value that you entered in the launch window. In this example, it is 0.25. Any values exceeding the decision interval of 0.25 indicate a shift or out-of-control condition. In this example, observation 4 appears to be where a shift occurred. Also note that no V-mask appears for one-sided CUSUM charts.
Legacy Control Chart Platform Options

Legacy control charts have red triangle menus that affect various parts of the platform:

- The menu on the top-most title bar affects the whole platform window. Its items vary with the type of chart that you select. See “Window Options for Legacy Control Charts” on page 342.

- There is a menu of items on the chart type title bar with options that affect each chart individually. See “Chart Options for Legacy Control Charts” on page 344.

Window Options for Legacy Control Charts

The red triangle menu on the window title bar lists options that affect the report window. If you request \texttt{XBar} and \texttt{R} at the same time, you can check each chart type to show or hide it. The specific options that are available depend on the type of control chart you request. Unavailable options show as grayed menu items.

**Show Limits Legend** Shows or hides the Avg, UCL, and LCL values to the right of the chart.

**Connect Through Missing** Connects points when some samples have missing values. In Figure 12.11, the left chart has no missing points. The middle chart has samples 2, 11, 19, and 27 missing with the points not connected. The right chart appears if you select the **Connect Through Missing** option, which is the default.

![Figure 12.11 Example of Connected through Missing Option](image)

**Use Median** For Runs Charts, when you select the **Show Center Line** option in the individual Runs Chart red triangle menu, a line is drawn through the center value of the column. The center line is determined by the **Use Median** setting of the main Runs Chart red triangle menu. When **Use Median** is selected, the median is used as the center line. Otherwise, the mean is used. When saving limits to a file, both the overall mean and median are saved.
**Capability**  (Not available when a Phase variable is specified.) Performs a Capability Analysis for your data. A pop-up window is first shown, where you can enter the Lower Spec Limit, Target, and Upper Spec Limit values for the process variable.

**Figure 12.12** Capability Analysis Window

![Capability Analysis Window]

An example of a capability analysis report is shown in Figure 12.13 for Coating.jmp when the Lower Spec Limit is set as 16.5, the Target is set to 21.5, and the Upper Spec Limit is set to 23.

**Figure 12.13** Capability Analysis Report for Coating.jmp

![Capability Analysis Report](image)

For additional information, see “Statistical Details for Capability Analysis” on page 358.

**Save Sigma**  Saves the computed value of sigma as a column property in the process variable column in the JMP data table.

**Save Limits**  Saves the control limits in one of the following ways:
in Column  Saves control limits as a column property in the existing data table for the response variable. If the limits are constant, LCL, Avg, and UCL values for each chart type in the report are saved. This option is not available with phase charts. In addition, the option has no effect if the sample sizes are not constant for each chart.

in New Table  Saves the standard deviation and mean for each chart into a new data table. If the limits are constant, the LCL, Avg, and UCL for each chart are saved as well. If there are phases, a new set of values is saved for each phase. You can use this data table to use the limits later. In the Control Chart launch window, click Get Limits and then select the saved data table. See the section “Saving and Retrieving Limits” on page 347.

Save Summaries  Creates a new data table that contains the sample label, sample sizes, the statistic being plotted, the center line, and the control limits. The specific statistics included in the table depend on the type of chart.

Alarm Script  Enables you to write and run a script that indicates when the data fail special causes tests. Results can be written to the log or spoken. See “Tests” on page 55 in the “Control Chart Builder” chapter of this guide. See the Scripting Guide for more information about writing custom Alarm Scripts.

See Using JMP for more information about the following options:

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Chart Options for Legacy Control Charts

The red triangle menu of chart options appears when you click the icon next to the chart name. Some options are also available under Chart Options when you right-click the chart. Not all of the options below are available for all control chart types.

Box Plots  Superimposes box plots on the subgroup means plotted in a Mean chart. The box plot shows the subgroup maximum, minimum, 75th percentile, 25th percentile, and median. Markers for subgroup means show unless you deselect the Show Points option. The control limits displayed apply only to the subgroup mean. The Box Plots option is available only for X charts. It is most appropriate for larger subgroup sample sizes (more than 10 samples in a subgroup).
**Needle**  Connects plotted points to the center line with a vertical line segment.

**Connect Points**  Shows or hides the line that connects the data points.

**Show Points**  Shows or hides the points representing summary statistics. Initially, the points show. You can use this option to suppress the markers denoting subgroup means when the **Box Plots** option is in effect.

**Connect Color**  Displays the JMP color palette for you to choose the color of the line segments used to connect points.

**Center Line Color**  Displays the JMP color palette for you to choose the color of the line segments used to draw the center line.

**Limits Color**  Displays the JMP color palette for you to choose the color of the line segments used in the upper and lower limits lines.

**Line Width**  Enables you to select the width of the control lines. Options are **Thin**, **Medium**, or **Thick**.

**Point Marker**  Enables you to select the marker used on the chart.

**Show Center Line**  Shows or hides the center line in the control chart.

**Show Control Limits**  Shows or hides the chart control limits and their legends.

**Limits Precision**  Sets the decimal limit for labels.

**Tests**  Shows a submenu that enables you to choose which tests to mark on the chart when the test is positive. Tests apply only for charts whose limits are $3\sigma$ limits. Tests 1 to 4 apply to Mean, Individual, and attribute charts. Tests 5 to 8 apply to Mean charts, Presummarize, and Individual Measurement charts only. If tests do not apply to a chart, the Tests option is dimmed. When sample sizes are unequal, the Test options are grayed out. If the samples change while the chart is open and they become equally sized, and the zone or test option is selected, the zones or tests are applied immediately and appear on the chart. These special tests are also referred to as the **Western Electric Rules**. For more information about special causes tests, see “Tests” on page 55 in the “Control Chart Builder” chapter.

**Westgard Rules**  Westgard rules are control rules that help you decide whether a process is in or out of control. The different tests are abbreviated with the decision rule for the particular test. See the text and chart in “Westgard Rules” on page 59 in the “Control Chart Builder” chapter.

**Test Beyond Limits**  Flags as a “*” any point that is beyond the limits. This test works on all charts with limits, regardless of the sample size being constant, and regardless of the size of $k$ or the width of the limits. For example, if you had unequal sample sizes, and wanted to flag any points beyond the limits of an R chart, you could use this command.
Show Zones  Shows or hides the *zone lines*. The zones are labeled A, B, and C as shown here in the Mean plot for weight in the Coating.jmp sample data. Control Chart tests use the zone lines as boundaries. The seven zone lines are set one sigma apart, centered on the center line.

**Figure 12.14** Show Zones

Shade Zones  Shows or hides the default green, yellow, and red colors for the three zone areas and the area outside the zones. Green represents the area one sigma from the center line, yellow represents the area two and three sigmas from the center line, and red represents the area beyond three sigmas. Shades can be shown with or without the zone lines.

**Tip:** To change the colors used to shade the zones, right-click in the control chart and select Customize. In the Customize Graph window, you can specify colors for each of the three zones.

**Figure 12.15** Shade Zones

OC Curve  Opens a new window that contains the operating characteristic (OC) curve, using all the calculated values directly from the active control chart. See “Operating Characteristic Curves Utility” on page 407 in the “Quality Utilities” chapter.
Chart Options for V-Mask CUSUM Control Charts

**Mask Color**  (Available only when the Show V Mask option is selected.) Enables you to select a line color for the V-mask.

**Show Shift**  Shows or hides the shift that you entered in the launch window.

**Show V Mask**  Shows or hides the V-mask based on the statistics that you specified in the CUSUM Control Charts launch window.

**Show Parameters**  Shows or hides a report that summarizes the CUSUM charting parameters.

**Show ARL**  Shows or hides the average run length (ARL) information. The average run length is the expected number of samples taken before an out-of-control condition is signaled:

- ARL (Delta), sometimes denoted ARL1, is the average run length for detecting a shift in the size of the specified Delta.
- ARL(0), sometimes denoted ARL0, is the in-control average run length for the specified parameters (Montgomery 2013).

Saving and Retrieving Limits

JMP can use previously established control limits for control charts:

- Upper and lower control limits, and a center line value.
- Parameters for computing limits such as a mean and standard deviation.

The control limits or limit parameter values must be either in a JMP data table, referred to as the Limits Table, or stored as a column property in the process column. When you specify the Control Chart command, you can retrieve the Limits Table with the Get Limits button on the Control Chart launch window.

**Tip:** To add specification limits to several columns at once, see “Manage Spec Limits Utility” on page 403 in the “Quality Utilities” chapter.

The easiest way to create a Limits Table is to save results computed by the Control Chart platform. The Save Limits command in the red triangle menu for each control chart automatically saves limits from the sample values. The type of data saved in the table varies according to the type of control chart in the analysis window. You can also use values from any source and create your own Limits Table.
All Limits Tables must have:

- A column of special keywords that identify each row.
- A column for each of the variables whose values are the known standard parameters or limits. This column name must be the same as the corresponding process variable name in the data table to be analyzed by the Control Chart platform.

The following table describes the limit keywords and their associated control chart for both legacy control charts and charts created with Control Chart Builder.

**Table 12.1 Limits Table Keys with Appropriate Charts and Meanings**

<table>
<thead>
<tr>
<th>Keywords</th>
<th>For Charts</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_KSigma</td>
<td>All except Control Chart Builder and V-Mask</td>
<td>multiples of the standard deviation of the statistics to calculate the control limits; set to missing if the limits are in terms of the alpha level</td>
</tr>
<tr>
<td></td>
<td>CUSUM</td>
<td></td>
</tr>
<tr>
<td>_Alpha</td>
<td>All except Control Chart Builder</td>
<td>Type I error probability used to calculate the control limits</td>
</tr>
<tr>
<td>_Range Span</td>
<td>IM, MR, MMR</td>
<td>number of consecutive measurements for which moving ranges are computed. Not applicable in the Control Chart Builder platform, where the range span is always equal to 2.</td>

<tr>
<td>_Data Units, Two Sided, Headstart, Beta, Delta</td>
<td>V-Mask CUSUM</td>
<td>specifications for V-Mask CUSUM chart</td>
</tr>
</tbody>
</table>

You can save limits in a new data table or as properties of the response column. When you save control limits using the in New Table command, the limit keywords written to the table depend on the current chart types displayed.
Figure 12.16 shows examples of control limits saved to a data table using Coating.jmp. The rows with values _Mean, _LCL, and _UCL are for the Individual Measurement chart. The values with the R suffix (_AvgR, _LCLR, and _UCLR) are for the Moving Range chart. If you create these charts again using this Limits Table, the Control Chart platform identifies the appropriate limits from keywords in the _LimitsKey column.

Note that values for _KSigma, _Alpha, and _Range Span can be specified in the Control Chart Launch window. JMP always looks at the values from the window first. Values specified in the window take precedence over those in an active Limits Table.

Rows with unknown keywords and rows marked with the excluded row state are ignored. Except for _Range Span, _KSigma, _Alpha, and _Sample Size, any needed values not specified are estimated from the data.

**Excluded, Hidden, and Deleted Samples**

The following table summarizes the effects of various conditions on samples and subgroups:
Chapter 12
Legacy Control Charts

Quality and Process Methods
Excluded, Hidden, and Deleted Samples

Some additional notes:

- Hide and Exclude operate only on the row state of the first observation in the sample. For example, if the second observation in the sample is hidden, but the first observation is not hidden, the sample still appears on the chart.

**Note:** Excluded rows in Presummarize charts are excluded from calculations, regardless of which position they are within a sample.

### Table 12.2 Excluded, Hidden, and Deleted Samples

| All rows of the sample are excluded before creating the chart. | Sample is not included in the calculation of the limits, but it appears on the graph. |
| Sample is excluded after creating the chart. | Sample is included in the calculation of the limits, and it appears in the graph. Nothing changes on the output by excluding a sample with the graph open. |
| Sample is hidden before creating the chart. | Sample is included in the calculation of the limits, but does not appear on the graph. |
| Sample is hidden after creating the chart. | Sample is included in the calculation of the limits, but does not appear on the graph. The sample marker disappears from the graph, the sample label still appears on the axis, but limits remain the same. |
| All rows of the sample are both excluded and hidden before creating the chart. | Sample is not included in the calculation of the limits, and it does not appear on the graph. |
| All rows of the sample are both excluded and hidden after creating the chart. | Sample is included in the calculation of the limits, but does not appear on the graph. The sample marker disappears from the graph, the sample label still appears on the axis, but limits remain the same. |
| Data set is subsetted with Sample deleted before creating chart. | Sample is not included in the calculation of the limits, the axis does not include a value for the sample, and the sample marker does not appear on the graph. |
| Data set is subsetted with Sample deleted after creating chart. | Sample is not included in the calculation of the limits, and does not appear on the graph. The sample marker disappears from the graph, the sample label is removed from the axis, the graph shifts, and the limits change. |
• An exception to the exclude/hide rule: Both hidden and excluded rows are included in the count of points for Tests for Special Causes. An excluded row can be labeled with a special cause flag. A hidden point cannot be labeled. If the flag for a Tests for Special Causes is on a hidden point, it will not appear in the chart.

• Because of the specific rules in place (Table 12.2 on page 351), the control charts do not support the Automatic Recalc script.

---

### Additional Examples of the Control Chart Platform

- “Presummarize Chart Example”
- “V-Mask CUSUM Chart Example”
- “One-Sided CUSUM Chart Example”
- “UWMA Chart Example”

### Presummarize Chart Example

This example uses the Coating.jmp data table.

1. Select **Help > Sample Data Library** and open Quality Control/Coating.jmp.
2. Select **Analyze > Quality and Process > Legacy Control Charts > Presummarize**.
3. Select Weight and click **Process**.
4. Select Sample and click **Sample Label**.
5. Select both **Individual on Group Means** and **Moving Range on Group Means**. The **Sample Grouped by Sample Label** button is automatically selected when you choose a Sample Label variable.

   When using **Presummarize** charts, you can select either **On Group Means** options or **On Group Std Devs** options or both. Each option creates two charts (an Individual Measurement, also known as an X chart, and a Moving Range chart) if both IR chart types are selected.

   The **On Group Means** options compute each sample mean and then plot the means and create an Individual Measurement and a Moving Range chart on the means.

   The **On Group Std Devs** options compute each sample standard deviation and plot the standard deviations as individual points. Individual Measurement and Moving Range charts for the standard deviations then appear.
6. Click **OK**.
Figure 12.17 Example of Charting Presummarized Data

Although the points for XBar and S charts are the same as the Individual on Group Means and Individual on Group Std Devs charts, the limits are different because they are computed as Individual charts.

Another way to generate the presummarized charts, with the Coating.jmp data table:

1. Choose Tables > Summary.
2. Select Sample and click Group.
3. Select Weight, and then click Statistics > Mean and Statistics > Std Dev.
4. Click OK.
5. Select Analyze > Quality and Process > Legacy Control Charts > IR.
6. Select Mean(Weight) and Std Dev(Weight) and click Process.
7. Click OK.

The resulting charts match the presummarized charts.
V-Mask CUSUM Chart Example

A machine fills 8-ounce cans of two-cycle engine oil additive. The filling process is believed to be in statistical control. The process is set so that the average weight of a filled can ($\mu_0$) is 8.10 ounces. Previous analysis shows that the standard deviation of fill weights ($\sigma_0$) is 0.05 ounces.

Subgroup samples of four cans are selected and weighed every hour for twelve hours. Each observation in the Oil1 Cusum.jmp data table contains one value of weight and its associated value of hour. The observations are sorted so that the values of hour are in increasing order.

1. Select Help > Sample Data Library and open Quality Control/Oil1 Cusum.jmp.
2. Select Analyze > Quality And Process > Legacy Control Charts > CUSUM.
4. Select hour and click Sample Label.
5. Select the Two Sided check box if it is not already checked.
6. In the Parameters area, click the H button and type 2.
7. Click Specify Stats.
8. Type 8.1 next to Target.
   8.1 is the average weight in ounces of a filled can. This is the target mean.
9. Type 1 next to Delta.
   1 is the absolute value of the smallest shift to be detected as a multiple of the process standard deviation or of the standard error.
10. Type 0.05 next to Sigma.
    0.05 is the known standard deviation of fill weights ($\sigma_0$) in ounces.
11. Click **OK**.

**Figure 12.19** Two-Sided CUSUM Chart for Oil1 Cusum.jmp Data

You can interpret the chart by comparing the points with the V-mask. The right edge of the V-mask is centered at the most recent point (the 12th hour). Because none of the points cross the arms of the V-mask, there is no evidence that a shift in the process has occurred. See “V-Mask CUSUM Chart Reports” on page 340.
One-Sided CUSUM Chart Example

Consider the data used in “V-Mask CUSUM Chart Example” on page 354, where the machine fills 8-ounce cans of engine oil. In order to cut costs, the manufacturer is now concerned about significant over-filling (and not so concerned about under-filling). Use a one-sided CUSUM chart to identify any instances of over-filling. Anything that is 0.25 ounces beyond the mean of 8.1 is considered a problem.

1. Select Help > Sample Data Library and open Quality Control/Oil1 Cusum.jmp.
2. Select Analyze > Quality And Process > Legacy Control Charts > CUSUM.
3. Deselect Two Sided.
4. Select weight and click Process.
5. Select hour and click Sample Label.
6. Click H and type 0.25.
7. Click Specify Stats.
8. Type 8.1 next to Target.
   8.1 is the average weight in ounces of a filled can. This is the target mean.
9. Type 1 next to Delta.
   1 is the absolute value of the smallest shift to be detected as a multiple of the process standard deviation or of the standard error.
10. Type 0.05 next to Sigma.
    0.05 is the known standard deviation of fill weights ($\sigma_0$) in ounces.
11. Click OK.

Figure 12.20 One-Sided CUSUM Chart for Oil1 Cusum.jmp Data
The decision interval is set at the H value that you entered (0.25). You can see that at the fourth hour, some significant over-filling occurred.

**UWMA Chart Example**

In the sample data table Clips1.jmp, the measure of interest is the gap between the ends of manufactured metal clips. To monitor the process for a change in the average gap, subgroup samples of five clips are selected daily. A UWMA chart with a moving average span of three is examined.

1. Select **Help > Sample Data Library** and open Quality Control/Clips1.jmp.
2. Select **Analyze > Quality and Process > Legacy Control Charts > UWMA**.
3. Select Gap and click **Process**.
4. Select Sample and click **Sample Label**.
5. Change the **Moving Average Span** to 3.
6. Click **OK**.

**Figure 12.21** UWMA Charts for the Clips1 data

The point for the first day is the mean of the five subgroup sample values for that day. The plotted point for the second day is the average of subgroup sample means for the first and second days. The points for the remaining days are the average of subsample means for each day and the two previous days.

The average clip gap appears to be decreasing, but no sample point falls outside the 3σ limits.
Statistical Details for the Control Chart Platform

- “Control Limits for Median Moving Range Charts”
- “Statistical Details for Capability Analysis”
- “Statistical Details for V-Mask CUSUM Control Charts”
- “Statistical Details for Weighted Moving Average Charts”

**Note:** For more information about other types of charts (such as XBar and R charts, P and NP charts, and more) see the “Statistical Details for Control Chart Builder” on page 89 in the “Control Chart Builder” chapter.

**Control Limits for Median Moving Range Charts**

Control limits for Median Moving Range charts are computed as follows:

\[
\begin{align*}
LCL_{\text{MMR}} &= \max(0, \text{MMR} - kd_3(n) \hat{\sigma}) \\
UCL_{\text{MMR}} &= \text{MMR} + kd_3(n) \hat{\sigma}
\end{align*}
\]

where:

- MMR is the median of the nonmissing moving ranges.
- \(\hat{\sigma} = \text{MMR}/0.954\)
- \(d_3(n)\) is the standard deviation of the range of \(n\) independent normally distributed variables with unit standard deviation.

**Statistical Details for Capability Analysis**

This section contains details about the computation of the statistics in the Capability Analysis report.

**Variation Statistics**

All capability analyses use the same formulas. Options differ in how sigma (\(\sigma\)) is computed:

**Long Term Sigma** Uses the overall sigma. This option is used for \(P_{pk}\) statistics, and computes sigma as follows:

\[
\hat{\sigma} = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n - 1}}
\]
**Note:** By default, the capability indices in the Long Term Sigma report use the Cp labeling that is used in the other sigma reports. To use Ppk labeling in the Long Term Sigma report, select the **File > Preferences > Platforms > Distribution > PpK Capability Labeling** preference.

**Control Chart Sigma** Uses a sigma that is determined by the control chart settings.

- If you specify a value for Sigma using the Specify Stats button in the control launch window, the specified value is used for computing capability indices.
- In an IR chart that uses the Moving Range (Average) option, the value for sigma is computed as follows:

\[
\hat{\sigma} = \frac{\bar{R}}{d_2(n)}
\]

where:

\(\bar{R}\) is the average of the moving ranges.

\(d_2(n)\) is the expected value of the range of \(n\) independent normally distributed variables with unit standard deviation, where \(n\) is the value of the Range Span option.

- In an IR chart that uses the Median Moving Range option, the value for sigma is computed as follows:

\[
\hat{\sigma} = \frac{MMR}{d_4(n)}
\]

where:

MMR is the median of the nonmissing moving ranges.

\(d_4(n)\) is the median of the range of \(n\) independent normally distributed variables with unit standard deviation, where \(n\) is the value of the Range Span option.

- In an XBar chart that uses the R option, the value for sigma is computed as follows:

\[
\hat{\sigma} = \frac{R_1}{d_2(n_1)} + \ldots + \frac{R_N}{d_2(n_N)}
\]

where:

\(R_i\) = range of \(i^{th}\) subgroup

\(n_i\) = sample size of \(i^{th}\) subgroup

\(d_2(n_i)\) = expected value of the range of \(n_i\) independent normally distributed variables with unit standard deviation

\(N\) = number of subgroups for which \(n_i \geq 2\)
– In an XBar chart that uses the S option, the value for sigma is computed as follows:

\[
\hat{\sigma} = \frac{s_1}{c_4(n_1)} + \ldots + \frac{s_N}{c_4(n_N)} \frac{1}{N}
\]

where:

- \( n_i \) = sample size of the \( i^{th} \) subgroup
- \( c_4(n_i) \) = expected value of the standard deviation of \( n_i \) independent normally distributed variables with unit standard deviation
- \( N \) = number of subgroups for which \( n_i \geq 2 \)
- \( s_i \) = sample standard deviation of the \( i^{th} \) subgroup

**Capability Indices for Normal Distributions**

This section provides details about the calculation of capability indices for normal data.

For a process characteristic with mean \( \mu \) and standard deviation \( \sigma \), the population-based capability indices are defined as follows:

\[
C_p = \frac{USL - LSL}{6\sigma}
\]

\[
C_{pl} = \frac{\mu - LSL}{3\sigma}
\]

\[
C_{pu} = \frac{USL - \mu}{3\sigma}
\]

\[
C_{pk} = \min(C_{pl}, C_{pu})
\]

\[
C_{pm} = \frac{\min(T - LSL, USL - T)}{3\sigma \sqrt{1 + \left(\frac{T - \mu}{\sigma}\right)^2}}
\]

where:

- \( LSL \) is the lower specification limit.
- \( USL \) is the upper specification limit.
- \( T \) is the target value.

For sample-based capability indices, the parameters are replaced by their estimates. The estimate for \( \sigma \) uses the method that you specified in the Capability Analysis window. See “Variation Statistics” on page 358.

If either of the specification limits is missing, the capability indices containing the missing specification limit are reported as missing.
Tip: A capability index of 1.33 is often considered to be the minimum value that is acceptable. For a normal distribution, a capability index of 1.33 corresponds to an expected number of nonconforming units of about 6 per 100,000.

Confidence Intervals for Capability Indices

Note: Confidence intervals for capability indices appear only in the Long Term Sigma report.

The 100(1 - α)% confidence interval for Cp is calculated as follows:

\[
\hat{C}_p \sqrt{\frac{2}{\chi^2_{\alpha/2, n-1}}} \leq \hat{C}_p \leq \hat{C}_p \sqrt{\frac{2}{\chi^2_{1-\alpha/2, n-1}}}
\]

where:

\( \hat{C}_p \) is the estimated value for \( C_p \).

\( \chi^2_{\alpha/2, n-1} \) is the \((\alpha/2)\)th quantile of a chi-square distribution with \( n - 1 \) degrees of freedom.

\( n \) is the number of observations.

The 100(1 - α)% confidence interval for Cpk is calculated as follows:

\[
\left( \hat{C}_{pk} \left[ 1 - \Phi^{-1}_{1 - \alpha/2} \sqrt{\frac{1}{9n\hat{C}_{pk}^2} + \frac{1}{2(n-1)}} \right], \hat{C}_{pk} \left[ 1 + \Phi^{-1}_{1 - \alpha/2} \sqrt{\frac{1}{9n\hat{C}_{pk}^2} + \frac{1}{2(n-1)}} \right] \right)
\]

where:

\( \hat{C}_{pk} \) is the estimated value for \( C_{pk} \).

\( \Phi^{-1}_{1 - \alpha/2} \) is the \((1 - \alpha/2)\)th quantile of a standard normal distribution.

\( n \) is the number of observations.

The 100(1 - α)% confidence interval for CPM is calculated as follows:

\[
\left( \hat{C}_{PM} \sqrt{\frac{2}{\chi^2_{\alpha/2, \gamma}}}, \hat{C}_{PM} \sqrt{\frac{2}{\chi^2_{1 - \alpha/2, \gamma}}} \right)
\]

where:

\( \hat{C}_{PM} \) is the estimated value for \( C_{PM} \).

\( \chi^2_{\alpha/2, \gamma} \) is the \((\alpha/2)\)th quantile of a chi-square distribution with \( \gamma \) degrees of freedom.
\[
\gamma = \frac{n \left( 1 + \left( \frac{\bar{x} - T}{s} \right)^2 \right)^2}{1 + 2 \left( \frac{\bar{x} - T}{s} \right)^2}
\]

\(n\) is the number of observations.
\(\bar{x}\) is the mean of the observations.
\(T\) is the target value.
\(s\) is the long-term sigma estimate.

**Note:** The confidence interval for CPM is computed only when the target value is centered between the lower and upper specification limits.

Lower and upper confidence limits for CPL and CPU are computed using the method of Chou et al. (1990).

The 100(1 - \(\alpha\))% confidence limits for CPL (denoted by CPL\(_L\) and CPL\(_U\)) satisfy the following equations:

\[
\Pr[t_{n-1}(\delta_L) \geq 3\hat{C}_{pl}\sqrt{n}] = \alpha/2 \quad \text{where} \quad \delta_L = 3CPL_L\sqrt{n}
\]

\[
\Pr[t_{n-1}(\delta_U) \leq 3\hat{C}_{pl}\sqrt{n}] = \alpha/2 \quad \text{where} \quad \delta_U = 3CPL_U\sqrt{n}
\]

where:
\(t_{n-1}(\delta)\) has a non-central \(t\)-distribution with \(n - 1\) degrees of freedom and noncentrality parameter \(\delta\).
\(\hat{C}_{pl}\) is the estimated value for Cpl.

The 100(1 - \(\alpha\))% confidence limits for CPU (denoted by CPU\(_L\) and CPU\(_U\)) satisfy the following equations:

\[
\Pr[t_{n-1}(\delta_L) \geq 3\hat{C}_{pu}\sqrt{n}] = \alpha/2 \quad \text{where} \quad \delta_L = 3CPU_L\sqrt{n}
\]

\[
\Pr[t_{n-1}(\delta_U) \leq 3\hat{C}_{pu}\sqrt{n}] = \alpha/2 \quad \text{where} \quad \delta_U = 3CPU_U\sqrt{n}
\]

where:
\(t_{n-1}(\delta)\) has a non-central \(t\)-distribution with \(n - 1\) degrees of freedom and noncentrality parameter \(\delta\).
\(\hat{C}_{pu}\) is the estimated value for Cpu.
Capability Indices for Nonnormal Distributions

This section describes how capability indices are calculated for nonnormal distributions. These generalized capability indices are defined as follows:

\[
C_p = \frac{USL - LSL}{P_{0.99865} - P_{0.00135}}
\]

\[
C_{pk} = \min(C_{pl}, C_{pu})
\]

\[
C_{pm} = \frac{\min\left(\frac{T - LSL}{P_{0.5} - P_{0.00135}}, \frac{USL - T}{P_{0.99865} - P_{0.5}}\right)}{\sqrt{1 + \left(\frac{\mu - T}{\sigma}\right)^2}}
\]

\[
C_{pl} = \frac{P_{0.5} - LSL}{P_{0.5} - P_{0.00135}}
\]

\[
C_{pu} = \frac{USL - P_{0.5}}{P_{0.99865} - P_{0.5}}
\]

where:

- \textit{LSL} is the lower specification limit.
- \textit{USL} is the upper specification limit.
- \textit{T} is the target value.
- \textit{P}_\alpha is the \alpha*100\textsuperscript{th} percentile of the fitted distribution.

For the calculation of \(C_{pm}\), \(\mu\) and \(\sigma\) are estimated using the expected value and square root of the variance of the fitted distribution. For more information about the relationship between the parameters in the Parameter Estimates report and the expected value and variance of the fitted distributions, see \textit{Basic Analysis}.

Sigma Quality Statistics

The Sigma Quality statistics for each Portion (Below LSL, Above USL, and Total Outside) are calculated as follows:

\[
\text{Sigma Quality} = \Phi^{-1}_{1 - \text{Pct}/100} + 1.5
\]

where:

- \text{Pct} is the value in the Percent column of the report.
- \(\Phi^{-1}_{1 - \text{Pct}/100}\) is the \(1 - \text{Pct}/100\)\textsuperscript{th} quantile of a standard normal distribution.
**Note:** Even though the Percent Below LSL and Percent Above USL sum to the Percent Total Outside value, the Sigma Quality Below LSL and Sigma Quality Above USL values do not sum to the Sigma Quality Total Outside value. This is because calculating Sigma Quality involves finding normal distribution quantiles, and is therefore not additive.

### Benchmark Z Statistics

Benchmark Z statistics are available only for capability analyses based on the normal distribution. The Benchmark Z statistics are calculated as follows:

\[
\begin{align*}
Z_{\text{Bench}} &= \Phi^{-1}(1 - P(\text{LSL}) - P(\text{USL})) \\
Z_{\text{LSL}} &= \frac{\mu - \text{LSL}}{\sigma} = 3 \times \text{Cpl} \\
Z_{\text{USL}} &= \frac{\text{USL} - \mu}{\sigma} = 3 \times \text{Cpu}
\end{align*}
\]

where:
- \(\text{LSL}\) is the lower specification limit.
- \(\text{USL}\) is the upper specification limit.
- \(\mu\) is the sample mean.
- \(\sigma\) is the sample standard deviation.
- \(\Phi^{-1}(1 - P(\text{LSL}) - P(\text{USL}))\) is the \((1 - P(\text{LSL}) - P(\text{USL}))\)th quantile of a standard normal distribution.
- \(P(\text{LSL}) = \text{Prob}(X < \text{LSL}) = 1 - \Phi(Z_{\text{LSL}})\).
- \(P(\text{USL}) = \text{Prob}(X > \text{USL}) = 1 - \Phi(Z_{\text{USL}})\).
- \(\Phi\) is the standard normal cumulative distribution function.

### Statistical Details for V-Mask CUSUM Control Charts

The following notation is used in these formulas:

- \(\mu\) denotes the mean of the population, also referred to as the process mean or the process level.
- \(\mu_0\) denotes the target mean (or goal) for the population. Sometimes, the symbol \(\bar{X}_0\) is used for \(\mu_0\). See the American Society for Quality Statistics Division (2004). You can provide \(\mu_0\) as the Target in the Known Statistics for CUSUM Chart area on the launch window.
- \(\sigma\) denotes the population standard deviation. \(\hat{\sigma}\) denotes an estimate of \(\sigma\).
- \(\sigma_0\) denotes a known standard deviation. You can provide \(\sigma_0\) as the Sigma in the Known Statistics for CUSUM Chart area on the launch window.
Chapter 12
Legacy Control Charts

n denotes the nominal sample size for the CUSUM chart.

δ denotes the shift in μ to be detected, expressed as a multiple of the standard deviation. You can provide δ as the Delta in the Known Statistics for CUSUM Chart area on the launch window.

Δ denotes the shift in μ to be detected, expressed in data units. If the sample size n is constant across subgroups, then the following computation applies:

\[ \Delta = \delta \sigma \bar{X} = (\delta \sigma) / \sqrt{n} \]

You can provide Δ as the Shift in the Known Statistics for CUSUM Chart area on the launch window.

Note: Some authors use the symbol D instead of Δ.

One-Sided CUSUM Charts

Positive Shifts

If the shift δ to be detected is positive, the CUSUM for the \( t^{th} \) subgroup is computed as follows:

\[ S_t = \max(0, S_{t-1} + (z_t - k)) \]

t = 1, 2, ..., n, where \( S_0 = 0 \), \( z_t \) is defined as for two-sided charts, and the parameter \( k \), termed the reference value, is positive. If the parameter \( k \) is not specified in the launch window, \( k \) is set to \( \delta / 2 \). The CUSUM \( S_t \) is referred to as an upper cumulative sum. \( S_t \) can be computed as follows:

\[
\max \left( 0, S_{t-1} + \frac{\bar{X}_t - (\mu_0 + k \sigma \bar{X}_t)}{\sigma \bar{X}_t} \right)
\]

The sequence \( S_t \) cumulates deviations in the subgroup means greater than \( k \) standard errors from \( \mu_0 \). If \( S_t \) exceeds a positive value \( h \) (referred to as the decision interval), a shift or out-of-control condition is signaled.

Negative Shifts

If the shift to be detected is negative, the CUSUM for the \( t^{th} \) subgroup is computed as follows:

\[ S_t = \max(0, S_{t-1} - (z_t + k)) \]
\[ t = 1, 2, ..., n, \text{ where } S_0 = 0, z_t \text{ is defined as for two-sided charts, and the parameter } k, \text{ termed the reference value, is positive. If the parameter } k \text{ is not specified in the launch window, } k \text{ is set to } \delta/2. \text{ The CUSUM } S_t \text{ is referred to as a lower cumulative sum. } S_t \text{ can be computed as follows:} \]

\[
\max \left( 0, S_{t-1} + \frac{\bar{X}_t - (\mu_0 - k \sigma \bar{X}_t^N)}{\sigma \bar{X}_t^N} \right)
\]

The sequence \( S_t \) cumulates the absolute value of deviations in the subgroup means less than \( k \) standard errors from \( \mu_0 \). If \( S_t \) exceeds a positive value \( h \) (referred to as the decision interval), a shift or out-of-control condition is signaled.

Note that \( S_t \) is always positive and \( h \) is always positive, regardless of whether \( \delta \) is positive or negative. For charts designed to detect a negative shift, some authors define a reflected version of \( S_t \) for which a shift is signaled when \( S_t \) is less than a negative limit.

Lucas and Crosier (1982) describe the properties of a fast initial response (FIR) feature for CUSUM charts in which the initial CUSUM \( S_0 \) is set to a “head start” value. Average run length calculations given by them show that the FIR feature has little effect when the process is in control and that it leads to a faster response to an initial out-of-control condition than a standard CUSUM chart. You can provide a Head Start value in the Known Statistics for CUSUM Chart area on the launch window.

**Constant Sample Sizes**

When the subgroup sample sizes are constant (= \( n \)), it might be preferable to compute CUSUMs that are scaled in the same units as the data. CUSUMs are then computed as follows:

\[
S_t = \max(0, S_{t-1} + (\bar{X}_t - (\mu_0 + k \sigma / \sqrt{n})))
\]

where \( \delta > 0 \)

\[
S_t = \max(0, S_{t-1} - (\bar{X}_t - (\mu_0 - k \sigma / \sqrt{n})))
\]

where \( \delta < 0 \). In either case, the parameter \( k \) is rescaled to \( k' = k\sigma / \sqrt{n} \). If the parameter \( k \) is not specified in the launch window, \( k' \) is set to \( \delta/2 \). A shift is signaled if \( S_t \) exceeds \( h' = h\sigma / \sqrt{n} \).

Some authors use the symbol \( H \) for \( h' \).

**Two-Sided CUSUM Charts**

If the CUSUM chart is two-sided, the cumulative sum \( S_t \) plotted for the \( t^{th} \) subgroup is defined as follows:

\[
S_t = S_{t-1} + z_t
\]
Chapter 12
Legacy Control Charts

Quality and Process Methods

Statistical Details for the Control Chart Platform

$t = 1, 2, ..., n$. Here $S_0=0$, and the term $z_t$ is calculated as follows:

$$z_t = (\bar{X}_t - \mu_0)/(\sigma / \sqrt{n_t})$$

where $\bar{X}_t$ is the $t^{th}$ subgroup average, and $n_t$ is the $t^{th}$ subgroup sample size. If the subgroup samples consist of individual measurements $x_t$ the term $z_t$ simplifies to the following computation:

$$z_t = (x_t - \mu_0)/\sigma$$

The first equation can be rewritten as follows:

$$S_t = \sum_{i=1}^{t} z_i = \sum_{i=1}^{t} (\bar{X}_i - \mu_0)/\sigma_{\bar{X}_i}$$

where the sequence $S_t$ cumulates standardized deviations of the subgroup averages from the target mean $\mu_0$.

In many applications, the subgroup sample sizes $n_i$ are constant ($n_i = n$), and the equation for $S_t$ can be simplified:

$$S_t = (1/\sigma_{\bar{X}}) \sum_{i=1}^{t} (\bar{X}_i - \mu_0) = (1/\sqrt{n}) \sum_{i=1}^{t} (\bar{X}_i - \mu_0)$$

In some applications, it might be preferable to compute $S_t$ as follows:

$$S_t = \sum_{i=1}^{t} (\bar{X}_i - \mu_0)$$

which is scaled in the same units as the data. In this case, the procedure rescales the V-mask parameters $h$ and $k$ to $h' = h\sigma / \sqrt{n}$ and $k' = k\sigma / \sqrt{n}$, respectively. Some authors use the symbols $F$ for $k'$ and $H$ for $h'$.

If the process is in control and the mean $\mu$ is at or near the target $\mu_0$, the random walk model applies. Therefore, the points might wander away from zero, but they will not exhibit a large trend since positive and negative displacements from $\mu_0$ tend to cancel each other. If $\mu$ shifts in the positive direction, the points exhibit an upward trend, and if $\mu$ shifts in the negative direction, the points exhibit a downward trend.
Statistical Details for Weighted Moving Average Charts

Control Limits for UWMA Charts

Control limits for UWMA charts are computed for each subgroup $i$ as follows:

$LCL_i = \mu_0 - k\frac{\hat{\sigma}}{\min(i, w)} \left[ \frac{1}{n_i} + \frac{1}{n_{i-1}} + \ldots + \frac{1}{n_{1+\max(i-w, 0)}} \right]$ 

$UCL_i = \mu_0 + k\frac{\hat{\sigma}}{\min(i, w)} \left[ \frac{1}{n_i} + \frac{1}{n_{i-1}} + \ldots + \frac{1}{n_{1+\max(i-w, 0)}} \right]$ 

where:

- $w$ is the span parameter (number of terms in moving average)
- $n_i$ is the sample size of the $i$th subgroup
- $k$ is the number of standard deviations
- $\mu_0$ is the weighted average of the subgroup means
- $\hat{\sigma}$ is the estimated process standard deviation

Control Limits for EWMA Charts

Control limits for EWMA charts are computed as follows:

$LCL = \mu_0 - k\hat{\sigma} \left[ \sum_{j=0}^{i-1} \frac{(1-r)^{2j}}{n_i-j} \right]$ 

$UCL = \mu_0 + k\hat{\sigma} \left[ \sum_{j=0}^{i-1} \frac{(1-r)^{2j}}{n_i-j} \right]$ 

where:

- $r$ is the EWMA weight parameter ($0 < r \leq 1$)
- $x_{ij}$ is the $j$th measurement in the $i$th subgroup, with $j = 1, 2, 3, \ldots, n_i$
- $n_i$ is the sample size of the $i$th subgroup
- $k$ is the number of standard deviations
- $\mu_0$ is the weighted average of the subgroup means
- $\hat{\sigma}$ is the estimated process standard deviation
Chapter 13

Pareto Plots
Focus Improvement Efforts on the Vital Few

Improve the statistical quality of your process or operation using Pareto plots. A Pareto plot is a chart that shows severity (frequency) of problems in a quality-related process or operation. Pareto plots help you decide which problems to solve first by highlighting the frequency and severity of problems.

Overview of the Pareto Plot Platform

The Pareto Plot platform produces charts to display the relative frequency or severity of problems in a quality-related process or operation. The Pareto plot is displayed initially as a bar chart that shows the classification of problems arranged in decreasing order. The column whose values are the cause of a problem is assigned the Y role and is called the process variable.

You can also generate a comparative Pareto plot, which combines two or more Pareto plots for the same process variable. The single display shows plots for each value in a column assigned the X role, or combination of levels from two X variables. Columns assigned the X role are called classification variables.

The Pareto plot can chart a single Y (process) variable with no X classification variables, with a single X, or with two X variables. The Pareto function does not distinguish between numeric and character variables or between modeling types. You can switch between a bar chart and a pie chart. All values are treated as discrete, and bars or wedges represent either counts or percentages.

Example of the Pareto Plot Platform

This example uses the Failure.jmp sample data table, which contains failure data and a frequency column. It lists causes of failure during the fabrication of integrated circuits and the number of times each type of defect occurred. From the analysis, you can determine which factors contribute most toward process failure.

1. Select Help > Sample Data Library and open Quality Control/Failure.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
3. Select failure and click Y, Cause.
   This column lists the causes of failure. It is the variable that you want to inspect.
4. Select N and click Freq.
   This column list the number of times that each type of failure occurred.
5. Click OK.
The left axis represents the count of failures, and the right axis represents the percent of failures in each category. The bars are in decreasing order with the most frequently occurring failure to the left. The curve indicates the cumulative failures from left to right.

6. Click the Pareto Plot red triangle and select **Label Cum Percent Points**.

   Note that Contamination accounts for approximately 45% of the failures. The point above the Oxide Defect bar shows that Contamination and Oxide Defect together account for approximately 71% of the failures.

7. Click the Pareto Plot red triangle and deselect **Label Cum Percent Points** and **Show Cum Percent Curve**.

8. Click the label for the y-axis labeled N and rename it **Count**.

9. Double-click the y-axis to display the **Y Axis Settings** window.
   - In the **Maximum** field, type 15.
   - In the **Increment** field, type 2.
   - In the **Axis Label Row** panel, select **Grid Lines** for the **Major** grid line.
   - Click **OK**.

10. Click the Pareto Plot red triangle and select **Category Legend**.
Figure 13.3 Pareto Plot with Display Options

Figure 13.3 shows the counts of different types of failures and has a category legend. The vertical count axis is rescaled and has grid lines at the major tick marks.

11. To view the data as a pie chart, click the Pareto Plot red triangle and select Pie Chart.

Contamination and Oxide Defect clearly represent the majority of the failures.
Launch the Pareto Plot Platform

Launch the Pareto Plot platform by selecting Analyze > Quality and Process > Pareto Plot.

Figure 13.5 The Pareto Plot Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The Pareto Plot launch window contains the following options:

Y, Cause  Identifies the column whose values are the cause of a problem. It is called the 
process variable and is the variable that you want to inspect.

X, Grouping  Identifies the grouping factor. The grouping variable produces one Pareto plot 
window with side-by-side plots for each value. You can have no grouping variable, one 
grouping variable (see “One-Way Comparative Pareto Plot Example” on page 385), or two 
grouping variables (see “Two-Way Comparative Pareto Plot Example” on page 387).

Weight  Assigns a variable to give the observations different weights.

Freq  Identifies the column whose values hold the frequencies.

By  Identifies a variable to produce a separate analysis for each value that appears in the 
column.

Threshold of Combined Causes  Enables you to specify a threshold for combining causes by 
specifying a minimum rate or count. Select the option and then select Tail % or Count and 
enter the threshold value. The Tail percent option combines smaller count groups against 
the percentage specified of the total (combined small groups count/total group count). The 
Count option enables you to specify a specific count threshold. For an example, see 
“Threshold of Combined Causes Example” on page 381.

Per Unit Analysis  Enables you to compare defect rates across groups. JMP calculates the 
defect rate as well as 95% confidence intervals of the defect rate. Select the option and then 
select Constant or Value in Freq Column and enter the sample size value or cause code, 
respectively. The Constant option enables you to specify a constant sample size on the
launch window. The Value In Freq Column option enables you to specify a unique sample size for a group through a special cause code to designate the rows as cause rows.

Although causes are allowed to be combined in Pareto plots, the calculations for these analyses do not change correspondingly.

For examples, see “Using a Constant Size across Groups Example” on page 382 and “Using a Non-Constant Sample Size across Groups Example” on page 384.

The Pareto Plot Report

The Pareto plot combines a bar chart displaying percentages of variables in the data with a line graph showing cumulative percentages of the variables.

Figure 13.6  Pareto Plot Example

The Pareto plot can chart a single $Y$ (process) variable with no $X$ classification variables, with a single $X$, or with two $X$ variables. The Pareto plot does not distinguish between numeric and character variables or between modeling types. All values are treated as discrete, and bars represent either counts or percentages. The following list describes the arrangement of the Pareto plot:

- A $Y$ variable with no $X$ classification variables produces a single chart with a bar for each value of the $Y$ variable. For an example, see “Example of the Pareto Plot Platform” on page 373.
• A $Y$ variable with one $X$ classification variable produces a row of Pareto plots. There is a plot for each level of the $X$ variable with bars for each $Y$ level. These plots are referred to as the *cells* of a comparative Pareto plot. There is a cell for each level of the $X$ (classification) variable. Because there is only one $X$ variable, this is called a *one-way comparative Pareto plot*. For an example, see “One-Way Comparative Pareto Plot Example” on page 385.

• A $Y$ variable with two $X$ variables produces rows and columns of Pareto plots. There is a row for each level of the first $X$ variable and a column for each level of the second $X$ variable. Because there are two $X$ variables, this is called a *two-way comparative Pareto plot*. The rows have a Pareto plot for each value of the first $X$ variable, as described previously. The upper left cell is called the *key cell*. Its bars are arranged in descending order. The bars in the other cells are in the same order as the key cell. You can reorder the rows and columns of cells. The cell that moves to the upper left corner becomes the new key cell and the bars in all other cells rearrange accordingly. For an example, see “Two-Way Comparative Pareto Plot Example” on page 387.

• Each bar is the color for which the rows for that $Y$ level are assigned in the associated data table. Otherwise, a single color is used for all of the bars whose $Y$ levels do not have rows with an assigned color. If the rows for a $Y$ level have different colors, the bar for that $Y$ level is the color of the first row for that $Y$ level in the data table.

You can change the type of scale and arrangement of bars and convert the bars into a pie chart using the options in the Pareto Plot red triangle menu. See “Pareto Plot Platform Options” on page 378.

---

**Pareto Plot Platform Options**

The Pareto Plot red triangle menu contains options that customize the appearance of the plots. It also has options in the *Causes* submenu that affect individual bars within a Pareto plot. The following commands affect the appearance of the Pareto plot as a whole:

**Percent Scale**  Shows or hides the count and percent left vertical axis display.

**N Legend**  Shows or hides the total sample size in the plot area.

**Category Legend**  Shows or hides labeled bars and a separate category legend.

**Pie Chart**  Shows or hides the bar chart and pie chart representation.

**Reorder Horizontal, Reorder Vertical**  Reorders grouped Pareto plots when there is one or more grouping variables.

**Ungroup Plots**  Splits up a group of Pareto charts into separate plots.

**Count Analysis**  Performs defect per unit analyses. Enables you to compare defect rates and perform ratio tests across and within groups:
Per Unit Rates  Compares defect rates across groups. If a sample size is specified, Defects Per Unit (DPU) and Parts Per Million (PPM) columns are added to the report.

Test Rate Within Groups  Performs a likelihood ratio Chi-square test to determine whether the rates across causes are the same within a group. See “Statistical Details for the Pareto Plot Platform” on page 388.

Test Rates Across Groups  Performs a likelihood ratio Chi-square test to determine whether the rate for each cause is the same across groups. See “Statistical Details for the Pareto Plot Platform” on page 388.

Show Cum Percent Curve  Shows or hides the cumulative percent curve above the bars and the cumulative percent axis on the vertical right axis.

Show Cum Percent Axis  Shows or hides the cumulative percent axis on the vertical right axis.

Show Cum Percent Points  Shows or hides the points on the cumulative percent curve.

Label Cum Percent Points  Shows or hides the labels on the points on the cumulative curve.

Cum Percent Curve Color  Changes the color of the cumulative percent curve.

Causes  Has options that affect one or more individual chart bars. See “Causes Options” on page 380, for a description of these options.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Causes Options

You can highlight a bar by clicking on it. Use Control-click to select multiple bars that are not contiguous. When you select bars, you can access the commands on the red triangle menu that affect Pareto plot bars. They are found on the Causes submenu on the red triangle menu. These options are also available with a right-click anywhere in the plot area. The following options apply to highlighted bars instead of to the chart as a whole:

**Combine Causes**  Combines selected (highlighted) bars. You can select either Selected, Last Causes, First Causes or select from a list of variables.

![Figure 13.7 Combine Causes Window](image)

**Separate Causes**  Separates selected bars into their original component bars.

**Move to First**  Moves one or more highlighted bars to the left (first) position.

**Move to Last**  Moves one or more highlighted bars to the right (last) position.

**Colors**  Shows the colors palette for coloring one or more highlighted bars.

**Markers**  Shows the markers palette for assigning a marker to the points on the cumulative percent curve, when the Show Cum Percent Points command is in effect.

**Label**  Displays the bar value at the top of all highlighted bars.

Additional Examples of the Pareto Plot Platform

- “Threshold of Combined Causes Example”
- “Using a Constant Size across Groups Example”
- “Using a Non-Constant Sample Size across Groups Example”
- “One-Way Comparative Pareto Plot Example”
- “Two-Way Comparative Pareto Plot Example”
Threshold of Combined Causes Example

This example uses the Failure.jmp sample data table, which contains failure data and a frequency column. It lists causes of failure during the fabrication of integrated circuits and the number of times each type of defect occurred. A threshold value of 2 is specified for this example.

1. Select Help > Sample Data Library and open Quality Control/Failure.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
3. Select failure and click Y, Cause.
4. Select N and click Freq.
5. Select Threshold of Combined Causes and then select Count.
6. Enter 2 as the threshold value.
7. Click OK.

Figure 13.8 Pareto Plot with a Threshold Count of 2

Figure 13.8 displays the plot after specifying a count of 2. All causes with counts 2 or fewer are combined into the final bar labeled 4 Others.

8. To separate the combined bars into original categories as shown in Figure 13.9, select Causes > Separate Causes.
Using a Constant Size across Groups Example

This example uses the Failures.jmp sample data table, which contains failure data and a frequency column. It lists causes of failure during the fabrication of integrated circuits and the number of times each type of defect occurred for two processes. A constant sample size of 1000 is specified for this example.

1. Select Help > Sample Data Library and open Quality Control/Failures.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
4. Select Process and click X, Grouping.
5. Select Count and click Freq.
6. Select Per Unit Analysis and then select Constant.
7. Enter 1000 in Sample Size.
8. Click OK.
Process A indicates Contamination as the top failure while Process B indicates Oxide Defect as the leading failure.

9. Click the Pareto Plot red triangle and select **Count Analysis > Test Rates Across Groups**.

**Figure 13.11 Test Rates across Groups Results**

Note that the DPU for Contamination across groups (Process A and B) is around 0.06.
Using a Non-Constant Sample Size across Groups Example

This example uses the Failuressize.jmp sample data table, which contains failure data and a frequency column. It lists causes of failure during the fabrication of integrated circuits and the number of times each type of defect occurred for two processes. Among the other causes (Oxide Defect, Silicon Defect, and so on) is a cause labeled size. Specifying size as the cause code designates the rows as size rows.

1. Select Help > Sample Data Library and open Quality Control/Failuressize.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
4. Select Process and click X, Grouping.
5. Select Count and click Freq.
6. Select Per Unit Analysis and then select Value in Freq Column.
7. Enter size in Cause Code.
8. Click OK.

Figure 13.12 Pareto Plot Report Window

9. Click the Pareto Plot red triangle and select Count Analysis > Per Unit Rates and Count Analysis > Test Rates Across Groups.
Chapter 13 Pareto Plots 385
Quality and Process Methods Additional Examples of the Pareto Plot Platform

Figure 13.13 Per Unit Rates and Test Rates across Groups Results

Note that the sample size of 101 is used to calculate the DPU for the causes in group A. However, the sample size of 145 is used to calculate the DPU for the causes in group B.

If there are two group variables (say, Day and Process), Per Unit Rates lists DPU or rates for every combination of Day and Process for each cause. However, Test Rate Across Groups only tests overall differences between groups.

One-Way Comparative Pareto Plot Example

This example uses the Failure2.jmp sample data table. This table records failures in a sample of capacitors manufactured before cleaning a tube in the diffusion furnace and in a sample manufactured after cleaning the furnace. For each type of failure, the variable clean identifies the samples with the values “before” or “after.”

1. Select Help > Sample Data Library and open Quality Control/Failure2.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
3. Select failure and click Y, Cause.
4. Select clean and click X, Grouping.
5. Select N and click Freq.
6. Click OK.
Figure 13.14 displays the side-by-side plots for each value of the variable, clean.

**Figure 13.14** One-way Comparative Pareto Plot

The horizontal and vertical axes are scaled identically for both plots. The bars in the first plot are in descending order of the \( y \)-axis values and determine the order for all cells.

7. Rearrange the order of the plots by clicking the title (after) in the first tile and dragging it to the title of the next tile (before).

A comparison of these two plots shows a reduction in oxide defects after cleaning. However, the plots are easier to interpret when presented as the before-and-after plot shown in Figure 13.15. Note that the order of the causes changes to reflect the order based on the first cell.
Figure 13.15 One-way Comparative Pareto Plot with Reordered Cells

Two-Way Comparative Pareto Plot Example

This example uses the Failure3.jmp sample data table. The data monitors production samples before and after a furnace cleaning for three days for a capacitor manufacturing process. The data table has a column called date with values OCT 1, OCT 2, and OCT 3.

1. Select Help > Sample Data Library and open Quality Control/Failure3.jmp.
2. Select Analyze > Quality and Process > Pareto Plot.
3. Select failure and click Y, Cause.
4. Select clean and date and click X, Grouping.
5. Select N and click Freq.
6. Click OK.

Figure 13.16 displays the Pareto plot with a two-way layout of plots that show each level of both X variables. The upper left cell is called the key cell. Its bars are arranged in descending order. The bars in the other cells are in the same order as the key cell.

7. Click Contamination and Metallization in the key cell and the bars for the corresponding categories highlight in all other cells.
Figure 13.16 Two-way Comparative Pareto Plot

The Pareto plot illustrates highlighting the *vital few*. In each cell of the two-way comparative plot, the bars representing the two most frequently occurring problems are selected. Contamination and Metallization are the two vital categories in all cells. After furnace cleaning, Contamination is less of a problem.

Statistical Details for the Pareto Plot Platform

Likelihood Ratio Chi-Square Test

Notation

The likelihood ratio Chi-square test statistic computed in the Pareto Plot platform uses the following notation:

- \( n_{ij} \) is the count for Cause \( i \) in Group \( j \).
• $E_j$ is the expected count for Group $j$. This is the mean count of each group, across causes.
• $E_i$ is the expected count for Cause $i$. This is the mean count of each cause, across groups.

**Likelihood Ratio Chi-Square Test Statistic within Groups**

$$G_j^2 = 2 \sum_{i=1}^{K} n_{ij} \ln \left( \frac{n_{ij}}{E_j} \right)$$

**Likelihood Ratio Chi-Square Test Statistic across Groups**

$$G_i^2 = 2 \sum_{j=1}^{J} n_{ij} \ln \left( \frac{n_{ij}}{E_i} \right)$$
Use the Diagram platform to construct cause-and-effect diagrams, also known as *Ishikawa charts* or *fishbone charts*. Use these diagrams to:

- Organize the causes of an effect (sources of a problem)
- Brainstorm
- Identify variables in preparation for further experimentation

Example of a Cause-and-Effect Diagram

You have data about defects in a circuit board. You want to examine the major factors and possible causes of the defects in a diagram.

1. Select **Help > Sample Data Library** and open Ishikawa.jmp.
2. Select **Analyze > Quality and Process > Diagram**.
3. Select Parent and click **X, Parent**.
4. Select Child and click **Y, Child**.
5. Click **OK**.

![Ishikawa.jmp Diagram](image)

The major factors are Inspection, Solder process, Raw card, Components, and Component insertion. From each major factor, possible causes branch off, such as Inspection, Measurement, and Test coverage for the Inspection factor.

You can focus on one area at a time to further examine the possible causes or sources of variation for each major factor.
Prepare the Data

Before you produce the diagram, begin with your data in two columns of a data table.

**Figure 14.3** Example of the Ishikawa.jmp Data Table

Notice that the **Parent** value Defects in circuit board (the effect) has five major factors, listed in the **Child** column. One of these major factors is Inspection, which has its own causes listed in the **Child** column. Parent values have children, and children can have their own children (and therefore be listed in both the **Parent** and **Child** columns.)

Launch the Diagram Platform

Launch the Diagram platform by selecting **Analyze > Quality And Process > Diagram**.

**Figure 14.4** The Diagram Launch Window
For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Tip:** To create a basic diagram that is not based on a data table, leave the **Y, Child**, and **X, Parent** fields empty and click **OK**. Then edit the nodes using the options in the right-click menu. See “**Right-Click Menus**” on page 395.

**Y, Child**  Represents the child factors contributing to the parent factors.

**X, Parent**  Represents the parent factors (including the effect) that have child factors.

**Label**  Includes the text from the Label columns in the nodes of the diagram.

**By**  Produces separate diagrams for each value of the By variable.

---

**The Cause-and-Effect Diagram**

In Figure 14.5, the effect or problem, Defects in circuit board, appears on the right as the center line. The major contributing factors appear at the end of the branches (Inspection, Solder process, Raw Card, and so on.) Possible causes branch off each major factor.

**Figure 14.5  Cause-and-Effect Diagram**

---

**Right-Click Menus**

Right-click a highlighted node to modify text, insert new nodes, change the diagram type, and more. Note the following:

- Right-click a title to change the font and color, positioning, visibility, or formatting.
- Click and highlight a node to rename it.
- Click and drag a node to move it.
Text Menu

The Text menu contains the following options:

Font  Select the font of the text or numeric characters.

Color  Select the color of the text or numeric characters.

Rotate Left, Rotate Right, Horizontal  Rotates the text or numbers to be horizontal, 90 degrees left, or 90 degrees right.

Insert Menu

Use the Insert menu to insert items onto existing nodes. The Insert menu contains the following options:

Before  Inserts a new node to the right of the highlighted node. For example, Figure 14.6 inserts Child 1.5 before Child 2.

After  Inserts a new node to the left of the highlighted node. For example, Figure 14.7 inserts Child 3 after Child 2.

Above  Inserts a new node at a level above the current node. For example, Figure 14.8 inserts Grandparent at a level above Parent.

Figure 14.6  Insert Before

Figure 14.7  Insert After

Figure 14.8  Insert Above
**Below**  Inserts a new node at a level below the current node. For example, Figure 14.9 inserts Grandchild at a level below Child 2.

**Figure 14.9**  Insert Below

Use the Move menu to move nodes or branches. The Move menu contains the following options:

- **First**: Moves the highlighted node to the first position under its parent.
- **Last**: Moves the highlighted node to the last position under its parent.
- **Other Side**: Moves the highlighted node to the opposite side of its parent line.
- **Force Left**: Makes all horizontally drawn elements appear to the left of their parent.
- **Force Right**: Makes all horizontally drawn elements appear to the right of their parent.
- **Force Up**: Makes all vertically drawn elements appear above their parent.
- **Force Down**: Makes all vertically drawn elements appear below their parent.
- **Force Alternate**: Draws children on alternate sides of the parent line.
**Figure 14.10 Force Options**

**Force Left**

**Force Alternate**

**Force Right**

**Force Up**

**Force Down**

### Other Menu Options

The right-click menu for a highlighted node also contains these options:

- **Change Type** Changes the entire chart type to **Fishbone**, **Hierarchy**, or **Nested**.
- **Uneditable** Disables all other commands except **Move** and **Change Type**.
- **Text Wrap Width** Specifies the width of labels where text wrapping occurs.
- **Make Into Data Table** Converts the currently highlighted node into a data table. Convert the all nodes by highlighting the whole diagram (effect).
- **Close** Shows the highlighted node.
- **Delete** Deletes the highlighted node and all of its children.

### Cause and Effect Diagram Menu Options

The Cause and Effect Diagram red triangle menu contains the following options:

See *Using JMP* for more information about the following options:

- **Redo** Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.
Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Save the Diagram

There are different ways to save your diagram. Choose from one of the following:

- save the diagram as a data table
- save the diagram as a journal
- save the diagram as a script

Save the Diagram as a Data Table

Note the following about this approach:

- If you have other processes that need to update the data table, this can be a good approach to choose.
- Very little customization is available, because the data table cannot represent the customization.

To save the diagram as a data table:

1. Highlight the entire diagram.
2. Right-click and select Make Into Data Table.
3. Save the new data table.

Save the Diagram as a Journal

Note the following about this approach:

- This option can be a good choice for impromptu work. For example, you can manually build the diagram, save it as a journal, then reopen the journal later and continue building and editing the diagram.
- Any customization exists only in the journal, and the journal is not connected to the data table.
To save the diagram as a journal:
1. Highlight the entire diagram.
2. Right-click and select Edit > Journal.
3. Save the new journal.

Save the Diagram as a Script

Note the following about this approach:

- If you have other processes that need to update the data table, this can be a good approach to choose.
- If you created the diagram from a data table, a simple script appears that relaunches against the data table with no customization.
- If you created the diagram without using a data table (or from a journal), a more complex script appears that contains all the commands needed to add and customize each area of the diagram.

To save the diagram as a script:
1. Click the red triangle next to Cause and Effect Diagram and select Save Script > To Script Window.
2. Save the new script.
This chapter covers utilities in the Analyze > Quality and Process menu. Specifically, the Manage Spec Limits utility and OC Curves utility are discussed.
## Contents

  - Launch the OC Curves Utility .......................................................... 407
  - OC Curves for Control Chart Options .............................................. 408
  - OC Curves for Acceptance Sampling Options ................................... 408
Quality Utilities

Manage Spec Limits Utility

The Manage Spec Limits utility enables you to quickly add or edit many specification limits for several columns at once. The specification limits are then used in any future analyses. You can also specify importance values for each process and indicate whether limits should appear in graphs as reference lines.

Example of the Manage Spec Limits Utility

1. Select Help > Sample Data Library and open Cities.jmp.
2. Select Analyze > Quality and Process > Manage Spec Limits.
3. Specify the columns that you want to set specification limits on. For this example, select OZONE, CO, SO2, and NO, and click Process Variables.

![Figure 15.1 Specify Columns](image)

4. Click OK.
5. Add your specification limits. You can do this by loading existing limits from a JMP data table (Load from Limits Table) or by entering limits manually. For this example, enter the following limits manually:
   - **OZONE**: LSL 0.12, USL 0.2
   - **CO**: LSL 6, USL 12
   - **SO2**: LSL 0.015, USL 0.06
   - **NO**: LSL 0.02, USL 0.04
6. Click the red triangle next to Manage Spec Limits and select Show Limits All.
Specification limits for all columns will appear in graphs for any future analyses. If you want to show the specification limits only for individual columns, check the **Show Limits** box next to those columns.

**Figure 15.2** Set Specification Limits

<table>
<thead>
<tr>
<th>Column</th>
<th>LSL</th>
<th>Target</th>
<th>USL</th>
<th>Show Limits</th>
<th>Process Importance</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>OZONE</td>
<td>0.12</td>
<td></td>
<td>0.2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CO</td>
<td>6</td>
<td></td>
<td>12</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SO2</td>
<td>0.015</td>
<td></td>
<td>0.06</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>NO</td>
<td>0.02</td>
<td></td>
<td>0.04</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

7. Choose how you want to save the specification limits. For this example, click **Save to Column Properties**. This saves them as column properties in the corresponding data table. You could also save them to a new data table (tall or wide format).

   In the Cities.jmp data table Columns panel, notice that asterisks indicating the Spec Limits column property appear next to OZONE, CO, SO2, and NO.

8. To see values that are outside the limits in the data table, click the red triangle next to Manage Spec Limits and select **Color Out of Spec Values**. Go to the Cities.jmp data table, and you can see that any values that are outside the limits are now colored.

9. Now, you can run any analysis. For this example, select **Analyze > Distribution**.

10. Select OZONE, CO, SO2, and NO, and click **Y, Columns**.

11. Click **OK**.
Figure 15.3 Specification Limits for OZONE in Distribution

The specification limits that you added to the OZONE column appear in the histogram. Because the column contains a Spec Limits column property, the Distribution report also contains a Capability Analysis report.
Manage Spec Limits Options

In the window where you set specification limits, there are buttons to save and load specification limits, and options in the Manage Spec Limits red triangle menu.

Report Table Columns

The table at the top of the Manage Spec Limits report contains a row for each process column specified in the launch window. This table enables you to specify specification limits as well as the following options for each column:

**Show Limits**  Specifies that the Show as Graph Reference Lines option is selected in the Spec Limits column property for the specified column.

**Process Importance**  Specifies the process importance value for each column. Process importance values provide a mechanism to sort processes in the order that you prefer. Process importance values are used to size markers in many platform graphs.

**Units**  Specifies the units for each column.

Buttons

**Load from Limits Table**  Loads specification limits from a JMP data table.

**Save to Column Properties**  Saves the specification limits as column properties in the associated data table.

**Save to Tall Spec Limits Table**  Saves the specification limits to a new data table in tall format.

**Save to Wide Spec Limits Table**  Saves the specification limits to a new data table in wide format.

Red Triangle Options

**Show Limits All**  Selects boxes under Show Limits for all of the columns. If Show Limits is selected for a column, the Show as Graph Reference Lines option is selected in the Spec Limits column property. The Show as Graph Reference Lines option displays the specification limits and target that you specify as reference lines in select analysis plots.

**Note:** If all boxes under Show Limits are selected, the Show Limits All option deselects all of the boxes under Show Limits.

**Round Decimals**  Sets the number of decimal places to which you want the specification limits rounded.
Color Out of Spec Values  Colors any values in the data table that are outside the specification limits for the columns.

See Using JMP for more information about the following options:

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Operating Characteristic Curves Utility

The Operating Characteristic (OC) Curves utility enables you to construct OC curves for control charts and attribute acceptance sampling plans. OC curves are available for XBar, P, NP, C, and U charts. For specified control charts, the OC curve shows the probability of failing to detect a shift of a particular size. In addition, there are OC curves for single and double attribute acceptance sampling plans. For a specified acceptance sampling plan, the OC curve shows how the probability of accepting a lot changes with the lot quality.

Note: The OC curves for control charts are two-sided curves. They are drawn for negative and positive shifts. Often OC curves display one curve for the absolute shift.

Launch the OC Curves Utility

Launch the Operating Characteristic Curves by selecting Analyze > Quality and Process > OC Curves. Select the OC curve of interest and click OK to launch.

Figure 15.4  OC Curves Launch Window
OC Curves for Control Chart Options

For control charts, you can use OC curves to explore how specifications impact $\beta$, which is the probability of failing to detect a specified shift of interest. Use the text boxes, sliders, or the LCL, Shift, and UCL handles on the OC curve to set and adjust specifications. The specifications are as follows:

**Lower Control Limit**  Specifies the lower control limit from your control chart.

**Upper Control Limit**  Specifies the upper control limit from your control chart.

**Sample Size**  (Not available for C charts.) Specifies the sample size used for your control chart measure.

**Sigma**  (Available only for XBar charts.) Specifies your control chart sigma.

**Shift**  Specifies the shift to detect.

**Beta**  Specifies the probability of failing to detect the specified shift given the control chart specifications. Beta updates as the specifications are changed.

OC Curves for Acceptance Sampling Options

For attributes acceptance sampling, you can use OC curves to explore how sampling plans and assumed product quality impact the probability of accepting a lot. Use the text boxes, sliders, or fraction defective handle on the OC curve to set and adjust your sampling plan.

Single Sampling OC Curve Options

**Sampling Type**  Enables you to select Lot Sampling or Binomial Sampling.

**Lot Sampling**  Enables you to specify and explore an acceptance plan based on a fixed lot size.

**Binomial Sampling**  Enables you to specify and explore an acceptance plan for a continuous process or other situation where the binomial distribution is appropriate.

**Lot size (N)**  (Available only for Lot Sampling.) Specifies the size of the lot that you are sampling from.

**Sample Size (n)**  Specifies the number of units for inspection.

**Acceptable failures (c1)**  specifies the number of allowable failures. If the number of observed defects is greater than $c1$, then the lot is rejected.

**Fraction Defective**  Specifies the expected fraction defective in the lot.
Probability of Acceptance  Specifies the probability of accepting the lot given the sampling plan as defined. The Probability of Acceptance updates as the specifications are changed, but you can also adjust this value directly. When you adjust the Probability of Acceptance directly, the Fraction Defective value is updated.

Double Sampling OC Curve Options

First Sample  Contains the following specifications for the first sample:

Number inspected (n1)  Specifies the number of units inspected in the first sample.

Acceptable failures (c1)  specifies the number of allowable failures in the first sample.

Second Sample  Contains the following specifications for the second sample:

Number inspected (n2)  Specifies the number of units inspected in the second sample.

Acceptable failures (c1+c2)  specifies the total number of allowable failures.

Fraction Defective  Specifies the expected fraction defective in the lot.

Probability of Acceptance  Specifies the probability of accepting the lot given the sampling plan as defined. The Probability of Acceptance updates as the specifications are changed, but you can also adjust this value directly. When you adjust the Probability of Acceptance directly, the Fraction Defective value is updated.

B Technology License Notices .................................................................. 417
Reliability and Survival Methods describes a number of methods and tools that are available in JMP to help you evaluate and improve reliability in a product or system and analyze survival data for people and products:

- The Life Distribution platform enables you to analyze the lifespan of a product, component, or system to improve quality and reliability. This analysis helps you determine the best material and manufacturing process for the product, thereby increasing the quality and reliability of the product. See Chapter 3, “Life Distribution”.

- The Fit Life by X platform helps you analyze lifetime events when only one factor is present. You can choose to model the relationship between the event and the factor using various transformations, or create a custom transformation of your data. See Chapter 4, “Fit Life by X”.

- The Cumulative Damage platform enables you to analyze an accelerated life test where the stress levels might have changed over time. See Chapter 5, “Cumulative Damage”.

- The Recurrence Analysis platform analyzes event times where the events can recur several times for each unit. Typically, these events occur when a unit breaks down, is repaired, and then put back into service after the repair. See Chapter 6, “Recurrence Analysis”.

- The Degradation platform analyzes degradation data to predict pseudo failure times. These pseudo failure times can then be analyzed by other reliability platforms to estimate failure distributions. You can include an explanatory factor. You can perform stability analysis to set product expiration dates. You can also fit custom destructive degradation models. See Chapter 7, “Degradation”.

- The Destructive Degradation platform models failure data for product characteristics whose measurement requires that the product be destroyed. This results in a single observation per product unit. You can also include an acceleration factor. A wide range of common degradation models is available. See Chapter 8, “Destructive Degradation”.

- The Reliability Forecast platform helps you predict the number of future failures. The analysis estimates the parameters for a life distribution using production dates, failure dates, and production volume. See Chapter 9, “Reliability Forecast”.

- The Reliability Growth platform models the change in reliability of a single repairable system over time as improvements are incorporated into its design. See Chapter 10, “Reliability Growth”.
• The Reliability Block Diagram platform displays the reliability relationship between a system's components and, if reliability distributions are given to the components, analytically obtains the reliability behavior. See Chapter 11, “Reliability Block Diagram”.

• The Repairable Systems Simulation platform enables you to interactively define the relationships between the components of a repairable system. It can also simulate the down time of the system. See Chapter 12, “Repairable Systems Simulation”.

• The Survival platform computes survival estimates for one or more groups. It can be used as a complete analysis or is useful as an exploratory analysis to gain information for more complex model fitting. See Chapter 13, “Survival Analysis”.

• The Fit Parametric Survival platform fits the time to event variable using linear regression models that can involve both location and scale effects. The fit is performed using several distributions. See Chapter 14, “Fit Parametric Survival”.

• The Fit Proportional Hazards platform fits the Cox proportional hazards model, which assumes a multiplying relationship between predictors and the hazard function. See Chapter 15, “Fit Proportional Hazards”.
The Life Distribution platform models time-to-event data. The platform accommodates both right-censored and interval-censored data. Use Life Distribution to do the following:

- Compare multiple distributional fits to determine which distribution best fits your data.
- Construct Bayesian fits.
- Model zero-failure data.
- Compare groups to analyze group differences.
- Analyze multiple causes of failure.
- Estimate the components of a mixture and estimate the probability that an observation comes from a given component.
- Estimate the components of a competing risk mixture and estimate the impact of a component on an observation.

Overview of the Life Distribution Platform

Life data analysis, or life distribution analysis, is the process of modeling the lifespan of a product, component, or system to predict lifetime or time to failure. For example, you can observe failure rates over time to predict when a computer component might fail. This technique enables you to compare materials and manufacturing processes for the product, enabling you to increase the quality and reliability of the product. Decisions on warranty periods and advertising claims can also be more accurate.

With the Life Distribution platform, you can analyze censored data in which some time observations are unknown. And if there are potentially multiple causes of failure, you can analyze the competing causes to estimate which cause is more influential.

You can use the Reliability Test Plan and Reliability Demonstration calculators to choose the appropriate sample sizes for reliability studies. These calculators are found at DOE > Sample Size and Power. See the Design of Experiments Guide.

Example of the Life Distribution Platform

Suppose you have failure times for 70 engine fans, with some of the failure times censored. You want to fit a distribution to the failure times and then estimate various measurements of reliability.

1. Select Help > Sample Data Library and open Reliability/Fan.jmp.
2. Select Analyze > Reliability and Survival > Life Distribution.
4. Select Censor and click Censor.
5. Click OK.

The Life Distribution report window appears.

6. In the Compare Distribution report, select Lognormal distribution and the corresponding Scale radio button.

A probability plot appears in the report window.
Figure 3.2  Probability Plot

In the probability plot, the data points generally fall along the red line, indicating that the lognormal fit is reasonable.

Below the Compare Distributions report, the Statistics report appears. This report provides a Model Comparison report, nonparametric and parametric estimates, profilers, and more.
The parameter estimates for the lognormal distribution are provided. The profilers are useful for visualizing the fitted distribution and for estimating probabilities and quantiles. For example, the Quantile Profiler indicates that the estimated median time to failure is 25,418.67 hours.
Launch the Life Distribution Platform

Launch the Life Distribution platform by selecting **Analyze > Reliability and Survival > Life Distribution**. For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Figure 3.4 The Life Distribution Launch Window**

![Life Distribution Launch Window](image)

**Launch Window Tabs**

The launch window includes two tabs:

- The Life Distribution tab models ungrouped data. The following types of reports can result:
  - The Life Distribution report appears when you do not specify a Failure Cause role. From this report, you can compare common distributions and examine statistics. See “Life Distribution Report” on page 37.
  - The Weibayes report appears when you have zero failures in your data. See “Weibayes Report” on page 59.
  - The Competing Cause report appears when you specify a Failure Cause role. In addition to the features in the Life Distribution report, you can also compare individual failure causes. See “Competing Cause Report” on page 60.

**Note:** You can examine Fixed Parameter and Bayesian models in the Life Distribution and Competing Cause reports.

- The Compare Groups tab enables you to specify a Grouping variable. The Compare Groups report compares different groups using a single specified distribution. For
example, you might compare Weibull fits for components grouped by supplier. In contrast, the Life Distribution tab compares several fitted distributions for a single group. See “Life Distribution - Compare Groups Report” on page 66.

Launch Window Options

The launch window contains the following options:

**Y, Time to Event**  One or more response columns. The number of response columns specified depends on the censoring structure in the data table.

- If one variable is specified, it is interpreted as the time to event (such as the time to failure) or time to right censoring. Use the Censor column to indicate right-censored responses. For more information about right censoring, see “Single Time to Event Column” on page 39.

- If two variables are specified, they are interpreted as interval-censored observations. The first Y variable gives the lower limit and the second Y variable gives the upper limit for each unit. For an example of using two response columns to represent various types of censoring, see Figure 3.5. For more information about censoring with two response columns, see “Two Time to Event Columns” on page 40.

**Figure 3.5** Censored Data Types for Two Response Variables

- If three or more variables are specified, the report contains a separate analysis computed using each specified variable as time to event data.

**Grouping**  (Appears only in the Compare Groups tab.) A column containing the groups that you want to compare. For an example, see “Examine the Same Distribution across Groups” on page 73.

**Censor**  A column that identifies right-censored observations. Select the value that identifies right-censored observations from the Censor Code menu beneath the Select Columns list. The Censor column is used only when one Y is entered.
**Failure Cause**  A column that contains multiple failure causes. If a Failure Cause column is selected, then a section is added to the window. This section contains check boxes that allow the failure mode to use ZI distributions, TH distributions, DS distributions, fixed parameter models, or Bayesian models for the analysis. The following options are also available:

**Distribution**  Specifies the initial distribution to fit for each failure cause. Select one distribution to fit for all causes; select **Individual Best** to let the platform automatically choose the best fit for each cause; or select **Manual Pick** to manually choose the distribution to fit for each failure cause after JMP creates the Life Distribution report. You can also change the distribution fits in the Life Distribution report itself.

**Comparison Criterion**  (Appears only when you choose the **Individual Best** distribution fit.) Specifies the method by which JMP chooses the best distribution: Corrected Akaike Information Criterion (AICc), Bayesian Information Criterion (BIC), or twice the negative log-likelihood (-2Loglikelihood). See *Fitting Linear Models*. You can change the method later in the Model Comparisons report. See “Model Comparisons” on page 45.

**Censor Indicator in Failure Cause Column**  Identifies the value used in the Failure Cause column to indicate that an observation did not fail. To specify such an indicator, select this option and then enter the indicator in the box that appears. You can also select a value from the list to the right of the box.

See Meeker and Escobar (1998, ch. 15) for a discussion of multiple failure causes. “Omit Competing Causes” on page 69 illustrates how to analyze multiple causes.

**Freq**  A column that contains frequencies or observation counts when the information in a row represents multiple units. If the value in a row is 0 or a positive number, then the value represents the frequencies or counts of observations for that row.

**Label**  A column that contains identifiers other than the row number. These labels appear on the Y axis in the event plot.

**By**  An optional variable whose levels define rows used to create separate models.

**Censor Code**  Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.

**Select Confidence Interval Method**  Defines the method used for computing confidence intervals for the parameters. The default is Wald, but you can select Likelihood instead. However, all confidence intervals provided in the profilers are based on the Wald method. This is done to reduce computation time. See “Estimation and Confidence Intervals” on page 83.
Failure Distribution by Cause (Appears only in the Life Distribution tab when a Cause is specified.) Specify which families of distributions should be available to model the life distributions for individual causes. Select an initial distribution, Individual Best, or Manual Pick from the Distribution menu. See “Failure Cause” on page 36.

Life Distribution Report

Tip: If you find that the report window is too long, select Tabbed Report from the Life Distribution red triangle menu.

If you have not selected a Failure Cause in the launch window, the Life Distribution report appears. Use this report to analyze lifetime data where some time observations might be censored. The Life Distribution report contains the following content and options:

• “Event Plot” on page 38
• “Compare Distributions” on page 41
• “Life Distribution: Statistics” on page 45
• “Life Distribution Report Options” on page 52
Event Plot

Click the Event Plot disclosure icon to see a plot of the failure or censoring times. For each row in the data table, the Event Plot shows a horizontal line indicating whether the units in the row have been censored. When units have been censored, the line indicates the nature of the censoring.

- The time period when the units in the row are known to be functioning is indicated with a solid line.
- The time period when it is not known if the units in the row are functioning is indicated with a dashed line.
The line terminates once the units in the row are known to have failed.

**Single Time to Event Column**

In the Fan.jmp sample data table there is a single Time column indicating failure time. When the failure time is unknown, the value Censored is recorded in the Censor column. All censored units are assumed to be right-censored. Figure 3.7 shows the Event Plot for this data.

**Note:** To construct the plot in Figure 3.7, select Help > Sample Data Library and open Reliability/Fan.jmp. Click the green triangle next to the Life Distribution - Exponential script. Click the Event Plot disclosure icon.

**Figure 3.7** Event Plot for Right-Censored Data

The unit in row 3 failed at Time 1150. Its lifetime is represented by a solid horizontal line that ends at Time 1150. The failure time is marked with an “x”.

The unit in row 5 is right censored. It was last known to be functioning at Time 1560. The time period during which the unit is known to be functioning is represented by a solid horizontal line that ends at Time 1560. At Time 1560, a right arrow is plotted. The line continues as a dashed line, indicating that the failure time is unknown, but greater than 1560.
Two Time to Event Columns

In the Censor Labels.jmp sample data table, there are two columns, Start Time and End Time. Start Time indicates when units in a row were last known to be functioning. End Time indicates when units in that row were first known to have failed.

The Start Time and End Time values indicate the following about the units:

- Units in rows 1 and 2 are left censored. They were known to fail before the time in the End Time column, but their exact failure times are unknown.
- Units in rows 3 and 4 are right censored. They were known to be last functioning at the time in the Start Time column, but their failure times are unknown.
- Units in rows 5 and 6 are interval censored. They were known to fail within the interval defined by the Start Time and End Time.
- Units in rows 7 and 8 are not censored. Their failure times are given by the values in the Start Time and End Time columns, which are identical.

Figure 3.8 shows the Event Plot for this data.

**Note:** To construct the plot in Figure 3.8, select Help > Sample Data Library and open Censor Labels.jmp. Click the green triangle next to the Life Distribution script.

**Figure 3.8 Event Plot for Mixed-Censored Data**

The line patterns in the Event Plot represent the various types of censoring:

- The pattern \( \cdot \cdot \cdot \) indicates right censoring. The unit failed after its last inspection.
- The pattern \( \cdot \cdot \cdot \) indicates left censoring. The unit failed after being put on test and prior to the indicated time, but it is not known when it was last functioning.
• The pattern $\rightarrow \cdots \rightarrow$ indicates that the unit failed during the time interval marked by the two arrow heads.

• The pattern $\rightarrow \times$ indicates no censoring. The unit failed at the time marked by the x.

**Compare Distributions**

The Compare Distributions report lets you fit and compare different failure time distributions. Two lists appear:

**Distribution** Select a distribution for the response. Different distributions appear based on characteristics of the data. For more information about which distributions are available, see “Available Parametric Distributions” on page 42.

**Scale** Select a scale for the probability axis. The probability scale corresponds to the distribution listed to the left of the Scale button. Using this scale, the fitted model is represented by a line. Suppose that you fit a given distribution and then scale the axis using that distribution. If the points generally fall along a line, this indicates that the distribution provides a reasonable fit.

The default plot shows the nonparametric estimates (Kaplan-Meier-Turnbull) for the uncensored data values and their confidence intervals. The confidence intervals are indicated by horizontal blue lines.

**Tip:** To customize the plot of the nonparametric estimates, select File > Preferences > Platforms > Life Distribution and select one or more of the following preferences: Show Shaded Pointwise Intervals, Show Shaded Simultaneous Intervals, or Show Staircase Style Function.

By default, there is a panel at the top of the plot that displays times of right-censored observations.

**Tip:** To hide the panel that contains markers for right-censored observations, select File > Preferences > Platforms > Life Distribution and uncheck Show Markers for Right Censored Observations.

For each distribution that you select, the Compare Distributions report is updated to show the following:

• the estimated cumulative distribution curve, which appears on the probability plot

• a shaded region that indicates confidence intervals for the cumulative distribution

• a Distribution Profiler that shows the cumulative probability of failure for a given period of time
Figure 3.9 shows an example of the Compare Distributions report. The Logistic (yellow) and Exponential (magenta) distributions are shown. The plot is scaled using the Exponential distribution.

**Figure 3.9** Compare Distributions Report and Distribution Profiler

---

**Available Parametric Distributions**

This section addresses the distributions available in the Compare Distributions report.

**Note:** Distributions for the Competing Cause report are covered in “Available Distributions for Competing Cause Compare Distributions Reports” on page 64.

The available distributions are listed and described in detail in “Parametric Distributions” on page 84. There are four major groupings of parametric distributions:

- “Basic Failure-Time Distributions” on page 43
- “Threshold Distributions” on page 43
- “Defective Subpopulation Distributions” on page 44
- “Zero-Inflated Distributions” on page 44

**Tip:** To restrict which distributions are available by default, select **File > Preferences > Platforms > Life Distribution** and uncheck the distributions that you do not want to appear. The distributions listed include the Threshold, Defective Subpopulation, Zero-Inflated, LogGenGamma, and GenGamma distributions. By default, all of the distributions are checked and available.
The rules that determine which distributions appear in the Compare Distributions panel depend on the particular implementation. As a general guide, distributions are available if they are not disabled in Preferences and if they are appropriate in the given situation.

**Basic Failure-Time Distributions**

The basic failure-time distributions are available whenever all failure times are positive. They include the following:

- Lognormal
- Weibull
- Loglogistic
- Fréchet
- Normal
- SEV
- Logistic
- LEV
- Exponential
- LogGenGamma
- GenGamma

**Note:** When there are negative or zero failure times, only the Normal, SEV, Logistic, LEV, and LogGenGamma are available.

**Threshold Distributions**

The threshold (TH) distributions are always available. Threshold distributions are log-location-scale distributions with threshold parameters. The threshold parameter shifts the distribution away from 0. These distributions assume that all units survive until the threshold value. Threshold distributions are useful for fitting moderate to heavily shifted distributions. The threshold distributions are the following:

- TH Lognormal
- TH Weibull
- TH Loglogistic
- TH Fréchet
Defective Subpopulation Distributions

The defective subpopulation (DS) distributions are available when all failure times are positive. These distributions are useful when only a fraction of the population has a particular defect leading to failure. Use the DS distribution options to model failures that occur on only a subpopulation. The DS distributions are the following:

- DS Lognormal
- DS Weibull
- DS Loglogistic
- DS Fréchet

Zero-Inflated Distributions

When the time-to-event data contain zero as the minimum value in the Life Distribution platform, the following zero-inflated distributions are available:

- Zero-Inflated Lognormal (ZI Lognormal)
- Zero-Inflated Weibull (ZI Weibull)
- Zero-Inflated Loglogistic (ZI Loglogistic)
- Zero-Inflated Fréchet (ZI Fréchet)

Zero-inflated distributions are used when some proportion of units fails at time zero. When the data contain more zeros than expected by a standard model, the number of zeros is inflated.

Zero-Failure Data

In the case of zero-failure data, none of the above distributions are available by default. To obtain Bayesian fits for those distributions where the Bayesian Estimate option is available, select File > Preferences > Platforms > Life Distribution and uncheck Weibayes Only for Zero Failure Data. See “Weibayes Only for Zero Failure Data” on page 51.

Parametric Distributions That Allow Bayesian Estimation

Bayesian estimation is available for the following parametric distributions:

- Lognormal
- Weibull
- Loglogistic
- Fréchet
- Normal
- SEV
• Logistic
• LEV

A list of distributions that are available as priors for hyperparameters of these distributions is given in “Prior Distributions for Bayesian Estimation” on page 96.

Life Distribution: Statistics

The Statistics report includes the following sub-reports:

• “Model Comparisons” on page 45
• “Summary of Data” on page 45
• “Nonparametric Estimate” on page 45
• “Parametric Estimate - <Distribution Name>” on page 46 (one report appears for each distribution that you select in the Compare Distributions report)

Model Comparisons

The Model Comparisons report provides the AICc, -2Loglikelihood, and BIC statistics for each fitted distribution. Smaller values of each of these statistics indicate a better fit. For more information about these statistics, see Fitting Linear Models.

Initially, the rows are sorted by AICc. To change the statistic used to sort the report, click the Life Distribution red triangle and select Comparison Criterion. See “Life Distribution Report Options” on page 52 for more information about this option.

Summary of Data

The Summary of Data report shows the total number of units observed, the number of uncensored units, and the numbers of right-censored, left-censored, and interval-censored units.

Nonparametric Estimate

The Nonparametric Estimate report shows nonparametric estimates for each observation. For right-censored data specified as a single Time to Event column, the report gives the following:

**Midpoint Estimate** Midpoint-adjusted Kaplan-Meier estimates.

**Lower 95%, Upper 95%** Pointwise 95% confidence intervals. You can change the confidence level by selecting Change Confidence Level from the report options.
Simultaneous Lower 95% (Nair), Simultaneous Upper 95% (Nair)  Simultaneous 95% confidence intervals. You can change the confidence level by selecting Change Confidence Level from the report options. See Nair (1984) and Meeker and Escobar (1998).

If failure times are represented by two Time to Event columns, the report gives Turnbull estimates (in a column called Estimate), pointwise confidence intervals, and simultaneous confidence intervals (Nair).

See “Nonparametric Fit” on page 83 for more information about nonparametric estimates.

Parametric Estimate - <Distribution Name>

A report called Parametric Estimate - <Distribution Name> appears for each distribution that is fit. The report gives the distribution’s parameter estimates, their standard errors, and confidence intervals. The criteria that appear in the Model Comparisons report are shown under Criterion.

Note: Whenever an estimate of the mean is provided, its confidence interval is computed as a Wald interval even if you select Likelihood as the Confidence Interval Method in the launch window. In this case, the notation Mean (Wald CI) appears in the Parameter column to indicate that the confidence interval for the mean is a Wald interval.

For more information about how the distributions are parametrized, see “Parametric Distributions” on page 84.

The Parametric Estimate report contains the following reports:

- “Covariance Matrix” on page 46
- “Profilers” on page 46
- Additional reports can be added by selecting report options from the Parametric Estimate red triangle menu. These include the Fix Parameter, Bayesian Estimates, Custom Estimation (Estimate Probability, Estimate Quantile), and Mean Remaining Life reports. See “Parametric Estimate Options” on page 47.

Covariance Matrix

For each distribution, the Covariance Matrix report shows the covariance matrix for the estimates.

Profilers

Four types of profilers appear for each distribution:

- The Distribution Profiler shows cumulative failure probability as a function of time.
• The Quantile Profiler shows failure time as a function of cumulative probability.
• The Hazard Profiler shows the hazard rate as a function of time.
• The Density Profiler shows the density function for the distribution.

The profilers contain the following red triangle menu options:

**Confidence Intervals**  The Distribution, Quantile, and Hazard profilers show Wald-based confidence curves for the plotted functions. This option shows or hides the confidence curves.

**Reset Factor Grid**  Displays a window for each factor enabling you to enter a specific value for the factor’s current setting, to lock that setting, and to control aspects of the grid. See Profilers.

**Factor Settings**  Provides a menu that consists of several options. See Profilers.

**Note:** The confidence intervals provided in the profilers are based on the Wald method even if the Likelihood Confidence Interval Method is selected in the launch window. This is done to reduce computation time.

### Parametric Estimate Options

The Parametric Estimate red triangle menu has the following options:

**Save Probability Estimates**  Saves the estimated failure probabilities and confidence intervals to the data table.

**Save Quantile Estimates**  Saves the estimated quantiles and confidence intervals to the data table.

**Save Hazard Estimates**  Saves the estimated hazard values and confidence intervals to the data table.

**Show Likelihood Contour**  Shows or hides a contour plot of the log-likelihood function. If you have selected the Weibull distribution, a second contour plot appears for the alpha-beta parameterization. This option is available only for distributions with two parameters.

**Show Likelihood Profiler**  Shows or hides a profiler of the log-likelihood function. This option is not available for the threshold (TH) distributions.

**Fix Parameter**  Opens a report where you can specify the value of parameters. Enter your fixed parameter values, select the appropriate check box, and then click **Update**. JMP re-estimates the other parameters, covariances, and profilers based on the new parameters, and shows them in the Fix Parameter report. A distribution profiler of the unconstrained model is shown below the distribution profiler for the fixed parameter
model. For an example in a competing cause situation, see “Specify a Fixed Parameter Model as a Distribution for a Cause” on page 97.

For the Weibull distribution, the Fix Parameter option lets you select the Weibayes method. For an example, see “Weibayes Estimates” on page 75. The Weibayes option is not available for interval-censored data.

**Bayesian Estimates**  Performs Bayesian estimation of parameters for certain distributions based on three methods of specifying prior distributions (Location and Scale Priors, Quantile and Parameter Priors, and Failure Probability Priors). See “Bayesian Estimation - <Distribution Name>” on page 48. This option is available only for the following distributions: Lognormal, Weibull, Loglogistic, Fréchet, Normal, SEV, Logistic, LEV.

**Custom Estimation**  Provides calculators that enable you to predict failure probabilities, survival probabilities, and quantiles for specific time and failure probability values. Each calculated quantity includes confidence intervals, which can be two-sided or one-sided (in either direction). Two reports appear: Estimate Probability and Estimate Quantile. See “Custom Estimation” on page 51.

**Mean Remaining Life**  Provides a calculator that enables you to estimate the mean remaining life of a unit. In the Mean Remaining Life Calculator, enter a Time and press Enter to see the estimate. Click the plus sign to enter additional times. This calculator is available for the following distributions: Lognormal, Weibull, Loglogistic, Fréchet, Normal, SEV, Logistic, LEV, and Exponential.

**Bayesian Estimation - <Distribution Name>**

For certain distributions, you can fit Bayesian models. This is done using rejection sampling or a Markov Chain Monte Carlo (MCMC) algorithm. More specifically, the platform attempts a basic rejection sampler. If the rejection sampler produces valid results, these results are reported. If the rejection sampler cannot produce valid results, the platform uses a random walk Metropolis-Hastings algorithm and adds a note to the top of the Bayesian Estimation report. See Robert and Casella (2004).

From the Parametric Estimate - <Distribution Name> report outline, select Bayesian Estimates. This opens an outline called Bayesian Estimation - <Distribution Name>. The initial report is a control panel where you can specify the parameters for the priors and control aspects of the simulation.

The following steps describe the workflow:

- Select a prior specification method from the Bayesian Estimation red triangle menu and set values for the parameters of the priors. See “Bayesian Estimation Red Triangle Options” on page 49.
- Specify the simulation options. See “Bayesian Estimates - Result <N>” on page 50.
- Select Fit Model to fit a model. See “Bayesian Estimates - Result <N>” on page 50.
Bayesian Estimation Red Triangle Options

You can choose from the following prior specification methods in the Bayesian Estimation red triangle menu:

**Location and Scale Priors**   Enables you to specify hyperparameters for prior distributions on generic parameters (location and scale parameters). Select the Prior Distribution red triangle menu to select a distribution for each parameter. You can enter new values for the hyperparameters of the priors. The initial values that are provided are estimates consistent with the MLEs. See “Prior Distributions for Bayesian Estimation” on page 96.

**Quantile and Parameter Priors**   Enables you to specify prior information about a quantile and the scale parameter (or Weibull $\beta$ if the parametric fit is Weibull). The quantile is defined by the value next to Probability. The default Probability value is 0.10, but you can specify a value that corresponds to the quantile of interest. Specify information about the prior information in terms of Lower and Upper 99% limits on the range of each prior distribution. See Meeker and Escobar (1998). The initial values that are provided are estimates consistent with the MLEs. See “Prior Distributions for Bayesian Estimation” on page 96.

**Failure Probability Priors**   Enables you to specify prior information about failure probabilities at two distinct time points. You can specify the two time points. The prior distribution for each time point is Beta. You can specify the prior distributions using either of two synchronized approaches:

1. Specify failure probability by estimates and error percentages. The prior information for each Beta prior distribution can be specified using a probability estimate and an estimate error. See Kaminskiy and Krivtsov (2005).

2. Specify failure probability estimate ranges. You can specify the 99% range for the two Beta distributions in the following ways:
   - For each failure time, enter an initial value for the Lower and Upper 99% Limits.
   - Click the vertical line segments in the graph and drag them to your two time points. Adjust the vertical spread of each marker to specify the 99% limits.

**Simulation Options**

For any of the prior specification methods that you select in the Bayesian Estimation red triangle menu, the following options appear at the bottom of the panel:

**Number of Monte Carlo Iterations**   Controls the sample size that will be drawn from the posterior distribution after a burn-in procedure.

**Random Seed**   Sets the initial state of the simulation. By default, it is the clock time. The number should be a positive integer greater than 1. If you specify 1, the current clock time is used.
Show Prior Scatter Plot  Select this option to draw random samples from the prior distributions and to plot results on a scatter plot. After you select Fit Model, the scatter plot appears in an outline entitled Prior Scatter Plot in the Bayesian Estimates - Results <N> report.

Overlay Likelihood Contour  Overlays likelihood-based contours on scatter plots in the Bayesian Estimates Results report.

Fit Model  Estimates the posterior lifetime distribution based on prior distributions that JMP fits using the values that you specified. Adds a report entitled Bayesian Estimates - Results <N>, where N is an integer that consecutively numbers the Bayesian Results reports.

Bayesian Estimates - Result <N>

Once you have specified priors using one of the red triangle menu options, select Fit Model. A Bayesian Estimates - Result <N> report is provided for each selection of priors. This report contains these headings:

Priors  Documents the specifications that you entered in the Bayesian Estimation report to fit the Bayesian model. The Priors report also specifies the random seed.

Posterior Estimates  Shows five marginal statistics that describe the posterior distribution of the generic parameters (location and scale parameters). The marginal statistics are the median, 0.025 quantile (Lower Bound), 0.975 quantile (Upper Bound), mean, and standard deviation computed from the Monte Carlo samples. When the posterior estimates are generated using the Quantile and Parameter Priors specification, this table also includes the posterior estimate of the quantile and Slope $\beta$ (for the Weibull distribution).

To compute statistics for other derived variables based on the posterior estimates of the generic parameters, click the Export Monte Carlo Samples link.

Prior Scatter Plot  Appears when you select Show Prior Scatter Plot before clicking Fit Model. Shows prior scatter plots of parameters or equivalent quantities associated with the prior specification method for the distribution.

Posterior Scatter Plot  Shows posterior scatter plots of parameters or equivalent quantities associated with the prior specification method for the distribution.

Profilers  Shows two profilers based on samples from the posterior distribution.

The values shown in the Distribution Profiler, at a given time $t$, are calculated as follows:

– For each set of sampled parameter values from the posterior distribution, the value of the cumulative distribution function at time $t$ is calculated.
– The predicted value is the median of these calculated values.
– The upper and lower confidence limits are the 0.025 and 0.975 quantiles of these calculated values.

The plot and confidence limits shown in the Quantile Profiler are obtained in a similar fashion. For a given Probability value $p$, the quantiles corresponding to $p$ are calculated from the distributions associated with the posterior parameter values.

**Weibayes Only for Zero Failure Data**

In a zero-failure situation, no units fail. All observations are right censored. If you have zero-failure data, it is possible to conduct either Bayesian estimation or Weibayes inference. See “Weibayes Report” on page 59.

**Note:** By default, zero-failure data is analyzed using the Weibayes method. If you want to conduct a broader Bayesian analysis on zero-failure data, select File > Preferences > Platforms > Life Distribution and uncheck Weibayes Only for Zero Failure Data.

**Custom Estimation**

The Custom Estimation option produces two reports: Estimate Probability and Estimate Quantile. The Estimate Probability report contains a calculator that enables you to predict failure and survival probabilities for specific time values. The Estimate Quantile report contains a calculator that enables you to predict quantiles for specific failure probability values. Both Wald-based and likelihood-based confidence intervals appear for each estimated quantity. The confidence level for these intervals is determined by the Change Confidence Level option in the Life Distribution red triangle menu.

**Estimate Probability**

In the Estimate Probability calculator, enter a value for Time. Press Enter to see the estimates of failure probabilities, survival probabilities, and corresponding confidence intervals. To calculate multiple probability estimates, click the plus sign, enter another Time value in the box, and press Enter. Click the minus sign to remove the last entry.

The Estimate Probability calculator contains an option, Side, that enables you to change the form of the intervals. Select one of the following suboptions:

**Two Sided**  Provides two-sided confidence intervals for failure probability and survival probability.

**Upper Failure Probability**  Provides one-sided confidence intervals that contain upper limits for the failure probability and lower limits for the survival probability.

**Lower Failure Probability**  Provides one-sided confidence intervals that contain lower limits for the failure probability and upper limits for the survival probability.
Estimate Quantile

In the Estimate Quantile report, enter a value for Failure Probability. Press Enter to see the quantile estimates and corresponding confidence intervals. To calculate multiple quantile estimates, click the plus sign, enter another Failure Probability value in the box, and press Enter. Click the minus sign to remove the last entry.

The Estimate Quantile calculator contains an option, Side, that enables you to change the form of the intervals. Select one of the following suboptions:

- **Two Sided**  Provides two-sided confidence intervals for quantiles.

- **Lower**  Provides one-sided confidence intervals that contain lower limits for quantiles.

- **Upper**  Provides one-sided confidence intervals that contain upper limits for quantiles.

---

**Life Distribution Report Options**

The Life Distribution red triangle menu contains the following options:

- **Fit All Distributions**  Fits all distributions other than the threshold (TH) distributions. The distributions are compared in the Model Comparisons report. See “Compare Distributions” on page 41.

  **Tip:** Select the **Comparison Criterion** option to change the criterion for finding the best distribution.

- **Fit All Nonnegative**  Fits all nonnegative distributions (Exponential, Lognormal, Loglogistic, Fréchet, Weibull, and Generalized Gamma). The distributions are compared in the Model Comparisons report. See “Compare Distributions” on page 41. Note the following:
  - The option does not fit DS or TH distributions.
  - If the data have negative values, then the option produces no results.
  - If the data have zeros, the option fits the four zero-inflated (ZI) distributions: ZI Lognormal, ZI Weibull, ZI Loglogistic, and ZI Fréchet. For more information about zero-inflated distributions, see “Zero-Inflated Distributions” on page 95.

- **Fit All DS Distributions**  Fits all defective subpopulation (DS) distributions: DS Lognormal, DS Weibull, DS Loglogistic, and DS Fréchet. For more information about defective subpopulation distributions, see “Distributions for Defective Subpopulations” on page 94.

- **Fit Mixture**  Fits a distribution that is a mixture of the distributions other than the threshold (TH) distributions. See “Mixture” on page 54.
Fit Competing Risk Mixture  Fits a competing risk mixture distribution to the data. See “Fit Competing Risk Mixture” on page 58.

Show Points  Shows or hides data points in the probability plot. The Life Distribution platform uses the midpoint estimates of the step function to construct probability plots. When you deselect Show Points, the midpoint estimates are replaced by Kaplan-Meier estimates.

Show Event Plot Frequency Label  (Appears only if you have specified a Freq variable.) Shows or hides the Frequency label in the Event Plot.

Show Survival Curve  Switches between the failure probability and the survival curve on the Compare Distributions probability plot and the Distribution Profiler plots.

Show Quantile Functions  Shows or hides a Quantile Profiler that overlays the plots for the selected distributions. The Quantile plot also shows points plotted at time values. The plot appears beneath the Compare Distributions report. If you select distributions in any of the Compare Distributions, Quantile Profiler, and Hazard Profiler plots, they appear in the other two plots.

Show Hazard Functions  Shows or hides a Hazard Profiler that overlays the plots for the selected distributions. The plot appears above the Statistics report. If you select distributions in any of the Compare Distributions, Quantile Profiler, and Hazard Profiler plots, they appear in the other two plots.

Tabbed Report  Shows graphs and data on individual tabs rather than in the default outline style.

Show Confidence Area  Shows or hides the shaded confidence regions in the plots.

Interval Type  Determines the type of confidence interval shown for the Nonparametric fit in the Compare Distributions plot. Select either pointwise or simultaneous confidence intervals.

Change Confidence Level  Enables you to change the confidence level for the entire platform. All plots and reports update accordingly.

Comparison Criterion  Enables you to select the criterion used to rank models in the Model Comparison report. For all three criteria, smaller values indicate better fit. Burnham and Anderson (2002) and Akaike (1974) discuss using AICc and BIC for model selection. See Fitting Linear Models.

See Using JMP for more information about the following options:
Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

If you have specified a By variable, separate Life Distribution reports appear for each level of the By variable.

Save By Group Results  For each By group, saves the estimates that appear in all Parametric Estimate reports for that group as a separate row in a new table.

Do Same Analyses for All Groups  Applies all of the selected options for the current group to all other By groups.

Mixture

The Fit Mixture option adds the Mixture outline to the report where you can fit a mixture distribution to the data. For an example, see “Fit Mixture Example” on page 77.

The mixture distribution's probability function \( F(x) \) is defined as follows:

\[
F(x) = \sum_{i=1}^{k} w_i F_i(x)
\]

where \( F_i(x) \) is one of the supported distributions, \( k \) is the number of components in the mixture, and the \( w_i \) are positive weights that sum to 1. The Fit Mixture option attempts to identify clusters of observations that are drawn from each of the component distributions, \( F_i(x) \). It estimates the parameters of the mixture and the probability that an observation is drawn from any given component.
Model Fit and Mixture Starting Value Methods

The fitting methodology is based on assumptions about the underlying clusters, called the Starting Value Method. Suppose that you designate \( k \) distributions. There are three Starting Value Methods:

- **Single Cluster** assumes that all observations are affected by all of the ingredient distributions to some extent. None of the densities stand out as affecting only a portion of the observations.
- **Separable Clusters** assumes that the ingredient distributions affect some observations more profoundly than others. For separable clusters, each of the \( k \) densities has an identifiable mode and defines a cluster.
- **Overlapping Clusters** assumes a situation that is intermediate between Single Cluster and Separable Clusters. Some densities stand out, but others jointly affect a portion of the observations. In this case, there are \( m \) clusters in the data, where \( m \) is less than \( k \), the total number of densities.

The fitting process consists of these steps:

1. Clusters of observations are defined.
2. Assignment of clusters to densities is based on the Starting Value Method:
   - For Separable Clusters, the highest likelihood assignment of clusters to the specified ingredient densities is determined by examining the possible permutations.
   - For Overlapping Clusters, the highest likelihood assignment of clusters to the specified ingredient densities is determined by examining the possible permutations of clusters and combinations of observations.

**Note:** Suppose that you fit a model using a given Starting Value Method and then select another Starting Value Method. If a better fit based on the likelihood value cannot be achieved, no new model is added.

Mixture Control Panel

The control panel consists of these items:

- **Ingredient**  Lists distributions that you can use as components of the fitted mixture distribution.

- **Quantity**  Select the number of components in the mixture distribution that have the given distribution. The sum of the Quantity values is \( k \), the number of densities in the mixture.

- **Starting Value Methods**  Select a method that reflects your assumptions about the mixture. See “Model Fit and Mixture Starting Value Methods” on page 55.
Overlay  Shows the nonparametric estimates (Kaplan-Meier-Turnbull) for the uncensored data values. When you fit a mixture, the plot is updated to show the model and 95% level confidence bands. The confidence level for these bands is determined by the Change Confidence Level option in the Life Distribution red triangle menu. A Legend appears to the right of the plot.

Go  Click Go to fit the desired mixture. The Model List is updated with the model that you fit, and a report with the name of the mixture model is added.

Fit Mixture Reports

Model List
The Model List report lists the mixture distributions that you fit. The report provides the number of parameters, the number of actual observations, and the AICc, -2Loglikelihood, and BIC statistics for each mixture distribution. For more information about these statistics, see Fitting Linear Models.

Note the following:
• Smaller values of each of these statistics indicate a better fit.
• The rows are sorted by AICc.
• The Comparison Criterion red triangle option does not affect the order of models in the Model List.
• The AICc, -2Loglikelihood, and BIC statistics also appear in the Model Comparisons table. This enables you to compare mixture distribution to other distributions for your data. See “Model Comparisons” on page 45.

Mixture Reports
The Model List report is followed by reports for each of the mixture distributions that you have fit. The title of each report describes the corresponding mixture using the specified ingredients and their quantities. The report lists the parameters, their estimates, standard errors, and 95% Wald confidence intervals. These intervals are not affected by the selection of Likelihood as the Confidence Interval Method in the launch window.

Parameter estimates are given for each distribution in the mixture. The Parameter column also includes parameters called Portion <i>, where i = 1, 2, ..., k-1. These are estimates of the weights wi for the mixture. Since the weights sum to 1, the kth weight can be computed from the first k - 1 weights.
Density Overlay Plot

The Density Overlay plot shows estimates of the density functions for each of the components in the mixture. A legend to the right of the plot enables you to select which density functions appear.

Mixture Report Options

The red triangle menu contains the following options:

Remove  Removes the model report and the entry for the model in the Model List.

Show Profilers  Shows four types of profilers for the combined mixture distribution $F$. See “Mixture Profiler Options” on page 57 for a description of their red triangle options.

– The Distribution Profiler shows cumulative failure probability as a function of time.
– The Quantile Profiler shows failure time as a function of cumulative probability.
– The Hazard Profiler shows the hazard rate as a function of time.
– The Density Profiler shows the density function for the distribution.

Save Predictions  For each mixture density, saves a column to the data table containing the probability that an observation belongs to that density. For the formulas used in the calculation, see “Fit Mixture Save Predictions Formulas” on page 101.

Mixture Profiler Options

The profilers for each mixture report contain the following red triangle options:

Confidence Intervals  The Distribution, Quantile, and Hazard profilers show 95% Wald-based confidence curves for the plotted functions. This option shows or hides the confidence curves. The confidence level for these curves is determined by the Change Confidence Level option in the Life Distribution red triangle menu.

Note: To reduce computation time, the confidence intervals provided in the profilers are based on the Wald method, even if the Likelihood Confidence Interval Method is selected in the launch window.

Reset Factor Grid  Displays a window for each factor enabling you to enter a specific value for the factor’s current setting, to lock that setting, and to control aspects of the grid. See Profilers.

Factor Settings  Provides a menu that consists of options relating to profiler settings, scripts, and linking profilers. See Profilers.
Fit Competing Risk Mixture

The Fit Competing Risk Mixture option enables you to fit competing risk mixture distributions. It estimates the probability that a given observation fails due to the cause represented by each of the component mixture distributions. For an example, see “Fit Competing Risk Mixture Example” on page 80.

The competing risk mixture probability distribution function \( F(x) \) is defined as follows:

\[
F(x) = 1 - \prod_{i=1}^{k} (1 - F_i(x))
\]

where \( F_i(x) \) represents the cumulative failure distributions for the \( i^{th} \) risk and \( k \) is the number of components (or risks) in the mixture. The Fit Competing Risk Mixture option attempts to identify clusters of observations that are drawn from each of the component distributions, \( F_i(x) \). It estimates the parameters of the mixture and the probability that an observation is drawn from any given component.

The Competing Risk Mixture report is structured in a fashion that mirrors the Mixture report. See “Mixture” on page 54. However, the Fit Competing Risk Mixture reports do not show a Density Overlay plot. They show a Distribution Overlay plot instead.

Distribution Overlay Plot

The Distribution Overlay plot shows the cumulative distribution functions for each of the mixture components and for the combined mixture (Aggregated). A legend to the right of the plot enables you to select which cumulative distribution functions appear.
Weibayes Report

If you have data with zero failures (right-centered) and you have not turned off the preference **Weibayes Only for Zero Failure Data**, a special Weibayes report appears. Figure 3.10 shows the Weibayes report for the Weibayes No Failures.jmp sample data table, found in the Reliability folder.

**Figure 3.10** Weibayes Report

The analysis begins by assuming an exponential model. The note at the top of the report provides a lower confidence bound for the parameter of an exponential distribution. This lower confidence bound is computed using the method described in Meeker and Escobar (1998, sec. 7.7).

The Weibayes section of the report conducts the Weibayes analysis. For a description of the procedure, see Nelson (1985).

To obtain Weibayes estimates, make sure that Weibayes and Weibull $\beta$ options are selected. Change the Weibull $\beta$ value and click Update. The estimates and profilers are updated. The values shown in the profilers use the conservative confidence bound. For an example, see “Weibayes Example for Data with No Failures” on page 75.

**Note:** If you deselect the Weibayes option, JMP shows the fixed parameter MLE.
When your data table contains at least one failure, a full Life Distribution report appears, but the maximum likelihood inference might not produce useful results. In this instance, a Weibayes analysis might be preferable. For an example, see “Weibayes Example for Data with One Failure” on page 76.

**Note:** To conduct Bayesian inference using the usual Life Distribution options when you have zero-failure data, select **File > Preferences > Platforms > Life Distribution** and deselect **Weibayes Only for Zero Failure Data** before launching the analysis.

### Competing Cause Report

**Tip:** If you find that the report window is too long, select **Tabbed Report** from the Competing Cause red triangle menu.

The Competing Cause report appears if you have assigned a Failure Cause column in the launch window. Use this report to analyze the competing causes to determine which causes are influential. For an example of this report, see “Omit Competing Causes” on page 69. For technical details, see “Competing Cause Details” on page 97.

The Competing Cause report contains the following content and options:

- “Cause Combination” on page 61
- “Competing Cause: Statistics” on page 62
- “Individual Causes” on page 63
- “Competing Cause Report Options” on page 64

### Competing Cause Workflow

Follow these steps to facilitate your use of the Competing Cause report:

1. For convenience, click the Competing Cause red triangle and select the Tabbed Report option.
2. Select the Individual Causes tab. For each failure cause, use the options in its individual Life Distribution outline to select a distributional fit. See “Individual Causes” on page 63.
3. Select the Cause Combination tab. For each failure cause, specify the desired distribution in each **Distribution** list. See “Cause Combination” on page 61.
4. Click **Update Model**.
5. Select the Statistics tab to explore and save results for the model. See “Competing Cause: Statistics” on page 62.
Note: Customizations made to the competing cause model report in the Statistics outline might be lost if you change the model and click Update Model again.

Competing Cause Model

In a competing cause situation, the aggregated failure function can be written as follows:

\[
F(x) = 1 - \prod_{i=1}^{k} (1 - F_i(x))
\]

where \( F_i(x) \) is the cumulative failure distribution for the \( i \)th cause and \( k \) is the total number of causes. The function \( F_i(x) \) is cause-specific. It reflects the probability of failure due to cause \( i \) alone and does not account for other causes of failure.

An alternative formulation is defined as follows:

\[
F(x) = \sum_{i=1}^{k} \tilde{F}_i(x)
\]

where each \( \tilde{F}_i \) is a monotone increasing function with values in the interval \([0, 1]\). The function \( \tilde{F}_i \) is called a subdistribution. This form of the aggregated failure distribution is used to predict proportions of failures that are associated with individual causes, accounting for failure due to other causes.

Cause Combination

The Cause Combination report lets you fit and compare different failure time distributions \( (F_i(x)) \) for the various causes. Different distributions are available based on selections that you have made in the launch window. Negative and zero-failure times are not allowed.

The default plot is based on a Linear scale and shows the following:

- Nonparametric estimates (Kaplan-Meier-Turnbull) for the uncensored data values and their confidence intervals. The confidence intervals are represented by horizontal blue lines.
- Fits of cumulative failure distributions \( (F_i(x)) \) to each of the causes. The initial distribution is the one that you selected in the launch window. If you selected Individual Best, the best distribution is computed for each group and these fits are shown. (This selection can be time-intensive.) If you selected Manual Pick, the initial Distribution is Nonparametric for all groups and nonparametric fits are shown. A legend appears to the right of the plot.
Life Distribution
Chapter 3
Competing Cause Report

- The Aggregated cumulative failure distribution, \( F(x) \), represented by a black line. This function is computed based on the selected cause distribution. If a nonparametric distribution is specified for a cause, the aggregated cumulative failure distribution extends only as far as the final time observation for that cause.

As you interact with the report, statistics for the aggregated model are re-evaluated.

The Cause Combination report contains these elements:

**Scale**  
Specifies the probability scale for the plot’s vertical axis. “Change the Scale” on page 71 illustrates how changing the scale affects the distribution fit.

**Omit**  
Check a box to remove the fit for the corresponding cause. Use this when a particular cause has been fixed. The Aggregated model updates to reflect the removal of the failures due to that cause. “Omit Competing Causes” on page 69 illustrates the effect of omitting causes.

**Cause**  
Lists the causes in the Cause column.

**Distribution**  
Lists the available distributions for each cause. To change the distribution for a specific failure cause, select the distribution from the Distribution list. Click Update Model to show the new distribution fit on the plot. The Cause Summary report is also updated.

**Count**  
Gives the number of observations with the given failure cause.

**Update Model**  
Shows the selected distributions in the plot; updates the Cause Summary report with the selected models; adds the selected model as the most recent one in the Individual Causes report.

**Competing Cause: Statistics**

The Statistics report for Competing Cause contains the following reports:

- “Cause Summary Report” on page 62
- “Profiler” on page 63

**Cause Summary Report**

The Cause Summary report shows information for the fit defined by the current selections under Distribution in the Cause Summary report. The report shows the number of failures for each cause and the parameter estimates for the distribution fit to each failure cause. When you change distribution fits in the Cause Combination report and click Update Model, the Cause Summary report is updated.

The following information is provided:

- The Cause column shows either labels of causes or the censor code.
• The Counts column lists the number of failures for each cause.

• A numerical entry in the Counts column indicates that the cause has enough failure events to consider. A cause with fewer than two events is considered right censored. The column also identifies missing causes.

• The Distribution column specifies the selected distribution for each cause.

• Depending on the selected distributions, various columns display the parameters of the distributions:
  – The location column specifies location parameters for various distributions.
  – The scale column specifies scale parameters for various distributions.
  – The Weibull $\alpha$ and Weibull $\beta$ columns show Weibull estimates of alpha and beta.
  – Other columns show parameters of other selected distributions.
  – A Convergence column appears if there are convergence issues.

The Cause Summary red triangle menu options enable you to save the probability, quantile, hazard, and density estimates for the aggregated failure distribution to the data table.

**Profilers**

The Distribution, Quantile, Hazard, and Density profilers help you visualize the aggregated failure distribution. The Distribution, Quantile, and Hazard profilers show 95% level confidence bands. See “Profilers” on page 46.

**Note:** If a nonparametric distribution is specified for a cause, the Hazard and Density profilers are not provided. Also, confidence limits are not provided in the Distribution and Quantile profilers.

**Individual Causes**

The Individual Causes report contains Life Distribution - Failure Cause: <Distribution Name> reports for each of the individual causes. Each Life Distribution - Failure Cause: <Distribution Name> report shows plots and distributional fit statistics for the individual failure cause indicated in the report title.

Whenever you click Update Model in the Cause Combination report, any new cause distribution that you select is added to the Life Distribution - Failure Cause: <Distribution Name> report for that cause. In the Life Distribution - Failure Cause <Distribution Name> report, the following occur:

• The distribution is selected in the Compare Distributions report.

• The distribution is added to the Model Comparisons report.

• A Parametric report is added for that distribution.
Each Life Distribution - Failure Cause <Distribution Name> report is a Life Distribution: Statistics report as described in “Life Distribution: Statistics” on page 45. However, all confidence intervals are Wald intervals. These intervals are not affected by the selection of Likelihood as the Confidence Interval Method in the launch window.

Available Distributions for Competing Cause Compare Distributions Reports

If you specify a Failure Cause in the launch window, you can specify which groupings of distributions and models you want to allow in the resulting Compare Distributions reports for Individual Causes. You can select ZI (Zero-Inflated), TH (Threshold), and DS (Defective Subpopulation) distributions. You can also select fixed parameter and Bayesian models.

**Note:** If you have disallowed any distributions in Preferences, these do not appear. Also, rules that govern which distributions appear for Life Distribution apply. See “Available Parametric Distributions” on page 42.

Competing Cause Report Options

The Competing Cause red triangle menu contains the following options:

**Tabbed Report**  Shows graphs and data on individual tabs rather than in the default outline style.

**Tabbed Report for Individual Causes**  Shows the Life Distribution - Failure Cause: <Distribution Name> reports in tabs, rather than as a stack of Life Distribution reports.

**Show Points**  Shows or hides data points in the Cause Combination plot. The Life Distribution platform uses the midpoint estimates of the step function to construct probability plots. When you deselect **Show Points**, the midpoint estimates are replaced by Kaplan-Meier estimates.

**Show Subdistributions**  Shows the profiler for each individual cause subdistribution $\hat{F}_i$. See “Individual Subdistribution Profiler for Cause” on page 65.

**Show Remaining Life Distribution**  Shows the remaining life distribution through the Distribution Profiler. This is conditional upon the unit surviving through a given time.

**Mean Remaining Life**  Estimates the mean remaining life of a unit, given a survival time. In the Mean Remaining Life Calculator, enter a time value and press **Enter** to see the estimate and confidence limits. Click the plus sign to enter additional times. Click the minus sign to remove the most recent entry.

To obtain a confidence interval, select the **Configuration** option from the Mean Remaining Life Calculator. Check **Use bootstrap to construct confidence intervals**. Enter appropriate
values, keeping in mind that computation can be time-intensive. See “Mean Remaining Life Calculator” on page 101.

Export Bootstrap Results  Appears only when a Bayesian model is selected and when Update Model has been applied.

Bootstrap Sample Size  When Bayesian Estimates or Weibayes results are used for any cause, the confidence limits for aggregated functions that appear in the Distribution Profiler must be simulated using parametric bootstrap. Use this option to specify the number of samples to be used in the bootstrap. See “Specify a Bayesian Model for a Cause” on page 100.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Individual Subdistribution Profiler for Cause

For a given cause, the Individual Subdistribution Profiler for Cause shows the estimated probability of failure, $\hat{F}_i$, from that cause at time $t$. The estimated probability takes into account failures from competing causes. See “Competing Cause Model” on page 61.

To show a profiler of the subdistribution for each cause, click the Competing Cause red triangle and select Show Subdistributions. The Individual Subdistribution Profiler for Cause report appears beneath the other profilers. It consists of a profiler and a calculator.

Note: When you select Show Subdistributions, the Cause Combination plot is updated to show the subdistribution functions for all causes.

Select a Cause from the list to the right of the profiler to see its profiler. Options that apply to the profiler are provided in the Individual Subdistribution Profiler for Cause red triangle menu. See “Profilers” on page 46.
Use the Calculator panel to find values of the subdistribution functions for all causes at one or more Time to Event values. Enter a value for the Time to Event variable. When you press Enter (or click outside the text box), values for each of the causes are updated. To add a Time to Event value, click the plus sign. To remove the most recent value, click the minus sign.

**Life Distribution - Compare Groups Report**

**Tip:** If you find that the report window is getting too long, select **Tabbed Report** from the red triangle menu next to Life Distribution - Compare Groups.

If you selected the Compare Groups tab in the launch window, the Life Distribution - Compare Groups report appears. This report compares different groups using a single specified distribution. For example, you might compare Weibull fits for components grouped by supplier. In contrast, the Life Distribution tab compares several fitted distributions for a single group.

You can compare the CDF, Quantile, Hazard, and Density functions. You can also consolidate the probability and quantile predictions of all groups.

For an example of this report, see “Examine the Same Distribution across Groups” on page 73.

The Compare Groups report can contain the following content and options:

- “Compare Distributions” on page 41 (no Distribution Profiler)
- “Compare Groups: Statistics” on page 66
- “Individual Group” on page 67
- “Life Distribution - Compare Groups Report Options” on page 67

**Compare Groups: Statistics**

The Statistics report for Compare Groups contains the following reports:

- “Summary” on page 67
- “Group Homogeneity Tests” on page 67
- “Model Comparisons” on page 45
- “Parameter Estimates” on page 67
Summary

The Summary report contains a row for each group and for the combined data. Each row shows the number of units that failed and the numbers that were left, interval, or right censored. Each row also gives the corresponding mean and standard error. For more information about how the mean and standard error are computed, see “Statistical Reports for Survival Analysis” on page 368 in the “Survival Analysis” chapter.

Group Homogeneity Tests

The Group Homogeneity Tests report contains results of three tests for equality of the hazard functions across groups. The tests differ in how the observations are weighted over time.

Log-Rank  The Log-Rank test uses equal weights for all time points.

Peto-Peto  The Peto-Peto test uses the survival proportion at each time point for weights.

Wilcoxon  The generalized Wilcoxon test uses the number at risk at each time point for weights. This test is referred to as the Gehan test in Klein and Moeschberger (1997).

For each of the above tests, the report includes the chi-square approximation, the associated degrees of freedom, and the p-value for each test. A small p-value suggests that the groups differ. For more information about these tests and comparisons of failure curves, see Klein and Moeschberger (1997, ch. 7).

Parameter Estimates

The Parameter Estimates outline contains reports entitled Parametric Estimate - <Distribution Name> for each distribution that is fit. For each group, the Parametric Estimate - <Distribution Name> report gives the distribution’s parameter estimates and their 95% level confidence intervals. The confidence level for these intervals is determined by the Change Confidence Level option in the Life Distribution - Compare Groups menu.

Individual Group

The tabs within the Individual Group report contain Life Distribution reports for each individual group. For more information about these reports, see “Life Distribution Report” on page 37 and “Life Distribution Report Options” on page 52.

Life Distribution - Compare Groups Report Options

Many of the options in the Compare Groups red triangle menu can also be found in the Life Distribution red triangle menu. See “Life Distribution Report Options” on page 52.
However, the following options are specific to Compare Groups:

**Show Quantile Functions**  Shows or hides the Compare Quantile report. Select a distribution. For each group, a curve is plotted showing the estimated quantiles for the time variable. Confidence bands are displayed. A legend is shown to the right of the plot. Only one distribution can be specified at a time.

**Show Hazard Functions**  Shows or hides the Compare Hazard report. Select a distribution. For each group, a curve is plotted showing the hazard function. Confidence bands are displayed. A legend is shown to the right of the plot. Only one distribution can be specified at a time.

**Show Density Functions**  Shows or hides the Compare Density report. Select a distribution. For each group, the density function and confidence bands are displayed. A legend is shown to the right of the plot. Only one distribution can be specified at a time.

**Estimate Probability**  Adds an Estimate Probability report corresponding to the most recently selected distribution under Compare Distribution. Enter a value for the Time to Event variable in the text box and press Enter. To add a Time to Event value, click the plus sign. To remove the most recent value, click the minus sign. See “Estimate Probability Report” on page 69.

**Estimate Quantile**  (Appears only if Compare Quantile is selected.) Adds an Estimate Quantile report corresponding to the most recently selected distribution under Compare Quantile. Enter a value for the probability of interest in the text box and press Enter. To add a Prob value, click the plus sign. To remove the most recent value, click the minus sign. For each group and probability value, the Time to Event quantile and 95% Wald and Likelihood confidence intervals are shown.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Estimate Probability Report

For each group and Time to Event value, this report provides the following:

**Midpoint Estimate**  Midpoint-adjusted Kaplan-Meier estimate of failure by the specified time.

**Lower 95%, Upper 95%**  Pointwise 95% confidence intervals for the probability of failure by the specified time.

**Simultaneous Lower 95% (Nair), Simultaneous Upper 95% (Nair)**  Simultaneous 95% confidence intervals for the probability of failure by the specified time. See Nair (1984) and Meeker and Escobar (1998).

**Survival Probability**  Midpoint-adjusted estimate of survival beyond the specified time.

**Survival Probability Lower 95%, Upper 95%**  Pointwise 95% confidence intervals for the probability of survival beyond the specified time.

**Survival Probability Simultaneous Lower 95% (Nair), Simultaneous Upper 95% (Nair)**  Simultaneous 95% confidence intervals for the probability of survival beyond the specified time. See Nair (1984) and Meeker and Escobar (1998).

### Additional Examples of the Life Distribution Platform

- “Omit Competing Causes”
- “Change the Scale”
- “Examine the Same Distribution across Groups”
- “Weibayes Estimates”
- “Fit Mixture Example”
- “Fit Competing Risk Mixture Example”

### Omit Competing Causes

This example illustrates how to decide on the best fit for competing causes.

1. Select Help > Sample Data Library and open Reliability/Blenders.jmp.
2. Select Analyze > Reliability and Survival > Life Distribution.
4. Select Causes and click Failure Cause.
5. Select Censor and click Censor.
6. Select **Individual Best** as the Distribution.

7. Make sure that **AICc** is the Comparison Criterion.

8. Click **OK**.

On the Competing Cause report, JMP shows the best distribution fit for each failure cause.

**Figure 3.11** Initial Competing Cause Report

![Initial Competing Cause Report](image)

9. In the Quantile Profiler, type 0.1 for the probability.

The estimated time by which 10% of the failures occur is 200.

**Figure 3.12** Estimated Failure Time for 10% of the Units

![Quantile Profiler](image)

10. Select **Omit** for bearing seal, belt, container throw, cord short, and engine fan (the causes with the fewest failures).

The estimated time by which 10% of the failures occur is now 263.
When power switch and stripped gear are the only causes of failure, the estimated time by which 10% of the failures occur increases by approximately 31%.

**Change the Scale**

In the initial Compare Distributions report, the probability and time axes are linear. But suppose that you want to see distribution estimates on a Fréchet scale.\(^1\)

1. Follow step 1 through step 5 in “Example of the Life Distribution Platform” on page 31.
2. In the Compare Distributions report, select **Fréchet** in the Scale column.
3. Click the Life Distribution red triangle and select **Interval Type > Pointwise**.

---

\(^1\) Using different scales is sometimes referred to as drawing the distribution on different types of *probability paper*. 
Figure 3.14 Nonparametric Estimates with a Fréchet Probability Scale

Using a Fréchet scale, the nonparametric estimates approximate a straight line, meaning that a Fréchet fit might be reasonable.

4. Select SEV in the Scale column.
The nonparametric estimates no longer approximate a straight line. You now know that the SEV distribution is not appropriate.

**Figure 3.15** Nonparametric Estimates with a SEV Probability Scale

---

**Examine the Same Distribution across Groups**

Suppose you want to compare the same distribution across different groups. You want to examine estimates of failure probabilities for a single type of capacitor operating at three different temperatures.

1. Select **Help > Sample Data Library** and open Reliability/Capacitor ALT.jmp.
2. Select **Analyze > Reliability and Survival > Life Distribution**.
3. Click the Compare Groups tab.
4. Select Hours and click **Y, Time to Event**.
5. Select Temperature and click **Grouping**.
6. Select Censor and click **Censor**.
7. Select Freq and click **Freq**.
8. Click **OK**.
The default graph shows the nonparametric estimates. At a higher temperature, the capacitor has a higher probability of failure. You want to try fitting a parametric distribution.

9. Select **Weibull** for Distribution and Scale.

**Figure 3.17** Compare Weibull Distribution for Groups
When plotted against a Weibull probability scale, the points come close to following three lines. This indicates that a Weibull distribution provides a reasonable fit for each of the Temperature groups.

**Weibayes Estimates**

There are two possible ways to obtain a Weibayes analysis:

- You have no failures (all observations are right-censored) and the preference **Weibayes Only for Zero Failure Data** is checked. Then the Weibayes report appears. See “**Weibayes Example for Data with No Failures**” on page 75.

- You have few failures. A full Life Distribution report is presented. Fit a Weibull distribution. In the Parametric Estimate - Weibull report, select the Fix Parameter option. Then select the Weibayes option in the Fixed Parameter report. See “**Weibayes Example for Data with One Failure**” on page 76.

**Weibayes Example for Data with No Failures**

You have data for a product that is mostly reliable. Thirty were tested for 1,000 hours with no failures occurring. You want to predict the failure probability at 2,000 hours.

1. Select **Help > Sample Data Library** and open Reliability/Weibayes No Failures.jmp.
2. Select **Analyze > Reliability and Survival > Life Distribution**.
3. Select **Time** and click **Y, Time to Event**.
4. Select **Censor** and click **Censor**.
5. Select **Freq** and click **Freq**.
6. Select **Likelihood** as the Confidence Interval Method.
7. Click **OK**.

A special Life Distribution report appears. **Weibayes** and **Weibull beta** should be selected.

8. Type 1.5 as the known Weibull $\beta$ value.

The value 1.5 is considered appropriate for this example.
9. Click **Update**.
Figure 3.18 Life Distribution Report for Zero Failures

From the Distribution Profiler, you can see that at 2,000 hours, the conservative probability is 24.6058%. That means that the one-tailed conservative 95% confidence limit for the failure probability is 24.6058%.

Weibayes Example for Data with One Failure

Suppose you have the same data, but this time, one failure occurred at 800 hours. Again, you want to predict the failure probability at 2,000 hours.

1. Select Help > Sample Data Library and open Reliability/Weibayes One Failure.jmp.
2. Select Analyze > Reliability and Survival > Life Distribution.
4. Select Censor and click Censor.
5. Select Freq and click Freq.
6. Select Likelihood as the Confidence Interval Method.
7. Click OK.
   The Life Distribution report appears.
8. Select the Weibull distribution in the Compare Distributions plot.
9. Click the red triangle next to Parametric Estimate - Weibull and select Fix Parameter.
10. Select Weibayes and Weibull beta in the Fix Parameter report.
11. Type 1.5 as the known Weibull $\beta$ value.
12. Click Update.
14. Hover over the top of the $Y$ axis. The cursor becomes a hand. Drag the axis downward until it reaches 0.5 as the top number.

**Figure 3.19** Life Distribution Report for One Failure

In the Distribution Profiler, the solid line shows the MLE. The dashed line shows the Weibayes conservative limit. You can see that at 2,000 hours, the conservative probability is 36.3351%. That means that the one-tailed conservative 95% confidence limit for the failure probability is 36.3351%.

**Fit Mixture Example**

In this example, you fit two mixture distributions and then identify observations belonging to one of the clusters for the second mixture.

**Fit Two Mixture Distributions**

1. Select Help > Sample Data Library and open Reliability/Mixture Demo.jmp.
2. Select Analyze > Reliability and Survival > Life Distribution.
3. Select $Y_1$ and click $Y$, Time to Event.
4. Click **OK**.

5. Click the Life Distribution red triangle and select **Fit Mixture**.

6. Type 2 in the **Quantity** box next to **Weibull**.

7. Select **Separable Clusters** in the Starting Value Methods panel.

8. Click **Go**.

**Figure 3.20 Fit Mixture for Weibull (2)**

JMP fits a mixture model consisting of two Weibull components. Portion 1 is estimated as 0.231688, indicating that approximately 23% of observations have the Weibull distribution with alpha = 9.483153 and beta = 3.001963. The remaining 77% are estimated to come from the second Weibull distribution.

To compare this model to another, you can change the Ingredient selections and the Quantity of components.
9. Type 1 next to **Lognormal** and 1 next to **Weibull**.
10. Click **Go**.

**Figure 3.21** Fit Mixture for Lognormal(1), Weibull(1)

The Overlay plot is updated to show both mixture models. The plots and statistics in the Model List indicate that the Lognormal(1), Weibull(1) mixture seems to give a fit that is very similar to the Weibull(2) mixture.

**Identify Observations Belonging to a Cluster**

1. Click the red triangle next to Lognormal(1), Weibull(1) and select **Save Predictions**.

Two columns are added to the data table:

- Lognormal(1), Weibull(1) - Predicted Probability from Lognormal
Lognormal(1), Weibull(1) - Predicted Probability from Weibull

2. Select **Analyze > Distribution.**
3. Select the two new columns from the Select Columns list and click **Y, Columns.**
4. Check **Histograms Only.**
5. Click **OK.**
6. In the histogram for Lognormal(1), Weibull(1) - Predicted Probability from Weibull, click in the bar corresponding to the value near 1.

**Figure 3.22** Histograms for Mixture Probabilities

In the data table, the 297 corresponding rows are selected. These are the observations that are likely to have come from the Weibull distribution with parameters alpha = 29.90 and beta = 10.41.

**Fit Competing Risk Mixture Example**

In this example, you compare the fit of a single Weibull distribution to a competing risk mixture distribution with two Weibull fits.

1. Select **Help > Sample Data Library** and open Reliability/Mixture Demo.jmp.
2. Select **Analyze > Reliability and Survival > Life Distribution.**
3. Select **Y2** and click **Y, Time to Event.**
4. Click **OK.**
5. In the Compare Distributions report, select **Weibull** distribution and the corresponding **Scale** radio button.

A probability plot for a single Weibull distribution fit appears. Note that the fit is not very good in the lower part of the range of Y2.
6. Click the Life Distribution red triangle and select **Fit Competing Risk Mixture**.

7. Scroll down to the Competing Risk Mixture report. Next to **Weibull**, type 2 in the **Quantity** box.

8. Click **Go**.

9. Scroll up to the Compare Distributions report. In the probability plot, right-click the vertical axis and select **Edit > Copy Axis Settings**.

10. Scroll down to the Competing Risk Mixture report. In the overlay plot, right-click the vertical axis and select **Edit > Paste Axis Settings**.

11. Do the same for the horizontal axis. In the probability plot, right-click the horizontal axis and select **Edit > Copy Axis Settings**.

12. In the overlay plot, right-click the horizontal axis and select **Edit > Paste Axis Settings**.

The probability plot for the Weibull(2) distribution fit appears. Note that the mixture of two Weibull distributions helps better capture the distribution in the lower part of the range of \( Y_2 \).
Figure 3.24  Weibull(2) Competing Risk Mixture Distribution Fit

Statistical Details for the Life Distribution Platform

This section covers the following topics:

- The distributions used in the Life Distribution platform. See “Distributions” on page 82.
- Technical information about the Competing Cause report. See “Competing Cause Details” on page 97.
- Technical information about median rank regression. See “Notes Regarding Median Rank Regression” on page 102.

Distributions

This section provides details for the distributional fits in the Life Distribution platform. Meeker and Escobar (1998, ch. 2-5) is an excellent source of theory, application, and discussion for both the nonparametric and parametric details that follow.
Estimation and Confidence Intervals

The parameters of all distributions, unless otherwise noted, are estimated using maximum likelihood estimates (MLEs). The only exceptions are the threshold distributions. If the smallest observation is an exact failure, then this observation is treated as interval-censored with a small interval. The parameter estimates are the MLEs estimated from this slightly modified data set. Without this modification, the likelihood can be unbounded, so an MLE might not exist. This approach is similar to that described in Meeker and Escobar (1998, p. 275), except that only the smallest exact failure is censored. This is the minimal change to the data that guarantees boundedness of the likelihood function.

The Life Distribution platform offers two methods for calculating confidence intervals for the distribution parameters. These methods are labeled as Wald or Likelihood and can be selected in the launch window for the Life Distribution platform. Wald confidence intervals are used as the default setting. The computations for the confidence intervals for the cumulative distribution function (cdf) start with Wald confidence intervals on the standardized variable. Next, the intervals are transformed to the cdf scale (Nelson 1982, pp. 332–333 and pp. 346-347). The confidence intervals given in the other graphs and profilers are transformed Wald intervals (Meeker and Escobar 1998, ch. 7). Joint confidence intervals for the parameters of a two-parameter distribution are shown in the log-likelihood contour plots. They are based on approximate likelihood ratios for the parameters (Meeker and Escobar 1998, ch. 8).

Nonparametric Fit

A nonparametric fit describes the basic curve of a distribution. For data with no censoring (failures only) and for data where the observations consist of both failures and right-censoring, JMP uses Kaplan-Meier estimates. For mixed, interval, or left censoring, JMP uses Turnbull estimates. When your data set contains only right-censored data, the Nonparametric Estimate report indicates that the nonparametric estimate cannot be calculated.

The Life Distribution platform uses the midpoint estimates of the step function to construct probability plots. The midpoint estimate is halfway between (or the average of) the current and previous Kaplan-Meier estimates.
**Parametric Distributions**

Parametric distributions provide a more concise distribution fit than nonparametric distributions. The estimates of failure-time distributions are also smoother. Parametric models are also useful for extrapolation (in time) to the lower or upper tails of a distribution.

**Note:** Many distributions in the Life Distribution platform are parameterized by location and scale. For lognormal fits, the median is also provided. A threshold parameter is also included in threshold distributions. Location corresponds to \( \mu \), scale corresponds to \( \sigma \), and threshold corresponds to \( \gamma \).

**Lognormal**

Lognormal distributions are used commonly for failure times when the range of the data is several powers of 10. This distribution is often considered as the multiplicative product of many small positive identically independently distributed random variables. It is reasonable when the log of the data values appears normally distributed. Examples of data appropriately modeled by the lognormal distribution include hospital cost data, metal fatigue crack growth, and the survival time of bacteria subjected to disinfectants. The pdf curve is usually characterized by strong right-skewness. The lognormal pdf and cdf are:

\[
f(x; \mu, \sigma) = \frac{1}{x\sigma} \phi_{\text{nor}}\left[\frac{\log(x) - \mu}{\sigma}\right], \quad x > 0
\]

\[
F(x; \mu, \sigma) = \Phi_{\text{nor}}\left[\frac{\log(x) - \mu}{\sigma}\right]
\]

where

\[
\phi_{\text{nor}}(z) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right)
\]

and

\[
\Phi_{\text{nor}}(z) = \int_{-\infty}^{z} \phi_{\text{nor}}(w) dw
\]

are the pdf and cdf, respectively, for the standardized normal, or nor(\(\mu = 0, \sigma = 1\)) distribution.
Weibull

The Weibull distribution can be used to model failure time data with either an increasing or a decreasing hazard rate. It is used frequently in reliability analysis because of its tremendous flexibility in modeling many different types of data, based on the values of the shape parameter, $\beta$. This distribution has been successfully used for describing the failure of electronic components, roller bearings, capacitors, and ceramics. Various shapes of the Weibull distribution can be revealed by changing the scale parameter, $\alpha$, and the shape parameter, $\beta$. The Weibull pdf and cdf are commonly represented as follows:

$$f(x;\alpha,\beta) = \frac{\beta}{\alpha}x^{(\beta-1)}\exp\left[-\left(\frac{x}{\alpha}\right)^\beta\right]; \quad x > 0, \alpha > 0, \beta > 0$$

$$F(x;\alpha,\beta) = 1 - \exp\left[-\left(\frac{x}{\alpha}\right)^\beta\right]$$

where $\alpha$ is a scale parameter, and $\beta$ is a shape parameter. The Weibull distribution is particularly versatile because it reduces to an exponential distribution when $\beta = 1$. An alternative parameterization commonly used in the literature and in JMP is to use $\sigma$ as the scale parameter and $\mu$ as the location parameter. These are easily converted to an $\alpha$ and $\beta$ parameterization using the following definitions:

$$\alpha = \exp(\mu)$$

and

$$\beta = \frac{1}{\sigma}$$

The pdf and the cdf of the Weibull distribution are also expressed as a log-transformed smallest extreme value distribution (SEV). This uses a location scale parameterization, with $\mu = \log(\alpha)$ and $\sigma = 1/\beta$,

$$f(x;\mu,\sigma) = \frac{1}{x\sigma}\phi_{\text{sev}}\left[\frac{\log(x) - \mu}{\sigma}\right], \quad x > 0, \sigma > 0$$

$$F(x;\mu,\sigma) = \Phi_{\text{sev}}\left[\frac{\log(x) - \mu}{\sigma}\right]$$

where

$$\phi_{\text{sev}}(z) = \exp[z - \exp(z)]$$

and

$$\Phi_{\text{sev}}(z) = 1 - \exp[-\exp(z)]$$
are the pdf and cdf, respectively, for the standardized smallest extreme value \((\mu = 0, \sigma = 1)\) distribution.

**Loglogistic**

The pdf of the loglogistic distribution is similar in shape to the lognormal distribution but has heavier tails. It is often used to model data exhibiting non-monotonic hazard functions, such as cancer mortality and financial wealth. The loglogistic pdf and cdf are:

\[
\begin{align*}
  f(x;\mu,\sigma) &= \frac{1}{x\sigma} \phi_{\text{logis}} \left[ \frac{\log(x) - \mu}{\sigma} \right] \\
  F(x;\mu,\sigma) &= \Phi_{\text{logis}} \left[ \frac{\log(x) - \mu}{\sigma} \right]
\end{align*}
\]

where

\[
\phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]^2}
\]

and

\[
\Phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]} = \frac{1}{1 + \exp(-z)}
\]

are the pdf and cdf, respectively, for the standardized logistic or logis distribution \((\mu = 0, \sigma = 1)\).

**Fréchet**

The Fréchet distribution is known as a log-largest extreme value distribution or sometimes as a Fréchet distribution of maxima when it is parameterized as the reciprocal of a Weibull distribution. This distribution is commonly used for financial data. The pdf and cdf are:

\[
\begin{align*}
  f(x;\mu,\sigma) &= \exp \left[ -\exp \left( -\frac{\log(x) - \mu}{\sigma} \right) \right] \exp \left( -\frac{\log(x) - \mu}{\sigma} \right) \frac{1}{x\sigma} \\
  F(x;\mu,\sigma) &= \exp \left[ -\exp \left( -\frac{\log(x) - \mu}{\sigma} \right) \right]
\end{align*}
\]

and are more generally parameterized as follows:

\[
\begin{align*}
  f(x;\mu, \sigma) &= \frac{1}{x\sigma} \phi_{\text{lev}} \left[ \frac{\log(x) - \mu}{\sigma} \right] \\
  F(x;\mu, \sigma) &= \Phi_{\text{lev}} \left[ \frac{\log(x) - \mu}{\sigma} \right]
\end{align*}
\]
where

\[ \phi_{\text{lev}}(z) = \exp[-z - \exp(-z)] \]

and

\[ \Phi_{\text{lev}}(z) = \exp[-\exp(-z)] \]

are the pdf and cdf, respectively, for the standardized largest extreme value LEV(\(\mu = 0, \sigma = 1\)) distribution.

**Normal**

The normal distribution is the most widely used distribution in most areas of statistics because of its relative simplicity and the ease of applying the central limit theorem. However, it is rarely used in reliability. It is most useful for data where \(\mu > 0\) and the coefficient of variation (\(\sigma / \mu\)) is small. Because the hazard function increases with no upper bound, it is particularly useful for data exhibiting wear-out failure. Examples include incandescent light bulbs, toaster heating elements, and mechanical strength of wires. The pdf and cdf are:

\[
f(x;\mu,\sigma) = \frac{1}{\sigma \phi_{\text{nor}}(\frac{x-\mu}{\sigma})}, \quad -\infty < x < \infty
\]

\[
F(x;\mu,\sigma) = \Phi_{\text{nor}}\left(\frac{x-\mu}{\sigma}\right)
\]

where

\[
\phi_{\text{nor}}(z) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right)
\]

and

\[
\Phi_{\text{nor}}(z) = \int_{-\infty}^{z} \phi_{\text{nor}}(w)\,dw
\]

are the pdf and cdf, respectively, for the standardized normal, or nor(\(\mu = 0, \sigma = 1\)) distribution.
Smallest Extreme Value (SEV)

This non-symmetric (left-skewed) distribution is useful in two cases. The first case is when the data indicate a small number of weak units in the lower tail of the distribution (the data indicate the smallest number of many observations). The second case is when \( \sigma \) is small relative to \( \mu \), because probabilities of being less than zero, when using the SEV distribution, are small. The smallest extreme value distribution is useful to describe data whose hazard rate becomes larger as the unit becomes older. Examples include human mortality of the aged and rainfall amounts during a drought. This distribution is sometimes referred to as a Gumbel distribution. The pdf and cdf are:

\[
f(x; \mu, \sigma) = \frac{1}{\sigma} \phi_{\text{sev}}\left(\frac{x - \mu}{\sigma}\right), \quad -\infty < \mu < \infty, \quad \sigma > 0
\]

\[
F(x; \mu, \sigma) = \Phi_{\text{sev}}\left(\frac{x - \mu}{\sigma}\right)
\]

where

\[
\phi_{\text{sev}}(z) = \exp[z - \exp(z)]
\]

and

\[
\Phi_{\text{sev}}(z) = 1 - \exp[-\exp(z)]
\]

are the pdf and cdf, respectively, for the standardized smallest extreme value, SEV(\( \mu = 0, \sigma = 1 \)) distribution.

Logistic

The logistic distribution has a shape similar to the normal distribution, but with longer tails. The logistic distribution is often used to model life data when negative failure times are not an issue. Logistic regression models for a binary or ordinal response assume the logistic distribution as the latent distribution. The pdf and cdf are:

\[
f(x; \mu, \sigma) = \frac{1}{\sigma} \phi_{\text{logis}}\left(\frac{x - \mu}{\sigma}\right), \quad -\infty < \mu < \infty \text{ and } \sigma > 0
\]

\[
F(x; \mu, \sigma) = \Phi_{\text{logis}}\left(\frac{x - \mu}{\sigma}\right)
\]

where

\[
\phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]^2}
\]
and
\[
\phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]} = \frac{1}{1 + \exp(-z)}
\]
are the pdf and cdf, respectively, for the standardized logistic or logis distribution (\(\mu = 0, \sigma = 1\)).

**Largest Extreme Value (LEV)**

This right-skewed distribution can be used to model failure times if \(\sigma\) is small relative to \(\mu > 0\). This distribution is not commonly used in reliability but is useful for estimating natural extreme phenomena, such as a catastrophic flood heights or extreme wind velocities. The pdf and cdf are:
\[
f(x;\mu,\sigma) = \frac{1}{\sigma} \phi_{\text{lev}}\left(\frac{x - \mu}{\sigma}\right), \quad -\infty < \mu < \infty \text{ and } \sigma > 0
\]
\[
F(x;\mu,\sigma) = \Phi_{\text{lev}}\left(\frac{x - \mu}{\sigma}\right)
\]
where
\[
\phi_{\text{lev}}(z) = \exp[-z - \exp(-z)]
\]
and
\[
\Phi_{\text{lev}}(z) = \exp[-\exp(-z)]
\]
are the pdf and cdf, respectively, for the standardized largest extreme value LEV(\(\mu = 0, \sigma = 1\)) distribution.

**Exponential**

Both one- and two-parameter exponential distributions are used in reliability. The pdf and cdf for the two-parameter exponential distribution are:
\[
f(x;\theta, \gamma) = \frac{1}{\theta} \exp\left(-\frac{x - \gamma}{\theta}\right), \quad \theta > 0
\]
\[
F(x;\theta, \gamma) = 1 - \exp\left(-\frac{x - \gamma}{\theta}\right)
\]
where \(\theta\) is a scale parameter and \(\gamma\) is both the threshold and the location parameter. Reliability analysis frequently uses the one-parameter exponential distribution, with \(\gamma = 0\). The exponential distribution is useful for describing failure times of components exhibiting wear-out far beyond their expected lifetimes. This distribution has a constant failure rate, which means that for small time increments, failure of a unit is independent of the unit’s age.
The exponential distribution should not be used for describing the life of mechanical components that can be exposed to fatigue, corrosion, or short-term wear. This distribution is, however, appropriate for modeling certain types of robust electronic components. It has been used successfully to describe the life of insulating oils and dielectric fluids (Nelson 1990, p. 53).

**Log Generalized Gamma (LogGenGamma)**

The log generalized gamma distribution contains the SEV, LEV, and Normal. The pdf and cdf are:

$$f(x; \mu, \sigma, \lambda) = \begin{cases} \frac{\lambda}{\sigma} \phi_{lg}(\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}) & \text{if } \lambda \neq 0 \\ \frac{1}{\sigma} \phi_{nor}(\omega) & \text{if } \lambda = 0 \end{cases}$$

$$F(x; \mu, \sigma, \lambda) = \begin{cases} 
\Phi_{lg}(\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}) & \text{if } \lambda > 0 \\
\Phi_{nor}(\omega) & \text{if } \lambda = 0 \\
1 - \Phi_{lg}(\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}) & \text{if } \lambda < 0 
\end{cases}$$

where $-\infty < x < \infty$, $\omega = (x - \mu)/\sigma$, and

$-\infty < \mu < \infty$, $-12 < \lambda < 12$, and $\sigma > 0$.

Note that

$$\phi_{lg}(z; \kappa) = \frac{1}{\Gamma(\kappa)} \exp[\kappa z - \exp(z)]$$

$$\Phi_{lg}(z; \kappa) = \Gamma_1[\exp(z); \kappa]$$

are the pdf and cdf, respectively, for the log-gamma variable and $\kappa > 0$ is a shape parameter. The standardized distributions above are dependent upon the shape parameter $\kappa$.

**Note:** In JMP, the shape parameter, $\lambda$, for the generalized gamma distribution is bounded between [-12,12] to provide numerical stability.
Extended Generalized Gamma (GenGamma)

The extended generalized gamma distribution can include many other distributions as special
cases, such as the generalized gamma, Weibull, lognormal, Fréchet, gamma, and exponential.
It is particularly useful for cases with little or no censoring. This distribution has been
successfully modeled for human cancer prognosis. The pdf and cdf are:

\[
f(x; \mu, \sigma, \lambda) = \begin{cases} 
\frac{|\lambda|}{x \sigma} \phi_{lg}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda \neq 0 \\
\frac{1}{x \sigma} \phi_{nor}(\omega) & \text{if } \lambda = 0
\end{cases}
\]

\[
F(x; \mu, \sigma, \lambda) = \begin{cases} 
\Phi_{lg}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda > 0 \\
\Phi_{nor}(\omega) & \text{if } \lambda = 0 \\
1 - \Phi_{lg}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda < 0
\end{cases}
\]

where \( x > 0 \), \( \omega = [\log(x) - \mu]/\sigma \), and

\(-\infty < \mu < \infty, -12 < \lambda < 12, \text{ and } \sigma > 0.\)

Note that

\[
\phi_{lg}(z; \kappa) = \frac{1}{\Gamma(\kappa)} \exp[\kappa z - \exp(z)]
\]

\[
\Phi_{lg}(z; \kappa) = \Gamma[\exp(z); \kappa]
\]

are the pdf and cdf, respectively, for the standardized log-gamma variable and \( \kappa > 0 \) is a shape
parameter.

The standardized distributions above are dependent upon the shape parameter \( \kappa \). Meeker and
Escobar (1998, ch. 5) give a detailed explanation of the extended generalized gamma
distribution.

**Note:** In JMP, the shape parameter, \( \lambda \), for the generalized gamma distribution is bounded
between \([-12, 12]\) to provide numerical stability.
Distributions with Threshold Parameters

Threshold Distributions are log-location-scale distributions with threshold parameters. Some of the distributions above are generalized by adding a threshold parameter, denoted by $\gamma$. The addition of this threshold parameter shifts the left endpoint of the distribution away from 0. Threshold parameters are sometimes called shift, minimum, or guarantee parameters because all units survive at least until threshold time. Note that while adding a threshold parameter shifts the distribution on the time axis, the shape, and spread of the distribution are not affected. Threshold distributions are useful for fitting moderately to heavily shifted distributions. The general forms for the pdf and cdf of a log-location-scale threshold distribution are:

$$f(x; \mu, \sigma, \gamma) = \frac{1}{\sigma(x - \gamma)} \phi \left[ \frac{\log(x - \gamma) - \mu}{\sigma} \right], \quad x > \gamma$$

$$F(x; \mu, \sigma, \gamma) = \Phi \left[ \frac{\log(x - \gamma) - \mu}{\sigma} \right]$$

where $\phi$ and $\Phi$ are the pdf and cdf, respectively, for the specific distribution. Examples of specific threshold distributions are shown below for the Weibull, lognormal, Fréchet, and loglogistic distributions, where, respectively, the SEV, Normal, LEV, and logis pdfs and cdfs are appropriately substituted.

**Note:** If the smallest observation is a failure (not censored), JMP creates a small interval around the point and treats the observation as interval censored. This padding around the failure bounds the log-likelihood function and improves estimation. If the smallest observation is censored, then no extra padding is added to the observation.

**TH Weibull**

The pdf and cdf of the three-parameter Weibull distribution are:

$$f(x; \mu, \sigma, \gamma) = \frac{1}{(x - \gamma)\sigma} \phi_{\text{sev}} \left[ \frac{\log(x - \gamma) - \mu}{\sigma} \right], \quad x > \gamma, \sigma > 0$$

$$F(x; \mu, \sigma, \gamma) = \Phi_{\text{sev}} \left( \frac{\log(x - \gamma) - \mu}{\sigma} \right) = 1 - \exp \left[ -\left( \frac{x - \gamma}{\alpha} \right)^\beta \right], \quad x > \gamma$$

where $\mu = \log(\alpha)$, and $\sigma = 1/\beta$ and where

$$\phi_{\text{sev}}(z) = \exp[z - \exp(z)]$$

and

$$\Phi_{\text{sev}}(z) = 1 - \exp[-\exp(z)]$$
are the pdf and cdf, respectively, for the standardized smallest extreme value, SEV(\(\mu = 0, \sigma = 1\)) distribution.

**TH Lognormal**

The pdf and cdf of the three-parameter lognormal distribution are:

\[
f(x; \mu, \sigma, \gamma) = \frac{1}{\sigma(x-\gamma)} \phi_{\text{nor}} \left[ \frac{\log(x-\gamma) - \mu}{\sigma} \right], \quad x > \gamma
\]

\[
F(x; \mu, \sigma, \gamma) = \Phi_{\text{nor}} \left[ \frac{\log(x-\gamma) - \mu}{\sigma} \right]
\]

where

\[
\phi_{\text{nor}}(z) = \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{z^2}{2} \right)
\]

and

\[
\Phi_{\text{nor}}(z) = \int_{-\infty}^{z} \phi_{\text{nor}}(w) dw
\]

are the pdf and cdf, respectively, for the standardized normal, or N(\(\mu = 0, \sigma = 1\)) distribution.

**TH Fréchet**

The pdf and cdf of the three-parameter Fréchet distribution are:

\[
f(x; \mu, \sigma, \gamma) = \frac{1}{\sigma(x-\gamma)} \phi_{\text{lev}} \left[ \frac{\log(x-\gamma) - \mu}{\sigma} \right], \quad x > \gamma
\]

\[
F(x; \mu, \sigma, \gamma) = \Phi_{\text{lev}} \left[ \frac{\log(x-\gamma) - \mu}{\sigma} \right]
\]

where

\[
\phi_{\text{lev}}(z) = \exp[-z - \exp(-z)]
\]

and

\[
\Phi_{\text{lev}}(z) = \exp[-\exp(-z)]
\]

are the pdf and cdf, respectively, for the standardized largest extreme value LEV(\(\mu = 0, \sigma = 1\)) distribution.
TH Loglogistic

The pdf and cdf of the three-parameter loglogistic distribution are:

\[
f(x; \mu, \sigma, \gamma) = \frac{1}{\sigma (x - \gamma)} \phi_{\text{logis}} \left( \frac{\log(x - \gamma) - \mu}{\sigma} \right), \quad x > \gamma
\]

\[
F(x; \mu, \sigma, \gamma) = \Phi_{\text{logis}} \left( \frac{\log(x - \gamma) - \mu}{\sigma} \right)
\]

where

\[
\phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]^2}
\]

and

\[
\Phi_{\text{logis}}(z) = \frac{\exp(z)}{[1 + \exp(z)]} = \frac{1}{1 + \exp(-z)}
\]

are the pdf and cdf, respectively, for the standardized logistic or logis distribution ($\mu = 0$, $\sigma = 1$).

Distributions for Defective Subpopulations

In reliability experiments, there are times when only a fraction of the population has a particular defect leading to failure. Because all units are not susceptible to failure, using the regular failure distributions is inappropriate and might produce misleading results. Use the DS distribution options to model failures that occur on only a subpopulation. The following DS distributions are available:

- DS Lognormal
- DS Weibull
- DS Loglogistic
- DS Fréchet

The pdf and cdf for defective subpopulation distributions are defined as follows:

\[
f(t) = \left[ p \left( \frac{1}{t \sigma} \right) \phi \left( \frac{\log(t) - \mu}{\sigma} \right) \right]
\]

\[
F(t) = p \Phi \left( \frac{\log(t) - \mu}{\sigma} \right)
\]

where:

$\text{p}$ is the defective subpopulation fraction

$t$ is the time of measurement for the lifetime event
\( \mu \) and \( \sigma \) are estimated by calculating the usual maximum likelihood estimations using the pdf and cdf of the corresponding defective subpopulation.

\( \phi(z) \) and \( \Phi(z) \) are the density and cumulative distribution function, respectively, for a standard distribution. For example, for a Weibull distribution,

\[
\phi(z) = \exp(z - \exp(z)) \quad \text{and} \quad \Phi(z) = 1 - \exp(-\exp(z)).
\]

See Tobias and Trindad (2012, p. 321) for more information about defective subpopulation models.

The defective subpopulation model is also known as a limited failure population model in Meeker and Escobar (1998, ch. 11).

**Zero-Inflated Distributions**

Zero-inflated distributions are used when some proportion \( \hat{p} \) of the data fail at \( t = 0 \). When the data contain more zeros than expected by a standard model, the number of zeros is inflated. When the time-to-event data contain zero as the minimum value in the Life Distribution platform, four zero-inflated distributions are available. These distributions include:

- Zero-Inflated Lognormal (ZI Lognormal)
- Zero-Inflated Weibull (ZI Weibull)
- Zero-Inflated Loglogistic (ZI Loglogistic)
- Zero-Inflated Fréchet (ZI Fréchet)

The pdf and cdf for zero-inflated distributions are defined as follows:

\[

t(t) = \left[ (1 - \hat{p}) \frac{1}{t \sigma} \right] \phi\left( \frac{\log(t) - \mu}{\sigma} \right) \\
F(t) = \hat{p} + (1 - \hat{p}) \Phi\left( \frac{\log(t) - \mu}{\sigma} \right)
\]

where:

- \( \hat{p} \) is the proportion of zero data values
- \( t \) is the time of measurement for the lifetime event
- \( \mu \) and \( \sigma \) are estimated by calculating the usual maximum likelihood estimations after removing zero values from the original data
- \( \phi(z) \) and \( \Phi(z) \) are the density and cumulative distribution function, respectively, for a standard distribution. For example, for a Weibull distribution,

\[
\phi(z) = \exp(z - \exp(z)) \quad \text{and} \quad \Phi(z) = 1 - \exp(-\exp(z)).
\]

See Lawless (2003, p. 34) for more information about zero-inflated distributions. Substitute \( \hat{p} = 1 - p \) and \( S_1(t) = 1 - \Phi(t) \) to obtain the form shown above.
See Tobias and Trindade (1995, p. 232) for more information about reliability distributions. This reference gives the general form for mixture distributions. Using the parameterization in Tobias and Trindade, the form above can be found by substituting $\alpha = p$, $F_d(t) = 1$, and $F_M(t) = \Phi(t)$.

### Prior Distributions for Bayesian Estimation

The following distributions are available for Location Scale Priors:

- Normal/Lognormal, with hyperparameters Location (mu) and Scale (sigma). For a definition, see “Lognormal” on page 84 and “Normal” on page 87.
- Uniform, with hyperparameters Low and End, which define the support of a Uniform distribution.
- Gamma, with hyperparameters Shape and Scale. The k/theta parameterization and the probability density function is used.
- Point Mass, with hyperparameter Location. This is a degenerated prior; there is only one possible value for the parameter that we are assigning a prior distribution to. The only possible value equals the value that is entered to this Location hyperparameter.

The following distributions are available for Quantile Parameter Priors:

- Normal/Lognormal, with a 99% probability range, specifies the prior distribution using the 0.005 and 0.995 percentiles of the distribution. JMP backs out the mu and sigma.
- Uniform, with hyperparameters Lower and Upper Limits, which define the support of a Uniform distribution.
- Log-Uniform, with Lower (a) and Upper (b) Limits. This distribution is uniform on the log scale between Log(a) and Log(b).
- Point Mass, with hyperparameter Location. This is a degenerated prior; there is only one possible value for the parameter that we are assigning a prior distribution to. The only possible value equals the value that is entered to this Location hyperparameter.

The following distributions are available for Failure Probability Priors:

- Beta, characterized by the probability density function.
  - Specify the Beta prior using estimates and error percentages (mean and variance). The mean equals the number entered in to the Estimate, and the variance equals (Error Percentage / 100 * Estimate)^2.
  - Specify the Beta prior using 0.005 and 0.995 percentiles of the distribution. JMP backs out the hyperparameters.
Competing Cause Details

For a competing cause model, a closed form for the aggregated distribution is defined as follows:

$$F(x) = 1 - \prod_{i=1}^{k} [1 - F_i(x)]$$

where the $F_i(x), i = 1, \ldots, k$, are individual failure distributions corresponding to causes. Confidence limits are readily available, because all involved estimates are MLEs.

Specify a Fixed Parameter Model as a Distribution for a Cause

If a Fixed Parameter model is specified for a cause, you must fix the parameter in the Individual Causes report for that cause. Fix the parameter in the desired Parametric Estimate report in the Life Distribution - Failure Cause: <Name> report. The fixed parameter becomes part of the aggregated distribution when you click Update Model.

This example illustrates how to include the Fixed Parameter model into the aggregated distribution:

1. Select Help > Sample Data Library and open Reliability/Appliance.jmp.
2. Select Analyze > Reliability and Survival > Life Distribution.
4. Select Cause Code and click Failure Cause.
5. Select Likelihood as the Confidence Interval Method.
6. Select Allow failure mode to use fixed parameter models.
7. Click OK.
By default, Cause = 1 is omitted, because there are not enough data. However, you do not want this cause to be omitted.

9. Click the red triangle next to Parametric Estimate - Weibull and select **Fix Parameter**.

10. Select Weibull beta and type 2.

11. Click Update.
In the Parametric Estimate - Weibull report, assuming $\beta$ equals 2, the alpha parameter is estimated to be 22463.391. Now you can use this for the failure distribution for Cause=1.

12. Scroll up to Cause Combination at the top of the report window.
14. For the distribution for Cause 1, select **Fixed Parameter Weibull**.
15. Click **Update Model**.
Now the aggregated model uses the Fixed Parameter Weibull results for Cause 1 in the overall competing cause model.

Specify a Bayesian Model for a Cause

The steps for specifying a Bayesian model for a cause are similar to those described in “Specify a Fixed Parameter Model as a Distribution for a Cause” on page 97. Define the model in the desired Bayesian Estimation report found in the corresponding Parametric Estimate outline under Statistics in the Life Distribution report for the individual cause. See “Bayesian Estimation - <Distribution Name>” on page 48.

To incorporate a Bayesian model into the aggregated model, non-Bayesian distributions for other causes must be amenable to a simulation-based framework. For example, suppose that a model has two failure causes. One is modeled using a Weibull distribution and the other using a Bayesian approach for estimating the parameters of a second Weibull. The parameters for the first Weibull distribution, denoted by the vector $\theta_1$, are estimated using maximum likelihood. The parameters for the second Weibull, $\theta_2$, are estimated using the Bayesian approach.

The quantiles and median of the aggregated mixture distribution, denoted $F(x, \theta_1, \theta_2)$, are obtained as follows:

- A parametric bootstrap is performed for the first Weibull, yielding random samples from the asymptotic distribution of the maximum likelihood estimate $\hat{\theta}_1$. Denote a sampled value from the asymptotic distribution of $\hat{\theta}_1$ by $\theta_1^*$.
- A sample is drawn from the posterior distribution of $\theta_2$, denoted by $\theta_2^*$.
• For each set of values \( \theta_1^* \) and \( \theta_2^* \), an estimate of \( F(x, \theta_1, \theta_2) \), denoted by \( F^*(x, \theta_1, \theta_2) \), is obtained.

• The values \( F^*(x, \theta_1, \theta_2) \) are used to obtain estimates of the quantiles and median of the aggregated distribution. These are the values displayed in the Distribution profiler at a given value of \( x \).

**Specify a Weibayes Model for a Cause**

The steps for specifying a Weibayes model for a cause are similar to those described in “Specify a Fixed Parameter Model as a Distribution for a Cause” on page 97. Select the Fix Parameter option in the Parametric Estimate - Weibull outline under Statistics in the Life Distribution report for the cause. In the Fix Parameter report, check the Weibayes option. The Weibayes model is treated as a Bayesian model and a bootstrap sample is drawn from the posterior distribution of the parameter alpha. See Liu and Wang (2013).

**Mean Remaining Life Calculator**

Use the Configuration option in the red triangle menu to set a value for the number of simulated failure times used in computing the mean remaining life. Denote this value by \( m \).

To obtain an estimate of the mean remaining life at time \( t \), \( m \) samples are drawn from the aggregated distribution conditioned on survival to time \( t \). Their average is computed.

To compute the confidence limits for the mean remaining life, you must select the box in the Configuration window. You then have the option to set the number of bootstrap samples. Denote this value by \( n \).

To compute the confidence interval, \( n \) samples of parameter estimates are drawn from either the asymptotic distributions of the MLEs, or the posterior distributions derived using Bayesian inference. For each sample of parameter values, an aggregated distribution is formed, from which \( m \) samples are drawn to compute a mean remaining life. The samples of \( n \) mean remaining life values are used to construct the confidence interval.

**Fit Mixture Save Predictions Formulas**

This section gives the formulas used in calculating values in the columns saved by the Fit Mixture report option Save Predictions.

Consider the following notation:

- \( \hat{p}_i \) is an estimate of the mixture proportion, \( w_i \)
- \( \hat{F}_i \) is the estimated probability distribution function \( F_i \)
- \( \hat{f}_i \) is the estimated probability density function for \( F_i \)
• If the observation \( y \) is not censored, the saved value is given by the following:

\[
\frac{\hat{p}_i \hat{f}_i(y)}{k} \sum_{i=1}^{k} \hat{p}_i \hat{f}_i(y)
\]

• If the observation is censored, the saved value is obtained by replacing the estimated density values in the formula for an uncensored observation by the following:

\[
\hat{F}_i(y) \text{ for right censoring}
\]
\[
1 - \hat{F}_i(y) \text{ for left censoring}
\]
\[
\hat{F}_i(y_{\text{high}}) - \hat{F}_i(y_{\text{low}}) \text{ for interval censoring}
\]

**Notes Regarding Median Rank Regression**

When there are no censored rows and no Weight column, median rank regression (MRR) for Weibull parameter estimates is available in the Life Distribution platform. The following conditions must be met before MRR estimates appear in the Life Distribution report:

• This Life Distribution platform preference is selected: Report Median Rank Regression Based Weibull Parameter Estimates When There Are No Censored Observations.

• There are no censored observations in the analysis. In other words, all observations represent failure times.

• There is no Weight column specified.

If all of the above conditions are met, the Parametric Estimate - Weibull report is modified to show MRR estimates as well as the usual maximum likelihood estimates (MLE). The column headings in the parameter estimates table are prefixed with MLE or MRR to denote which estimation method was used to produce each column of estimates. There are no confidence intervals available for the MRR estimates.

**Caution:** The use of MRR estimates is not recommended. Median rank regression uses least squares estimation to produce estimates, instead of maximum likelihood. There are no commonly accepted methods to apply least squares estimation to censored data. Further, Genschel and Meeker (2010) show that the MLE method is more precise. They provide simulation results that are based on the fact that the true estimates are known, but in reality, the accuracy of MRR estimates is unknown. Because MRR is a loosely defined and ad hoc estimation procedure, different software packages produce different MRR estimates for the same data.
The Fit Life by X platform helps you analyze lifetime events when only one factor is present. You can choose to model the relationship between the event and the factor using various transformations, or create a custom transformation of your data. You also have the flexibility of comparing different distributions at the same factor level and comparing the same distribution across different factor levels.

Overview of the Fit Life by X Platform

The Fit Life by X platform provides the tools needed for accelerated life-testing analysis. Accelerated tests are routinely used in industry to provide failure-time information about products or components in a relatively short time frame. Common accelerating factors include temperature, voltage, pressure, and usage rate. Results are extrapolated to obtain time-to-failure estimates at lower, normal operating levels of the accelerating factors. These results are used to assess reliability, detect and correct failure modes, compare manufacturers, and certify components.

The Fit Life by X platform includes many commonly used transformations to model physical and chemical relationships between the event and the factor of interest. Examples include transformation using Arrhenius (Celsius, Fahrenheit, and Kelvin) relationship time-acceleration factors and Voltage-acceleration mechanisms. Linear, Log, Logit, Reciprocal, Square Root, Box-Cox, Location, Location and Scale, and Custom acceleration models are also included in this platform.

You can use the DOE > Accelerated Life Test Design platform to design accelerated life test experiments. See the Design of Experiments Guide.

Meeker and Escobar (1998, p. 495) offer the following strategy for analyzing accelerated lifetime data:

1. Examine the data graphically. One useful way to visualize the data is by examining a scatterplot of the time-to-failure variable versus the accelerating factor.
2. Fit distributions individually to the data at different levels of the accelerating factor. Repeat for different assumed distributions.
3. Fit an overall model with a plausible relationship between the time-to-failure variable and the accelerating factor.
4. Compare the model in Step 3 with the individual analyses in Step 2, assessing the lack of fit for the overall model.
5. Perform residual and various diagnostic analyses to verify model assumptions.
6. Assess the plausibility of the data to make inferences.
Example of the Fit Life by X Platform

This example uses the Devalt.jmp sample data table, from Meeker and Escobar (1998), and can be found in the Reliability folder of the sample data. It contains time-to-failure data for a device at accelerated operating temperatures. No time-to-failure observation is recorded for the normal operating temperature of 10 degrees Celsius; all other observations are shown as time-to-failure or censored values at accelerated temperature levels of 40, 60, and 80 degrees Celsius.

1. Select Help > Sample Data Library and open Reliability/Devalt.jmp.
2. Select Analyze > Reliability and Survival > Fit Life by X.
3. Select Hours and click Y, Time to Event.
4. Select Temp and click X.
5. Select Censor and click Censor.
7. Select Weight and click Freq.
8. Keep Arrhenius Celsius as the relationship, and keep the Nested Model Tests option selected.
9. Select Weibull as the distribution.
10. Keep Wald as the confidence interval method.

Figure 4.2 Fit Life by X Launch Window

11. Click OK.
The report window shows summary data, diagnostic plots, comparison data and results, including detailed statistics and prediction profilers. Separate result sections are shown for each selected distribution. Distribution, Quantile, Hazard, Density, and Acceleration Factor Profilers are included for each of the specified distributions.
Launch the Fit Life by X Platform

Launch the Fit Life by X platform by selecting **Analyze > Reliability and Survival > Fit Life by X**. For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Figure 4.4** The Fit Life by X Launch Window

The Fit Life by X launch window contains the following options:

**Y, Time to Event**  Identifies the time to event (such as the time to failure) or time to censoring. With interval censoring, specify two Y variables, where one Y variable gives the lower limit and the other Y variable gives the upper limit for each unit. For more information about censoring, see “Event Plot” on page 38 in the “Life Distribution” chapter.

**X**  Identifies the accelerating factor.

**Censor**  Identifies censored observations. Select the value that identifies right-censored observations from the Censor Code menu beneath the Select Columns list. The Censor column is used only when one Y is entered.

**Freq**  Identifies frequencies or observation counts when there are multiple units. If the value is 0 or a positive integer, then the value represents the frequencies or counts of observations for each row when there are multiple units recorded.
By  Identifies a column that creates a report consisting of separate analyses for each level of the variable.

Censor Code  Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.

Relationship  Identifies the relationship between the event and the accelerating factor. Table 4.1 defines the model for each relationship.

Table 4.1 Models for Relationship Options

<table>

<td>user-defined ( \mu ) and ( \sigma )</td>
</tr>
</tbody>
</table>

If you select Box-Cox, a text edit box appears below the Use Condition option. Use this box to specify a lambda value. The \( \text{BoxCox}(X) \) transformation for a specified \( \lambda \) is defined as follows:
If you want to use a Custom relationship for your model, see “Custom Relationship” on page 131.

**Nested Model Tests**  Appends a nonparametric overlay plot, nested model tests, and a multiple probability plot to the report window.

**Use Condition**  Enables you to enter a value for the explanatory variable, X, of the acceleration factor. You can also set the use condition value after launching the platform using the Set Time Acceleration Use Condition option from the Fit Life by X red triangle menu.

**Distribution**  Specifies one distribution (Weibull, Lognormal, Loglogistic, Fréchet, SEV, Normal, Logistic, LEV, or Exponential distributions) at a time. Lognormal is the default setting.

**Select Confidence Interval Method**  Displays the method for computing confidence intervals for the parameters. The default is Wald, but you can select Likelihood instead. The Wald method is an approximation and runs faster. The Likelihood method provides more precise parameters but takes longer to compute.

**Note:** The Confidence Interval Method preference enables you to select the Likelihood method as the default confidence interval method. You can change this preference in Preferences > Platforms > Fit Life by X.

### The Fit Life by X Report

The initial report window includes the following sections:

- “Summary of Data” on page 113
- “Scatterplot” on page 113
- “Nonparametric Overlay” on page 115
- “Comparisons” on page 116
  Distribution, Quantile, Hazard, Density, and Acceleration Factor profilers, along with criteria values under Comparison Criterion can be viewed and compared.
- “Results” on page 120
Parametric estimates, covariance matrices, nested model tests, and diagnostics can be examined and compared for each of the selected distributions. You can also perform custom estimation and obtain Bayesian estimates for the distribution parameters.

Summary of Data

The Summary of Data section gives the total number of observations, the number of uncensored values, and the number of censored values (right, left, and interval). Figure 4.5 shows the summary data for the Devalt.jmp sample data table.

**Figure 4.5** Summary of Data Example

<table>

Scatterplot

The Scatterplot of the lifetime event versus the explanatory variable is shown at the top of the report window. For the Devalt.jmp sample data, the Scatterplot shows Hours versus Temp. Table 4.2 indicates how each type of failure is represented on the Scatterplot in the report window. To increase the size of the markers on the graph, right-click the graph, select Marker Size, and then select one of the marker sizes listed.

Scatterplot Options

The Scatterplot red triangle menu contains the following options:

Add Density Curve Specify the density curve that you want, one at a time, by entering any value within the range of the accelerating factor. You can then select different distributions by selecting the appropriate check box(es) that appear after you add a curve.

Remove Density Curves Displays previously entered density curve values. Remove curves by selecting the appropriate check box.

Show Density Curves Displays the density curves. If the Location or the Location and Scale model is fit, or if Nested Model Tests is selected in the launch window, then the density curves for all of the given explanatory variable levels are shown. After the curves have been created, the Show Density Curves option toggles the curves on and off the plot.

Add Quantile Lines Specify the quantile lines that you want, three at a time. You can add more quantiles by continually selecting Add Quantile Lines. Default quantile values are 0.1, 0.5, and 0.9. Invalid quantile values, such as missing values, are ignored. If desired, you can enter just one quantile value, leaving the other entries blank.

Show Quantile Line CI Bands Shows or hides confidence intervals around the quantile lines.

Set Level of Quantile Line CI Bands Specifies the confidence level for the confidence intervals around the quantile lines.

Remove Quantile Lines Displays previously entered quantile values. Remove lines by selecting the appropriate check box.

Transposed Axes Swaps the horizontal and vertical axes.

Use Transformation Scale The default view of the scatterplot incorporates the transformation scale. Select this option to switch between the linear and nonlinear scales for the horizontal axis.
Figure 4.6 shows the initial scatterplot; Figure 4.7 shows the resulting scatterplot with the **Show Density Curves** and **Add Quantile Lines** options selected displaying the curves and the lines for the various Temp levels for the Weibull distribution. You can also view density curves across all the levels of Temp for the other distributions. These distributions can be selected one at a time or can be viewed simultaneously by checking the boxes to the left of the desired distribution name(s).

**Figure 4.7 Scatterplot with Density Curve and Quantile Line Options**

---

**Nonparametric Overlay**

The Nonparametric Overlay plot is displayed after the scatterplot. Differences among groups can readily be detected by examining this plot. You can choose different scales for viewing these differences. You can change the interval type on a Nonparametric fit probability plot between **Simultaneous** and **Pointwise** (results displayed when **Show Nonparametric CI** is selected). You can also select whether to show parametric or nonparametric confidence intervals.

Pointwise estimates show the pointwise 95% confidence bands on the plot while simultaneous confidence intervals show the simultaneous confidence bands for all groups on the plot. Meeker and Escobar (1998, ch. 3) discuss pointwise and simultaneous confidence intervals and the motivation for simultaneous confidence intervals in a lifetime analysis.
Wilcoxon Group Homogeneity Test

For this example, the **Wilcoxon Group Homogeneity Test**, shown in Figure 4.8, indicates that there is a difference among groups. The high chi-square value and low p-value are consistent with the differences seen among the Temp groups in the Nonparametric Overlay plot.

**Figure 4.8 Nonparametric Overlay Plot and Wilcoxon Test for Devalt.jmp**

Comparisons

The Comparisons report section, shown in Figure 4.9, shows profilers for the selected distributions in the Nonparametric Overlay section, and includes the following tabs:

- Distribution
- Quantile
- Hazard
- Density
- Acceleration Factor
- Comparison Criterion

To show a specific profiler, select the appropriate distribution option in the Nonparametric Overlay section.
Profilers

The first five tabs show profilers for the selected distributions. Curves shown in the first four profilers correspond to both the time-to-event and explanatory variables. The Acceleration Factor profiler tab corresponds only to the acceleration factor (explanatory variable). Figure 4.9 shows the Distribution Profiler for the Weibull, Lognormal, Fréchet, and Loglogistic distributions.

Figure 4.9 Distribution Profiler

Comparable results appear on the Quantile, Hazard, and Density tabs. The Distribution, Quantile, Hazard, Density, and Acceleration Factor Profilers behave similarly to the Prediction Profiler in other platforms. For example, the vertical lines of Temp and Hours can be dragged to see how each of the distribution values change with temperature and time. For a detailed explanation of the Prediction Profiler, see Profilers.
Quantile

You can use the Quantile profiler for extrapolation. Suppose that the data are represented by a Weibull distribution. From viewing the Weibull Acceleration Factor Profiler in Figure 4.11, you see that the acceleration factor at 45 degrees Celsius is 17.42132 for a use condition temperature of 10 degrees Celsius. Select the Quantile tab to see the Quantile Profiler for the Weibull distribution. Select and drag the vertical line in the probability plot so that the probability reads 0.5. From viewing Figure 4.10, where the Probability is set to 0.5, you find that the quantile for the failure probability of 0.5 at 45 degrees Celsius is 13943.92 hours. So, at 10 degrees Celsius, you can expect that 50% of the units fail by $13943.92 \times 17.42132 = 242921$ hours.

Figure 4.10  Weibull Quantile Profiler for Devalt.jmp

Acceleration Factor

Selecting the Acceleration Factor tab shows the Acceleration Factor Profiler for the time-to-event variable for each specified distribution. To produce Figure 4.11, select Fit All Distributions from the Fit Life by X red triangle menu. Modify the use condition value for the explanatory variable by selecting Set Time Acceleration Use Condition from the Fit Life by X red triangle menu and entering the desired value. Note that the explanatory variable and the use condition value appear beside the profiler title.
The Acceleration Factor Profiler lets you estimate time-to-failure for accelerated test conditions when compared with the use condition value and a parametric distribution assumption. The interpretation of a time-acceleration plot is generally the ratio of the $p^{th}$ quantile of the use condition to the $p^{th}$ quantile of the accelerated test condition. This relation applies only when the distribution is Lognormal, Weibull, Loglogistic, or Fréchet, and the scale parameter is constant for all levels. For more information about the parameterizations of the distributions, see “Distributions” on page 82 in the “Life Distribution” chapter.

**Note:** The Acceleration Factor Profiler does not appear in the following instances: when the explanatory variable is discrete; the explanatory variable is treated as discrete; a customized formula does not use a unity scale factor; or the distribution is Normal, SEV, Logistic, or LEV.
Comparison Criterion

The **Comparison Criterion** tab shows the \(-2\)Loglikelihood, AICc, and BIC criteria for the distributions of interest. Figure 4.12 shows these values for the Weibull, Lognormal, Loglogistic, and Fréchet distributions. Distributions providing better fits to the data are shown at the top of the Comparisons report, sorted by AICc.

**Figure 4.12** Comparison Criterion Report Tab

![Comparison Criterion Report Tab](image)

This report suggests that the Lognormal and Loglogistic distributions provide the best fits for the data, because the lowest criteria values are seen for these distributions. For more information about the criteria, see *Fitting Linear Models*.

Results

The Results section of the report window shows more detailed statistics and prediction profilers than those shown in the Comparisons report. Separate result sections are shown for each selected distribution. Figure 4.13 shows a portion of the Weibull results, Nested Model Tests, and Diagnostics plots for Devalt.jmp.

Statistical results, diagnostic plots, and Distribution, Quantile, Hazard, Density, and Acceleration Factor Profilers are included for each of your specified distributions. The Custom Estimation tab lets you estimate specific failure probabilities and quantiles, using both Wald and Profile interval methods. When the Box-Cox Relationship is selected on the platform launch window, the Sensitivity tab appears. This tab shows how the Relative Likelihood and B10 Life change as a function of Box-Cox lambda.
Statistics

For each parametric distribution, there is a Statistics section that shows parameter estimates, a covariance matrix, confidence intervals, summary statistics, and diagnostic plots. You can save probability, quantile, and hazard estimates by selecting any or all of these options from the Statistics red triangle menu for each parametric distribution. The estimates and the corresponding lower and upper confidence limits are saved as columns in your data table.

Nested Model Tests

Nested Model Tests are included, if you selected the option on the platform launch window. The Nested Model Tests include statistics and diagnostic plots for the following models:

**Separate Location and Scale**  Assumes that the location and scale parameters are different for all levels of the explanatory variable. This option is equivalent to fitting the distribution by the levels of the explanatory variable. The Separate Location and Scale model has multiple location parameters and multiple scale parameters (Figure 4.14).

**Separate Location**  Assumes that the location parameters are different, but the scale parameters are the same for all levels of the explanatory variable. The Separate Location model has multiple location parameters and only one scale parameter (Figure 4.15).
**Regression**  The default model shown in the initial Fit Life by X report window (Figure 4.16).

**No Effect**  Assumes that the explanatory variable does not affect the response. This option is equivalent to fitting all of the data values to the selected distribution. The No Effect Model has one location parameter and one scale parameter (Figure 4.17).

Separate Location and Scale, Separate Location, and Regression analyses results are shown by default. Regression parameter estimates and the location parameter formula are shown under the Estimates section, by default. The Diagnostics plots for the No Effect model can be displayed by selecting the check box to the left of No Effect under the Nested Model Tests title.

To see results for each of the models (independently of the other models), click the underlined model of interest (listed under Nested Model Tests) and then uncheck the check boxes for the other models.

If the Nested Model Tests option was not checked in the launch window, then the Separate Location and Scale and Separate Location models are not assessed. In this case, estimates are given for the regression model for each distribution that you select and the Cox-Snell Residual P-P Plot is the only diagnostic plot.

**Note:** When Separate Location and Scale or Separate Location models are fit for the Weibull distribution, both parameterizations of the Weibull distribution are shown in the Estimates table, as is the case in Figure 4.14 and Figure 4.15. For more information about the Weibull parameterizations, see “Weibull” on page 358 in the “Survival Analysis” chapter.

**Diagnostics**

The Multiple Probability Plots shown in Figure 4.13 are used to validate the distributional assumption for the different levels of the accelerating variable. If the line for each level does not run through the data points for that level, the distributional assumption might not hold. Side-by-side comparisons of the diagnostic plots provide a visual comparison for the validity of the different models. See Meeker and Escobar (1998, sec. 19.2.2) for a discussion of multiple probability plots. Each multiple probability plot has an option below the legend that enables you to show or hide shaded parametric confidence intervals for each line in the plot.

The Cox-Snell Residual P-P Plots are used to validate the distributional assumption for the data. If the data points deviate far from the diagonal, then the distributional assumption might be violated. The Cox-Snell Residual P-P Plot red triangle menu has an option called **Save Residuals** that enables you to save the residual data to the data table. See Meeker and Escobar (1998, sec. 17.6.1) for a discussion of Cox-Snell residuals.

The Residuals versus Fitted Plots are used to validate the distributional assumption for the different levels of the accelerating variable. The plots show standardized residuals on the vertical axis and the X variable on the horizontal axis. The Residuals vs Fitted red triangle menu has an option called **Save Residuals** that enables you to save the standardized residual data to the data table.
Figure 4.14  Separate Location and Scale Model with the Weibull Distribution for Devalt.jmp Data

\[ \begin{array}{cccc}

Profilers and Surface Plots

In addition to a statistical summary and diagnostic plots, the Fit Life by X report window also includes profilers and surface plots for each of your specified distributions. To view the Weibull time-accelerating factor and explanatory variable profilers, click the Distribution tab under Weibull Results. To see the surface plot, click the disclosure icon to the left of the Weibull title (under the profilers). The profilers and surface plot behave similarly to other platforms. See Profilers.

The report window also includes a tab labeled Acceleration Factor. Clicking the Acceleration Factor tab shows the Acceleration Factor Profiler. This profiler is an enlargement of the Weibull plot shown under the Acceleration Factor tab in the Comparisons section of the report window. Figure 4.18 shows the Acceleration Factor Profiler for the Weibull distribution of Devalt.jmp. The use condition level for the explanatory variable can be modified by selecting the Set Time Acceleration Use Condition option in the Fit Life by X red triangle menu.

Figure 4.18  Weibull Acceleration Factor Profiler for Devalt.jmp

Custom Estimation

For each parametric distribution, there is a Custom Estimation section that contains two reports: Estimate Quantile and Estimate Probability. For distributions with positive support, the Custom Estimation section also contains an Estimate Mean Remaining Life (MRLF) report.
Estimate Quantile

The Estimate Quantile report contains a calculator that enables you to predict quantiles for specific failure probability values. In the Estimate Quantile calculator, enter a value for Prob and the X variable. Press Enter to see the quantile estimates and corresponding confidence intervals. To calculate multiple quantile estimates, click the plus sign, enter another Prob value, another X value, or both, and press Enter. Click the minus sign to remove the last entry. If you enter more than one value in either column, the table contains all combinations of Prob and X values.

By default, Wald-based intervals are shown. Click Likelihood CI in the Interval Type outline to switch to likelihood-based confidence intervals. The confidence level for these intervals is determined by the Change Confidence Level option in the Fit Life by X red triangle menu.

Estimate Probability

The Estimate Probability report contains a calculator that enables you to predict failure and survival probabilities for specific time values. In the Estimate Probability calculator, enter a value for Time and the X variable. Press Enter to see the failure probability estimates and corresponding confidence intervals. To calculate multiple failure probability estimates, click the plus sign, enter another Time value, another X value, or both, and press Enter. Click the minus sign to remove the last entry. If you enter more than one value in either column, the table contains all combinations of Time and X values.

By default, Wald-based intervals are shown. Click Likelihood CI in the Interval Type outline to switch to likelihood-based confidence intervals. The confidence level for these intervals is determined by the Change Confidence Level option in the Fit Life by X red triangle menu.

Estimate Mean Remaining Life (MRLF)

The Estimate Mean Remaining Life (MRLF) report contains a calculator that enables you to predict mean remaining life for specific time values. In the Estimate Mean Remaining Life (MRLF) calculator, enter a value for Survival Time and the X variable. Press Enter to see the mean remaining life estimates and corresponding Wald-based confidence intervals. The confidence level for these intervals is determined by the Change Confidence Level option in the Fit Life by X red triangle menu. To calculate multiple mean remaining life estimates, click the plus sign, enter another Survival Time value, another X value, or both and press Enter. Click the minus sign to remove the last entry. If you enter more than one value in either column, the table contains all combinations of Survival Time and X values.

Note: When the survival time equals zero, the calculated mean remaining life (MRLF) value is equivalent to the mean time to failure (MTTF) value.
Bayesian Estimates

For each parametric distribution other than Exponential, there is a Bayesian Estimates section that enables you to obtain Bayesian parameter estimates. The Bayesian Estimates section is not available if the Relationship in the Fit Life by X launch window is Custom, No Effect, Location, or Location and Scale.

Bayesian estimation in the Fit Life by X platform is done using rejection sampling or a Markov Chain Monte Carlo (MCMC) algorithm. More specifically, the platform attempts a basic rejection sampler. If the rejection sampler produces valid results, these results are reported. If the rejection sampler cannot produce valid results, the platform uses a random walk Metropolis-Hastings algorithm and adds a note to the top of the Bayesian Estimation report. See Robert and Casella (2004).

The initial report is a control panel where you can specify prior distributions for the parameters and control aspects of the simulation. To obtain posterior estimates of the parameters, specify the prior distributions and the simulation options, and then click Fit Model.

To specify the prior distributions of the parameters, you must specify information about a quantile of the distribution and the slope $\beta_1$ and scale $\sigma$ parameters. (For the Weibull distribution, you specify the Weibull $\beta$ rather than $\sigma$.) The quantile is defined by two values: the probability of the quantile and the value of the X variable at the specified quantile. The default Probability value is 0.10, but you can specify a value that corresponds to the quantile of interest. Specify information about the range of the prior distribution. For Normal and Lognormal prior distributions, the range is specified in terms of Lower and Upper 99% limits. For Uniform and Log-Uniform prior distributions, the range is specified in terms of the Lower and Upper limits. See Meeker and Escobar (1998). The initial values that are provided are estimates consistent with the maximum likelihood estimates in the Statistics section of the report.

The following options for the simulation appear below the prior distribution specification table:

**Number of Monte Carlo Iterations** Sets the sample size that will be drawn from the posterior distribution after a burn-in procedure is completed.

**Random Seed** Sets the initial state of the simulation. By default, it is the clock time. The number should be a positive integer greater than 1. If you specify 1, the current clock time is used.
Bayesian Estimates - Result <N> Report

After you specify prior distributions and the simulation options, click **Fit Model** to perform the simulation. A Bayesian Estimates - Result <N> report is provided for each simulation. This report contains the following headings:

**Priors**  Shows the specifications that you entered in the Bayesian Estimates report to run the simulation. The Prior report also contains the random seed.

**Posterior Estimates**  Shows five marginal statistics that describe the posterior distribution of \( \beta_0, \beta_1, \sigma \), and the quantile. The marginal statistics are the median, 0.025 quantile (Lower Bound), 0.975 quantile (Upper Bound), mean, and standard deviation computed from the Monte Carlo samples. If the Weibull distribution is specified, this table contains the posterior estimate of the Weibull \( \beta \) instead of \( \sigma \).

To compute statistics for other derived variables based on the posterior estimates of the generic parameters, click the Export Monte Carlo Samples link.

**Posterior Scatter Plot**  Shows two scatter plots of values from the Monte Carlo simulation. The scatter plot on the left shows the values of the posterior parameters as they are specified in the Priors report. The scatter plot on the right shows the values of the posterior parameters as they are specified in the Posterior Estimates report.

**Profilers**  Shows two profilers based on samples from the posterior distribution. The values shown in the profilers, at the specified values of the X and Time variables, are calculated using the following steps:

- For each set of sampled parameter values from the posterior distribution, the values of the cumulative distribution function and the quantile function are calculated at the specified values of the X and Time variables.
- The predicted values of the cumulative distribution function and the quantile function are the medians of the calculated values.
- The upper and lower confidence limits are the 0.025 and 0.975 quantiles of the calculated values. The confidence level for these limits is determined by the **Change Confidence Level** option in the Fit Life by X red triangle menu.

**Distribution Profiler**  Shows the parametric cumulative distribution function as a function of the X variable and Time.

**Quantile Profiler**  Shows the parametric quantile function as a function of the X variable and a specified probability.

Bayesian Estimates - Result <N> Options

The Bayesian Estimates - Result <N> red triangle menu contains the following options:

**Remove**  Removes the current Bayesian Estimates report from the Fit Life by X report.
Export Monte Carlo Samples  Saves the results of the Monte Carlo simulation to a new data table. You can use this table to compute statistics of the posterior estimates.

Custom Relationship

If you want to use a custom transformation to model the relationship between the lifetime event and the accelerating factor, use the Custom option. This option is found in the list under Relationship in the launch window. Enter comma delimited values into the entry fields for the location (µ) and scale (σ) parameters. For the Devalt.jmp sample data, an example entry for µ could be “1, log(:Temp), log(:Temp)^2”, and an entry for σ could be “1, log(:Temp)”, where 1 indicates that an intercept is included in the model. Select the Use Exponential Link check box to ensure that the sigma parameter is positive.

Figure 4.19 Custom Relationship Specification in Fit Life by X Launch Window

After selecting OK, location and scale transformations are created and included at the bottom of the Estimates report section.
Figure 4.20  Weibull Estimates and Formulas for Custom Relationship

For an example of how to use a custom transformation, see “Custom Relationship Example” on page 135. Analysis proceeds similarly to the “Example of the Fit Life by X Platform” on page 108, where the Arrhenius Celsius Relationship was specified.

Fit Life by X Platform Options

The Fit Life by X red triangle menu contains the following options:

**Fit Lognormal**  Fits a lognormal distribution to the data.

**Fit Weibull**    Fits a Weibull distribution to the data.

**Fit Loglogistic**  Fits a loglogistic distribution to the data.

**Fit Fréchet**  Fits a Fréchet distribution to the data.

**Fit Exponential**  Fits an exponential distribution to the data.

**Fit SEV**  Fits a smallest extreme value (SEV) distribution to the data.

**Fit Normal**  Fits a normal distribution to the data.

**Fit Logistic**  Fits a logistic distribution to the data.

**Fit LEV**  Fits a largest extreme value (LEV) distribution to the data.

**Fit All Distributions**  Fits all distributions to the data.

**Set Time Acceleration Use Condition**  Enables you to enter a use condition value for the explanatory variable of the acceleration factor in a pop-up window.

**Change Confidence Level**  Enables you to enter a desired confidence level, for the plots and statistics, in a pop-up window. The default confidence level is 0.95.
Tabbed Report  Lets you specify how you want the report window displayed. Two options are available: Tabbed Overall Report and Tabbed Individual Report. Tabbed Individual Report is checked by default. You can select one, both or none.

Show Surface Plot  Shows or hides the surface plot for the distribution on and off in the individual distribution results section of the report. The surface plot is shown in the Distribution, Quantile, Hazard, and Density sections for the individual distributions, and it is on by default.

Show Points  Shows or hides the data points on and off in the Nonparametric Overlay plot and in the Multiple Probability Plots. The points are shown in the plots by default. If this option is unchecked, step functions are shown instead.

Scatterplot  Shows a scatterplot of a lifetime event versus an explanatory variable.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

---

Additional Examples of the Fit Life by X Platform

- “Capacitor Example”
- “Custom Relationship Example”

Capacitor Example

This example uses Capacitor ALT.jmp and can be found in the Reliability folder of the sample data. It contains simulated data that gives censored observations for three levels of temperature, for a reliability study. Observations are shown as censored values at temperature levels of 85, 105, and 125 degrees Celsius.

1. Select Help > Sample Data Library and open Reliability/Capacitor ALT.jmp.
2. Select **Analyze > Reliability and Survival > Fit Life by X**.
3. Select Hours and click **Y, Time to Event**.
4. Select Temperature and click **X**.
5. Select Censor and click Censor.
6. Leave the **Censor Code** as Censored.
7. Select Freq as **Freq**.
8. Keep **Arrhenius Celsius** as the relationship, and keep the **Nested Model Tests** option selected.
9. Select **Weibull** as the distribution.
10. Keep **Wald** as the confidence interval method.

**Figure 4.21** Fit Life by X Launch Window

11. Click **OK**.
The report window shows summary data, diagnostic plots, comparison data and results, including detailed statistics and prediction profilers. Separate result sections are shown for each selected distribution. Distribution, Quantile, Hazard, Density, and Acceleration Factor Profilers are included for each of the specified distributions.

**Custom Relationship Example**

To create a quadratic model with Log(Temp) for the Weibull location parameter and a log-linear model with Log(Temp) for the Weibull scale parameter, follow these steps:

1. Select **Help > Sample Data Library** and open Reliability/Devalt.jmp.
2. Select **Analyze > Reliability and Survival > Fit Life by X**.
3. Select Hours and click **Y, Time to Event**.
4. Select Temp and click **X**.
5. Select Censor and click Censor.
6. Select Weight and click Freq.
7. Select Custom as the Relationship from the list.
8. In the entry field for \( \mu \), enter \( 1, \log(:\text{Temp}), \log(:\text{Temp})^2 \).
   (The 1 indicates that an intercept is included in the model.)
9. In the entry field for \( \sigma \), enter \( 1, \log(:\text{Temp}) \).
10. Select the check box for Use Exponential Link.
11. Deselect the check box for Nested Model Tests.
12. In the entry field for Use Condition, enter 10.
13. Select Weibull as the Distribution.

   Figure 4.23 shows the completed launch window using the Custom option.

   **Note:** The Nested Model Tests check box is not checked for non-constant scale models. Nested Model test results are not supported for this option.

14. Click OK.

**Figure 4.23** Custom Relationship Specification in Fit Life by X Launch Window

Figure 4.24 shows the location and scale transformations, which are subsequently created and included at the bottom of the Estimates report section.
Analysis proceeds similarly to the “Example of the Fit Life by X Platform” on page 108, where the Arrhenius Celsius Relationship was specified.

Figure 4.24 Weibull Estimates and Formulas for Custom Relationship
Cumulative damage models, which include step-stress models, enable you to analyze an accelerated life test where the stress levels might be changed over time. The stress can be applied by many different forces: load, temperature, pressure. A typical cumulative damage experiment consists of multiple test units. Each unit has an initial stress level, and the stress level can be changed throughout the experiment. The response is the failure time or time-to-event. The platform plots the failure events and enables you to fit multiple distributions to your data.

Overview of the Cumulative Damage Platform

A cumulative damage experiment, also called a varying-stress experiment, is an accelerated life test where the stress levels can change over time. The stress can be applied by many different forces: load, temperature, pressure. A typical cumulative damage experiment consists of multiple test units. Each unit has an initial stress level, and the stress level can be changed throughout the experiment.

The most common cumulative damage experiment is a step-stress experiment. A step-stress experiment uses multiple units with varying levels of stress applied. Stress can be applied using factors such as temperature, pressure, or voltage. For each unit, there is an initial stress level. At specified time points, the stress levels are adjusted based on different patterns of stress levels. Between stress level changes, the stress level remains constant.

The Cumulative Damage platform also includes three other varying-stress pattern models:

- In a ramp-stress experiment, the stress levels start at an initial value and then increase linearly over time at a specified slope.
- In a sinusoid-stress experiment, the stress levels fluctuate in a periodic fashion that is defined by a sine wave.
- In a piecewise ramp-stress experiment, the stress levels are defined at specified time points similar to the step-stress case. However, the stress level is not required to stay constant between time points. Rather, it changes linearly from a starting stress level to an ending stress level between time points. If a pair of starting and ending stress levels are equal, the interval is equivalent to a step-stress interval.

For more information about varying-stress and step-stress models, see Nelson (2004, ch. 10).

Example of the Cumulative Damage Platform

A step-stress experiment is conducted on 40 test units at varying stress conditions. Your goal is to estimate the probability of failure at 10,000 time units given a stress level of 0.75. These data tables are based on data from Nelson (2004, ch. 10).

The Reliability/CD Step Stress Pattern.jmp data table contains a column called Pattern ID that identifies four different stress patterns. The stress level at a particular step is the ratio of Voltage to Thickness. (Note that these two columns are hidden.) Thickness is held constant for each stress pattern. However, Voltage is set to different levels and increases within each pattern.
The Reliability/CD Step Stress.jmp data table contains the time to failure data.

   The CD Step Stress table contains failure time data:
   - The Time column gives the failure times.
   - The Pattern ID column identifies the stress pattern.
   - The Censor column indicates whether the failure time is exact or censored.

   Each row of the table corresponds to one test unit.

   The CD Step Stress Pattern table contains the four stress patterns (identified as 1 through 4). The levels of the stress factor, Stress, are varied within each value of the Pattern ID column. The Duration column represents how many time units a particular level of the stress factor lasted.

2. Select Analyze > Reliability and Survival > Cumulative Damage.

   The launch window has two sections: one for the failure time data (Time-to-Event) and one for the stress pattern data (Stress Pattern).

3. Click Select Table in the Time-to-Event panel.

   A Time-to-Event Data Table window appears, which prompts you to specify the data table for the failure time data.

4. Select CD Step Stress and click OK.

   The columns from this table now populate the Select Columns list in the Time-to-Event panel.

5. Select Time and click Time to Event.

6. Select Censor and click Censor.

7. Select Pattern ID for Pattern ID.

8. Click Select Table in the Stress Pattern panel.

9. Select CD Step Stress Pattern and click OK.

   The columns from this table now populate the Select Columns list in the Stress Pattern panel.

10. Select Duration and click Stress Duration.

11. Select Stress and click Stress.

12. Select Pattern ID and click Pattern ID.

13. Click OK.
Chapter 5
Reliability and Survival Methods

Cumulative Damage
Example of the Cumulative Damage Platform

Figure 5.2 Event Plot and Stress Patterns Plot

The initial report contains the Event Plot and a plot of the defined stress patterns. All four stress patterns increase the stress level quickly over the first 40 time units, after which they increase at much different rates.

14. Click the Cumulative Damage red triangle and select Fit All.

Figure 5.3 Model List Report

From the Model List report, you determine that the best fitting distribution is the Exponential distribution.

15. In the Results report, scroll to the Exponential report.

16. In the Distribution Profiler report, set the current value of Stress to 0.75.

17. Set the current value of Time to 10000.
Figure 5.4 Distribution Profiler for Exponential Distribution at Specified Settings

Figure 5.4 shows that the predicted probability of failure for a test unit under constant stress of 0.75 at 10000 time units is 0.007233, with a 95% confidence interval of 0.001368 to 0.037754.
Launch the Cumulative Damage Platform

Launch the Cumulative Damage platform by selecting **Analyze > Reliability and Survival > Cumulative Damage**. You must supply the Cumulative Damage platform with two data tables as input. The first data table is time-to-event data for each unit under test. The second data table defines the stress patterns used for each unit.

**Figure 5.5** The Cumulative Damage Launch Window

The launch window includes a separate tab for each step-stress data format. For more information about the various stress patterns, see “**Stress Pattern**” on page 147. For more information about the options in the Select Columns red triangle menu, see *Using JMP*. 
Each of the step-stress format tabs contains two panels for specifying variables for the model:

- The Time-to-Event panel is common to all of the step-stress formats. This panel is similar to the Fit Life by X platform launch window.
- The Stress Pattern panel is used to describe the type of stress. Consequently, its format depends on the selected step-stress tab.

**Time to Event**

The Time to Event panel in the Cumulative Damage launch window contains the following options:

**Time to Event** Identifies the time to event (such as the time to failure) or time to censoring. For interval censoring, your data table should contain two columns, where one gives the lower bound and the other gives the upper bound of the failure time for each unit. Enter the two censoring columns as Time to Event. For more information about censoring, see “Event Plot” on page 38 in the “Life Distribution” chapter.

**Censor** Identifies right-censored observations. Select the value that identifies right-censored observations from the Censor Code menu beneath the Select Columns list. The Censor column is used only when one Y is entered.

**Freq** Identifies frequencies or observation counts when there are multiple units. If the value is 0 or a positive integer, then the value represents the frequencies or counts of observations with the given row’s settings.

**Pattern ID** Contains values that specify the stress pattern in the Stress Pattern data table that was used for the given row.

**Censor Code** Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.

**Relationship** Identifies the relationship between the event and the stress factor. Table 5.1 defines the model for each relationship.

**Table 5.1 Models for Relationship Options**

<table>

</tbody>
</table>

The BoxCox( \( X \) ) transformation is defined as follows:

\[
x_i^{(\lambda)} = \begin{cases} 
  \frac{x_i^\lambda - 1}{\lambda} & \text{if } \lambda \neq 0 \\
  \ln(x_i) & \text{if } \lambda = 0
\end{cases}
\]

If you select **Custom**, additional controls appear that require you to define the Custom transformation that models the relationship between the lifetime event and the stress factor.

If you want to use a Custom relationship for your model, see “Custom Relationship” on page 131 in the “Fit Life by \( X \)” chapter.

**Distribution**  Specifies an initial time-to-failure distribution. Select from Weibull, Lognormal, Loglogistic, Fréchet, or Exponential. Weibull is the default setting. For more information about the distributions, see “Distributions” on page 82 in the “Life Distribution” chapter.

**Stress Pattern**

Specify the stress patterns used in the experiment using the second panel.
Step Stress Pattern

The Step Stress pattern has stress levels that are changed at arbitrary time points. The duration of each stress step and associated stress level must be specified in ascending time order.

The Stress Pattern panel in the Step Stress tab contains the following options:

**Stress Duration**  The column that contains the length in time units of each stress step.

**Stress**  The column that contains the level of the stress setting.

**Pattern ID**  The column that contains a unique identifier for the stress pattern. This column is used to match stress patterns in the Stress Pattern data table with the observations in the Time-to-Event data table.

**Pattern Continuation**  Specifies how to handle failures that occur after the final time period in the defined stress pattern. This panel contains the following options:

- **Terminate**  A failure that occurs at a time beyond the final time period in the defined stress pattern produces an error, and the model is not fit.

- **Extend**  A failure that occurs at a time beyond the final time period in the defined stress pattern assumes the same stress level as the level in the final time period.

- **Repeat**  A failure that occurs at a time beyond the final time period in the defined stress pattern assumes the same stress level as if the stress pattern were being repeated. For example, if a failure occurs 10 time units after the final time period in the defined stress pattern, then the stress level at that failure time is set to the stress level at 10 time units after the beginning of the defined stress pattern.

**Note:** The default Pattern Continuation setting for the Step Stress Pattern is Terminate.

Ramp Stress Pattern

The Ramp Stress pattern defines stress as a linear function of time. Each pattern is defined by an intercept (the stress level at time zero) and a slope (the increase in the stress level for every one time unit). Each pattern is described in a single row in the stress pattern data table.

**Intercept**  The column that contains the intercept for each pattern.

**Slope**  The column that contains the slope for each pattern.

**Pattern ID**  The column that contains a unique identifier for the stress pattern. This column is used to match stress patterns in the Stress Pattern data table with the observations in the Time-to-Event data table.
Sinusoid Stress Pattern

The Sinusoid Stress pattern defines stress as a periodic function. The pattern is defined by a level, an amplitude, a period, and a phase. Each pattern is described in a single row in the stress pattern data table. The pattern is defined as follows:

\[ S(t) = \text{level} + \text{amplitude} \times \sin(\text{phase} + (2\pi t) / \text{period}) \]

- **Level** The column that contains the level for each pattern.
- **Amplitude** The column that contains the amplitude for each pattern.
- **Period** The column that contains the period for each pattern.
- **Phase** The column that contains the phase for each pattern.
- **Pattern ID** The column that contains a unique identifier for the stress pattern. This column is used to match stress patterns in the Stress Pattern data table with the observations in the Time-to-Event data table.

Piecewise Ramp Stress Pattern

The Piecewise Ramp Stress pattern defines stress as a piecewise linear function of time. The line segments for the stress level over time can be disjoint or continuous. Line segments can also be flat, so that step stress and ramp stress can be combined. The line segments are defined in the stress pattern data table by the time duration of the segment and the start and end levels of the stress setting.

- **Stress Duration** The column that contains the length in time units of each stress step.
- **Stress Ramp** The two columns that contain the stress levels at the start and end of the step.
- **Pattern ID** The column that contains a unique identifier for the stress pattern. This column is used to match stress patterns in the Stress Pattern data table with the observations in the Time-to-Event data table.

**Pattern Continuation** The Pattern Continuation panel enables you to specify the stress levels that occur after the final time period in the defined stress pattern. This panel contains the following options:

- **Terminate** A failure that occurs at a time beyond the final time period in the defined stress pattern produces an error, and the model is not fit.
- **Extend** A failure that occurs at a time beyond the final time period in the defined stress pattern assumes the same stress level as the level in the final time period.
Repeat A failure that occurs at a time beyond the final time period in the defined stress pattern assumes the same stress level as if the stress pattern were being repeated. For example, if a failure occurs 10 time units after the final time period in the defined stress pattern, then the stress level at that failure time is set to the stress level at 10 time units after the beginning of the defined stress pattern.

Note: The default Pattern Continuation setting for the Piecewise Ramp Stress Pattern is Terminate.

The Cumulative Damage Report

After you click OK, the Cumulative Damage report window appears. By default, the Cumulative Damage report contains an event plot, a stress patterns report, a model list, and model results.

Event Plot

The Event Plot in Cumulative Damage displays time to failure or censoring. See “Event Plot” on page 38 in the “Life Distribution” chapter.

Stress Patterns Report

The Stress Patterns report shows a plot of the stress level over time for each of the stress pattern IDs. The Simulate option in this report enables you to simulate new data. Figure 5.6 shows an example of the Stress Patterns report plot. See “Stress Patterns Options” on page 152.

Figure 5.6 Stress Patterns Report
Model List

The Model List report provides the -2Loglikelihood, number of parameters, AICc, and BIC statistics for each fitted distribution. Smaller values of each of these statistics (other than number of parameters) indicate a better fit. For more information about these statistics, see *Fitting Linear Models*.

Model Results

The Results report contains a separate report for each fitted distribution. Each report contains the following:

**Parameter Estimates**  Shows the estimates, standard errors, and Wald-based 95% confidence intervals.

The fitted equation appears below the Parameter Estimates table. This equation takes into account the fitted parameter estimates and the relationship specified in the launch window.

**Distribution Profiler**  Shows cumulative failure probability as a function of time.

**Quantile Profiler**  Shows failure time as a function of cumulative probability.

**Hazard Profiler**  Shows the hazard rate as a function of time.

**Density Profiler**  Shows the density function for the distribution.

**Probability Plot of Standardized Residuals**  Shows a plot of standardized residuals for the model on a probability scale axis.

The Probability Plot of Standardized Residuals red triangle menu has a Save Residuals option that saves the standardized residuals to three new columns in the failure time data table. The three columns are Left Residuals, Right Residuals, and Residual Weight.

**Cox-Snell Residual P-P Plot**  Shows a residual plot that is used to validate the distributional assumption for the data.

The Cox-Snell Residual P-P Plot red triangle menu has a Save Residuals option that saves the Cox-Snell residuals to three new columns in the failure time data table. The three columns are Left Residuals, Right Residuals, and Residual Weight. See Meeker and Escobar (1998, sec. 17.6.1) for a discussion of Cox-Snell residuals.
Cumulative Damage Platform Options

The Cumulative Damage red triangle menu contains the following options:

**Fit All**  Fits the distributions that were not selected in the launch window. The available distributions are listed under “Distribution” on page 147.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

**Stress Patterns Options**

The Stress Pattern red triangle menu contains the Simulate option, which shows or hides the Simulation Configuration panel.

**The Simulation Control Panel**

Figure 5.7 shows the Simulation Configuration Panel. The initial values for Distribution and the parameter settings are determined by the parameter estimates for the distribution specified in the Cumulative Damage launch window. The graph shows the estimated failure distribution functions over time for the stress patterns defined in the Stress Pattern data table.
Figure 5.7 Simulation Configuration Panel

The Simulation Configuration panel enables you to simulate new failure time data based on a distribution and stress pattern. The stress pattern defined in the Stress Pattern data table used in the launch of the platform is also used for the simulation. This panel contains the following options:

**Distribution**  The distribution to be used for the simulation. The available distributions are the same as in the Cumulative Damage launch window. For more information about the distributions, see “Distributions” on page 82 in the “Life Distribution” chapter.

**b0**  The intercept for the location parameter of the distribution.

**b1**  The slope for the location parameter of the distribution.

**lambda**  (Available only for the Box-Cox relationship.) The lambda value for the Box-Cox relationship.

**b2, s0, s1, and so on**  (Available only for the Custom relationship.) Other parameters that are defined in the Custom relationship in the Cumulative Damage launch window.

**Beta**  (Available only for the Weibull distribution.) The Beta parameter of the Weibull distribution.

**sigma**  (Available only for the Lognormal, Loglogistic, and Fréchet distributions.) The sigma parameter of the distribution.

**N per Pattern**  The number of points generated in the simulation for each stress pattern.

**Random Seed**  (Optional) A nonzero random seed that ensures the reproducibility of simulation results.

**Termination**  (Not available when the specified Pattern Continuation in the Cumulative Damage launch window is Terminate.) A time beyond which surviving test units are censored.
Simulate

The plot in the Simulation Configuration panel shows the implied distributions for each of the stress patterns over time. Click the Simulate button to generate a new JMP data table that contains the results of the simulation.

Additional Example of the Cumulative Damage Platform

This section contains additional examples using the Cumulative Damage platform.

Example of Simulating New Data

This example illustrates using the Simulation Configuration panel in the Cumulative Damage report window to generate new step stress data. This example uses the same data as the example in “Example of the Cumulative Damage Platform” on page 141.

2. In the CD Step Stress data table, run the script Cumulative Damage.
3. Click the Stress Patterns red triangle and select Simulate.

Figure 5.8 Simulation Configuration Panel

The Simulation Configuration panel appears in the Stress Patterns report. The selection for Distribution is Weibull. The fitted values for b0 and b1 are used as initial values for the simulation.

4. Select Exponential for Distribution.
5. Enter 10 for b0.
6. Enter -18 for \( b_1 \).
7. (Optional) Enter 14678 for Random Seed.
8. Click Simulate.

**Figure 5.9 Partial Results of Simulation**

</table>

Figure 5.9 shows a partial listing of the simulated data table. The stress pattern with Pattern ID equal to 1 is defined only up to 145 time units. Since the Pattern Configuration setting in the launch window was set to Terminate, the simulation censors any simulated values at 145 for stress pattern 1.
The Recurrence Analysis platform analyzes event times, where the events can recur several times for each unit, item, or person. In an industrial setting, these events can occur when a unit breaks down, is repaired, and then put back into service after the repair. The units are followed until they are ultimately taken out of service.

In a medical setting, recurrence analysis can be used to analyze data from continuing treatments of a long-term disease, such as the recurrence of tumors in patients receiving treatment for bladder cancer.

The goal of the analysis is to obtain the mean cumulative function (MCF), which shows the total cost per unit as a function of time. Cost can be a count of the number of repairs, or it can be the actual cost of repair.

Figure 6.1  Recurrence Analysis Example

Overview of the Recurrence Analysis Platform

Recurrent event data involves the cumulative frequency or cost of repairs as units age. In JMP, the Recurrence Analysis platform analyzes recurrent events data.

The data for recurrence analysis have one row for each observed event and a closing row with the last observed age of a unit. Any number of units or systems can be included. In addition, these units or systems can include any number of recurrences.

Example of the Recurrence Analysis Platform

A typical unit might be a system, such as a component of an engine or appliance. For example, consider the sample data table Engine Valve Seat.jmp, which records valve seat replacements in locomotive engines. See Meeker and Escobar (1998, p. 395) and Nelson (2003). A partial listing of this data is shown in Figure 6.2. The EngineID column identifies a specific locomotive unit. Age is time in days from beginning of service to replacement of the engine valve seat. Note that an engine can have multiple rows with its age at each replacement and its cost, corresponding to multiple repairs. Here, Cost=0 indicates the last observed age of a locomotive.

Figure 6.2 Partial Engine Valve Seat Data Table

Complete the launch window as shown in Figure 6.5.

When you click OK, the Recurrence platform shows the reports in Figure 6.3 and Figure 6.4. The MCF plot shows the sample mean cumulative function. For each age, this is the nonparametric estimate of the mean cumulative cost or number of events per unit. This function goes up as the units get older and total costs grow. The plot in Figure 6.3 shows that about 580 days is the age that averages one repair event.
The event plot in Figure 6.4 shows a time line for each unit. There are markers at each time of repair, and each line extends to that unit’s last observed age. For example, unit 409 was last observed at 389 days and had three valve replacements.
### Figure 6.4 Event Plot for Valve Seat Replacements

The event plot shows the age and cost associated with each engine, highlighting the replacements over time.
Launch the Recurrence Analysis Platform

Launch the Recurrence Analysis platform by selecting Analyze > Reliability and Survival > Recurrence Analysis.

Figure 6.5 Recurrence Analysis Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Y, Age, Event Timestamp Specify either the unit's age at the time of an event or the timestamp of the event. If the Y column is an event timestamp, then you must specify the start and the end timestamp so that JMP can calculate age.

Label, System ID Identifies the unit for each event and censoring age.

Cost Identifies a column that must contain one of the following values:

- A 1, indicating that an event has occurred (a unit failed or was repaired, replaced, or adjusted). When indicators (1s) are specified, the MCF is the mean cumulative count of events per unit as a function of age.
- A cost for the event (the cost of the repair, replacement, or adjustment). When costs are specified, the MCF is a mean cumulative cost per unit as a function of age and the markers in the Event Plot are sized by the cost values.
– A zero, indicating that the unit went out-of-service, or is no longer being studied. All units (each System ID) must have one row with a zero for this column, with the Y, Age, Event Timestamp column containing the final observed age. If each unit does not have exactly one last observed age in the table (where the Cost column cell is zero), then an error message appears.

**Note:** Cost indicators for Recurrence Analysis are the reverse of censor indicators seen in Life Distribution or Survival Analysis. For the cost variable, the value of 1 indicates an event, such as repair; the value of 0 indicates that the unit is no longer in service. For the censor variable, the value of 1 indicates censored values, and the value of 0 indicates the event or failure of the unit (non-censored value).

**Grouping** Produces separate MCF estimates for the different groups that are identified by this column.

**Cause** Specifies multiple failure modes.

**Timestamp at Start** Specifies the column with the origin timestamp. If you have starting times as event records, select the First Event is Start Timestamp option instead. JMP calculates age by subtracting the values in this column.

**Timestamp at End** Specifies the column with the end-of-service timestamp. If end times are given for all units, specify that column here. If end times are not given for all units, specify the Default End Timestamp option instead. But if you have a record in which Cost is equal to zero, JMP uses that record as the end timestamp and you do not need to specify this role.

**Age Scaling** Specifies the time units for modeling. For example, if your timestamps are coded in seconds, you can change them to hours.

### Recurrence Analysis Platform Options

The Recurrence Analysis red triangle menu contains the following options:

**MCF Plot** Shows or hides the mean cumulative function (MCF) plot.

**MCF Confid Limits** Shows or hides lines corresponding to the approximate 95% confidence limits of the mean cumulative function (MCF).

**Event Plot** Shows or hides the Event Plot. If a Cost column is specified in the launch window, the markers in the Event Plot are sized by the values in the Cost column.

**Calendar Event Plot** (Available only when the events are designated by a timestamp rather than an age.) Shows or hides the Calendar Event Plot, which shows events with calendar
date on the horizontal axis. This plot is next to the Event Plot and the units in each plot are aligned vertically.

**Plot Interarrival by Age**  Shows or hides the Interarrival by Age plot, which plots the time between successive events on the vertical axis and the event times on the horizontal axis. You can use this plot to determine whether there are changes in the time between events in your data. For a recurrence analysis, the interarrival times should be independent and identically distributed over time. For more information about interarrival plots, see Tobias and Trindade (2012, p. 420).

**Plot MCF Differences**  (Available only when you specify a grouping variable.) Shows or hides a plot of the difference of MCFs, including a 95% confidence interval for that difference. The MCFs are significantly different where the confidence interval lines do not cross the zero line. This option is available only when you specify a grouping variable.

**MCF Plot Each Group**  (Available only when you specify a grouping variable.) Shows or hides a report that contains a mean cumulative function (MCF) plot for each level of the grouping variable.

This option can be used to get an MCF Plot for each unit if the *Label, System ID* variable is also specified as the *Grouping* variable.

**Fit Model**  Enables you to fit models for the Recurrence Intensity and Cumulative functions. See “Fit Model” on page 164.

**Fit Model**

The Fit Model option is used to fit models for the Recurrence Intensity and Cumulative functions. There are four models available for describing the intensity and cumulative functions. You can fit the models with constant parameters, or with parameters that are functions of effects.

Select Fit Model from the Recurrence Analysis red triangle menu to produce the Recurrence Model Specification window shown in Figure 6.6.
Figure 6.6 Recurrence Model Specification

You can select one of four models, with the following Intensity and Cumulative functions:

**Power Nonhomogeneous Poisson Process**

\[ I(t) = \left( \frac{\theta}{t} \right)^{\beta} \]
\[ C(t) = \left( \frac{\theta}{t} \right)^{\beta} \]

**Proportional Intensity Poisson Process**

\[ I(t) = \delta t^{\delta - 1} e^\gamma \]
\[ C(t) = t^\delta e^\gamma \]

**Loglinear Nonhomogeneous Poisson Process**

\[ I(t) = e^\gamma + \delta t \]
\[ C(t) = \frac{I(t) - I(0)}{\delta} = \frac{e^\gamma + \delta t - e^\gamma}{\delta} \]
Homogeneous Poisson Process

\[ I(t) = e^{\gamma t} \]
\[ C(t) = te^{\gamma t} \]

where \( t \) is the age of the product.

Table 6.1 defines each model parameter as a scale parameter or a shape parameter.

<table>
<thead>
<tr>
<th>Model</th>
<th>Scale Parameter</th>
<th>Shape Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power NHPP</td>
<td>( \theta )</td>
<td>( \beta )</td>
</tr>
<tr>
<td>Proportional Intensity PP</td>
<td>( \gamma )</td>
<td>( \delta )</td>
</tr>
<tr>
<td>Loglinear NHPP</td>
<td>( \gamma )</td>
<td>( \delta )</td>
</tr>
<tr>
<td>Homogeneous PP</td>
<td>( \gamma )</td>
<td>none</td>
</tr>
</tbody>
</table>

Note the following:

- For the Recurrence Model Specification window (Figure 6.6), if you include Scale Effects or Shape Effects, the scale and shape parameters in Table 6.1 are modeled as functions of the effects. To fit the models with constant scale and shape parameters, do not include any Scale Effects or Shape Effects.
- The Homogeneous Poisson Process is a special case compared to the other models. The Power NHPP and the Proportional Intensity Poisson Process are equivalent for one-term models, but the Proportional Intensity model seems to fit more reliably for complex models.

Click **Run Model** to fit the model and see the model report.
The Fitted Recurrence Model red triangle menu contains the following options:

**Profiler**  Shows or hides the Profiler showing the Intensity and Cumulative functions.

**Effect Marginals**  Evaluates the parameter functions for each level of the categorical effect, holding other effects at neutral values. This helps you see how different the parameter functions are between groups. This is available only when you specify categorical effects.

**Test Homogeneity**  Tests if the process is homogeneous. This option is not available for the Homogeneous Poisson Process model.

**Effect Likelihood Ratio Test**  Produces a test for each effect in the model. This option is available only if there are effects in the model.

**Specific Intensity and Cumulative**  Computes the intensity and cumulative values associated with particular time and effect values. The confidence intervals are profile likelihood intervals.

**Specific Time for Cumulative**  Computes the time associated with a particular number of recurrences and effect values.

**Save Intensity Formula**  Saves the Intensity formula to the data table.

**Save Cumulative Formula**  Saves the Cumulative formula to the data table.

**Publish Intensity Formula**  Creates the Intensity formula and saves it as a formula column script in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See *Predictive and Specialized Modeling*.

**Publish Cumulative Formula**  Creates the Cumulative formula and saves it as a formula column script in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See *Predictive and Specialized Modeling*. 

---

**Figure 6.7  Model Report**

![Model Report](image)
Simulate from Model  Enables you to simulate new data from the estimated recurrence model. This option creates a new data table of simulated observations that are based on options that are specified in the Simulate from Model window. See “Simulate from Model” on page 168.

Remove Fit  Removes the model report.

Simulate from Model

When you select the Simulate from Model option from the Fitted Recurrence Model red triangle menu, the Simulate from Model window appears. This window contains the following specifications for the simulation:

Maximum Number of Events  Specifies the maximum number of events to be simulated in each level of the System ID.

Maximum Age  Specifies the maximum time for a simulated event.

Number of Units  Specifies the number of units in each level of the System ID.

Note: If the model contains terms other than the Intercept and Constant terms, the simulated data table contains this number of units for all level combinations of the regression terms. If the regression term is continuous, it is divided into 5 levels.

After you click OK, a new data table that contains the results appears. This table contains a script that enables you to analyze the simulated observations in the Recurrence platform.

Additional Examples of the Recurrence Analysis Platform

- “Bladder Cancer Recurrences Example”
- “Diesel Ship Engines Example”
Bladder Cancer Recurrences Example

The sample data file Bladder Cancer.jmp contains data on cancerous bladder tumor recurrences from the Veteran’s Administration Co-operative Urological Research Group. See Andrews and Herzberg (1985, table 45). All patients presented with superficial bladder tumors, which were removed upon entering the trial. Each patient was then assigned to one of three treatment groups: placebo pills, pyridoxine (vitamin B6) pills, or periodic chemotherapy with Thiotepa. The following analysis of tumor recurrence explores the progression of the disease, and whether there is a difference among the three treatments.

Launch the platform with the options shown in Figure 6.8.

Figure 6.8  Bladder Cancer Launch Window

Figure 6.9 shows the MCF plots for the three treatments.
Note that all three of the MCF curves are essentially straight lines. The slopes (rates of recurrence) are therefore constant over time, implying that patients do not seem to get better or worse as the disease progresses.

To examine if there are differences among the treatments, click the Recurrence Analysis red triangle and select **Plot MCF Differences**.
To determine whether there is a statistically significant difference between treatments, examine the confidence limits on the differences plot. If the limits do not include zero, the treatments are convincingly different. The graphs in Figure 6.10 show there is no significant difference among the treatments.
Diesel Ship Engines Example

The sample data table Diesel Ship Engines.jmp contains data on engine repair times for two ships (Grampus4 and Halfbeak4) that have been in service for an extended period of time. See Meeker and Escobar (1998). You want to examine the progression of repairs and gain a sense of how often repairs might need to be done in the future. These observations can help you decide when an engine should be taken out of service.

2. Ensure that rows 57 and 129 are set as Excluded.

   **Note:** If they are not set to Excluded, select rows 57 and 129 and select Rows > Exclude/Unexclude.

3. Select Analyze > Reliability and Survival > Recurrence Analysis.
4. Complete the launch window as shown in Figure 6.11.

**Figure 6.11** Diesel Ship Engines Launch Window

5. Click **OK**.
Looking at the Event Plot, you can see that repairs for the Grampus4 engine have been relatively consistent. Repairs for the Halfbeak4 engine have been more sporadic, and there appears to be an abrupt increase in repairs somewhere around the 19,000 hour mark. This increase is even more obvious in the MCF Plot.

Continue your analysis by fitting a parametric model to help predict future performance.

6. Click the Recurrence Analysis red triangle and select **Fit Model**.
7. In the Recurrence Model Specification, select the **Loglinear Nonhomogeneous Poisson Process**.
8. Add the System ID column as both a Scale Effect and a Shape Effect.
9. Click **Run Model**.
Figure 6.13 Diesel Ship Engines Fitted Model

10. Click the Fitted Recurrence Model red triangle and select **Profiler**.
Compare the number of future repairs for the Grampus4 engine to the Halfbeak4 engine. Change the event time value to see the effect on the cumulative number of future repairs.

- To see how many repairs will be needed after 30,000 hours of service, type 30,000 for the event time. The Grampus4 engine will require about 114 repairs. To see the values for Halfbeak4, click and drag the dotted line from Grampus4 to Halfbeak4. The Halfbeak4 engine will require about 140 repairs.

- To see how many repairs will be needed after 80,000 hours of service, type 80,000 for the event time. The Halfbeak4 engine will require about 248,169 repairs. Click and drag the dotted line from Halfbeak4 to Grampus4. The Grampus4 engine will require about 418 repairs.

You can conclude that in the future, the Halfbeak4 engine will require many more repairs than the Grampus4 engine.
Chapter 7
Degradation
Model Product Deterioration over Time

Using the Degradation platform, you can analyze degradation data to predict pseudo failure times. These pseudo failure times can then be analyzed by other reliability platforms to estimate failure distributions.

Both linear and nonlinear degradation paths can be modeled. You can specify an accelerating factor to analyze accelerated degradation data.

You can also perform stability analysis, which is useful when setting pharmaceutical product expiration dates.

Overview of the Degradation Platform

In reliability analyses, the primary objective is to model the failure times of the product under study. In many situations, these failures occur because the product degrades (weakens) over time. But, sometimes failures do not occur. In these situations, modeling the product degradation over time is helpful in making predictions about failure times. When an accelerating factor is included in the data, you can fit an accelerated degradation model.

The Degradation platform can model data that follows linear or nonlinear degradation paths. If a path is nonlinear, transformations are available to linearize the path. If linearization is not possible, you can specify a nonlinear model.

You can also use the Degradation platform to perform stability analysis. Three types of linear models are fit, and an expiration date is estimated. Stability analysis is used in setting pharmaceutical product expiration dates.

Example of the Degradation Platform

This example uses the GaAs Laser.jmp data table from Meeker and Escobar (1998), which contains measurements of the percent increase in operating current taken on several gallium arsenide lasers. When the percent increase reaches 10%, the laser is considered to have failed.

1. Select Help > Sample Data Library and open Reliability/GaAs Laser.jmp.
2. Select Analyze > Reliability and Survival > Degradation.
4. Select Hours and click Time.
5. Select Unit and click Label, System ID.
6. Type 10 in the text box for Upper Spec Limit.
7. Click OK.
Figure 7.2 Initial Degradation Report
Figure 7.2 shows the initial Degradation report. The Overlay plot shows the measurements of Current versus Time for each unit in the data. The horizontal line at Current = 10 corresponds to the upper specification limit at 10%. Units with values above this limit are considered to have failed. Three of the fifteen units have reached that point by the end of the study period. The Inverse Prediction outline shows the predicted Hours value for which each unit fails, based on your specified model.

The default model fits a separate slope and intercept for each unit, using linear transformations. You can fit other models using the Model Specification outline.

The Residual Plot tab in Figure 7.2 shows residuals based on your specified model. The top plot shows residuals for all units plotted against Hours and overlaid on one plot. The bottom plot shows individual plots of the residuals for each unit in a rectangular array.

Launch the Degradation Platform

Launch the Degradation platform by selecting Analyze > Reliability and Survival > Degradation. Figure 7.3 shows the Degradation launch window using the GaAs Laser.jmp data table (located in the Reliability folder). For more information about the options in the Select Columns red triangle menu, see Using JMP.

Analysis Types

The launch window is split into three tabs, representing three different types of analyses:

**Repeated Measures Degradation**  Performs linear or nonlinear degradation analysis. This option allows only one Y, Response variable. It does not allow censoring.
**Destructive Degradation** Choose this type of analysis if units are destroyed during the measurement process. This option allows censoring. See “Destructive Degradation” on page 203.

**Note:** The Destructive Degradation platform provides a flexible collection of predefined models for destructive testing. See the “Destructive Degradation” chapter on page 213.

**Stability Test** Performs a stability analysis for setting pharmaceutical product expiration dates. This option allows only one Y, Response variable. See “Stability Analysis” on page 208.

**Launch Window Options**

The launch window contains the following options:

- **Y, Response** Assign the column with degradation measurements.
- **Time** Assign the column containing the time values.
- **X** (Available only in the Repeated Measures Degradation and Destructive Degradation tabs.) Assign an explanatory variable. Use this role to specify the accelerating factor in an accelerated degradation model.
- **Label, System ID** (Available only in the Repeated Measures Degradation and Stability Test tabs.) Assign the column that designates the unit IDs.
- **Freq** Assign a column giving a frequency for each row.
- **Censor** (Available only in the Destructive Degradation tab.) Assign a column that designates if a unit is censored.
- **By** Assign a variable to produce an analysis for each level of the variable.
- **Censor Code** (Available only in the Destructive Degradation tab.) Specify the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.
- **Upper Spec Limit** Assign an upper specification limit. (Optional except for Stability Test tab.)
- **Lower Spec Limit** Assign a lower specification limit. (Optional except for Stability Test tab.)
Censoring Time  (Available only in the Repeated Measures Degradation and Stability Test tabs.) Assign a Time value that represents censoring of pseudo failures when you use Inverse Prediction. See “Inverse Prediction” on page 196.

The Degradation Reports

The Repeated Measures Degradation and Destructive Degradation methods show a report that fits a default model. As shown in the Model Specification outline in Figure 7.4, this model fits each unit with its own intercept and slope, using a linear transformation of the response and time columns. Separate intercepts and slopes are fit for each value of the Label, System ID variable, or, if only an X variable is specified, separate intercepts and slopes are fit for each level of the X variable. The Stability Test method fits three models.
Figure 7.4 Initial Repeated Measures Degradation Report with Transformation Outlines Open

To reproduce this example, see “Example of the Degradation Platform” on page 179.
The reports for Repeated Measures Degradation, Destructive Degradation, and Stability Test include the following:

**Overlay**

An Overlay plot of the Y, Response variable versus the Time variable. In this example, the plot is of Current versus Hours. The Overlay plot red triangle menu has the Save Estimates option, which creates a new data table containing the estimated slopes and intercepts for all units.

**Model Specification**

Specify your model and generate a report for that model. See “Model Specification” on page 186. (Available only for the Repeated Measures Degradation and Destructive Degradation methods.)

**Stability Tests Outline**

Compare models and estimate expiration dates. See “Stability Analysis” on page 208. (Available only for the Stability Test method.)

**Reports**

Shows analysis results for three different models and the best model. See “Stability Analysis” on page 208. (Available for the Stability Test method by default. Also available for the Repeated Measures Degradation and Destructive Degradation methods after you click Generate Report for Current Model.)

**Tabbed Reports**

**Residual Plot** Shows a single residual plot with all the units overlaid and separate residual plots for each unit arranged in a rectangular grid. The red triangle menu has the following options:

- **Save Residuals** Saves the residuals of the current model to a new data table.
- **Jittering** Adds random noise to the points in the time direction. This is useful for visualizing the data if there are a lot of points clustered together.
- **Separate Groups** Adds space between the groups to visually separate the groups. This option appears only when an X variable is specified on the platform launch window.
- **Jittering Scale** Changes the magnitude of the jittering and group separation. This option appears only if Jittering is selected.
- **Inverse Prediction** Enables you to predict the time at which the Y variable reaches a specified value. See “Inverse Prediction” on page 196.
**Model Specification**

You can use the Model Specification outline to specify the model that you want to fit to the degradation data. There are two types of Model Specifications:

**Simple Linear Path**  Used to model linear degradation paths, or nonlinear paths that can be transformed to linear. See “Simple Linear Path” on page 186.

**Nonlinear Path**  Used to model nonlinear degradation paths, especially those that cannot be transformed to linear. See “Nonlinear Path” on page 188.

To change between the two specifications, use the Degradation Path Style submenu from the Degradation Data Analysis red triangle menu.

**Simple Linear Path**

To model linear degradation paths, select **Degradation Path Style > Simple Linear Path** from the Degradation Data Analysis red triangle menu.

Use the Simple Linear Path Model specification to specify the form of the linear model that you want to fit to the degradation path. You can model linear paths, or nonlinear paths that can be transformed to linear.

**Figure 7.5**  Simple Linear Path Model Specification

![Simple Linear Path Model Specification](image)

The Simple Linear Path model specification contains the following options:

**Intercept**  Specifies the form of the intercept in the model:

- **Different**  Fits a different intercept for each level of the ID variable.
Common in Group  Fits the same intercept for each level of the ID variable in the same level of the X variable, and fits different intercepts between levels.

Common  Fits the same intercept for all levels of the ID variable.

Zero  Restricts the intercept to be zero for all levels of the ID variable.

Slope  Specifies the form of the slope in the model:

Different  Fits a different slope for each level of the ID variable.

Common in Group  Fits the same slope for each level of the ID variable in the same level of the X variable, and fits different slopes between levels.

Common  Fits the same slope for all levels of the ID variable.

Reset Axes to Linear  Resets the Overlay plot axes to their initial settings.

<Y, Response> Transformation  If a transformation on the Y variable can linearize the degradation path, select the transformation (Linear, ln(x), exp(x), x^2, sqrt(x) or Custom) here. For more information about the Custom option, see “Custom Transformations” on page 187.

<Time> Transformation  If a transformation for the Time variable can linearize the degradation path, select the transformation (Linear, ln(x), x^2, sqrt(x) or Custom) here. For more information about the Custom option, see “Custom Transformations” on page 187.

Generate Report for Current Model  Creates a report for the current model settings. This includes a Model Summary report, and Estimates report giving the parameter estimates. See “Model Reports” on page 201.

Custom Transformations

If you need to perform a transformation that is not given, use the Custom option. For example, to transform the response variable using exp(-x^2), enter the transformation as shown in the Scale box in Figure 7.6. Also, enter the inverse transformation in the Inverse Scale box.

Note: JMP automatically attempts to solve for the inverse transformation. If it can solve for the inverse, it automatically enters it in the Inverse Scale box. If it cannot solve for the inverse, you must enter it manually.
Name the transformation using the text box. When finished, click the **Use & Save** button to apply the transformation. Select a transformation from the menu if you have created multiple custom transformations. Click the **Delete** button to delete a custom transformation.

### Nonlinear Path

To model nonlinear degradation paths, select **Degradation Path Style > Nonlinear Path** from the Degradation Data Analysis red triangle menu. This is useful if a degradation path cannot be linearized using transformations, or if you have a custom nonlinear model that you want to fit to the data.

To facilitate explaining the Nonlinear Path Model Specification, open the Device B.jmp data table. The data consists of power decrease measurements taken on 34 units, across four levels of temperature. Follow these steps:

1. Select **Help > Sample Data Library** and open Reliability/Device B.jmp.
2. Select **Analyze > Reliability and Survival > Degradation**.
3. Select Power Drop and click **Y, Response**.
4. Select Hours and click **Time**.
5. Select Degrees C and click **X**.
   
   The temperature setting is the accelerating factor in the experiment.
6. Select Device and click **Label, System ID**.
7. Click **OK**.

The initial overlay plot of the data appears.
The degradation paths appear linear for the first several hundred hours, but then start to curve. To fit a nonlinear model, select **Degradation Path Style > Nonlinear Path** from the Degradation Data Analysis red triangle menu to show the Nonlinear Path Model Specification outline (Figure 7.8).

**Note:** To view the Edit button displayed in Figure 7.8, you must select the interactive formula editor preference (**File > Preferences > Platforms > Degradation > Use Interactive Formula Editor**) before launching the Degradation platform.

The first step to create a model is to select one of the options on the menu initially labeled **Empty**:

- For more information about Reaction Rate models, see “**Reaction Rate Models**” on page 190.
For more information about Constant Rate models, see “Constant Rate Models” on page 190.
For more information about using a Prediction Column, see “Prediction Columns” on page 191.

Reaction Rate Models

The Reaction Rate options are applicable when the degradation occurs from a single chemical reaction, and the reaction rate is a function of temperature only. Select Reaction Rate or Reaction Rate Type 1 from the menu shown in Figure 7.8. Although similar to the Reaction Rate model, the Reaction Rate Type 1 model contains an offset term that changes the basic assumption concerning the response value’s sign.

The Setup window prompts you to select the temperature scale, and the baseline temperature. The baseline temperature should be representative of the temperatures used in the study. For this example, select Reaction Rate and then select Celsius as the Temperature Unit. Click OK to return to the report. For more information about all the features for Model Specification, see “Model Specification Details” on page 192.

Constant Rate Models

The Constant Rate option is for modeling degradation paths that are linear with respect to time (or linear with respect to time after transforming the response or time). The reaction rate is a function of temperature only.

Select Constant Rate from the menu shown in Figure 7.8. The Constant Rate Model Settings window prompts you to enter transformations for the Path, Rate, and Time.
**Figure 7.9** Constant Rate Transformation

Once a selection is made for each transformation, the associated formula appears in the lower left corner as shown in Figure 7.9.

After all selections are made, click **OK** to return to the report. For more information about all the features for Model Specification, see “Model Specification Details” on page 192.

**Prediction Columns**

The Prediction Column option enables you to use a custom model that is stored as a formula in a data table column. The easiest approach is to create the formula column before launching the Degradation platform. You can also create the formula column from within the Degradation platform if you want to use one of the built-in models in the Nonlinear Model Library.

For more information about how to create a custom model and store it as a column formula, see “Fit a Custom Model” on page 194 or *Predictive and Specialized Modeling*.

Select **Prediction Column** from the list that appears beneath the Expression area in Figure 7.8. The Model Specification outline changes to prompt you to select the column that contains the model.
Figure 7.10 Column Selection

At this point, do one of three things:

- If the model that you want to use already exists as a formula in a column of the data table, select the corresponding column here, and then click OK. You are returned to the Nonlinear Path Model Specification. For more information about all the features for that specification, see “Model Specification Details” on page 192.

- If the model that you want to use does not already exist in the data table, you can click the Model Library button to use one of the built-in models. For more information about using the Model Library button, see “Model Library” on page 195 or Predictive and Specialized Modeling. After the model is created, select Redo > Redo Analysis from the Degradation Data Analysis red triangle menu. Then, return to the column selection shown in Figure 7.10. Select the column that contains the model, and then click OK. You are returned to the Nonlinear Path Model Specification. For more information about all the features for that specification, see “Model Specification Details” on page 192.

- If the model that you want to use is not in the data table, and you do not want to use one of the built-in models, then you are not ready to use this model specification. First, create the model, relaunch the Degradation platform, and then return to the column selection (Figure 7.10). Select the column containing the model, and then click OK. You are returned to the Nonlinear Path Model Specification. For more information about all the features for that specification, see “Model Specification Details” on page 192.

Model Specification Details

After you select one of the model types and supply the required information, you are returned to the Nonlinear Path Model Specification window.

Note: To view the Edit button displayed in Figure 7.11, you must select the interactive formula editor preference (File > Preferences > Platforms > Degradation > Use Interactive Formula Editor) before launching the Degradation platform.

A model is now shown in the script box that uses the Parameter statement. Initial values for the parameters are estimated from the data. For more information about creating models that use parameters, see “Fit a Custom Model” on page 194 or Predictive and Specialized Modeling.
If desired, enter a name in the text box to name the model. For this example, use the name “Device RR”. After that, click the **Use & Save** button to enter the model and activate the other buttons and features. Figure 7.11 shows the Model Specification window after clicking the Use & Save button.

**Figure 7.11 Model Specification**

- The **Fit Model** button is used to fit the model to the data.
- The **Fit by System ID** is used to fit the model to every level of **Label, System ID**.
- The **Delete** button is used to delete a model from the model menu.
- The **Generate Report for Current Model** button creates a report for the current model settings. See “Model Reports” on page 201.

The initial parameter values are shown at the bottom, along with sliders for visualizing how changes in the parameters affect the model. The fitted lines are shown on the Overlay plot.

Move the parameter sliders to see how changes affect the fitted lines.

Here are the parameters for the Reaction Rate model (Meeker and Escobar 1998):

- **Dinf** ($D_\infty$) - asymptotic degradation level
- **Ru** ($R_U$) - reaction rate at use temperature ($temp_U$)
- **Ea** ($Ea$) - reaction-specific activation energy

The above parameters are calculated as follows:

$$D(t; \text{temp}) = D_\infty \times [1-\exp[-R_U \times AF(\text{temp}) \times t]]$$
where $R_U$ is the reaction rate at use temperature $temp_U$, $R_U \times AF(temp)$ is the reaction rate at a general temperature $temp$, and for $temp > temp_U$, $AF(temp) > 1$

and

$$AF(temp) = \frac{R(temp)}{R(temp_U)} = \exp\left[\frac{Ea(11604.5181215503)}{(temp_K)} - \frac{11604.5181215503}{(temp_K)}\right]$$

where $temp_U K$ and $temp K$ are temperatures expressed on the Kelvin scale.

To compute the optimal values for the parameters, click the **Fit Model** or **Fit by System ID** button.

To fix a value for a parameter, check the box under **Fixed** for the parameter. When fixed, that parameter is held constant in the model fitting process.

**Entering a Model with the Formula Editor**

You can use the Formula Editor to enter a model. Click the **Edit** button to open the Formula Editor to enter parameters and the model. For more information about entering parameters and formulas in the Formula Editor, see *Using JMP*.

**Note:** To view the Edit button displayed in Figure 7.12, you must select the interactive formula editor preference (File > Preferences > Platforms > Degradation > Use Interactive Formula Editor) before launching the Degradation platform.

**Figure 7.12 Alternate Model Specification Report**

![Alternate Model Specification Report](image)

**Fit a Custom Model**

If you want to fit a custom model, you must first create a formula column with initial parameter estimates. This method requires a few more steps than fitting a built-in model, but it allows any nonlinear model to be fit. Also, you can provide a custom loss function, and specify several other options for the fitting process.

1. Open your data table.
2. Create a new column in the data table.
3. Open the Formula Editor for the new column.
4. Select Parameters from the list in the lower left corner.
5. Click New Parameter.
6. Enter the name of the parameter.
7. Enter the initial value of the parameter.
   Repeat steps 4 to 6 to create all the parameters in the model.
8. Build the model formula using the data table columns, parameters, and formula editor functions.
9. Click OK.

Parameters for Models with a Grouping Variable

In the formula editor, when you add a parameter, note the check box for Expand Into Categories, selecting column. This option is used to add several parameters (one for each level of a categorical variable for example) at once. When you select this option, a window appears that enables you to select a column. After selection, a new parameter appears in the Parameters list with the name D_column, where D is the name that you gave the parameter. When you use this parameter in the formula, a Match expression is inserted, containing a separate parameter for each level of the grouping variable.

Model Library

The Model Library can assist you in creating a formula column with parameters and initial values. Click Model Library under Model Specification to open the library. Select a model in the list to see its formula in the Formula box.

Click Show Graph to show a 2-D theoretical curve for one-parameter models and a 3-D surface plot for two-parameter models. No graph is available for models with more than two explanatory (X) variables. Use the slider bars to change the default starting values for the parameters. You can also click the values and enter new values directly.

The Reset button sets the starting values for the parameters back to their default values.

Click Show Points to overlay the actual data points to the plot. A window opens, asking you to assign columns into X and Y roles, and an optional Group role. The Group role allows for fitting the model to every level of a categorical variable. If you specify a Group role here, also specify the same column in the Label, System ID role in the platform launch window.

For most models, the starting values are constants. Showing points enables you to adjust the parameter values to see how well the model fits for different values of the parameters.
Click **Make Formula** to create a new column in the data table. This column has the formula as a function of the specified X variable and uses the parameter values specified in the graph window.

**Note:** If you click **Make Formula** before you click the **Show Graph** or **Show Points** buttons, you are asked to provide the X and Y roles, and an optional Group role. After that, you are brought back to the plot so that you have the option to adjust the starting values for the parameters. Once the starting values for the parameters are satisfactory, click **Make Formula** again to create the new column.

Once the formula is created in the data table, click the Degradation Data Analysis red triangle and select **Redo > Redo Analysis**. Then, return to the column selection shown in **Figure 7.10** on page 192. Select the column that contains the model, and then click **OK**. You are returned to the Nonlinear Path Model Specification. For more information about all the features for that specification, see “**Model Specification Details**” on page 192.

**Note:** You can customize the models included in the Nonlinear Model Library by modifying the built-in script named **NonlinLib.jsl**. This script is located in the **Resources/Builtins** folder in the folder that contains JMP (Windows) or in the Application Package (macOS).

---

**Inverse Prediction**

Use the Inverse Prediction tab to predict the time at which the Y variable reaches a specified value. These times are sometime called pseudo failure times.

**Figure 7.13  Inverse Prediction Tab**

Enter either the Lower or Upper Spec Limit. Generally, if your Y variable decreases over time, then enter a Lower Spec Limit. If the Y variable increases over time, then enter an Upper Spec Limit.

For the **GaAs Laser** example, enter 10 for the Upper Spec Limit and click **Go**. A plot is produced showing the estimated times until the units reach a 10% increase in operating current.
The Inverse Prediction red triangle menu contains the following options:

**Save Crossing Time**  Saves the pseudo failure times to a new data table. The table contains a Life Distribution or Fit Life by X script that can be used to fit a distribution to the pseudo failure times. When one of the Inverse Prediction Interval options is enabled, the table also includes the intervals.

**Set Upper Spec Limit**  Sets the upper specification limit.

**Set Lower Spec Limit**  Sets the lower specification limit.

**Set Censoring Time**  Sets the censoring time. The plot updates to show the Censoring Time as a dotted vertical line. If Inverse Prediction Interval > No Interval is selected, observations that exceed the Censoring Time are displayed on horizontal lines starting at the Censoring Time. If Confidence Interval or Prediction Interval is selected, horizontal lines extend indefinitely to the right of observations whose upper limits exceed the Censoring Time. The Censoring Time is reflected in data tables constructed using Save Crossing Time and Generate Pseudo Failure Data.

**Use Interpolation through Data**  Specifies the use of linear interpolation between points (instead of the fitted model) to predict when a unit crosses the specification limit. The behavior depends on whether a unit has observations that exceed the specification limit.

- If a unit has observations exceeding the specification limit, the inverse prediction is the linear interpolation between the observations that surround the specification limit.
– If a unit does not have observations exceeding the specification limit, the inverse prediction is censored and has a value equal to the maximum observed time for that unit.

**Inverse Prediction Interval**  Specifies that confidence or prediction intervals for the pseudo failure times are shown on the Inverse Prediction plot. When intervals are enabled, the intervals are also included in the data table that is created when using the Save Crossing Time option.

**Inverse Prediction Alpha**  Specifies the alpha level used for the intervals.

**Inverse Prediction Side**  Specifies one or two sided intervals.

---

**Prediction Graph**

Use the Prediction Graph tab to predict the Y variable for a specified Time value.

**Figure 7.15  Prediction Plot Tab**

For the GaAs Laser example, no data was collected after 4000 hours. If you want to predict the percent increase in operating current after 5000 hours, enter 5000 and click Go. A plot is produced showing the estimated percent decrease after 5000 hours for all the units.
The Prediction Plot red triangle menu contains the following options:

**Save Predictions**  Saves the predicted Y values to a data table. When one of the Longitudinal Prediction Interval options is enabled, the table also includes the intervals.

**Longitudinal Prediction Interval**  Shows or hides confidence or prediction intervals for the estimated Y on the Prediction Plot. When intervals are enabled, the intervals are also included in the data table that is created when using the Save Predictions option.

**Longitudinal Prediction Time**  Specifies the time value for which you want to predict the Y.

**Longitudinal Prediction Alpha**  Specifies the alpha level used for the intervals.

---

**Degradation Platform Options**

The Degradation Data Analysis red triangle menu contains the following options:

**Path Definition**  The Y variable at a given time is assumed to have a distribution. You can model the mean, location parameter, or median of that distribution.

- **Mean Path**  Specifies that the mean is the parameter to be modeled.
- **Location Parameter Path**  Specifies that the location parameter of the distribution is the parameter to be modeled.
**Degradation Platform Options**

**Reliability and Survival Methods**

**Median Path** specifies that the median of the distribution is the parameter to be modeled.

When the Location Parameter or Median Path option is selected, a menu appears in the Model Specification that enables you to select the distribution of the response.

**Degradation Path Style** contains options for selecting the style of degradation path to fit.

**Simple Linear Path** enables you to fit linear degradation paths and nonlinear paths that can be transformed to linear paths. See “Simple Linear Path” on page 186.

**Nonlinear Path** enables you to fit nonlinear degradation paths. See “Nonlinear Path” on page 188.

**Graph Options** contains options for modifying the appearance of graphs in the report.

**Connect Data Markers** shows or hides lines connecting the points on the Overlay plot.

**Show Fitted Lines** shows or hides the fitted lines on the Overlay plot.

**Show Spec Limits** shows or hides the specification limits on the Overlay plot.

**Show Residual Plot** shows or hides the residual plot.

**Show Inverse Prediction Plot** shows or hides the inverse prediction plot.

**Show Curve Interval** shows or hides the confidence intervals on the fitted lines on the Overlay plot.

**Curve Interval Alpha** enables you to change the alpha used for the confidence interval curves.

**Show Median Curves** shows or hides median lines on the plot when the Path Definition is set to Location Parameter Path.

**Show Legend** shows or hides a legend for the markers used on the Overlay plot.

**No Tab List** shows or hides the Residual Plot, Inverse Prediction, and Prediction Graph in tabs or in stacked reports.

**Prediction Settings** contains options for modifying the settings used in the model predictions.

**Upper Spec Limit** specifies the upper specification limit.

**Lower Spec Limit** specifies the lower specification limit.

**Censoring Time** specifies the censoring time. See “Inverse Prediction” on page 196.

**Baseline** specifies the normal use conditions for an X variable in nonlinear degradation paths. A path with this value usually results in an Overlay plot.
Inverse Prediction  Specifies the interval type, alpha level, and one- or two-sided intervals for inverse prediction. To do inverse prediction, you must also specify the lower or upper specification limit. See “Inverse Prediction” on page 196.

Longitudinal Prediction  Specifies the Time value, interval type, and alpha level for longitudinal prediction. See “Prediction Graph” on page 198.

Applications  Contains options for further analysis of the degradation data.

Generate Pseudo Failure Data  Creates a data table giving the predicted time each unit crosses the specification limit. The table contains a Life Distribution or Fit Life by X script that can be used to fit a distribution to the pseudo failure times.

Test Stability  Performs stability analysis. See “Stability Analysis” on page 208.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Model Reports

When the Generate Report for Current Model button is clicked, summary reports are added in two places:

- An entry is added to the Model List report. See “Model Lists” on page 201.
- An entry is added to the Reports report. See “Reports” on page 202.

Model Lists

The Model List report gives summary statistics and other options for every fitted model. Figure 7.17 shows an example of the Model List with summaries for three models.

**Display**  Select the model that you want represented in the Overlay plot, Residual Plot, Inverse Prediction plot, and Prediction Graph.

**Model Type**  Gives the type of path, either linear or nonlinear.

**Report**  Select the check boxes to display the report for a model. For more information about the reports, see “Reports” on page 202.

**Nparm**  Gives the number of parameters estimated for the model.

**-2LogLikelihood**  Gives twice the negative of the log-likelihood. See *Fitting Linear Models*.

**AICc**  Gives the corrected Akaike Criterion. See *Fitting Linear Models*.

**BIC**  Gives the Bayesian Information Criterion. See *Fitting Linear Models*.

**SSE**  Gives the error sums-of-squares for the model.

**DF**  Gives the error degrees of freedom.

**Description**  Gives a description of the model.

### Reports

The Reports outline node gives details about each model fit. The report includes a Model Summary report, and an Estimate report.

The Model Summary report contains the following information:

**<Y, Response> Scale**  The transformation on the response variable.

**<Time> Scale**  The transformation on the time variable.

**SSE**  The error sums-of-squares.

**Nparm**  The number of parameters estimated for the model.

**DF**  The error degrees of freedom.

**RSquare**  The R-square.

**MSE**  The mean square error.
The Estimate report contains the following information:

**Parameter**  The name of the parameter.

**Estimate**  The estimate of the parameter.

**Std Error**  The standard error of the parameter estimate.

**t Ratio**  The t statistic for the parameter, computed as the Estimate divided by the Std Error.

**Prob>|t|**  The p-value for a two-sided test for the parameter.

---

**Destructive Degradation**

To measure a product characteristic, sometimes the product must be destroyed. For example, when measuring breaking strength, the product is stressed until it breaks. Regular degradation analysis no longer applies in these situations. You can handle these situations in one of two ways:

- If your failure time model is a standard one, it might be covered by the Destructive Degradation platform. See the “Destructive Degradation” chapter on page 213.
- If you are using custom transformations of the time or response variables and custom nonlinear models, use the Degradation platform. In the launch window, select the Destructive Degradation tab.

**Example of Accelerated Destructive Degradation**

This example fits a custom nonlinear model. The data consist of measurements on the strength of an adhesive bond. The product is stressed until the bond breaks, and the required breaking strength is recorded. Because units at normal use conditions are unlikely to break, the units were tested at several levels of an acceleration factor (temperature). You want to estimate the strength (in newtons) of units after 52 weeks (one year) at use conditions of 25°C.

**Complete the Launch Window**

1. Select Help > Sample Data Library and open Reliability/Adhesive Bond.jmp.
2. Select Analyze > Reliability and Survival > Degradation.
3. Select the Destructive Degradation tab.
4. Select Strength and click Y, Response.
5. Select Weeks and click Time.
6. Select Degrees and click X.
7. Select Censor and click Censor.
8. Click **OK**.

**Define and Fit the Model**

1. Select **Lognormal** from the menu in the Location Parameter Path Specification panel in the Model Specification outline.
   
   This specifies a lognormal transformation for the response, Strength.

2. Click the Degradation Data Analysis red triangle and select **Degradation Path Style > Nonlinear Path**.

   This adds a script window to the report. You insert a script that specifies your model in this window.

3. Copy the JSL formula below and paste it into the script window under Nonlinear Path:

   ```julia
   Parameter(
     {b1 = 50, b2 = 50, b3 = -1},
     b1 * :Degrees + b2 * Exp( b3 * Sqrt( :Weeks ) )
   )
   ```

   The script defines a model for Strength in terms of parameters b1, b2, and b3. The script specifies initial values for the parameters.

4. In the text box at the bottom of the report, change Empty to Custom Model.
5. Click **Use & Save**.

**Figure 7.20** Updated Model Specification Outline

The report is updated to include controls for changing initial values for the parameters. Initial values for the parameters are set to the values specified in the formula in the script editor.

6. Click **Fit Model**.
Figure 7.21  Plot of Fitted Model

The Parameter panel in the Model Specification outline is updated to show the parameter estimates for the fitted model. The model fit is shown in the Overlay plot. You can drag the axes to show the points, as is done in Figure 7.21. The legend identifies the curves.

Obtain Predicted Values and Prediction Intervals

Next, you obtain a predicted value and prediction interval for Strength after 52 weeks at the baseline use condition of 25°C.

1. Click the Degradation Data Analysis red triangle and select  Prediction Settings.
2. In the Prediction Settings window:
   - Enter 25 for Baseline.
   - Enter 52 for Time in the Longitudinal Prediction panel.
   - Select Prediction Interval from the menu in the Longitudinal Prediction panel.
3. Click **OK**.

4. Select the **Prediction Graph** tab in the report.

**Figure 7.23** Prediction Plot at Weeks = 52

The Prediction Plot shows the predicted value and its 95% level prediction interval above the axis label of 25 (Baseline).

5. Click the Prediction Plot red triangle and select **Save Predictions**.

Predicted values for the three values of Degrees and for the desired baseline of 25 degrees are saved to a data table. The predicted strength of the adhesive bond after 1 year at 25° C is 61.96, with a prediction interval of 42.42 to 90.50.
Stability Analysis

Stability analysis is used in setting pharmaceutical product expiration dates. Three linear degradation models are fit, and an expiration date is estimated following International Conference on Harmonisation (ICH) guidelines. The ICH guidelines are used for the general framework of determining if batches can be pooled for expiration dating (ICH Q1E 2003). For specific implementation details, see the STAB macro and FDA guidelines in Chow (2007, Appendix B).

The Stability Tests report summarizes three degradation models and their corresponding earliest crossing times. The best model is selected and displayed in the Overlay plot. The models are listed in the order of complexity.

The first model fits different intercepts and different slopes to each batch. (In the procedure steps and model comparisons described below, this is the full model.) When this model is used for estimating the expiration date, the mean square error (MSE) is not pooled across batches. Prediction intervals are computed for each batch using individual mean squared errors, and the interval that crosses the specification limit first is used to estimate the expiration date. The earliest crossing times are based on 95% two-sided prediction intervals when there are two specification limits provided; the earliest crossing times are based on 95% one-sided prediction intervals when there is only one specification limit provided.

The second model fits different intercepts to each batch, but fits a common slope across all batches. The third model fits a common intercept and a common slope across all batches. When this model is appropriate, it provides the expiration date furthest into the future.

Figure 7.24 Stability Tests Summary

The Model Comparisons section of the Stability Tests report summarizes the tests of significance for each of the stability models. The Legend describes each source. The procedure for determining the best model for expiration dating considers the $p$-values for Sources C and B. The sources are listed below in reverse order to accommodate the order of steps in the procedure.
Tip: The ICH guidelines specify using a significance level of 0.25 to determine the appropriate model. You can follow the steps below and compare the \( p \)-values at each source to a different significance level. If this results in a different model being selected, you can use the radio buttons in the Display column of the table in the Stability Tests summary report.

**Source E**  Specifies the sum of squared responses minus the Source D sum of squares. The value in the Mean Square column for Source E is the Source E SS value divided by the Source E degrees of freedom, which are equal to the number of parameters in the full model (different intercepts and different slopes).

**Source D**  Specifies the error sum of squares and corresponding MSE for the full model (different intercepts and different slopes).

**Source C**  Specifies the test of equal slopes. This is a test of the second model (different intercepts and common slope) versus the full model (different intercepts and different slopes).

- If the \( p \)-value is less than 0.25, the slopes are assumed to be different across batches. The procedure stops and the full model (different intercepts and different slopes) is used to estimate the expiration date.
- If the \( p \)-value is greater than or equal to 0.25, the slopes are assumed to be common across batches and you then evaluate the intercepts using Source B.

**Source B**  Specifies the test for equal intercepts. This is a test of the third model (common intercepts and common slopes) versus the second model (different intercepts and common slope).

- If the \( p \)-value is less than 0.25, the intercepts are assumed to be different across batches, and the second model (different intercepts and common slope) is used to estimate the expiration date.
- If the \( p \)-value is greater than or equal to 0.25, the intercepts are assumed to be common across batches, and the third model (common intercepts and common slopes) is used to estimate the expiration date.

**Source A**  Specifies the test of the third model (common intercepts and common slopes) versus the full model (different intercepts and different slopes). This test is not used in the procedure to determine the best model for expiration dating.

The Reports section contains models fit by the Test Stability option. The following four models are fit by the Test Stability option:

- A different intercept, different slope model where the MSE (mean squared error) is pooled across batches. (This is an alternative to the first model in the Summary report.)
- A different intercept, common slope model. (This is the second model in Summary report.)
- A common intercept, common slope model. (This is the third model in Summary report.)
- A different intercept, different slope model where the MSE (mean squared error) is not pooled across batches. (This is the first model in the Summary report.)

**Caution:** In addition to the four models fit by the Test Stability option, the Reports section also contains any models fit in the Degradation platform prior to running the Test Stability option.

**Example**

Use the data in the Stability.jmp sample data table to establish an expiration data for a new product. The data consists of product concentration measurements on four batches. A concentration of 95 is considered the end of the product’s usefulness.

To perform the stability analysis, do the following steps:

2. Select Analyze > Reliability and Survival > Degradation.
3. Select the Stability Test tab.
4. Select Concentration (mg/Kg) and click Y, Response.
5. Select Time and click Time.
6. Select Batch Number and click Label, System ID.
7. Enter 95 for the Lower Spec Limit.
8. Click **OK**.

**Figure 7.26** Stability Models

The test for equal slopes has a \( p \)-value of 0.8043. Because this is larger than a significance level of 0.25, the test is not rejected, and you conclude the degradation slopes are equal between batches.

The test for equal intercepts and slopes has a \( p \)-value of <.0001. Because this is smaller than a significance level of 0.25, the test is rejected, and you conclude that the intercepts are different between batches.

Because the test for equal slopes was not rejected, and the test for equal intercepts was rejected, the chosen model is the one with Different Intercepts and Common Slope. This model is the one selected in the report, and gives an estimated expiration date of 23.475.
To measure a product characteristic, sometimes the product must be destroyed. For example, when measuring breaking strength, the product is stressed until it breaks. Because the test is destructive, there is only one observation per product unit. In such a situation, you can model product reliability using the Destructive Degradation platform.

The platform models how a (typically) nonnegative response changes over time. Observations are assumed to be independent and measure the value of the response and the time at failure. A large and flexible collection of pre-defined models is provided. The models include location-scale and log-location-scale distributions whose location parameters are functions of time. The models allow explanatory variables and additional parameters. When an explanatory variable is specified, the platform fits an accelerated destructive degradation model.

**Note:** If you require a model that is not represented among the models provided, you can use the Degradation platform. See “Destructive Degradation” on page 203 in the “Degradation” chapter.

For more information about destructive degradation and reliability, see Escobar et al. (2003) and Meeker and Escobar (1998).

Example of the Destructive Degradation Platform

This example of an accelerated destructive degradation model is patterned after an example from Escobar et al. (2003). The data consist of measurements on the strength (measured in newtons) of an adhesive bond. Temperature is considered to be an acceleration factor. The product is stressed until the bond breaks and the required breaking stress is recorded. Because units at normal temperatures are unlikely to break, the units were tested at several levels over a wide range of temperatures. Strength less than 50 newtons is considered failure. You want to estimate the proportion of units with a strength below 50 newtons after 260 weeks (5 years) at a reference temperature of 35 degrees Celsius.

This example has three stages:

- “Perform the Initial Analysis” on page 215
- “Change the Model and Generate the Report” on page 216
- “Using the Profilers for Prediction” on page 219

Perform the Initial Analysis

1. Select Help > Sample Data Library and open Reliability/Adhesive Bond.jmp.
2. Select Analyze > Reliability and Survival > Destructive Degradation.
3. Select Strength and click Y, Response.
4. Select Weeks and click Time.
5. Select Degrees and click X.
   The temperature is the accelerating factor in the experiment.
6. Select Censor and click Censor.
   Notice that the Censor Code is set to Right.
7. Click OK.
The platform specifies a default model. The default model assumes that the data are described by a single Normal distribution, whose location parameter is a linear function of time.

**Change the Model and Generate the Report**

1. Select **Log** for the **Y** (Strength) Transformation.
2. Select **Sqrt** for the Time (Weeks) Transformation.
3. Select $\mu = b_0 + b_1 \cdot f(\text{time})$ for the Path Definition.

The subscript “x” denotes the accelerating variable, which is **Degrees** in this example.

**Note:** This model is linear in all parameters.
4. Click **Generate Report**.
The estimates of the slope $b_1$ at the three values of Degrees suggest that degradation occurs more quickly at higher temperatures. Failure mechanisms that depend on chemical processes are often well modeled using the Arrhenius model for temperature. For this reason, you now fit a model where an Arrhenius transformation is applied to Degrees, which is measured on a Celsius scale.

5. Select $\mu = b_0 + \text{Exp}(b_1 + b_2 \cdot \text{Arrhenius}(X)) \cdot f(\text{time})$ for the Path Definition.

   **Note:** This model is not linear in the parameters.

6. Select *Celsius* and click **OK**.
7. Click Generate Report.

Using the Profilers for Prediction

Because the Arrhenius model shows a better fit, as indicated by its smaller AICc and BIC values (Figure 8.6), you continue your analysis using this model.
Recall that strength less than 50 newtons is considered failure. You are interested in units lasting 156 weeks (three years) at a reference temperature of 35 degrees Celsius. Change the settings in the profilers to reflect these values. Click the value in red beneath each plot’s horizontal axis and enter the new value.

1. In the Degradation profiler for the Arrhenius model, set **Weeks** to 156 and **Degrees** to 35.

   **Figure 8.7 Degradation Profiler**

   The predicted **Strength** at these settings is 62.25173, with a 95% prediction interval ranging from 50.0318 to 77.4563. Failures are not very likely at these or less extreme settings.

2. In the Crossing Time Distribution Profiler, set **Weeks** to 156, **Degrees** to 35, and **Strength** to 50.

   **Figure 8.8 Crossing Time Distribution Profiler**

   At 156 weeks at a temperature of 35 degrees Celsius, the probability that the value of Strength is less than 50 is 0.024668. The 95% confidence interval ranges from 0.00342 to 0.10995. The probability of failure at these or less extreme conditions is about 2%.

3. In the Crossing Time Quantile Profiler, set **Degrees** to 35, **Probability** to 0.02, and **Strength** to 50.

4. Adjust the vertical axis of the Crossing Time Quantile Profiler so that the maximum value is about 350.
The number of weeks within which 2% of units fail at a temperature of 35 degrees Celsius is estimated to be 146.0928. The 95% confidence interval ranges from 89.1159 to 277.458.

Launch the Destructive Degradation Platform

Launch the Destructive Degradation platform by selecting Analyze > Reliability and Survival > Destructive Degradation. Figure 8.10 shows the Destructive Degradation launch window using the Adhesive Bond.jmp data table (located in the Reliability folder).

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The Destructive Degradation launch window contains the following options:

**Y, Response** Identifies the column containing the degradation measurements. When your response values are interval-censored, you can enter two columns. See “Specify Two Y Columns” on page 222.

**Time** Identifies the column containing the time values.

**X** Identifies an optional explanatory variable. If the distribution of Y changes not only over time, but is also impacted by some other variable, that additional variable can be supplied
Launch the Destructive Degradation Platform Reliability and Survival Methods as X. Use this role to specify the accelerating factor in an accelerated destructive degradation model.

**Freq** Identifies frequencies or observation counts when there are multiple units. If the value is 0 or a positive integer, then the value represents the frequencies or counts of observations with the given row’s settings.

**Censor** Identifies an optional column that identifies censored response measurements. When there is only one column in the Y role, this column indicates whether the response Y in a given row is exact or right censored. A right-censored observation is one where the exact measurement is unknown, but is known to be larger than the Y value in the corresponding row.

Select the value that identifies right-censored observations from the Censor Code menu. Rows corresponding to other values in the Censor column are treated as uncensored. Rows with missing censor code values are excluded from the analysis. JMP attempts to detect the censor code and display it in the list.

**By** Identifies an optional By variable. A separate analysis is produced for each level of this variable.

**Censor Code** Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.

### Specify Two Y Columns

You can specify two Y columns when some of the degradation measurements are interval censored or left censored. For a given row, the values in the two Y columns determine the type of censoring.

- If the two Y values are equal and neither is missing, then the common measurement is treated as exact.
- If the two Y values are not equal and neither is missing, then the measurement is interval censored and assumed to be between the two values.
- If only the first value is missing, then the measurement is left censored and assumed to be smaller than the second value.
- If only the second value is missing, then the measurement is right censored and assumed to be larger than the first value.
The only way to fit left-censored measurements in the Destructive Degradation platform is through the use of two Y columns.

The Destructive Degradation Plot Options and Models

The Degradation Data Analysis plot shows the data and a graphical representation of the model that is currently specified based on selections of Distribution, Transformation, and Path Definition. The plot shown in Figure 8.11 is for the Adhesive Bond.jmp data table and represents a model that includes an optional X variable.

Figure 8.11  Destructive Degradation Plot and Options

Note the following about the plot:
- Data values are represented by markers.

</tr>
</tbody>
</table>

**Note:** By default, the markers are not colored. To color them to match the model color scheme, select **Rows > Color or Mark by Column**. Select the X column. Deselect **Continuous Scale**. Select **JMP Default** from the Colors menu.

- For each level of X, a colored band appears. If the model does not include an X variable, then a single band appears. For a given value of Time, the upper and lower bounds of the band are the 0.025 and 0.975 percentiles of the fitted distribution of Y. The colors of the bands correspond to the values of X, as indicated by the legend to the upper right of the plot.

**Note:** Marker colors correspond to the color states assigned in the data table.

- The solid curve in the center of a band is the median of the fitted distribution of Y for the corresponding value of X over time. If the model does not include an X variable, then the curve plots the median of Y over time.

**Plot Options**

**Distribution** Choose a location-scale or a log-location-scale distribution.

**Note:** It is not recommended to fit a log-location-scale distribution model when you specify a Log transformation for the response column.

**Transformation** Choose a transformation function for the response Y and for the Time variable.
**Note:** If you apply the Log transformation to a column that contains nonpositive values, the rows with nonpositive values are omitted from the model fit. If you apply the Sqrt transformation to a column that contains negative values, the rows with negative values are omitted from the model fit.

**Path Definition**  Choose a linear or a nonlinear path for the regression model. For more information about each model, see “Models” on page 225.

**Generate Report**  Creates a report for the specified model. The first time you select Generate Report, a Model List outline is created. When you select Generate Report to fit other models, the Model List outline is updated and an outline is added for each model.

**Models**

The following table provides the equations for each model in the Path Definition list. For a description of each model, follow the link.

**Note:** The thumbnail sketch shown to the left of each equation shows a generic plot of the behavior of the location parameter, $\mu$, over time. In the report’s main plot, the plot of the estimated median can differ from the thumbnail based on your selections for Distribution and Transformation.

</table>

Models That Are Linear in Transformed Time

**Common Path with Intercept**

This model fits a single distribution whose location parameter changes linearly over transformed time. This model fits a common intercept and a common slope, regardless of whether there is an X variable.

**Common Path without Intercept**

This model fits a single distribution whose location parameter changes linearly over transformed time but whose value at time zero is zero. Based on selections for Distribution and Transformation, the median curve might not be a straight line and might not pass through origin. This model fits a zero intercept and a common slope, regardless of whether there is an X variable.

**Common Slope**

In this model, the location parameters are linear functions of transformed time with separate intercepts for the values of X but a common slope. Based on selections for Distribution and Transformation, the model fits might appear as curves. For example, selecting a Lognormal distribution gives the plot in Figure 8.12.
Figure 8.12  Common Slope Model Using a Lognormal Distribution

Individual Path with Intercept
In this model, the location parameters are linear functions of transformed time with separate intercepts and separate slopes for the values of X.

Individual Path without Intercept
In this model, the location parameters are linear functions of transformed time with zero intercepts and separate slopes for the values of X.

Common Intercept
In this model, the location parameters are linear functions of transformed time with a common intercept and separate slopes for the values of X.

First-Order Kinetics Models

Four first-order kinetics models where the location parameter is a nonlinear function based on an Arrhenius transformation of temperature are provided. Each of these location models fit separate models for each value of the optional explanatory variable X.

When you first select any of these models, you must specify the measurement scale for temperature and a reference temperature value, $X_0$. The specified reference temperature affects the interpretation of $b_2$ in these models. The $b_2$ parameter is the rate constant at $X_0$. The value for $X_0$ is used to construct a time acceleration factor (Meeker and Escobar 1998). If you subsequently select another of the first-order kinetics models or the Arrhenius Rate model (see “Arrhenius Rate” on page 229), the platform remembers and uses these specifications.
First-Order Kinetics Type 1

In this model, \( b1 \) and \( b2 \) are positive. On a linear scale, the curves have an upper asymptote at \( b0 \) as time approaches infinity.

First-Order Kinetics Type 2

In this model, the location parameter is zero at time zero. Both \( b0 \) and \( b1 \) are positive. On a linear scale, the curves have an upper asymptote at \( b0 \) as time approaches infinity. You can think of the Type 2 model as a vertically shifted version of the Type 1 model.

First-Order Kinetics Type 3

In this model, both \( b1 \) and \( b2 \) are positive. Because of the sign preceding \( b1 \) is the opposite of the sign preceding \( b1 \) in the Type 1 model, this model is an inverted version of the Type 1 model. On a linear scale, it has a lower asymptote at \( b0 \) as time approaches infinity.

Given data exhibiting a negative slope over time, the fitted model can produce a plot similar to Figure 8.13. The figure is for Adhesive Bond.jmp. The selected temperature measurement scale is Celsius and the specified reference temperature under typical use conditions is 35 degrees.

Figure 8.13  Example of First-Order Kinetics Model Type 3

First-Order Kinetics Type 4

This model is a vertically shifted version of the Type 3 model. On a linear scale, the curves have a lower asymptote at 0 as time approaches infinity.
Rate Models

Three models where the location parameter is an exponential function of the transformed X variable are provided. Each of these location models fits common intercept and separate slope models for each value of the optional explanatory variable X. For each of these models, on a linear scale, the location parameter is linear in the transformed time values.

Arrhenius Rate

This model involves an exponential function of the Arrhenius transformation multiplied by transformed time. When you select this model, you are asked to specify the measurement scale for temperature, unless you have already supplied this information.

Polynomial Rate

This model involves an exponential function of a linear function of the log of X multiplied by transformed time.

Exponential Rate

This model involves an exponential function of a linear function of X multiplied by transformed time.

The Destructive Degradation Report

The Destructive Degradation report contains an outline for each model that you fit. When you fit a model, the Model List is updated with a row for that model.

Note: All models are fit using the maximum likelihood method.
Model List

The first four columns in the Model List reflect the choices that you made in the plot options. The -Loglikelihood, AICc, and BIC statistics are information-based measures that can be used for model comparisons. For descriptions of these measures, see *Fitting Linear Models*.

The three information-based measures in the Model List are comparable across models as long as the models being compared have the same Number of Actual Observations. If this is not the case, exercise caution because different models might use different subsets. The Number of Actual Observations might be reduced due to the choice of distribution or the choice of transformation. Choosing a log-location-scale distribution excludes all non-positive Y values. Also, the Log and Sqrt transformations exclude all non-positive values.

Each row of the Model List table has a red triangle menu with the following options:

**Scroll To**  Scrolls the report window to the corresponding model outline.

**Remove**  Removes the model from the Model List and removes the corresponding model outline from the report.

Model Outlines

The outline for each model contains a red triangle menu with the following option:

**Remove**  Removes the model outline from the report and removes the model from the Model List.

The outline for each model contains the following reports:

**Formula Picture**  Shows the equation for the location parameter.

**Estimate**  Shows parameter estimates and their standard deviations. This report also contains 95% Wald-based confidence intervals for the parameters.

**Note:** If you specify a reference temperature \(X_0\), this value is also displayed at the top of the Estimate report.

**Distribution, Quantile, and Inverse Prediction**  For more information about the profilers, see “Profilers” on page 231.

**Residual Plots**  For more information about the residual plots, see “Residual Plots” on page 232.
Profilers

Three profilers appear in the model report.

Degradation Profiler

The Degradation Profiler shows a profiler view of the Degradation Data Analysis plot for the given model. The response is the degradation response Y. The profiler includes a plot against the Time variable and a plot against the optional explanatory variable X (if you have specified one). The plot against Time shows the median of the fitted distribution of Y as a solid curve. The dashed curves show the 0.025 and 0.975 percentiles of the fitted distribution of Y.
Crossing Time Distribution Profiler

Use the Crossing Time Distribution Profiler to determine the probability that the degradation measurement falls below a given threshold at some point in time.

The profiler plots the estimated cumulative distribution function of the response Y as a function of Time, the optional X variable, and Y. The plots for Time and Y show Wald confidence intervals.

Crossing Time Quantile Profiler

Use the Crossing Time Quantile Profiler to determine the time at which a specified proportion of measurements falls below a given threshold value.

The profiler plots the estimated Time as a function of the optional X variable, quantile values for Y (Probability), and Y. The plots for Probability and Y show Wald confidence intervals.

Residual Plots

Four residual plots appear in the model report. Use these plots to validate the distributional assumption for the model. For more information about the standardized residuals, see “Statistical Details for the Destructive Degradation Platform” on page 233.

Cox-Snell Residual P-P Plot

If the points deviate far from the diagonal, then the distributional assumption might be violated. The Cox-Snell Residual P-P Plot red triangle menu has an option called Save Residuals that enables you to save the residual data to the data table. See Meeker and Escobar (1998, sec. 17.6.1) for a discussion of Cox-Snell residuals.

Probability Plot of Standardized Residuals

If the points deviate far from the diagonal, then the distributional assumption might be violated. The Probability Plot of Standardized Residuals red triangle menu has an option called Save Residuals that enables you to save the residual data to the data table.

Standardized Residuals versus Time

Use the Standardized Residuals versus Time plot to examine differences in variability over time. The Standardized Residuals versus Time red triangle menu has an option called Save Residuals that enables you to save the residual data to the data table.
Standardized Residuals versus Predicted

Use the Standardized Residuals versus Predicted plot to examine differences in variability over the range of predicted values. The Standardized Residuals versus Predicted red triangle menu has an option called Save Residuals that enables you to save the residual data to the data table.

Destructive Degradation Platform Options

The Degradation Data Analysis red triangle menu contains the following options:

**Graph Options**  Provides options for modifying the platform graphs.

**Shade**  Turns the shading on or off. By default, the upper and lower bounds of each shaded band at a given value of time correspond to the 0.025 and 0.975 quantiles of the distribution of Y.

**Shade Coverage**  If shading is on, you can enter a proportion to increase or decrease the amount of shading coverage.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Statistical Details for the Destructive Degradation Platform

The destructive degradation model can be expressed as follows:

\[ g(Y) \sim F(\mu, \sigma) \]
\[ \mu = h(f(Time), X) \]

where:

- \( g(Y) \) is the transformed \( Y \) variable
- \( F \) is the selected probability distribution
- \( \mu \) is the location parameter, defined by \( h \)
- \( h \) is a function that relates the transformed \( Time \) variable and the explanatory variable \( X \)
- \( \sigma \) is the scale parameter of the distribution
- \( f(Time) \) is the transformed \( Time \) variable
- \( X \) is an optional explanatory variable

The standardized residuals are obtained as follows:

- For location-scale distributions, the standardized residuals are \((y-\mu)/\sigma.\)
- For log-location-scale distributions, the standardized residuals are \((\log(y)-\mu)/\sigma.\)
The Reliability Forecast platform helps you predict the number of future failures. JMP estimates the parameters for a life distribution using production dates, failure dates, and production volume.

Using the interactive graphs, you can adjust factors such as future production volumes and contract length to estimate future failures. Repair costs can be incorporated into the analysis to forecast the total cost of repairs across all failed units.

**Figure 9.1** Example of a Reliability Forecast

Additional Example Using the Reliability Forecast Platform .............................. 250
Overview of the Reliability Forecast Platform

The Reliability Forecast platform helps you predict the number of future failures. JMP estimates the parameters for a life distribution using production dates, failure dates, and production volume. Using the interactive graphs, you can adjust factors such as future production volumes and contract length to estimate future failures. Repair costs can be incorporated into the analysis to forecast the total cost of repairs across all failed units.

Example Using the Reliability Forecast Platform

You have data on seven months of production and returns. You want to use this information to forecast the total number of units that will be returned for repair through February 2011. The product has a 12-month contract.

1. Select Help > Sample Data Library and open Reliability/Small Production.jmp.
2. Select Analyze > Reliability and Survival > Reliability Forecast.
3. On the Nevada Format tab, select Sold Quantity and click Production Count.
4. Select Sold Month and click Timestamp.
5. Select the other columns and click Failure Count.
6. Click OK.
Figure 9.2  Observed Data Report

In the Observed Data report, the bottom left shows bar charts of previous failures. Cumulative failures are shown in the line graphs on the right. Note that production levels are fairly consistent. As production accumulates over time, more units are at risk of failure, so the cumulative failure rate gradually increases. The consistent production levels also result in similar cumulative failure rates and counts from month to month.

7. Click the Life Distribution disclosure icon.

JMP fits production and failure data with a Weibull distribution using the Life Distribution platform (Figure 9.3). JMP then uses the fitted Weibull distribution to forecast returns for the next five months (Figure 9.4).
Figure 9.3 Life Distribution Report

The Forecast report shows previous production in the left graph (Figure 9.4). In the right graph, you see that the number of previous failures increased steadily over time.

Figure 9.4 Forecast Report

8. In the Forecast report, type 12 for the Contract Length.
9. In the left Forecast graph, drag the animated hotspot over to July 2010 and upward to approximately 3500.
   Orange bars appear in the left graph to represent future production. The monthly returned failures in the right graph increase gradually through August 2010.
Figure 9.5  Production and Failure Estimates

10. In the left graph, drag the February 2010 hotspot to approximately 3000 and then drag the March 2010 hotspot to approximately 3300.

11. In the right graph, drag the right hotspot to February 2011.

   JMP estimates that the number of returns will gradually increase through August 2010 and decrease by February 2011.

Figure 9.6  Future Production Counts and Forecasted Failures
Launch the Reliability Forecast Platform

Launch the Reliability Forecast platform by selecting Analyze > Reliability and Survival > Reliability Forecast.

Figure 9.7  The Reliability Forecast Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The launch window includes a tab for each contract data format: Nevada, Dates, and Time to Event (for time to failure data). The following sections describe these formats.

Nevada Format

Contract data is commonly stored in the Nevada format: shipment or production dates and failure counts within specified periods are shaped like the state of Nevada. Figure 9.8 shows the Small Production.jmp sample data table.

Figure 9.8  Example of the Nevada Format
The Nevada Format tab contains the following options:

**Interval Censored Failure**  Considers the returned quantity to be interval censored. The interval is between the last recorded time and the time that the failure was observed. This option is selected by default.

**Life Time Unit**  Physical date-time format of all time stamps, including column titles for return counts. The platform uses this setting in forecasting step increments.

**Production Count**  Column that identifies the number of units produced.

**Timestamp**  Column that contains the production date.

**Failure Count**  Column that contains the number of failed units.

**Group ID**  Column by which observations are grouped. Each group has its own distribution fit and forecast. A combined forecast is also included.

**Dates Format**

The Dates format focuses on production and failure dates. One data table specifies the production counts for each time period. The other table provides failure dates, failure counts, and the corresponding production times of the failures.

Figure 9.9 shows the Small Production part1.jmp and Small Production part2.jmp sample data tables.

**Figure 9.9 Example of the Dates Format**

</table>

The Dates Format tab is divided into Production Data and Failure Data sections.

**Production Data**

**Select Table**  Select the table that contains the number of units and the production dates.
Failure Data

**Select Table**  Select the table that contains failure data, such as the number of failed units, production dates, and failure dates.

**Left Censor**  Column that identifies censored observations.

**Timestamp**  Column that links production observations to failure observations, indicating which batch a failed unit came from.

**Censor Code**  Value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.

Other options are identical to those on the Nevada Format tab. See “Nevada Format” on page 241.

**Time to Event Format**

The Time to Event format shows production and failure data. Unlike the Nevada and Dates formats, Time to Event data does not include date-time information, such as production or failure dates. This format can also accommodate arbitrary censoring schemes in the data. See “Defining Risk Sets with Time to Event Data” on page 247.

Figure 9.10 shows the Small Production Time to Event.jmp sample data table. For an example that uses time-to-event data, see “Additional Example Using the Reliability Forecast Platform” on page 250.

</tbody>
</table>
The Time to Event Format tab contains the following options:

**Forecast Start Time**  Time at which the forecast begins. Enter the first value that you want on the horizontal axis. To enable forecasting, you must select Numeric for the Life Time Unit and set the Forecast Start Time to zero.

**Censor Code**  Code for censored observations. Available only when you assign a Censor variable.

Other options are identical to those on the Nevada Format tab. See “Nevada Format” on page 241.

---

**The Reliability Forecast Report**

The Reliability Forecast report contains the Observed Data report, Life Distribution report, and Forecast report. Use these reports to view the current data, compare distributions to find the right fit, and then adjust factors that affect forecasting. You can also save the forecast to a data table for use in financial forecasts. See Figure 9.1 “Example of a Reliability Forecast” on page 235 for an example of the report.

The Reliability Forecast red triangle menu contains options for filtering the observed data by date and saving the data in another format. See “Reliability Forecast Platform Options” on page 249.

**Observed Data Report**

The Observed Data report gives you a quick view of Nevada and Dates data (Figure 9.11).

- Bar charts show the production and failure counts for the specified production periods.
- Line charts show the cumulative forecast by production period.

**Note:** Time-to-event data does not include date-time information, such as production or failure dates, so the platform does not create an Observed Data report for this format.

**Life Distribution Report**

The Life Distribution report lets you compare distributions and work with profilers to find the right fit. When you select a distribution in the Forecast report, the Life Distribution report is updated. For more information about this report, see the “Life Distribution” chapter on page 29. (Some of the options described in the Life Distribution chapter are not available in the Life Distribution report in the Reliability Forecast platform.)
**Forecast Report**

The Forecast report provides interactive graphs that help you forecast failures. By dragging hotspots, you can add anticipated production counts and see how they affect the forecast.

**Adjusting Risk Sets**

**Future Production**

In the left graph, the blue bars represent previous production counts. To add anticipated production, follow these steps:

1. Drag a hotspot to the right to add one or more production periods. The orange bars represent future production.

   ![Figure 9.11 Add Production Periods](image)

2. Drag each bar upward or downward to change the production count for each period.
Tip: To adjust future production counts, click the Forecast red triangle and select Spreadsheet Configuration of Risk Sets. See “Spreadsheet Configuration of Risk Sets” on page 248.

Existing Production

To remove a risk set from the forecast results, right-click a blue bar and select Exclude. To return that data to the risk set, right-click and select Include.

Tip: To adjust existing production counts, click the Forecast red triangle and select Spreadsheet Configuration of Risk Sets. See “Spreadsheet Configuration of Risk Sets” on page 248.

Forecasting Failures

When you adjust production in the left graph, the right graph is updated to estimate future failures (Figure 9.13). Dragging a hotspot lets you change the forecast period. The orange line then shortens or lengthens to show the estimated failure counts.
Defining Risk Sets with Time to Event Data

You can obtain forecasts for arbitrary risk sets using the Time to Event Format tab. In the launch window’s Time to Event Format tab, you must select Numeric for the Life Time Unit and set the Forecast Start Time to zero. Enter appropriate columns for Time to Event, Censor, Freq, and Group ID.

The plot on the left provides locations for bars representing existing production. Drag the hotspot at 0 to the left to create existing risk sets. Drag the hotspot at 1 to the right to create future production risk sets.

You can specify existing and future risk sets using the Spreadsheet Configuration of Risk Sets option. For time-to-event data, you must enter negative time values for the existing risk set in the Future Risk area. See “Spreadsheet Configuration of Risk Sets” on page 248.

For an example that uses time-to-event data, see “Additional Example Using the Reliability Forecast Platform” on page 250.

Forecast Graph Options

To explore your data further, you can change the contract length, distribution type, and other options.

- To forecast failures for a different contract period, enter the number next to Use Contract Length. Change the time unit if necessary.
- To change the distribution fit, select a distribution from the Choose Distribution list. The distribution is then fit to the future graph of future risk. The distribution fit appears in the Life Distribution report plot, and a new profiler is added. Changing the distribution fit in the Life Distribution report does not change the fit in the Forecast graph.
If you are more interested in the total number of failures over time, select **Cumulative Counts**. Otherwise, JMP shows failures incrementally, which can make trends easier to identify.

- To show 95% confidence limits for the anticipated number of failures, select **Show Interval**.

**Forecast Report Options**

The Forecast red triangle menu contains the following options:

- **Animation** Controls the flashing of the hotspots. You can also right-click a blue bar in the existing risk set and select or deselect **Animation**.

- **Interactive Configuration of Risk Sets** Determines whether you can drag hotspots in the graphs.

- **Spreadsheet Configuration of Risk Sets** Lets you specify production counts and periods (rather than adding them to the interactive graphs). You can also exclude production periods from the analysis.
  - To remove an existing time period from analysis, highlight the period in the Existing Risk area, click, and then select **Exclude**. Or select **Include** to return the period to the forecast.
  - To edit production, double-click in the appropriate Future Risk field and enter the new values.
  - To add a production period to the forecast, right-click in the Future Risk area and select one of the **Append** options. (**Append Rows** adds one row; **Append N Rows** lets you specify the number of rows.)

As you change these values, the graphs update accordingly.

**Note:** If you launched the platform using the Time to Event Format tab, values for the existing risk set must be entered in the Future Risk area using negative time values.

**Import Future Risk Set** Lets you import future production data from another open data table. The new predictions then appear in the future risk graph. The imported data must have a column for timestamps and for quantities.

**Show Interval** Shows or hides 95% confidence limits in the graph. This option works the same as selecting **Show Interval** next to the graphs.

After you select **Show Interval**, the **Forecast Interval Type** option appears in the menu. Select one of the following interval types:

- **Plugin Interval** Considers only forecasting errors given a fixed distribution.
**Prediction Interval**  
Considers forecasting errors when a distribution is estimated with estimation errors (for example, with a non-fixed distribution).

If you select Prediction Interval, the **Prediction Interval Settings** option appears in the menu. Approximate intervals are initially shown in the graph. Select **Monte Carlo Sample Size** or **Random Seed** to specify those values instead. To use the system clock, enter a missing number.

**Use Contract Length**  
Determines whether the specified contract length is considered in the forecast. This option works the same as selecting **Use Contract Length** next to the graphs.

**Use Failure Cost**  
Shows failure cost instead of the failure count in the future risk graph.

After you select **Use Failure Cost**, the **Set Failure Cost** option appears in the menu. This option enables you to set a cost for each failure. If you specified a Group variable in the launch window, the Set Failure Cost window enables you to specify separate costs for failures in each group.

**Save Forecast Data Table**  
Saves the cumulative and incremental number of returns in a new data table, along with the variables that you selected in the launch window. For grouped analyses, table names include the group ID and the word “Aggregated”. Existing returns are also included in the aggregated data tables.

---

**Reliability Forecast Platform Options**

The Reliability Forecast red triangle menu contains the following options:

**Save Data in Time to Event Format**  
Saves Nevada or Dates data in a Time to Event formatted table.

**Show Legend**  
Shows or hides a legend for the Observed Data report. Unavailable for Time to Event data.

**Show Graph Filter**  
Shows or hides the Graph Filter so that you can select which production periods to show in the Observed Data graphs. Bars fade for deselected periods. Deselect the periods to show the graph in its original state. Unavailable for Time to Event data.

See *Using JMP* for more information about the following options:

**Redo**  
Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  
Contains options that enable you to save a script that reproduces the report to several destinations.
Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

**Additional Example Using the Reliability Forecast Platform**

You have seven months of production and returns data that are stored in time-to-event format. You want to use this information to forecast the total number of units that will be returned for repair in the next 6 months. The product has a 4-month contract.

1. Select Help > Sample Data Library and open Reliability/Small Production Time to Event.jmp.
2. Select Analyze > Reliability and Survival > Reliability Forecast.
3. On the Time to Event Format tab, select Time (Month ) and Time Right. Click Time to Event.
4. Select Freq and click Freq.
5. Click OK.
6. In the Forecast report, type 4 for the Contract Length.
7. (Optional.) Click the Life Distribution disclosure icon.
   The Life Distribution report shows a Weibull fit for the production and failure data. The Reliability Forecast platform then uses the fitted Weibull distribution to forecast returns.

**Specify the Current and Future Production Counts**

8. Set the vertical axis settings to prepare for past and future production counts. Right-click the vertical axis in the left Forecast graph and select Axis Settings. Specify the following axis settings:
   1. Type -250 for the Minimum.
   2. Type 4250 for the Maximum.
   3. Type 500 for the Increment.
   4. Click OK.
9. Set the horizontal axis to cover the previous 8 and next 8 months. Right-click the horizontal axis in the left Forecast graph and select Axis Settings. Specify the following axis settings:
   1. Type -8 for the Minimum.
   2. Type 8 for the Maximum.
   3. Click OK.
10. Set the past 7 months of production counts. In the left Forecast graph, drag the leftmost animated hotspot left to -7.

11. Set the future 5 months of production estimates. In the left Forecast graph, drag the rightmost animated hotspot right to 5.

Figure 9.14  Risk Set after Dragging Animated Hotspots

12. In the Forecast red triangle menu, select Spreadsheet Configuration of Risk Sets.

13. Drag the bottom of the Future Risk panel down so that you can see all 13 rows of the Future Risk table.

Note: When using time-to-event formatted data, the existing production quantities must be specified in the Future Risk table using negative numeric time values.

14. Type in the Count values that are shown in Figure 9.15.

Figure 9.15  Future Risk Count Specifications
15. In the Forecasting Type panel, select **Cumulative Counts**.

16. In the Interval panel, select **Show Interval**.

17. Right-click the horizontal axis in the right Forecast graph and select **Axis Settings**. Add a reference line at month 6 using the following steps:
   1. Type 6 for the Value.
   2. Click **Add**.
   3. Click **OK**.

The forecast for the total number of units that will be returned for repair in the next 6 months is approximately 600 with confidence interval about 550 to 650.

**Tip:** You can use the **Save Forecast Data Table** option in the Forecast red triangle menu to see exact values for the forecasts and intervals.

---

**Figure 9.16** Forecast Results
The Reliability Growth platform models the change in reliability of a single repairable system over time as improvements are incorporated into its design. A reliability growth testing program attempts to increase the system’s mean time between failures (MTBF) by integrating design improvements as failures are discovered.

The Reliability Growth platform fits Crow-AMSAA models. These are non-homogeneous Poisson processes with Weibull intensity functions. Separate models can accommodate various phases of a reliability growth program. The platform also fits models for multiple systems.

Overview of the Reliability Growth Platform

The Reliability Growth platform fits Crow-AMSAA models, described in MIL-HDBK-189 (1981). A Crow-AMSAA model is a non-homogeneous Poisson process (NHPP) model with Weibull intensity; it is also known as a power law process. Such a model allows the failure intensity to vary over time. The failure intensity is defined by the two parameters beta and lambda.

For single-prototype data, the platform fits four classes of models and performs automatic change-point detection. The following reports are available:

- Simple Crow-AMSAA model, where both parameters are estimated using maximum likelihood.
- Crow-AMSAA with Modified MLE, where the maximum likelihood estimate for beta is corrected for bias.
- Fixed Parameter Crow-AMSAA model, where the user is allowed to fix either or both parameters.
- Piecewise Weibull NHPP model, where the parameters are estimated for each test phase, taking failure history from previous phases into account.
- Reinitialized Weibull NHPP model, where both parameters are estimated for each test phase in a manner that ignores failure history from previous phases.
- Automatic estimation of a change-point and the associated piecewise Weibull NHPP model, for reliability growth situations where different failure intensities can define two distinct test phases.

For multiple-prototype data, the platform fits the following classes of models:

- Piecewise Weibull NHPP model, where each system in a multi-phase study follows the same piecewise Weibull NHPP model. The differences among the systems are assumed to be due to the randomness of individual realizations of the same model. This model contains one beta parameter for each phase and one lambda parameter.
- Piecewise Weibull NHPP with Different Intercepts model, where each system in a multi-phase study follows a separate piecewise Weibull NHPP model. This model contains one beta parameter for each phase and one lambda parameter for each system.
- Distinct Phase Weibull NHPP model, where each system in a multi-phase study follows the same Crow-AMSAA model in each phase. This model contains one beta parameter and one lambda parameter for each phase.
- Distinct Weibull NHPP model, where each system in a multi-phase study follows a separate Crow-AMSAA model in each phase. This model contains one beta parameter and one lambda parameter for each combination of system and phase in the study.
Distinct System Weibull NHPP model, where each system in the study follows a separate Crow-AMSAA model with different parameters.

Identical System Weibull NHPP model, where each system in the study follows a single Crow-AMSAA model. The differences among the systems are assumed to be due to the randomness of individual realizations of the same model.

Interactive profilers enable you to explore changes in MTBF, failure intensity, and cumulative failures over time. When you suspect a change in intensity over the testing period, you can use the change-point detection option to estimate a change-point and its corresponding model.

Example Using the Reliability Growth Platform

Suppose that you are testing a prototype for a new class of turbine engines. The testing program has been ongoing for over a year and has been through three phases.

The data are given in the TurbineEngineDesign1.jmp sample data table, found in the Reliability subfolder. For each failure that occurred, the number of days since test initiation was recorded in the column Day. The number of failures on a given day, or equivalently, the number of required fixes, was recorded in the column Fixes.

The first 100-day phase of the program was considered the initial testing phase. Failures were addressed with aggressive design changes, resulting in a substantially revised design. This was followed by another 100-day phase, during which failures in the revised design were addressed with design changes to subsystems. The third and final testing phase ran for 250 days. During this final phase, failures were addressed with local design changes.

Each phase of the testing was terminated based on the designated number of days, so that the phases are time terminated. Specifically, a given phase is time terminated at the start time of the next phase. However, the failure times are exact (not censored).

2. Select Analyze > Reliability and Survival > Reliability Growth.
3. On the Time to Event Format tab, select Day and click Time to Event.
4. Select Fixes and click Event Count.
5. Select Design Phase and click Phase.
6. Click OK.

The Reliability Growth report appears. The Cumulative Events plot shows the cumulative number of failures by day. Vertical dashed blue lines show the two transitions between the three phases.
7. Click the **Mean Time Between Failures** disclosure icon.

   This provides a plot with horizontal lines at the mean times between failures computed over intervals of a predetermined size. An option in the red triangle menu enables you to specify the interval size.

**Figure 10.3** Mean Time between Failures Plot

8. Click the **Duane Plot** disclosure icon.
This provides a plot that displays the Cumulative MTBF estimates on the vertical axis versus the time to event variable on the horizontal axis. If the data follow the Crow-AMSAA model, the points should fall along a line when plotted on log-log paper.

**Figure 10.4** Duane Plot

9. Click the Reliability Growth red triangle and select **Fit Model > Piecewise Weibull NHPP**. This fits Weibull NHPP models to the three phases of the testing program, treating these phases as multiple stages of a single reliability growth program (Figure 10.5). Options in the Piecewise Weibull NHPP red triangle menu provide various other plots and reports.

Launch the Reliability Growth Platform

Launch the Reliability Growth platform by selecting Analyze > Reliability and Survival > Reliability Growth. The launch window, using data from TurbineEngineDesign1.jmp, is shown in Figure 10.6.

Figure 10.6 Reliability Growth Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The launch window includes a tab for each of four data formats: Time to Event Format, Dates Format, Concurrent Systems, and Parallel Systems.

- The Dates Format assumes that time is recorded in a date/time format, indicating an absolute date or time. On the Dates Format tab, the time column or columns are given the Timestamp role.

- The other three data formats assume that time is recorded as the number of time units; for example, days or hours, since initial start-up of the system. The test start time is assumed to be time zero. On the Time to Event Format tab, the time column or columns are given the Time to Event role.

Rows with missing data in the columns Time to Event, Timestamp, Event Count, Phase, or System ID are not included in the analysis.

Note: All data formats for the Reliability Growth platform require that times or time intervals be specified in non-decreasing order.
Launch Window Roles

The roles that are available for variables in the Reliability Growth launch window are determined by the specified data format tab. The roles are explained in this section.

Time to Event

Time to Event is the number of time units that elapse between the start of the test and the occurrence of an event (a failure or test termination). The test start time is assumed to be time zero. Note that the Time to Event role is available only on the Time to Event Format tab.

Two conventions are allowed (See “Exact Failure Times versus Interval Censoring” on page 262.):

- A single column can be entered. In this case, it is assumed that the column gives the exact elapsed times at which events occurred.
- Two columns can be entered, giving interval start and end times. If an interval’s start and end times differ, it is assumed that the corresponding events given in the Event Count column occurred at some unknown time within that interval. We say that the data are interval-censored. If the interval start and end times are identical, it is assumed that the corresponding events occurred at that specific time point, so that the times are exact (not censored).

The platform requires that the time columns be sorted in non-decreasing order. When two columns giving interval start and end times are provided, these intervals must not overlap (except at their endpoints). Intervals with zero event counts that fall strictly within a phase can be omitted, as they do not affect the likelihood function.

Timestamp

Timestamp is an absolute time (for example, a date). As with Time to Event, Timestamp allows times to be entered using either a single column or two columns. Note that the Timestamp role is available only on the Dates Format tab.

For times entered as Timestamp, the first row of the table is considered to give the test start time:

- When a single column is entered, the timestamp corresponding to the test start, with an event count of 0, should appear in the first row.
- When two columns, giving time intervals, are entered, the first entry in the first column should be the test start timestamp. (See “Phase” on page 262.)

Other details are analogous to those described for Time to Event Format in the section “Time to Event” on page 261. See also “Exact Failure Times versus Interval Censoring” on page 262.
**Event Count**

Event Count is the number of events, usually failures addressed by corrective actions (fixes), occurring at the specified time or within the specified time interval. If no column is entered as Event Count, it is assumed that the Event Count for each row is one.

**System ID**

System ID identifies the prototype for an observation for multiple-prototype data. The System ID role is available only in the Concurrent Systems and Parallel Systems data formats. It is a required role for both data formats.

**Phase**

Reliability growth programs often involve several periods, or phases, of active testing. These testing phases can be specified in the optional Phase column. For the Time to Event Format and Dates Format data formats, the Phase variable can be of any data or modeling type. For the Parallel Systems data format, the data type of the Phase variable must be Numeric. For more information about structuring multi-phase data, see “Test Phases” on page 263. For an example, see “Piecewise NHPP Weibull Model Fitting with Interval-Censored Data” on page 286.

**By**

This produces a separate analysis for each value that appears in the column.

**Data Table Structure**

The Time to Event Format and the Dates Format enable you to enter either a single column or two columns as Time to Event or Timestamp, respectively. The Concurrent Systems and the Parallel Systems enable you to enter one column corresponding to each level of the System ID variable. There are examples of multiple-prototype data tables in the Reliability folder of the Sample Data folder: Concurrent Systems.jmp for Concurrent Systems and four tables with the prefix Parallel Systems for Parallel Systems.

This section describes how to use these two approaches to specify the testing structure.

**Exact Failure Times versus Interval Censoring**

In some testing situations, the system being tested is checked periodically for failures. In this case, failures are known to have occurred within time intervals, but the precise time of a failure is not known. We say that the failure times are *interval-censored*. 
The Reliability Growth platform accommodates both exact, non-censored failure-time data, and interval-censored data. When a single column is entered as Time to Event or Timestamp, the times are considered exact times (not censored).

When two columns are entered, the platform views these as defining the start and end points of time intervals. If an interval’s start and end times differ, then the times for failures occurring within that interval are considered to be interval-censored. If the end points are identical, then the times for the corresponding failures are assumed to be exact and equal to that common time value. So, you can represent both exact and interval-censored failure times by using two time columns.

In particular, exact failures times can be represented in one of two ways: As times given by a single time column, or as intervals with identical endpoints, given by two time columns.

Model-fitting in the Reliability Growth platform relies on the likelihood function. The likelihood function takes into account whether interval-censoring is present or not. So, mixing interval-censored with exact failure times is permitted.

### Failure and Time Termination

A test plan can call for test termination once a specific number of failures has been achieved or once a certain span of time has elapsed. For example, a test plan might terminate testing after 50 failures occur. Another plan might terminate testing after a six-month period.

If testing terminates based on a specified number of failures, we say that the test is failure terminated. If testing is terminated based on a specified time interval, we say that the test is time terminated. The likelihood functions used in the Reliability Growth platform reflect whether the test phases are failure or time terminated.

### Test Phases

Reliability growth testing often involves several phases of testing. For example, the system being developed or the testing program might experience substantial changes at specific time points. The data table conveys the start time for each phase and whether each phase is failure or time terminated, as described below.

#### Single Test Phase

When there is a single test phase, the platform infers whether the test is failure or time terminated from the time and event count entries in the last row of the data table.

- If the last row contains an exact failure time with a nonzero event count, the test is considered failure terminated.
- If the last row contains an exact failure time with a zero event count, the test is considered time terminated.
• If the last row contains an interval with nonzero width, the test is considered time terminated with termination time equal to the right endpoint of that interval.

**Note:** To indicate that a test has been time terminated, be sure to include a last row in your data table showing the test termination time. If you are entering a single column as Time to Event or Timestamp, the last row should show a zero event count. If you are entering two columns as Time to Event or Timestamp, the right endpoint of the last interval should be the test-termination time. In this case, if there were no failures during the last interval, you should enter a zero event count.

**Multiple Test Phases**

When using Time to Event Format, the start time for any phase other than the first should be included in the time column(s). When using Dates Format, the start times for all phases should be included in the time column(s). If no events occurred at a phase start time, the corresponding entry in the Event Count column should be zero. For times given in two columns, it might be necessary to reflect the phase start time using an interval with identical endpoints and an event count of zero.

In a multi-phase testing situation, the platform infers whether each phase, other than the last, is failure or time terminated from the entries in the last row preceding a phase change. Suppose that Phase A ends and that Phase B begins at time $t_B$. In this case, the first row corresponding to Phase B contains an entry for time $t_B$.

• If the failure time for the last failure in Phase A is exact and if that time differs from $t_B$, then Phase A is considered to be time terminated. The termination time is equal to $t_B$.
• If the failure time for the last failure in Phase A is exact and is equal to $t_B$, then Phase A is considered to be failure terminated.
• If the last failure in Phase A is interval-censored, then Phase A is considered to be time terminated with termination time equal to $t_B$.

The platform infers whether the final phase is failure or time terminated from the entry in the last row of the data table.

• If the last row contains an exact failure time with a nonzero event count, the test is considered failure terminated.
• If the last row contains an exact failure time with a zero event count, or an interval with nonzero width, the test is considered time terminated. In the case of an interval, the termination time is taken as the right endpoint.
The Reliability Growth Report

The Observed Data report appears by default. If the Parallel Systems data format is specified in the launch window, the Model Descriptions and Feasibilities report also appears by default.

Model Descriptions and Feasibilities

The Model Description and Feasibilities report lists the name and descriptions of the parallel systems models. It also contains a column that shows if a model is available for the current data. If a model is listed as not available, the reason is reported in the right-most column of this table.

Observed Data Report

The Observed Data report contains the Cumulative Events plot, the Mean Time Between Failures plot, and the Duane plot. These are shown in Figure 10.7, where we have opened the Mean Time Between Failures and Duane Plot reports. To produce this report, follow the instructions in “Example Using the Reliability Growth Platform” on page 256.
Figure 10.7 Observed Data Report
**Cumulative Events Plot**

This plot shows how events are accumulating over time. The vertical coordinate for each point on the Cumulative Events plot equals the total number of events that have occurred by the time given by the point’s horizontal coordinate.

Whenever a model is fit, that model is represented on the Cumulative Events plot. Specifically, the cumulative events estimated by the model are shown by a curve, and 95% confidence intervals are shown by a solid band. Check boxes to the right of the plot enable you to control which models are displayed.

For the Parallel Systems data format, the Cumulative Events plot has a separate panel in the plot for each level of the System ID variable. It also contains a panel at the bottom of the plot that overlays the cumulative events for all levels of the System ID variable. The levels of the System ID variable are designated by colors.

**Mean Time Between Failures Plot**

The Mean Time Between Failures plot shows mean times between failures averaged over small time intervals of equal length. These are not tied to the Phases. The default number of equal length intervals is based on the number of rows.

**Mean Time Between Failures Plot Options**

Click the Mean Time Between Failures red triangle and select Options to open a window that enables you to specify intervals over which to average.

Two types of averaging are offered:

- Equal Interval Average MTBF (Mean Time Between Failures) enables you to specify a common interval size.
- Customized Average MTBF enables you to specify cut-off points for time intervals.
  - Double-click within a table cell to change its value.
  - Right-click in the table to open a menu that enables you to add and remove rows.

**Duane Plot**

The Duane Plot displays Cumulative MTBF estimates plotted against the Time to Event variable, with both axes on a log10 scale. If the data follow the Crow-AMSAA model, the points should follow a line when plotted on log-log paper.

**Note:** The Duane Plot is available only if failure times are exact and Time to Event Format is used. The plot is not available for interval-censored data or data entered in Dates Format.
The line displayed on the plot is the least squares regression line for the regression of log10 of Cumulative MTBF on log10 of the Time to Event variable.

**Note:** The Duane Plot does not reflect Phase variables. Rows where the Time to Event variable defines Phase changes are ignored in constructing the plot and fitting the regression line.

**Intercept and Slope**

Intercept and Slope values are displayed to the right of the plot.

- The Intercept value is given, for historical reasons, as the intercept for a fit in the natural logarithmic scale. Specifically, the natural logarithm of Cumulative MTBF is regressed on the natural logarithm of Time to Event. The value of Intercept is the value predicted by this regression equation at log(1) = 0, where \( \log \) is the natural logarithm. To obtain the intercept for a fit in terms of base 10 logarithms, divide the Intercept value by log(10). See Tobias and Trindade (2012, ch. 13).

- The Slope value is the slope for a fit in either the natural or the logarithmic scale. This follows from the properties of logarithms.

**Reliability Growth Platform Options**

The Reliability Growth red triangle menu has the following options:

**Fit Model** If the Time to Event Format, Dates Format, or Concurrent Systems data formats are specified in the launch window, this menu contains options to fit various Non-Homogeneous Poisson Process (NHPP) models. These options are described in detail below. Depending on the choices made in the launch window, the possible options are:

- “Crow AMSAA” on page 270
- “Crow AMSAA with Modified MLE” on page 276
- “Fixed Parameter Crow AMSAA” on page 277
- “Piecewise Weibull NHPP” on page 278
- “Reinitialized Weibull NHPP” on page 282
- “Piecewise Weibull NHPP Change Point Detection” on page 285

**Fit Parallel System Model** If the Parallel Systems data format is specified in the launch window, this menu contains options to fit various models for multiple-prototype data. The possible options in this menu are dependent on choices made in the launch window.

See *Using JMP* for more information about the following options:
Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Model List

Once a model is fit, the Model List report appears. This report provides various statistical measures that describe the fit of the model. As additional models are fit, they are added to the Model List, which provides a convenient summary for model comparison. The models are sorted in ascending order based on AICc. The Model List report contains the following statistics:

Nparm  The number of parameters in the model.

-2Loglikelihood  The likelihood function is a measure of how probable the observed data are, given the estimated model parameters. In a general sense, the higher the likelihood, the better the model fit. It follows that smaller values of twice the negative of the log-likelihood (-2Loglikelihood) indicate better model fits.

AICc  The Corrected Akaike’s Information Criterion.

BIC  The Bayesian Information Criterion.

See Fitting Linear Models for more information about -2Loglikelihood, AICc, and BIC.

Model Reports

This section describes the reports generated when the available models are fit as well as the options available in those model reports.

- “Crow AMSAA”
- “Crow AMSAA with Modified MLE”
- “Fixed Parameter Crow AMSAA”
- “Piecewise Weibull NHPP”
- “Reinitialized Weibull NHPP”
- “Piecewise Weibull NHPP Change Point Detection”
Crow AMSAA

This option fits a Crow-AMSAA model (MIL-HDBK-189 1981). A Crow-AMSAA model is a nonhomogeneous Poisson process with failure intensity as a function of time \( t \) given by \( \rho(t) = \lambda \beta t^{\beta-1} \). Here, \( \lambda \) is a scale parameter and \( \beta \) is a growth parameter. This function is also called a Weibull intensity, and the process itself is also called a power law process (Rigdon and Basu 2000; Meeker and Escobar 1998). Note that the Recurrence platform fits the Power Nonhomogeneous Poisson Process. The Power Nonhomogeneous Poisson Process is equivalent to the Crow-AMSAA model, although it uses a different parameterization. See “Fit Model” on page 164 in the “Recurrence Analysis” chapter.

The intensity function is a concept applied to repairable systems. Its value at time \( t \) is the limiting value of the probability of a failure in a small interval around \( t \), divided by the length of this interval; the limit is taken as the interval length goes to zero. You can think of the intensity function as measuring the likelihood of the system failing at a given time. If \( \beta < 1 \), the system is improving over time. If \( \beta > 1 \), the system is deteriorating over time. If \( \beta = 1 \), the rate of occurrence of failures is constant.

When the Crow AMSAA option is selected, the Cumulative Events plot updates to show the cumulative events curve estimated by the model. For each time point, the shaded band around this curve defines a 95% confidence interval for the true cumulative number of events at that time. The Model List report also updates. Figure 10.8 shows the Observed Data report for the data in TurbineEngineDesign1.jmp.

Figure 10.8  Crow AMSAA Cumulative Events Plot and Model List Report
Crow-AMSAA Report

A Crow-AMSAA report opens within the Models report. If Time to Event Format is used, the Crow-AMSAA report shows an MTBF plot with both axes scaled logarithmically. See “MTBF Plot” on page 271.

MTBF Plot

The mean time between failures (MTBF) plot is displayed by default (Figure 10.9). For each time point, the shaded band around the MTBF plot defines a 95% confidence interval for the true MTBF at time \( t \). The plot is shown with both axes logarithmically scaled. With this scaling, the MTBF plot is linear.

Figure 10.9  MTBF Plot

To see why the MTBF plot is linear when logarithmic scaling is used, consider the following. The mean time between failures is the reciprocal of the intensity function. For the Weibull intensity function, the MTBF is \( 1/(\lambda t^\beta) \), where \( t \) represents the time since testing initiation. It follows that the logarithm of the MTBF is a linear function of \( \log(t) \), with slope \( 1 - \beta \). The estimated MTBF is defined by replacing the parameters \( \lambda \) and \( \beta \) by their estimates. So the log of the estimated MTBF is a linear function of \( \log(t) \).

Estimates

Maximum likelihood estimates for \( \lambda \), \( \beta \), and the Reliability Growth Slope \( (1 - \beta) \), appear in the Estimates report below the plot (Figure 10.9). Standard errors and 95% confidence intervals for \( \lambda \), \( \beta \), and \( 1 - \beta \) are given. For more information about the calculations, see “Parameter Estimates for Crow-AMSAA Models” on page 291.
Covariance Matrix

Estimated covariance matrix for the estimates of the parameters of the fitted model. This report is closed by default.

Crow-AMSAA Options

This section describes the options that are available in the Crow-AMSAA red triangle menu when a Crow AMSAA model is fit.

Show MTBF Plot

This option shows or hides the MTBF Plot. See “MTBF Plot” on page 271.

Show Intensity Plot

This plot shows the estimated intensity function. The Weibull intensity function is given by \( \rho(t) = \lambda \beta t^{\beta-1} \), so it follows that \( \log(\text{Intensity}) \) is a linear function of \( \log(t) \). Both axes are scaled logarithmically.

Show Cumulative Events Plot

This plot shows the estimated cumulative number of events. The observed cumulative numbers of events are also displayed on this plot. Both axes are scaled logarithmically.
For the Crow-AMSAA model, the cumulative number of events at time $t$ is given by $\lambda t^\beta$. It follows that the logarithm of the cumulative number of events is a linear function of $\log(t)$. So, the plot of the estimated Cumulative Events is linear when plotted against logarithmically scaled axes.

**Show Profilers**

Three profilers are displayed, showing estimated MTBF, Failure Intensity, and Cumulative Events. These profilers do not use logarithmic scaling. By dragging the red vertical dashed line in any profiler, you can explore model estimates at various time points; the value of the selected time point is shown in red beneath the plot. Also, you can set the time axis to a specific value by pressing Ctrl while you click in the plot. A blue vertical dashed line denotes the time point of the last observed failure.

The profilers also display 95% confidence bands for the estimated quantities. For the specified time setting, the estimated quantity (in red) and 95% confidence limits (in black) are shown to the left of the profiler. See “Profilers” on page 292.

Note that you can link these profilers by selecting **Factor Settings > Link Profilers** from any of the profiler red triangle menus. For more information about the use and interpretation of profilers, see *Fitting Linear Models*. See also *Profilers*. 
Achieved MTBF

A confidence interval for the MTBF at the point when testing concludes is often of interest. For uncensored failure time data, this report gives an estimate of the Achieved MTBF and a 95% confidence interval for the Achieved MTBF. You can specify a 100*(1-\(\alpha\))% confidence interval by entering a value for Alpha. The report is shown in Figure 10.13. For censored data, only the estimated MTBF at test termination is reported.

Figure 10.13  Achieved MTBF Report

There are infinitely many possible failure-time sequences from an NHPP; the observed data represent only one of these. Suppose that the test is failure terminated at the \(n^{th}\) failure. The confidence interval computed in the Achieved MTBF report takes into account the fact that the \(n\) failure times are random. If the test is time terminated, then the number of failures as well as their failure times are random. Because of this, the confidence interval for the Achieved MTBF differs from the confidence interval provided by the MTBF Profiler at the last observed failure time. See Crow (1982) and Lee and Lee (1978).

When the test is failure terminated, the confidence interval for the Achieved MTBF is exact. However, when the test is time terminated, an exact interval cannot be obtained. In this case, the limits are conservative in the sense that the interval contains the Achieved MTBF with probability at least 1-\(\alpha\).
Goodness of Fit

The Goodness of Fit report tests the null hypothesis that the data follow a Crow-AMSAA model. Depending on whether one or two time columns are entered, either a Cramér-von Mises (see “Cramér-von Mises Test for Data with Uncensored Failure Times” on page 275) or a chi-squared test (see “Chi-Squared Goodness of Fit Test for Interval-Censored Failure Times” on page 275) is performed.

Cramér-von Mises Test for Data with Uncensored Failure Times

When the data are entered in the launch window as a single Time to Event or Timestamp column, the goodness of fit test is a Cramér-von Mises test. For the Cramér-von Mises test, large values of the test statistic lead to rejection of the null hypothesis and the conclusion that the model does not fit adequately. The test uses an unbiased estimate of beta, given in the report. The value of the test statistic is found below the Cramér-von Mises heading.

The entry below the p-Value heading indicates how unlikely it is for the test statistic to be as large as what is observed if the data come from a Crow-AMSAA model. The platform computes p-values up to 0.25. If the test statistic is smaller than the value that corresponds to a p-value of 0.25, the report indicates that its p-value is >=0.25. For more information about this test, see Crow (1975).

Figure 10.14 shows the goodness-of-fit test for the fit of a Crow-AMSAA model to the data in TurbineEngineDesign1.jmp. The computed test statistic corresponds to a p-value that is less than 0.01. We conclude that the Crow-AMSAA model does not provide an adequate fit to the data.

Chi-Squared Goodness of Fit Test for Interval-Censored Failure Times

When the data are entered in the launch window as two Time to Event or Timestamp columns, a chi-squared goodness of fit test is performed. The chi-squared test is based on comparing observed to expected numbers of failures in the time intervals defined. Large values of the test statistic lead to rejection of the null hypothesis and the conclusion that the model does not fit.
In the Reliability Growth platform, the chi-squared goodness of fit test is intended for interval-censored data where the time intervals specified in the data table cover the entire time period of the test. This means that the start time of an interval is the end time of the preceding interval. In particular, intervals where no failures occurred should be included in the data table. If some intervals are not consecutive, or if some intervals have identical start and end times, the algorithm makes appropriate accommodations. But the resulting test is only approximately correct.

**Crow AMSAA with Modified MLE**

In the Crow-AMSAA model, the maximum likelihood estimate (MLE) of $\beta$ is biased. This option fits a Crow AMSAA model where $\beta$ is adjusted for bias.

**Note:** This option is available only when the data are entered in the launch window as a single Time to Event or Timestamp column. It is not available for interval-censored data.

Figure 10.15 shows a Crow-AMSAA with Modified MLE fit to the data in TurbineEngineDesign1.jmp.

**Figure 10.15  Crow-AMSAA with Modified MLE Report**

The formula for the bias-corrected estimate of $\beta$ depends on whether the test is failure terminated or time terminated. See “Parameter Estimates for Crow-AMSAA with Modified MLE” on page 291.
When the Crow-AMSAA with Modified MLE option is selected, the Cumulative Events Plot updates to display this model. The Model List also updates. The Crow-AMSAA with Modified MLE report opens to show the MTBF plot, Estimates, and Covariance Matrix for the Crow-AMSAA with Modified MLE fit; this plot is described in the section “MTBF Plot” on page 283.

In addition to Show MTBF plot, available options are Show Intensity Plot, Show Cumulative Events Plot, Show Profilers, Achieved MTBF, and Goodness of Fit. These reports are described under “Crow AMSAA” on page 270. For more information about how the modified MLEs are used to construct these reports, see “Parameter Estimates for Crow-AMSAA with Modified MLE” on page 291. Details about the Goodness of Fit and Achieved MTBF reports specific to the modified MLE option are given below.

**Goodness of Fit**

Because the Crow-AMSAA with Modified MLE option is available only when the data are entered as a single Time to Event or Timestamp column, the Goodness of Fit test is a Cramér-von Mises test. Because the estimate of $\beta$ is used in this test is bias-corrected, the test results are identical to those of the Goodness of Fit test for the Crow-AMSAA model.

**Achieved MTBF**

The achieved MTBF is estimated using the modified MLEs. However, the confidence interval for the achieved MTBF uses the true MLE and is identical to the interval given by the Crow AMSAA model.

**Fixed Parameter Crow AMSAA**

This option enables you to specify parameter values for a Crow-AMSAA fit. If a Crow-AMSAA report has not been obtained before choosing the Fixed Parameter Crow-AMSAA option, then both a Crow-AMSAA report and a Fixed Parameter Crow-AMSAA report are provided.

When the Fixed Parameter Crow-AMSAA option is selected, the Cumulative Events Plot updates to display this model. The Model List also updates. The Fixed Parameter Crow-AMSAA report opens to show the MTBF plot for the Crow-AMSAA fit; this plot is described in the section “MTBF Plot” on page 283.

In addition to Show MTBF plot, available options are Show Intensity Plot, Show Cumulative Events Plot, and Show Profilers. The construction and interpretation of these plots is described under “Crow AMSAA” on page 270.
Estimates

The initial parameter estimates are the MLEs from the Crow-AMSAA fit. Either parameter can be fixed by checking the box next to the desired parameter and then entering the desired value. The model is re-estimated and the MTBF plot updates to describe this model. Figure 10.16 shows a fixed-parameter Crow-AMSAA fit to the data in TurbineEngineDesign1.jmp, with the value of beta set at 0.4.

Figure 10.16 Fixed Parameter Crow-AMSAA Report

Piecewise Weibull NHPP

The Piecewise Weibull NHPP model can be fit when a Phase column specifying at least two values has been entered in the launch window. Crow-AMSAA models are fit to each of the phases under the constraint that the cumulative number of events at the start of a phase matches that number at the end of the preceding phase. For proper display of phase transition times, the first row for every Phase other than the first must give that phase’s start time. See “Multiple Test Phases” on page 264.

When the report is run, the Cumulative Events plot updates to show the piecewise model. Blue vertical dashed lines show the transition times for each of the phases. The Model List also updates. See Figure 10.17, where both a Crow-AMSAA model and a piecewise Weibull NHPP model have been fit to the data in TurbineEngineDesign1.jmp. Note that both models are compared in the Model List report.
Figure 10.17 Cumulative Events Plot and Model List Report

**Piecewise Weibull NHPP Report**

By default, the Piecewise Weibull NHPP report shows the estimated MTBF plot. The phases are differentiated with different colors. The Estimates and Covariance Matrix reports are shown below the plot.
Figure 10.18  Piecewise Weibull NHPP Report

MTBF Plot

The MTBF plot and the Estimates report appear by default when the Piecewise Weibull NHPP option is chosen (Figure 10.18). When Time to Event Format is used, the axes are logarithmically scaled. For more information about the plot, see “MTBF Plot” on page 271.

Estimates

The Estimates report gives estimates of the model parameters. Note that only the estimate for the value of $\lambda$ corresponding to the first phase is given. In the piecewise model, the cumulative events at the end of one phase must match the number at the beginning of the subsequent phase. Because of these constraints, the estimate of $\lambda$ for the first phase and the estimates of the $\beta$s determine the remaining $\lambda$s.

The method used to calculate the estimates, their standard errors, and the confidence limits is similar to that used for the simple Crow-AMSAA model. See “Parameter Estimates for Crow-AMSAA Models” on page 291. The likelihood function reflects the additional parameters and the constraints on the cumulative numbers of events.

Covariance Matrix

Estimated covariance matrix for the estimates of the parameters of the fitted model. This report is closed by default.
Piecewise Weibull NHPP Options

This section describes the options available in the Piecewise Weibull NHPP red triangle menu.

Show MTBF Plot

This option shows or hides the MTBF plot. See “MTBF Plot” on page 271.

Show Intensity Plot

The Intensity plot shows the estimated intensity function and confidence bounds over the design phases. The intensity function is generally discontinuous at a phase transition. Color coding facilitates differentiation of phases. If Time to Event Format is used, the axes are logarithmically scaled. See “Show Intensity Plot” on page 272.

Show Cumulative Events Plot

The Cumulative Events plot shows the estimated cumulative number of events, along with confidence bounds, over the design phases. The model requires that the cumulative events at the end of one phase match the number at the beginning of the subsequent phase. Color coding facilitates differentiation of phases. If Time to Event Format is used, the axes are logarithmically scaled. See “Show Cumulative Events Plot” on page 272.

Show Profilers

Three profilers are displayed, showing estimated MTBF, Failure Intensity, and Cumulative Events. These profilers do not use logarithmic scaling. For more information about interpreting and using these profilers, see the section “Show Profilers” on page 273.

It is important to note that, due to the default resolution of the profiler plot, discontinuities are not displayed clearly in the MTBF or Failure Intensity Profilers. In the neighborhood of a phase transition, the profiler trace shows a nearly vertical, but slightly sloped, line; this line represents a discontinuity (Figure 10.19). Such a line at a phase transition should not be used for estimation. Obtain a higher-resolution display to make these lines appear more vertical:

1. Press Ctrl while clicking in the profiler plot.
2. Enter a larger value for Number of Plotted Points in the window. (See Figure 10.20, where we have specified 500 as the Number of Plotted Points.)
**Figure 10.19** Profilers

![Profilers Figure](image)

**Figure 10.20** Factor Settings Window

![Factor Settings Window](image)

### Reinitialized Weibull NHPP

This option fits an independent growth model to the data from each test phase. Fitting models in this fashion can be useful when the factors influencing the growth rate, either in terms of testing or engineering, have changed substantially between phases. In such a situation, you might want to compare the test phases independently. The Reinitialized Weibull NHPP option is available when a Phase column specifying at least two phases has been entered in the launch window.

For the algorithm to fit this model, each row that contains the first occurrence of a new phase must contain the start date.

- Suppose that a single column is entered as Time to Event or Timestamp. Then the start time for a new phase, with a zero Event Count, must appear in the first row for that phase. See the sample data table `ProductionEquipment.jmp`, in the Reliability subfolder, for an example.
- If two columns are entered, then an interval whose left endpoint is that start time must appear in the first row, with the appropriate event count. The sample data table
TurbineEngineDesign2.jmp, found in the Reliability subfolder, provides an example. Also, see “Piecewise NHPP Weibull Model Fitting with Interval-Censored Data” on page 286. See “Multiple Test Phases” on page 264.

Independent Crow-AMSAA models are fit to the data from each of the phases. When the report is run, the Cumulative Events plot updates to show the reinitialized models. Blue vertical dashed lines show the transition points for each of the phases. The Model List also updates.

**Reinitialized Weibull NHPP Report**

By default, the Reinitialized Weibull NHPP report shows the estimated MTBF plot. The phases are differentiated with different colors. The Estimates and Covariance Matrix reports are shown below the plot. (See Figure 10.21, which uses the ProductionEquipment.jmp sample data file from the Reliability subfolder.)

**Figure 10.21** Reinitialized Weibull NHPP Report

**MTBF Plot**

The MTBF plot opens by default when the Reinitialized Weibull NHPP option is chosen. For more information about the plot, see “MTBF Plot” on page 271.
Estimates

The Estimates report gives estimates of \( \lambda \) and \( \beta \) for each of the phases. For a given phase, \( \lambda \) and \( \beta \) are estimated using only the data from that phase. The calculations assume that the phase begins at time 0 and reflect whether the phase is failure or time terminated, as defined by the data table structure. (See “Test Phases” on page 263.) Also shown are standard errors and 95% confidence limits. These values are computed as described in “Parameter Estimates for Crow-AMSAA Models” on page 291.

Covariance Matrix

Estimated covariance matrix for the estimates of the parameters of the fitted model. This report is closed by default.

Reinitialized Weibull NHPP Options

This section describes the options available in the Reinitialized Weibull NHPP red triangle menu.

Show MTBF Plot

This option shows or hides the MTBF plot. See “MTBF Plot” on page 271.

Show Intensity Plot

The Intensity plot shows the estimated intensity functions for the phases, along with confidence bands. Because the intensity functions are computed based only on the data within a phase, they are discontinuous at phase transitions. Color coding facilitates differentiation of phases. See “Show Intensity Plot” on page 272.

Show Cumulative Events Plot

The Cumulative Events plot for the Reinitialized Weibull NHPP model portrays the estimated cumulative number of events, with confidence bounds, over the design phases in the following way. Let \( t \) represent the time since the first phase of testing began. The model for the phase that is in effect at time \( t \) is evaluated at time \( t \). In particular, the model for the phase that is in effect is not evaluated at the time since the beginning of the specific phase; rather it is evaluated at the time since the beginning of the first phase of testing.

At phase transitions, the cumulative events functions are discontinuous. The Cumulative Events plot matches the estimated cumulative number of events at the beginning of one phase to the cumulative number at the end of the previous phase. This matching allows the user to compare the observed cumulative events to the estimated cumulative events functions. Color coding facilitates differentiation of phases.
Show Profilers

Three profilers are displayed, showing estimated MTBF, Failure Intensity, and Cumulative Events. Note that the Cumulative Events Profiler is constructed as described in the Cumulative Events Plot section. In particular, the cumulative number of events at the beginning of one phase is matched to the number at the end of the previous phase. See “Show Profilers” on page 281.

Piecewise Weibull NHPP Change Point Detection

The Piecewise Weibull NHPP Change Point Detection option attempts to find a time point where the reliability model changes. This might be useful if you suspect that a change in reliability growth has occurred over the testing period. Note that detection seeks only a single change point, corresponding to two potential phases.

This option is available only when a Phase has not been entered in the launch window and one of the following is true:

- a single column has been entered as Time to Event or Timestamp in the launch window (indicating that failure times are exact), and
- two columns have been entered as Time to Event in the Concurrent Systems panel of the launch window.

When the Piecewise Weibull NHPP Change Point Detection option is selected, the estimated model plot and confidence bands are added to the Cumulative Events report under Observed Data. The Model List updates, giving statistics that are conditioned on the estimated change point. Under Models, a Piecewise Weibull NHPP Change Point Detection report is provided.

The default Piecewise Weibull NHPP Change Point Detection report shows the MTBF plot, Estimates, and Covariance Matrix. (See Figure 10.22, which uses the data in BrakeReliability.jmp, found in the Reliability subfolder.) Note that the Change Point, shown at the bottom of the Estimates report, is estimated as 12/21/2011. The standard errors and confidence intervals consider the change point to be known. The plot and the Estimates report are described in the section “Piecewise Weibull NHPP” on page 278.
**Additional Examples of the Reliability Growth Platform**

- “Piecewise NHPP Weibull Model Fitting with Interval-Censored Data”
- “Piecewise Weibull NHPP Change Point Detection with Time in Dates Format”

**Piecewise NHPP Weibull Model Fitting with Interval-Censored Data**

The sample data file `TurbineEngineDesign2.jmp`, found in the Reliability subfolder, contains data on failures for a turbine engine design over three phases of a testing program. The first two columns give time intervals during which failures occurred. These intervals are recorded as days since the start of testing. The exact failure times are not known; it is known only that failures occurred within these intervals.
The reports of failures are provided generally at weekly intervals. Intervals during which there were no failures and which fell strictly within a phase are not included in the data table (for example, the interval 106 to 112 is not represented in the table). Because these make no contribution to the likelihood function, they are not needed for estimation of model parameters.

However, to fit a Piecewise Weibull NHPP or Reinitialized Weibull NHPP model, it is important that the start times for all phases be provided in the Time to Event or Timestamp columns.

Here, the three phases began at days 0 (Initial phase), 91 (Revised phase), and 200 (Final phase). There were failures during the weeks that began the Initial and Revised phases. However, no failures were reported between days 196 and 231. For this reason, an interval with beginning and ending days equal to 200 was included in the table (row 23), reflecting 0 failures. This is necessary so that JMP knows the start time of the Final phase.

The test was terminated at 385 days. This is an example of interval-censored failure times with time terminated phases.

**Note:** The phase start times are required for proper display of the transition times for the Piecewise Weibull NHPP model; they are required for estimation of the Reinitialized Weibull NHPP model. For interval-censored data, the algorithm defines the beginning time for a phase as the start date recorded in the row containing the first occurrence of that phase designation. In our example, if row 23 were not in the table, the beginning time of the Final phase would be taken as 231.

2. Select Analyze > Reliability and Survival > Reliability Growth.
3. On the Time to Event Format tab, select the columns Interval Start and Interval End, and click Time to Event.
4. Select Fixes and click Event Count.
5. Select Design Phase and click Phase.
6. Click OK.
7. Click the Reliability Growth red triangle and select Fit Model > Piecewise Weibull NHPP.

The Cumulative Events plot from the Observed Data report is shown in Figure 10.23. The vertical dashed blue lines indicate the phase transition points. The first occurrence of Revised in the column Design Phase is in row 14. So, the start of the Revised phase is taken to be the Interval Start value in row 14, namely, day 91. Similarly, the first occurrence of Final in the column Design Phase is in row 23. So, the start of the Final phase is taken to be the Interval Start value in row 23, namely, day 200.
The Piecewise Weibull NHPP report is found under the Models outline node. Here we see the mean time between failures increasing over the three phases. From the Estimates report, we see that the estimates of beta decrease over the three testing phases.

Figure 10.24 MTBF Plot
Piecewise Weibull NHPP Change Point Detection with Time in Dates Format

The file BrakeReliability.jmp, found in the Reliability subfolder, contains data on fixes to a braking system. The Date column gives the dates when Fixes, given in the second column, were implemented. For this data, the failure times are known. Note that the Date column must be in ascending order.

The test start time is the first entry in the Date column, 09/29/2011, and the corresponding value for Fixes is set at 0. This is needed in order to convey the start time for testing. If there had been a nonzero value for Fixes in this first row, the corresponding date would have been treated as the test start time. However, the value of Fixes would have been treated as 0 in the analysis.

The test termination time is given in the last row as 05/31/2012. Because the value in Fixes in the last row is 0, the test is considered to be time terminated on 5/31/2012. If there had been a nonzero value for Fixes in this last row, the test would have been considered failure terminated.

1. Select Help > Sample Data Library and open Reliability/BrakeReliability.jmp.
2. Select Analyze > Reliability and Survival > Reliability Growth.
3. Select the Dates Format tab.
4. Select Date and click Timestamp.
5. Select Fixes and click Event Count.
6. Click OK.
7. Click the Reliability Growth red triangle and select Fit Model > Crow AMSAA.

The Cumulative Events plot in the Observed Data report updates to show the model. The model does not seem to fit the data very well.
8. Click the Reliability Growth red triangle and select **Fit Model > Piecewise Weibull NHPP**
   **Change Point Detection**.

   The Cumulative Events plot in the Observed Data report updates to show the piecewise
   model fit using change-point detection. Both models are shown in Figure 10.26. Though
   the data are rather sparse, the piecewise model seems to provide a better fit to the data.

Statistical Details for the Reliability Growth Platform

- “Statistical Details for the Crow-AMSAA Report”
- “Statistical Details for the Piecewise Weibull NHPP Change Point Detection Report”

Statistical Details for the Crow-AMSAA Report

This section contains details for the parameter estimates and profilers that appear in the Crow-AMSAA Report.

Parameter Estimates for Crow-AMSAA Models

With the exception of the Crow-AMSAA with Modified MLE option, the estimates for $\lambda$ and $\beta$ are maximum likelihood estimates, which are computed as follows. The likelihood function is derived using the methodology in Meeker and Escobar (1998). It is reparametrized in terms of \( \text{param}_1 = \log(\lambda) \) and \( \text{param}_2 = \log(\beta) \). This is done to enable the use of an unconstrained optimization algorithm, namely, an algorithm that searches from $-\infty$ to $+\infty$. The MLEs for \( \text{param}_1 \) and \( \text{param}_2 \) are obtained.

The standard errors for $\lambda$ and $\beta$ are obtained from the Fisher information matrix. Confidence limits for \( \text{param}_1 \) and \( \text{param}_2 \) are calculated based on the asymptotic distribution of the MLEs, using the Wald statistic. These estimates and their confidence limits are then transformed back to the original units using the exponential function.

Parameter Estimates for Crow-AMSAA with Modified MLE

For the Crow AMSAA with Modified MLE option, the estimate for $\beta$ is corrected for bias. The formula for the bias-corrected estimate of $\beta$ depends on whether the test is failure terminated or time terminated.

Denote the MLE for $\beta$ by $\hat{\beta}$, let $n$ be the number of observations, and let $T$ be the total test time. The bias-corrected estimate (modified MLE) of $\beta$ is $\tilde{\beta}$, where:

$$
\tilde{\beta} = \left( \frac{n-2}{n} \right) \hat{\beta} \quad \text{for a failure-terminated test}
$$

$$
\tilde{\beta} = \left( \frac{n-1}{n} \right) \hat{\beta} \quad \text{for a time-terminated test}
$$
The modified MLE for $\lambda$, denoted $\bar{\lambda}$, is calculated according to the expression given by the likelihood function, but based on the adjusted value of beta:

$$\bar{\lambda} = \frac{n}{T^{\bar{\beta}}}$$

The covariance matrix for the parameters is estimated using the Fisher information matrix. (See “Parameter Estimates for Crow-AMSAA Models” on page 291.) However, the bias-corrected estimates for $\lambda$ and $\beta$ are substituted for the MLEs in the resulting formulas. All confidence bands in plots and confidence intervals in reports are based on this procedure.

**Profilers**

For the Crow-AMSAA models, the estimates for the MTBF, Intensity, and Cumulative Events given in the profilers are obtained by replacing the parameters $\lambda$ and $\beta$ in their theoretical expressions by their MLEs. In the case of the Crow-AMSAA with Modified MLE option, the modified MLEs are used. Confidence limits are obtained by applying the delta method to the log of the expression of interest.

For example, consider the cumulative events function. The cumulative number of events at time $t$ since testing initiation is given by $N(t) = \lambda t^{\bar{\beta}}$. It follows that $\log(N(t)) = \log(\lambda) + \beta \log(t)$. The parameters $\lambda$ and $\beta$ in $\log(N(t))$ are replaced by their MLEs (or modified MLEs) to estimate $\log(N(t))$. The delta method is applied to this expression to obtain an estimate of its variance. This estimate is used to construct a 95% Wald-based confidence interval. The resulting confidence limits are then transformed using the exponential function to give confidence limits for the estimated cumulative number of events at time $t$.

**Statistical Details for the Piecewise Weibull NHPP Change Point Detection Report**

The change point is estimated as follows:

- Using consecutive event times, disjoint intervals are defined.
- Each point within such an interval can be considered to be a change point defining a piecewise Weibull NHPP model with two phases. So long as the two phases defined by that point each consist of at least two events, the algorithm can compute MLEs for the parameters of that model. The log-likelihood for that model can also be computed.
- Within each of the disjoint intervals, a constrained optimization routine is used to find a local optimum for the log-likelihood function.
- These local optima are compared, and the point corresponding to the largest is chosen as the estimated change point.

Note that this procedure differs from the grid-based approach described in Guo et al. (2010).
The Reliability Block Diagram platform is available only in JMP Pro.

The Reliability Block Diagram platform displays the reliability relationships among a system’s components. If reliability distributions are assigned to the components, the platform analytically models the reliability behavior. A Reliability Block Diagram (also known as a dependence diagram) illustrates how component reliability contributes to the success or failure of a system.

Overview of the Reliability Block Diagram Platform

The Reliability Block Diagram platform enables you to diagram a system and its related components to show how component reliability affects the success of the whole system. Each block in a Reliability Block Diagram represents a component in the system and is connected to other components in the system.

A Reliability Block Diagram can include components connected either in series or in parallel. A failure in any series component causes the entire system to fail. In a parallel-connected (or redundant) system, all parallel components must fail for the entire system to fail. In addition, the diagram can include K out of N components where \( k \)-out-of-\( n \) components must function for the system to function.

The Reliability Block Diagram template places a Start block on the left side and an End block on the right side of the diagram. Using the Shape tools, you diagram the system to be analyzed beginning at the Start block and connecting components to reach the End block.

Example Using the Reliability Block Diagram Platform

In this example, you learn how to create a new Reliability Block Diagram.

1. Select Analyze > Reliability and Survival > Reliability Block Diagram.

A blank Reliability Block Diagram window appears.
Figure 11.2 New Reliability Block Diagram

Note: The Distribution profiler appears by default.

2. In the Designs panel, select and rename New Diagram 1 to Computer.
   The Workspace is now named System Diagram [Computer].

3. Deselect Run in the Start block.
   With Run selected, the platform updates the diagram’s reliability calculations after each change to the system diagram. These changes can include adding or deleting components, changing a component’s configuration, and adding or deleting a connection.
   With Run deselected, the platform does not update the reliability calculations after any changes.

   Tip: Deselect Run when you are diagramming large systems. Select Run when the diagram is complete.

4. Proceed with “Add Components” on page 297.
Add Components

The Reliability Block Diagram drawing elements that are located in the toolbar are called *shapes*. The term *component* refers to a shape that represents a constituent part of the system.

1. Click the Basic icon **Basic** on the Shape toolbar and drag the shape to the System Diagram to the right of the Start block.
2. Select the label, replace New Basic 1 by Power Supply, and press Enter.

**Figure 11.3** Basic Shape

When you click the label or the shape, connection arrows appear. The arrows disappear when you click elsewhere in the template.

3. Drag a second Basic shape to the right of the Power Supply shape.
4. Select the label and type CPU.

**Figure 11.4** Example System Diagram

**Note:** You will align the shapes later, in the section “Align Shapes” on page 299.

5. Drag a Parallel shape **Parallel** to a position to the right and below the CPU shape.
6. Select the label and type Peripherals.
7. Drag a K out of N shape **K out of N** to a position to the right and above the CPU shape.
8. Select the label and type Hard Drives.
9. Drag a Knot shape to the right of the previous shapes.
10. Select the label and type Join.
11. Drag a Series shape to a position to the right of the Knot shape.
12. Select the label and type Input Devices.

Figure 11.5 Partial System Diagram

13. Drag a Basic shape to a position to the right of the Input Devices shape.
14. Select the label and type Monitor.
Figure 11.7 System Diagram Showing All Shapes

15. Proceed with “Align Shapes” on page 299.

**Align Shapes**

1. To vertically align the shapes for Hard Drives and Peripherals, select the components:
   - Hard Drives
   - Peripherals

   **Tip:** To select shapes, drag the cursor around the shapes or press Shift and click each shape.

2. With the shapes selected, right-click one of the shapes and select **Align Selected Vertices Vertically**.

3. To horizontally align the remaining shapes, select the following components:
   - Start
   - Power Supply
   - CPU
   - Join
   - Input Devices
   - Monitor
   - End

4. With the shapes selected, right-click one of the shapes and select **Align Selected Vertices Horizontally**.
5. Proceed with “Connect Shapes” on page 300.

**Connect Shapes**

To connect shapes, select a shape to display its connection arrows. Suppose you want to connect shape A to shape B. Select shape A. Drag the right arrow to shape B to indicate that shape A precedes shape B. Drag the left arrow to shape B to indicate that shape B precedes shape A. To connect the shapes in your diagram, select the right arrows to connect to the next shape in the sequence.

1. Select the Start block (blue arrow) to display the connection arrow.
2. Select the single connection arrow and drag it to the Power Supply component.

**Figure 11.9 Connecting Shapes**

3. For each of the following components, click the first component, select its right connection arrow, and drag the arrow to the second component:
   1. Power Supply → CPU
2. CPU → Hard Drive
3. CPU → Peripherals
4. Hard Drives → Join
5. Peripherals → Join
6. Join → Input Devices
7. Input Devices → Monitor
8. Monitor → End block

Figure 11.10 Completed System Diagram

4. Proceed with “Configure Components” on page 301.

Configure Components

1. In the Configuration panel, enter the Configuration settings for the components. See “Configuration Settings” on page 309.

Table 11.1 Configuration Settings

</tr>
</tbody>
</table>

The Reliability Block Diagram is complete (Figure 11.11).

2. Select Run.
   The system’s reliability information is updated. This is reflected in the Distribution plot in the Profiler pane.

3. To save the Reliability Block Diagram as a JMP Scripting Language (JSL) file, select File > Save and name it exampleRBDcomplete.jsl.
The Reliability Block Diagram Window

The Reliability Block Diagram window is divided into the following panels:

- **Designs**: Lists system diagrams that were created using the Reliability Block Diagram platform.
- **Library**: Lists sub-system designs that are available for reuse in creating new system diagrams.

**Note**: Each system diagram that appears in the Designs and the Library panels contains its own red triangle menu. The options in each of those red triangle menus are described in “Options for Design and Library Items” on page 312.

- **Workspace**: Displays the Shape toolbar, the System Diagram, and the Preview window.

  **Tip**: To hide the Preview window, right-click in the Workspace and deselect Preview.

- **Profiler Panel**: Displays the Distribution profiler, Configuration settings, and various system and component profilers and plots that you select from the Diagram red triangle menu.
Figure 11.12 Example of a Reliability Block Diagram

The Shape toolbar includes the following drawing tools:

- **Basic**
  Adds a single block shape to the system diagram.

- **Series**
  Adds a series block shape that represents a group of components connected in a series. All components must function for the system to function.

- **Parallel**
  Adds a parallel block shape that represents a group of components that are in parallel. At least one of the components must function for the system to function.

- **K out of N**
  Adds a \( k \)-out-of-\( n \) block shape where you specify \( k \) and \( n \). At least \( k \) of the components must function for the system to function.

- **Knot**
  Adds a knot shape to the system diagram that enables you to join Parallel or K out of N components that have different Distribution property settings.

**Preview Window**

When the system diagram is too large to appear in the workspace, the Preview window enables you to reposition the portion of the system diagram that appears in the workspace. The viewing area is indicated in the Preview window by a white background. Drag the viewing area to reposition the view of the Workspace to another part of the system diagram.
Figure 11.13 Preview Window with Visible Part of Diagram on White Background

Reliability Block Diagram Platform Options

The Reliability Block Diagram red triangle menu contains the following options for the Reliability Block Diagram window:

**Save and Save As** Enables you to save a Reliability Block Diagram, or save an existing Reliability Block Diagram with a new name, to a JMP Scripting Language (JSL) script that is automatically executed when it is opened in JMP. See the Scripting Guide for more information about Auto-Submit scripts.

*Note:* The Save and Save As red triangle options are equivalent to File > Save and File > Save As. They are available in the red triangle menu for convenience.

**Show Design Diagram** If Show Design Comparisons is selected, this option enables you to hide or show the system diagram in the Workspace.

**Show Design Comparisons** Displays a Distribution Overlay profiler and Remaining Life Distribution Overlay profiler for the selected system diagrams. See “Show Design Comparisons” on page 306.

**Import Component Distribution Settings** Enables you to import configuration settings for the system diagram from a data table. The table must contain columns for the diagram category, diagram name, component name, distribution, and one or more parameters. The number of parameters depends on the specified distribution.
Note: The strings in the imported table must be exact matches to the strings in the system diagram.

**New Design Item**  Enables you to add a new design diagram to the Designs panel. See “Add a New Design Item” on page 307.

**New Library Item**  Enables you to add a new item to the Library panel. The Library panel lets you create subsystem diagrams for use in multiple system designs. See “Add a New Library Item” on page 308.

Note: Library items are available only for use in diagrams that are contained in the Designs panel of a JSL file. They are not available to other diagrams in other JSL files.

---

**Show Design Comparisons**

The **Show Design Comparisons** option displays a Distribution Overlay plot and a Remaining Life Distribution Overlay plot. These plots appear in the Workspace below the System Diagram. See Figure 11.14 and Figure 11.15.

- The Distribution Overlay plot shows the probability of system failure for each of the designs in the Designs panel.
- The Remaining Life Distribution Overlay plot shows the conditional probability of failure for each design in the Designs panel, given that the systems have survived to a specified survival time. Enter the Survival Time in the box to the right of the plot. Alternatively, select the small rectangle at the origin and drag it to the right to dynamically set the Survival Time.

Check boxes enable you to select which designs are represented in the plots. This enables you to compare a subset of designs with respect to failure probabilities.

**Tip:** To hide the system diagram in the Workspace, click the Reliability Block Diagram red triangle and deselect **Show Design Diagram**. Alternatively, to show more of the Design Comparisons, reposition the horizontal splitter upward.
**Add a New Design Item**

The **New Design Item** option adds a new system design to the Designs panel list.

- Click the Reliability Block Diagram red triangle and select **New Design Item**.
- A design named New Diagram X, where X is a number that identifies the diagram name, is added to the Designs panel list.
- To name the design, select the label and enter a name.
- Use the Shape toolbar to draw the system diagram. (See “Example Using the Reliability Block Diagram Platform” on page 295.)
Tip: You can also copy and paste the body of a diagram from another block diagram template. The Start and End shapes are not copied. After you paste the diagram, you must reconnect the Start and End shapes.

- Configure the components.
- Save the file.

To display a design in the System Diagram window and to view its Profiler panel, double-click its icon in the Designs panel.

Add a New Library Item

The **New Library Item** option adds a new sub-system to the Library panel list.

Tip: Drag a system design from the Designs panel to the Library panel to add it to the Library as a sub-system.

- Click the Reliability Block Diagram red triangle and select **New Library Item**.
- A sub-system called New Diagram X, where X is a number that identifies the diagram name, is added to the Library panel list.
- To name the sub-system, select the label and enter a name.
- Use the Shape toolbar to draw the sub-system diagram.
- Configure the components.
- Create connections from the Start block to the End block.
- Save the file.

Workspace Options

The Workspace panel supports several right-click commands for adjusting the view of the panel. Here are some of the available commands:

**Zoom In**   Enables you to zoom in to the system diagram.

**Zoom Out**   Enables you to zoom out from the system diagram.

Tip: On Windows, you can press Ctrl and use the mouse scroll wheel to zoom in to and out from the diagram.

**Zoom Scale** Opens the Set Zoom Scale window enabling you to zoom in or out using a scaling factor. The scaling factor ranges from 0.75 (75%) to 5.0 (500%).

**Preview**   Enables you to hide or show the Preview window in the Workspace panel.
**Align Selected Vertices Vertically**  Enables you to align shapes on a vertical line.

**Align Selected Vertices Horizontally**  Enables you to align shapes on a horizontal line.

**Create Series Diagram**  Enables you to create a series diagram using the nodes in the diagram. The order of the series is determined by the order of node creation. This option is available only when the diagram does not contain any arrows.

**Create Parallel Diagram**  Enables you to create a parallel diagram using the nodes in the diagram. This option is available only when the diagram does not contain any arrows.

---

**Configuration Settings**

Each component in a Reliability Block Diagram can be assigned a failure distribution. The available failure distributions are listed in Table 11.2 on page 309. To see the formulas and parameterization for these failure distributions, see “Distributions” on page 82 in the “Life Distribution” chapter.

**Distribution Configurations**

When a component is added to the diagram, an outline for that component appears beneath the Configuration outline.

**Note:** You can omit a component from the analysis by checking the box next to Omit.

Select a Distribution and enter the required parameter values.

To view Configuration settings for the components in a selected design or subsystem, do the following:

- To view the Configuration settings for a specific component, select the component’s shape.
- To view Configuration settings for more than one component, select multiple components’ shapes using the Arrow tool or pressing Control and clicking.
- To view Configuration settings for all components, deselect any shapes by clicking in a blank portion of the Workspace.

For each component in the diagram, you can either omit the component from calculations by checking the box next to Omit or:

- From the Distribution list, select the appropriate distribution. For all selections other than Nonparametric, enter parameter values for the distribution. For Nonparametric, see “Specify a Nonparametric Distribution” on page 311.
- For Series and Parallel components, you must also enter a value for N, the total number of components contained in the series or parallel shape.
- For K out of N components, you must also enter K, the minimum number of components that must function for the system to function, and N, the total number of components in the shape.
- For Knot components, enter the Minimum Available Dependences. The Knot shape enables you to configure a *k*-out-of-*n* shape where the shapes that are joined have different distributions. The Minimum Number of Dependencies is *k*, the minimum number of paths leading to the Knot that need to function in order for the system to function.

Figure 11.16 Example of a Weibull Configuration for a K out of N Shape
Specify a Nonparametric Distribution

The Nonparametric option under Distribution enables you to approximate an arbitrary distribution. Enter data or import a file containing a large set of data. This data is used to approximate the distribution.

After selecting Nonparametric, click the icon next to Data. The Provide Data window appears, enabling you to either enter data or import a data file. Once you have imported or entered your data, the data is used to calculate a nonparametric distribution for the component.

Figure 11.17  Provide Data Window

To import data from a file, do the following.

1. Open the JMP data table that contains the data to import.
2. In the Provide Data window, click **Import**.
   
   The Select Data Table window appears.
3. From the Data Table list, select the data table.
4. Click **OK**.
5. In the panel beneath the data grid, specify which columns represent Time to Event data, as well as Censor and Freq data if appropriate.
6. In the Provide Data window, click **OK**.

To enter data manually, do the following.

1. Create columns for Time to Event data, as well as Censor and Freq data, if appropriate.
2. Enter the data into the columns.
3. In the panel beneath the data grid, specify which columns represent Time to Event data, as well as Censor and Freq data if appropriate.
4. In the Provide Data window, click **OK**.

---

**Options for Design and Library Items**

The available options for Design and Library items are listed below:

- **Show Configuration** shows or hides the Configuration outline. See “Configuration Settings” on page 309.
- Options to show various profilers. See “Profiler” on page 313 and the following:
  - “Distribution Profiler” on page 313
  - “Remaining Life Distribution Profiler” on page 313
  - “Reliability Profiler” on page 314
  - “Quantile Profiler” on page 314
  - “Density Profiler” on page 314
  - “Hazard Profiler” on page 314
  - “Cumulative Hazard Profiler” on page 314
- Options to show plots for component importance measures and mean time to failure. See “Component Importance and Time to Failure” on page 315 and the following:
  - Birnbaum’s Component Importance” on page 315
  - “Remaining Life BCI” on page 316
  - “Component Integrated Importance” on page 316
  - “Mean Time to Failure” on page 317
- Options to show overlay plots for the components in a system diagram. See “Component Plots” on page 317 and the following:
  - “Component Distribution Functions” on page 317
  - “Component Reliability Functions” on page 318
  - “Component Density Functions” on page 318
  - “Component Hazard Functions” on page 319
  - “Component Cumulative Hazard Functions” on page 319
- “Print Algebraic Reliability Formula” on page 320
- “Generate Algebraic Expression Data Table” on page 321
• “Clone and Delete” on page 321

Profilers

Various profilers are provided to help you analyze the reliability properties of a system. You can view profilers for each system diagram that is listed in the Designs and the Library panels. This section describes the profilers. The profilers appear in the Profilers panel of the report.

Red Triangle Options for Profilers

Each profiler has a red triangle menu that contains the following commands:

- **Reset Factor Grid**: Displays a window where you can enter a current setting and values that control the display. See Profilers for more information about setting the factor grid.

- **Factor Settings**: Select this option to configure the profiler’s settings and to link the profilers. See Profilers for more information about Factor Settings.

**Note**: Adjust the X and Y axes of a profiler to view the desired portion of the graph.

Distribution Profiler

The Distribution Profiler displays the probability that the system fails as a function of time. The Distribution profiler for the system appears by default.

**Figure 11.18** Distribution

Remaining Life Distribution Profiler

The Remaining Life Distribution profiler for the system shows the probability that the system fails given that it has survived a specified amount of time, designated as Survival Time. By default, Survival Time is set to zero, and the remaining life distribution function is equivalent to the distribution function.
Enter a value for **Survival Time** to indicate the time to which the system has survived without failing. As an alternative to entering a value, select the small rectangle at the origin of the graph and drag it to the right to dynamically set the Survival Time.

**Figure 11.19 Remaining Life Distribution**

![Remaining Life Distribution](image)

**Reliability Profiler**

The Reliability profiler for the system shows the probability that the system will function as a function of time. The reliability function is also known as the survival function.

**Quantile Profiler**

The Quantile profiler for the system shows time as a function of the failure probability. Note that the Quantile function is the inverse of the Distribution function.

**Density Profiler**

The Density profiler for the system shows the probability density function associated with the system’s failure distribution function.

**Hazard Profiler**

The Hazard profiler for the system shows the instantaneous failure rate at a given time.

**Cumulative Hazard Profiler**

The Cumulative Hazard profiler for the system shows the cumulative hazard function as a function of time.
Component Importance and Time to Failure

Plots that analyze component importance and mean time to failure are provided for each system diagram that is listed in the Designs and the Library panels. This section describes the component importance measures and mean time to failure. These plots and statistics appear in the profilers panel of the report.

Note: Check boxes in the legend of each component importance plot enable you to select which components to view in that plot.

Birnbaum’s Component Importance

Select Show BCI to show an overlay plot of the Birnbaum’s Component Importance measures for each component of the selected system diagram. A component’s BCI at a given time is the probability that the system fails if the component fails. A component with a large BCI is critical to system reliability.

Figure 11.21 Birnbaum’s Component Importance
**Remaining Life BCI**

Select **Show Remaining Life BCI** to show an overlay plot of the Birnbaum’s Component Importance for Remaining Life. The BCI for Remaining Life is the probability that the system fails if the component fails, given that the system has survived a specified amount of time, designated as Survival Time. By default, Survival Time is set to zero, and the BCI for Remaining Life is equivalent to the Birnbaum’s Component Importance.

Enter a value for **Survival Time** to indicate the time to which the system has survived without failing. As an alternative to entering a value, select the small rectangle at the origin of the graph and drag it to the right to dynamically set the Survival Time.

**Figure 11.22** Birnbaum’s Component Importance for Remaining Life

**Component Integrated Importance**

Select **Show Component Integrated Importance** to show an overlay plot of the integrated importance measures for the components of the Reliability Block Diagram. The integrated importance measure for each component takes into account the failure rate of the component as well as the likelihood of failing instantaneously. See Si et al. (2012).
Figure 11.23 Component Integrated Importance

Mean Time to Failure

Select Show MTTF to view the Mean Time to Failure (MTTF) for the system.

Note: The formula that is used to calculate the Mean Time to Failure depends on the specified failure distributions and Configuration settings for each component in the system.

Component Plots

A system diagram usually contains many individual components. The reliability functions of each of these components can be examined in overlay plots. You can view component overlay plots for each system diagram that is listed in the Designs and the Library panels. This section describes the component overlay plots. These plots appear in the profilers panel of the report.

Note: Check boxes in the legend of each component plot enable you to select which components to view in that plot.

Component Distribution Functions

Select Show Component Distribution Functions to show an overlay plot of the distribution functions for the components of the Reliability Block Diagram.
Figure 11.24 Component Distribution Functions

![Component Distribution Functions](image)

Component Reliability Functions

Select **Show Component Reliability Functions** to show an overlay plot of the reliability functions for the components of the Reliability Block Diagram.

Figure 11.25 Component Reliability Functions

![Component Reliability Functions](image)

Component Density Functions

Select **Show Component Density Functions** to show an overlay plot of the density functions for the components of the Reliability Block Diagram.
Figure 11.26 Component Density Functions

Component Hazard Functions

Select Show Component Hazard Functions to show an overlay plot of the hazard functions for the components of the Reliability Block Diagram.

Figure 11.27 Component Hazard Functions

Component Cumulative Hazard Functions

Select Show Component Cumulative Hazard Functions to show an overlay plot of the cumulative hazard functions for the components of the Reliability Block Diagram.
Print Algebraic Reliability Formula

The Print Algebraic Reliability to the Log Window option prints the reliability formula for the selected system diagram to the Log window.

1. (Windows only) Select View > Log.
   
   Or
   
   (macOS only) Select Window > Log.

2. Open the exampleRBDcomplete.jsl file that you created.

3. In the Designs panel, select Computer.

4. Click the Computer red triangle and select Print Algebraic Reliability to the Log Window.

   The Log window displays the formula for the Algebraic Reliability of the selected block diagram.

Figure 11.29  Algebraic Reliability in Log Window

```plaintext
/*
Reliability Block Diagram[]Algebraic Reliability:
R["Power Supply"] * R["CPU"] * R["Input Devices"] * R["Monitor"]
+ R["Power Supply"] * R["CPU"] * F["Peripheral"] * R["Hard Drives"] * R[
"Input Devices"] * R["Monitor"]
*/
```

Note: Reliability formulas use “R” to represent a component’s reliability and “F” to represent probability of a component’s failure.
Generate Algebraic Expression Data Table

The Generate Algebraic Expression Data Table option creates a new data table that contains the algebraic reliability expression as a column formula. The table contains a column for each component in the system. The final column contains the system reliability algebraic expression as a JSL column formula that use the preceding columns as arguments.

Clone and Delete

Each system diagram that is listed in the Designs and the Library panels has options that aid in managing the design and library items. This section describes the Clone and Delete operations.

Clone a Design or Library Item

The Clone option creates a new system design or library sub-system identical to the selected system design or library sub-system.

- Select the Clone option from the red triangle menu for the design or library item to be copied.
  
  A new design or library item is added to the Designs or Library list.

- Save the file.

Delete a Design or Library Item

The Delete option removes the selected system design or a library sub-system from the panel.

- Select the Delete option from the red triangle menu for the design or library item to be deleted.
  
  The specified design or library item is deleted from the Designs or Library list.

- Save the file.
The Repairable Systems Simulation platform is available only in JMP Pro.

The Repairable Systems Simulation (RSS) platform enables you to explore the reliability within complex repairable systems. A repairable system consists of individual components that age and require maintenance. The state of a repairable system changes as its components fail and are subsequently repaired.

Repairable systems are involved in many aspects of modern life. They can range in size from refrigerators and houses to power plants and telephone communication networks.

The RSS platform enables you to simulate different system configurations in order to optimize your repairable system. For example, you can extend the useful life of costly components or maximize production outputs while maintaining a safe system operation.

Overview of the Repairable Systems Simulation Platform

The Repairable Systems Simulation (RSS) platform enables you to simulate a repairable system and to analyze its outage time. Outage time is the total time a system is not in the On state as a result of either planned maintenance or unintentional failure.

A repairable system is represented by a system diagram. Block shapes in the system diagram represent one or more components that connect to other components. A component that is performing work in the block is said to be functional. Components can be connected in series or in parallel. When components are connected in series, the system fails if any of the components in the series fails. When components are connected in parallel, the system fails if all of the parallel components fail.

A component pathway is said to be uninterrupted when at least one path between the Start and End blocks does not pass through a block shape failure. During a simulation, the system remains in the On state as long as there is an uninterrupted component pathway. If a block shape failure interrupts the component pathway, the system is set to the Down state. If a block shape fails but the component pathway is not interrupted, the system remains in the On state.

You can add unique events and actions to characterize the repairable nature of individual components. An event is a specific occurrence within the system, such as component failure, scheduled maintenance, or the start of a simulation iteration. Events trigger the execution of one or more actions, which express how components behave. Actions can alter the state of a component or the entire system.

Example Using the Repairable Systems Simulation Platform

In this example, you run 100 iterations of a simulation of a car system and analyze the system’s estimated outage time over the course of 10 years.

1. Select Help > Sample Data, click Open the Sample Scripts Directory, and open Car Repair Simulation.jsl.
Figure 12.2 Car Repair System Diagram

An RSS window that diagrams a car system appears. In the diagram, the first block on the left is the Start block. Notice in the Configuration panel, on the right side of the RSS window, that the simulation is set to run for 3650 days.

2. (Optional) Enter 555 next to Seed.
   Because the simulation involves random component failures, this action ensures that you obtain the exact results shown below.

3. Click the green triangle below the Start block to simulate the car system.
   A data table that contains the simulation results appears.

4. Click the green arrow next to the Launch Repairable Systems Simulation Results Explorer script.
   A window appears containing the Repairable Systems Simulation Results report. For more information about how to interpret these results, see “Repairable Systems Simulation Results” on page 342.

Figure 12.3 Partial RSS Report

You predict that the car will be available between 3,600 and 3,640 days over the next 10 years. Because the values shown in the Point Estimation of System Availability graph are
close to one, you conclude that the car will be mostly available to drive over the next 10 years. You are interested in which components cause the most downtime for the system.

5. Click the red triangle next to Repairable Systems Simulation Results - Number and select Box Plot of Total System Downtime by Component.

**Figure 12.4** Partial Box Plot of Total System Downtime by Component Report

You conclude that the tires cause the most downtime for the car system. To increase the average total system availability, you might consider using more durable tires or carrying another spare tire.

---

**The Repairable Systems Simulation Window**

Launch the Repairable Systems Simulation platform by selecting Analyze > Reliability and Survival > Repairable Systems Simulation. The Repairable Systems Simulation window is divided into the following panels:

- “System Diagram” on page 328
- “Shapes Toolbar” on page 329
- “Configuration Panel” on page 330
- “Add Event Panel” on page 333
- “Add Action Panel” on page 334
Figure 12.5 The Repairable Systems Simulation Window

System Diagram

The System Diagram is the space where you can diagram a repairable system. A new System Diagram contains a Start block and an End block.

The following options are available in a pop-up menu when you right-click in the System Diagram:

**Run Simulation**  Runs the simulation using the current Simulation Settings in the Configuration panel. The results of the simulation are reproducible if a nonzero value is specified for Seed.

**Run Multithreaded Simulation**  Runs a multithreaded simulation of the system. The results of the simulation are not reproducible when you run a multithreaded simulation.

**Diagram Operation**  Contains options to control the appearance of the diagram:

**Delete**  (Available only if a block, event, or action is selected.) Removes the selected items from the diagram.
Show Block Names  Shows or hides the names that appear below the blocks in the diagram.

Zoom In  Increases the Zoom Scale value by a factor of 0.9.

Zoom Out  Decreases the Zoom Scale by a factor of 0.9.

Tip: On Windows, you can press Ctrl and use the mouse scroll wheel to zoom in and out from the diagram.

Zoom Scale  Enables the user to set the scale of the zoom on a scale of 0 to 10000. The original Zoom Scale value is 1. The Zoom Scale value increases as you zoom into the diagram.

Preview  Shows or hides the Preview window in the lower right corner of the System Diagram.

Show Event Action Link Across Blocks  Shows or hides the green arrows that represent action links from one block to another. If this option is turned off, action links for selected events and actions still appear.

Align Selected Vertices Vertically  (Available only if more than one block is selected.) Updates the horizontal position of the selected blocks so that they are aligned vertically.

Align Selected Vertices Horizontally  (Available only if more than one block is selected.) Updates the vertical position of the selected blocks so that they are aligned horizontally.

When you right-click an item in the System Diagram, additional submenu items appear in the pop-up menu. The submenu items that appear depend on the type of item. These options enable you to add, remove, or change the events and actions attached to a block item.

Shapes Toolbar

The Shapes toolbar contains the block shapes used to represent components in the System Diagram. Add block shapes to the System Diagram by clicking the icon for the block shape and dragging it onto the System Diagram. The Shapes toolbar includes the following block shape icons:

- **Basic**  Adds a single block shape that represents a single component.

- **Series**  Adds a series block shape that represents a group of identical components that are connected in series. All of the components must be functional for the block to remain functional.
Adds a parallel block shape that represents a group of identical components that are connected in parallel. At least one of the components must be functional for the block to remain functional.

Adds a $k$-out-of-$n$ block shape that represents a group of $n$ identical components that are connected in parallel. At least $k$ of the $n$ components must be functional for the block to remain functional.

Adds a standby block shape that represents a group of $n$ identical components that are connected in parallel. Only $k$ components are active, or performing work in the system. The remaining inactive components act as standby components that are activated when any of the $k$ active components fail. The block must have at least $k$ functional and activated components for the block to remain functional.

Adds a stress sharing block shape that represents $n$ identical components that are connected in parallel. Components fail one at a time, and remaining components fail at a quicker rate. The block must have at least one functional component and the block must successfully reallocate stress across remaining components for the block to remain functional.

Adds a knot block shape that represents a combination of the block shapes that point to the knot. At least a specified number of the block shapes that point to the knot must be functional for the knot to remain functional.

For information about the settings available for block shapes, see “Configuration Panel” on page 330.

**Configuration Panel**

The Simulation Settings report appears at the top of the Configuration panel. The component settings for every selected component appear below the Simulation Settings outline. Configuration settings for selected events and actions appear below the block shape to which the action or event belongs.

**Simulation Settings**

Alter the settings for the simulation in the Simulation Settings report, which is available in the Configuration panel. The following settings are available:

- **Duration** The length of time that is simulated in each iteration.
- **Time Unit** The unit of time to use for the simulation.

**Note:** Recurring events and non-immediate actions use the Time Unit specified in Simulation Settings.
N Simulations  The number of iterations in the simulation.

Seed  (Optional) A random seed that ensures the reproducibility of simulation results. By default, the Seed is set to zero, which does not produce reproducible results. When you save the analysis to a script, the random seed that you enter is saved to the script.

Caution: If you run a simulation by right-clicking and selecting Run Multithreaded Simulation, the results are not reproducible, even if you specify a random seed.

Block Settings

Select a block shape in the System Diagram to see its settings in the Configuration panel.

Each block shape, except the knot block, has a Turn On System Exemption option. If this option is selected for a block, the block is not turned on when the Turn On System action is invoked.

Each block shape, except the knot block, has a failure distribution that determines the rate at which the block shape’s individual components randomly fail. The failure distribution for a basic block determines the rate at which the block fails, because basic blocks represent only one component. For more information about the available failure distribution options, see “Distribution Options” on page 338. Under the Distribution option, you can specify the Time Unit and distribution-dependent parameters for the block.

Series and Parallel

A series block fails when one of its components fails. A parallel block fails when all of its components fail. The following option is available for series and parallel blocks:

N  Specifies the number of identical components contained in the block.

K-out-of-N

K-out-of-N blocks contain $n$ identical components. The block fails when fewer than $k$ of the components are functional. The following options are available for K-out-of-N blocks:

K  Specifies the minimum number of functional components required for the block to remain functional.

N  Specifies the number of identical components contained in the block.
Standby

Standby blocks have secondary components, called standby components, that are inactive. Active components perform work within a standby block. Inactive components do not perform work within a standby block, and are activated one at a time as active components fail. Occasionally, the activation process is not successful. A component switch might fail when activating a standby component. A standby block fails when less than $k$ of its $n$ identical components are active. The following options are available for standby blocks:

**K** Specifies the number of components that are initially active. This is also the minimum number of active components that is required for the block to remain functional.

**N** Specifies the total number of identical components within the block. The difference between $k$ and $n$ is equal to the number of standby components.

**Switch Type** Specifies the mechanism that activates a single standby component if any active component fails.

**Single Switch** A single switch exists in the block. If the activation of a standby component fails, then the block also fails.

**Individual Switches** A switch exists for each standby component. If the activation of a standby component fails, that standby component cannot be activated. The standby block attempts to activate the next standby component until a standby component is activated. If no remaining switches are functional and fewer than $k$ of the components are active, then the block fails.

**Switch Reliability** Specifies the probability of success of activating a standby component when any active component fails.

**Standby Type** Specifies the state and failure distribution of the standby components.

**Cold** Standby components do not age until they are activated.

**Warm** Standby components age according to a secondary failure distribution while they are inactive. When standby components are activated, they age according to the primary failure distribution. Use the secondary failure distribution to mimic reduced stress on standby components that are not performing work in the standby block.

**Stress Sharing**

A stress sharing block distributes stress equally among its components. As components fail, the components that remain functional experience increased stress and subsequently fail at an increased rate.

**N** Specifies the total number of identical components contained in the block.
Switch Reliability  Specifies the probability of successfully reallocating stress among the remaining functional components. The block fails if the reallocation of stress fails.

Stress Sharing Type  Specifies how stress is shared among functional components.

Basic (default)  Specifies that stress is shared equally among the remaining functional components. This type of stress sharing is referred to as Load Sharing. The characteristic life of individual components is proportional to the number of components that share the work load.

Custom  Specifies that components share stress according to the JSL code that appears in the Sharing Formula option. The Sharing Formula defines how stress changes when components fail.

Knot

Knot blocks do not have a failure distribution. Knot blocks fail only if the number of connected blocks shapes that are functional falls below the specified minimum number. The following option is available for knot blocks:

Minimum Available  Specifies the minimum number of functional blocks that must point to the knot block for the knot block to remain functional.

Add Event Panel

Events represent discrete occurrences in a simulation. You can use events to trigger actions. There is no limit to how many actions a single event can trigger. The following options are available in the Add Event Panel:

Note: Some block shapes do not have all of the available event types.

Block Failure  Occurs when the block fails. If the component pathway is interrupted, the system is set to the Down state.

Scheduled  Occurs at a specified recurring interval. The Max Occurrence option sets a limit on the number of occurrences of this event in a simulation. By default, Max Occurrence is set to missing. In this case, the event continues to occur until the end of the simulation. See “Event Settings” on page 340.

Inservice Based  Occurs when the component reaches a specified age. A component’s age is the cumulative time that it has been functional and active. Age stops increasing when a component fails or its block is turned off. The Max Occurrence sets a limit on how many times this event can take place in a simulation. By default, the event continues to occur until the end of the simulation. See “Event Settings” on page 340.
**System is Down**  Occurs when the system is set to either the Down or the Off state. The system state can be changed intentionally or unintentionally.

**Initialization**  Occurs when each simulation iteration begins. Use this event to arrange actions that have to complete before the system runs.

**Create an Event**

1. To create an event, select a block shape in the System Diagram to display the Add Event and Add Action panels at the bottom of the System Diagram.
2. Select one of the options in the Add Event panel to define an event for the selected block shape.

![Figure 12.6 Block Failure Event](image)

An orange square that represents the new event appears above the component. Notice that a connection arrow appears on the right side of the selected event.

**Add Action Panel**

An action defines component and system behavior that is triggered by either a connected event or a connected action. Connected actions are triggered upon completion of the prior action. The following options are available in the Add Action Panel:

**Note:** Some block shapes do not have all of the available action types.

Create an Action

1. To create an action, select a block shape in the System Diagram to display the Add Event and Add Action panels at the bottom of the System Diagram.
2. Select one of the options from the Add Action panel to define an action for the selected block shape.
A blue action square is created above the selected block shape. Actions are triggered when a connected event occurs. Create an event that triggers the action that you defined.

3. Select one of the options from the Add Event panel to define an event for the selected block shape.

An orange event square is created above the block shape. Notice the connection arrow on the right side of the event.

4. Click the connection arrow and drag it to the blue action square that you created in step 2.

A green arrow connects the event and action squares. When the event occurs in a simulation iteration, it triggers the connected action.

5. Select the blue action square that you created in step 2.

You can connect additional actions that are triggered upon completion of the previous action by using the addition sign that appears on the right side of the selected action.

6. Click the addition sign and drag it to an empty area in the System Diagram.

A list of the available actions appears.

7. Select one of the options from the action list to create an action that is connected to the first action.

Figure 12.7  Create an Action

A green arrow connects the two actions. The second action is triggered upon completion of the first action.

Repairable Systems Simulation Platform Options

The Repairable Systems Simulation red triangle menu contains the following options:

Save and Save As  Enables you to save a Repairable Systems Simulation to a JMP Scripting Language (JSL) script that is automatically executed when it is opened in JMP. See the Scripting Guide for more information about Auto-Submit scripts.

Note: The Save and Save As red triangle options are equivalent to selecting File > Save and File > Save As, respectively. They are available in the red triangle menu for convenience.
Import Component Distribution Settings

Enables you to import configuration settings for the system diagram from a data table. The table must contain columns for the component name, distribution, and one or more parameters. The number of parameters depends on the specified distribution.

**Note:** The strings in the imported table must be exact matches to the strings in the system diagram.

---

### Options for Block Items

To view settings for the components in a selected design or subsystem, do the following:

- To view the Configuration settings for a block shape, select the block shape in the System Diagram.
- To view Configuration settings for more than one block shape, select multiple block shapes using the Arrow tool, press Ctrl, and click multiple block shapes.

### Distribution Options

Each block shape randomly fails according to its specified failure distribution. In addition, you specify a time unit for the distribution. The block shape’s time unit can be different from the time unit option that you specify in the simulation settings. The Turn On Count option is based on the number of times the individual block shape has been set to the On state.

The available failure distributions are listed in Table 12.2.

To see the formulas and parameterization for these failure distributions, see “Distributions” on page 82 in the “Life Distribution” chapter.

Specify a Nonparametric or Estimated Distribution

The Nonparametric and Estimated options under Distribution enable you to approximate an arbitrary distribution. You can enter data manually or import a file that contains data. These data are used to approximate the distribution.

After selecting Nonparametric or Estimated, click the icon next to Data. The Provide Data window appears, which enables you to either enter data or import a data file. After you have imported or entered your data, the data are used to calculate a distribution for the component.

Figure 12.8 Provide Data Window
To import data from a file, do the following:

1. Before clicking the icon, open the JMP data table that contains the data to import.
2. Click the icon next to Data.
3. In the Provide Data window, click **Import**.
   The Select Data Table window appears.
4. From the Data Table list, select a data table.
5. Click **OK**.
6. In the panel beneath the data grid, specify the columns that represent Time to Event data.
7. Specify Censor and Freq columns, if appropriate.
8. In the Provide Data window, click **OK**.

To enter data manually, do the following:

1. Create columns for Time to Event data.
2. Create columns for Censor and Freq data, if appropriate.
3. Enter the data in the columns.
4. In the panel beneath the data grid, specify which columns represent Time to Event data, as well as Censor and Freq data if appropriate. See step 5 and step 6 above.
5. In the Provide Data window, click **OK**.

**Event Settings**

Select an event in the System Diagram to see its settings in the Configuration panel. You can change the Event Name setting to distinguish the event from others. Only the Scheduled and Inservice events have additional settings, which are listed here:

**Scheduled**

Scheduled events have the following options:

**Recurring Interval**  Specifies the length of the time interval between event occurrences.

**Max Occurrences**  Specifies the maximum number of times this event can occur.

**Inservice**

Inservice events have the following options:

**Inservice**  Specifies the interval of component run time to wait before this event occurs.
**Note:** Component run time accumulates only when the system is in the On state and the component is functional.

**Max Occurrences**  Specifies the maximum number of times this event can occur.

### Action Settings

Select an action in the System Diagram to see its settings in the Configuration panel. You can change the Action Name setting to distinguish the action from others. By default, actions are completed immediately. Non-immediate completion time options are available in the Completion Time Options menu.

**Figure 12.9** Action Settings

![Action Settings](image)

The following options appear in the Completion Time Options list:

- **Immediate (default)**  Specifies that no time passes between starting and completion behavior.
- **Constant**  Specifies that the time lapse is always the specified Completion Time.
- **Choice**  Specifies that the time lapse is randomly chosen from the specified list of comma-separated values.
- **Uniform**  Specifies that the time lapse is randomly chosen from a uniform distribution with the specified Minimum and Maximum.
- **Triangle**  Specifies that the time lapse is randomly chosen from a triangular distribution with the specified Minimum, Mode, and Maximum.
- **Normal**  Specifies that the time lapse is randomly chosen from a normal distribution with the specified Mean and Standard Deviation.
Results Table

When you click the green arrow under the Start block to run the simulation, the results of the simulation appear in a data table. This table describes the events and subsequent actions that occurred in each simulation iteration.

The results table contains the following columns:

- **Sim ID**  Identifies the simulation iteration to which the event or action belongs.
- **Time**  Gives the exact time that the event or action took place in the simulation.
- **Subject**  Gives the name of the block shape to which the event or action is connected or System in the case of system events and actions.
- **Predicate**  Gives the name of the event or action that took place.
- **State**  Gives the state of the Subject at that exact Time. The initialization and termination of each action are denoted with Start and Finish, respectively.
- **Note**  Gives an additional description of an action. The end of each simulation iteration is denoted with End.
Notice that the first entry in Figure 12.10 is the start of the Initialization Spare in Trunk action, which has an immediate completion time. The action turns the Spare component off and then finishes while Time is still 0.

The next event that occurs is Tire 2 is Unrepairable when approximately 65 days have passed in the first simulation iteration. In row five, the system is unintentionally set to the Down state because only three tires are functional. The Need 4 Tires to Drive knot requires at least four tires, including the Spare, to be functional. The Tire 2 is Unrepairable event simultaneously triggers the Replace Tire 2 action and the Use Spare action. The Drive with Spare action is triggered in row eleven, and the system is set to the On state.

Notice that Tire 2 failed and was replaced by the Spare at the same time. No time elapsed between the time that the system was set to the Down state and the time that the system was returned to the On state. Because the subsequent actions had an immediate completion time, the Tire 2 is Unrepairable event did not cause any system outage time. The results explorer shows the system outage time that accumulates when actions are non-immediate.

**Results Explorer**

When you click the green arrow next to the Launch Repairable Systems Simulation Results Explorer script in the results data table, a report appears that contains an analysis of the simulation results.
Figure 12.11 Partial RSS Explorer Report

By default, the report contains two types of graphs. The first type of graph, shown on the left side of Figure 12.11, is a point estimate graph. The point estimate graph displays aggregated simulation results on the vertical axis plotted against simulation iteration time on the horizontal axis. The range of the horizontal axis is the duration that you specify in the simulation settings. The estimated probability of the system being available at a given time is shown in red next to the vertical axis. Below the point estimate is a 95% confidence interval for the point estimate.

**Tip:** To see the point estimation of system availability at a specific time in the simulation iteration, click the red number below the horizontal axis. Specify a time within the range of the simulation duration and press Enter.

The second type of graph, shown on the right side of Figure 12.11, is a histogram of the system available time from the simulation iterations. The bins in the histograms are representative of one of the following:

- Total simulation time.
- Proportion of the simulation duration.

**Tip:** Select the Export Data option beside a graph to create a data table with the data that the graph uses.

By default, the report contains the following graphs:

**Point Estimation of System Availability Profiler**  Shows a profiler graph over time of the estimated probability that the system is in the On or the Off state during a simulation iteration.

**System Available Time Distribution**  Shows a histogram of the total time that the system was available for each simulation iteration.

**System Availability Distribution**  Shows a histogram of the total time that the system was available for each simulation iteration divided by the duration of the simulation. This distribution is the same as the System Available Time Distribution, except that it is shown as a proportion of the duration of the simulation.
Point Estimation of System In Service Probability Profiler  
Shows a profiler graph over time of the estimated probability that the system is in the On state during a simulation iteration.

System In Service Time Distribution  
Shows a histogram of the total time that the system was in the On state for each simulation iteration.

System In Service Probability Distribution  
Shows a histogram of the total time that the system was in the On state for each simulation iteration divided by the duration of the simulation. This distribution is the same as System In Service Time Distribution, except that the distribution is shown as a proportion of the duration of the simulation.

Point Estimation of System Unplanned Outage Profiler  
Shows a profiler graph over time of the estimated probability that the system is in the Down state during a simulation iteration.

System Unplanned Outage Distribution  
Shows a histogram of the total time that the system was in the Down state for each simulation iteration.

System Unplanned Outage Percentage Distribution  
Shows a histogram of the total time that the system was in the Down state for each simulation iteration divided by the duration of the simulation. This distribution is the same as System Unplanned Outage Distribution, except that the distribution is shown as a proportion of the duration of the simulation.

Repairable Systems Simulation Results Options

The Repairable Systems Simulation Results red triangle menu contains the following options:

Point Estimation of Component Availability  
For each block shape in the system diagram, this option shows the following reports:
- Point Estimation of Availability Profiler
- Available Time Distribution
- Availability Distribution
- Point Estimation of Unplanned Outage Profiler
- Unplanned Outage Time Distribution
- Unplanned Outage Distribution

System Availability by Period  
Shows a graph that enables you to examine the average system availability during specified time periods. Use the By Time panel to define the time period as an interval of time. Use the By Event panel to define the time period as a specified number of occurrences of one event. When you click Go, the report shows a bar chart of the average system availability during each period.
Box Plot of System Total Downtime by Component  Shows a box plot of the total time the system was in the Down or Off states caused by individual components. The components are ordered by contribution from the most outage time to the least outage time, similar to a Pareto chart.

Box Plot of System Unplanned Total Outage Time by Component  Shows a box plot of total time the system was in the Down state caused by individual components. The components are ordered by contribution from the most outage time to the least outage time, similar to a Pareto chart.

See Using JMP for more information about the following options:

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script**  Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script**  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

**RSS Results Explorer Point Estimation Profilers**

Each point estimation profiler within the Repairable Systems Simulation Results Explorer report has a red triangle menu that contains the following options:

**Confidence Intervals**  Shows or hides the 95% confidence intervals on the point estimation graphs.

**Reset Factor Grid**  Opens the Factor Settings window, which enables you to modify the parameters of the point estimation graph. See Profilers for more information about setting the factor grid.

**Factor Settings**  Provides additional options affecting the Factor Grid. See Profilers for more information about Factor Settings.
Survival data contain duration times until the occurrence of a specific event and are sometimes referred to as event-time response data. The event is usually failure, such as the failure of an engine or death of a patient. If the event does not occur before the end of a study for an observation, the observation is said to be censored.

The Survival platform fits a single Y that represents time to event (or time to failure). Use the Survival platform to examine the distribution of the failure times.

**Tip:** To fit explanatory models, use the Fit Parametric Survival platform or the Fit Proportional Hazards platform.

Overview of the Survival Analysis Platform

Survival data need to be analyzed with specialized methods for two reasons:

1. The survival times usually have specialized non-normal distributions, like the exponential, Weibull, and lognormal.
2. Some of the data could be censored.

Survival functions are calculated using the nonparametric Kaplan-Meier method for one or more groups of either complete or right-censored data. Complete data have no censored values. Right-censoring is when you do not know the exact survival time, but you know that it is greater than the specified value. Right-censoring occurs when the study ends without all the units failing, or when a patient has to leave the study before it is finished. The censored observations cannot be ignored without biasing the analysis. The elements of a survival model are:

- A time indicating how long until the unit (or patient) either experienced the event or was censored. Time is the model response ($Y$).
- A censoring indicator that denotes whether an observation experienced the event or was censored. JMP uses the convention that the code for a censored unit is 1 and the code for a non-censored event is zero.
- Explanatory variables (if a regression model is used.)
- Interval censoring is when a data point is somewhere on an interval between two values. If interval censoring is needed, then two $Y$ variables hold the lower and upper limits bounding the event time.

Common terms used for reliability and survival data include lifetime, life, survival, failure-time, time-to-event, and duration.

The Survival platform computes product-limit (Kaplan-Meier) survival estimates for one or more groups. It can be used as a complete analysis or is useful as an exploratory analysis to gain information for more complex model fitting. The Kaplan-Meier Survival platform does the following:

- Shows a plot of the estimated survival function for each group. A plot for the whole sample is optional.
- Calculates and lists survival function estimates for each group and for the combined sample.
- Shows exponential, Weibull, and lognormal diagnostic failure plots to graphically check the appropriateness of using these distributions for further regression modeling. Parameter estimates are available on request.
- Computes the Log Rank and generalized Wilcoxon Chi-square statistics to test homogeneity of the estimated survival function across groups.
• Analyzes competing causes, prompting for a cause of failure variable, and estimating a Weibull failure time distribution for censoring patterns corresponding to each cause.

---

**Example of Survival Analysis**

An experiment was undertaken to characterize the survival time of rats exposed to a carcinogen in two treatment groups. The data are in the Rats.jmp sample data table. The event in this example is death. The objective is to see whether rats in one treatment group live longer (more days) than rats in the other treatment group.

1. Select **Help > Sample Data Library** and open Rats.jmp.
   - The data in the days column is the survival time. Notice that some observations are censored.
2. Select **Analyze > Reliability and Survival > Survival**.
3. Select days and click **Y, Time to Event**.
4. Select Group and click **Grouping**.
5. Select Censor and click **Censor**.
6. Click **OK**.
It appears that the rats in treatment group 1 are living longer than the rats in treatment group 2.
Launch the Survival Platform

Launch the Survival platform by selecting Analyze > Reliability and Survival > Survival.

Figure 13.3 The Survival Launch Window

For more information about the options in the Select Columns red triangle menu, see Using JMP.

The Survival launch window contains the following options:

**Y, Time to Event**  Identifies the time to event or time to censoring. If you have interval censoring, specify two Y variables, representing the lower and upper limits.

**Grouping**  Classifies the data into groups that are fit separately.

**Censor**  Identifies censored values. Enter the value that identifies censoring in the Censor Code box. This column can contain more than two distinct values under the following conditions:

- All censored rows contain the value that is entered in the Censor Code box.
- Non-censored rows have a value other than what is in the Censor Code box.

**Freq**  Indicates the column whose values are the frequencies of observations for each row when there are multiple units recorded. If the value is 0 or a positive integer, then the value represents the frequencies or counts of observations for each row.

**By**  Performs a separate analysis for each level of a classification or grouping variable.

**Plot Failure Instead of Survival**  Shows a failure probability plot instead of its reverse (a survival probability plot).

**Censor Code**  Identifies the value in the Censor column that designates right-censored observations. The default value is 1.
The Survival Plot

The Survival platform shows overlay step plots of estimated survival functions for each group. A legend identifies groups by color and line type.

**Figure 13.4** The Survival Plot

Reports beneath the plot show summary statistics and quantiles for survival times. Estimated survival times for each observation are computed within groups. Survival times are computed from the combined sample. When there is more than one group, statistical tests compare the survival curves.

If there are any failures that occur at time zero, the Failures at Time Zero report appears when you request a distribution fit from the Product-Limit Survival Fit red triangle menu. This report contains a table of counts of zero-time failures for each level of the Grouping variable. If there is no Grouping variable specified, there is one row in the table labeled Combined. The table also contains a column labeled Prob Time>0. This column is the proportion of observations in each group that has a nonzero failure time.
Survival Platform Options

The Product-Limit Survival Fit red triangle menu contains the following options:

**Survival Plot**  Shows the overlaid survival plots for each group.

**Failure Plot**  Shows the overlaid failure plots (proportion failing over time) for each group (in the tradition of the reliability literature.) A failure plot reverses the vertical axis to show the number of failures rather than the number of survivors.

*Note:* The Failure Plot option replaces the Reverse Y Axis option found in older versions of JMP (which is still available in scripts).

**Plot Options**  Contains the following options:

*Note:* The first seven options (Show Points, Show Kaplan Meier, Show Combined, Show Confid Interval, Show Simultaneous CI, Show Shaded Pointwise CI, and Show Shaded Simultaneous CI) and the last two options (Fitted Survival CI, Fitted Failure CI) pertain to the initial survival plot and failure plot. The other five (Midstep Quantile Points, Connect Quantile Points, Fitted Quantile, Fitted Quantile CI Lines, Fitted Quantile CI Shaded) pertain only to the distributional plots.

**Show Points**  Shows the sample points at each step of the survival plot. Failures appear at the bottom of the steps, and censorings are indicated by points above the steps.

**Show Kaplan Meier**  Shows the Kaplan-Meier curves. This option is on by default.

**Show Combined**  Shows the survival curve for the combined groups in the Survival Plot.

**Show Confid Interval**  Shows the pointwise 95% confidence bands on the survival plot for groups and for the combined plot when it appears with the Show Combined option.

**Show Points, Show Combined**  When you select the Show Points and Show Combined options, the survival plot for the total or combined sample appears as a gray line. The points also appear at the plot steps of each group.

**Show Simultaneous CI**  Shows the simultaneous confidence bands for all groups on the plot. Meeker and Escobar (1998, ch. 3) discuss pointwise and simultaneous confidence intervals and the motivation for simultaneous confidence intervals in survival analysis.

**Midstep Quantile Points**  Changes the plotting positions to use the modified Kaplan-Meier plotting positions. These plotting positions are equivalent to taking mid-step positions of the Kaplan-Meier curve, rather than the bottom-of-step positions. This option is recommended, so it is on by default.
**Connect Quantile Points**  Shows the lines in the plot. This option is on by default.

**Fitted Quantile**  Shows the straight-line fit on the fitted Weibull, lognormal, or exponential plot. This option is on by default.

**Fitted Quantile CI Lines**  Shows the 95% confidence bands for the fitted Weibull, lognormal, or exponential plot.

**Fitted Quantile CI Shaded**  Shows the display of the 95% confidence bands for a fit as a shaded area or dashed lines.

**Fitted Survival CI**  Shows the confidence intervals (on the survival plot) of the fitted distribution.

**Fitted Failure CI**  Shows the confidence intervals (on the failure plot) of the fitted distribution.

**Exponential Plot**  Plots the cumulative exponential failure probability by time for each group. Lines that are approximately linear empirically indicate the appropriateness of using an exponential model for further analysis. For example, in Figure 13.5, the lines for Group 1 and Group 2 in the Exponential Plot are curved rather than straight. This indicates that the exponential distribution is not appropriate for this data. See "Exponential, Weibull, and Lognormal Plots and Fits" on page 356.

**Exponential Fit**  Produces the Exponential Parameters table and the linear fit to the exponential cumulative distribution function in the Exponential Plot (Figure 13.5). The parameter Theta corresponds to the mean failure time. See "Exponential, Weibull, and Lognormal Plots and Fits" on page 356.

**Weibull Plot**  Plots the cumulative Weibull failure probability by log(time) for each group. A Weibull plot that has approximately parallel and straight lines indicates a Weibull survival distribution model might be appropriate to use for further analysis. See "Exponential, Weibull, and Lognormal Plots and Fits" on page 356.

**Weibull Fit**  Produces the linear fit to the Weibull cumulative distribution function in the Weibull plot and two popular forms of Weibull estimates. These estimates are shown in the Extreme-value Parameter Estimates table and the Weibull Parameter Estimates tables (Figure 13.5). The Alpha parameter is the 0.632 quantile of the failure-time distribution. The Extreme-value table shows a different parameterization of the same fit, where Lambda = ln(Alpha) and Delta = 1/Beta. See "Exponential, Weibull, and Lognormal Plots and Fits" on page 356.

**LogNormal Plot**  Plots the cumulative lognormal failure probability by log(time) for each group. A lognormal plot that has approximately parallel and straight lines indicates a lognormal distribution is appropriate to use for further analysis. See "Exponential, Weibull, and Lognormal Plots and Fits" on page 356.
Survival Analysis
Survival Platform Options

LogNormal Fit  Produces the linear fit to the lognormal cumulative distribution function in the lognormal plot and the LogNormal Parameter Estimates table shown in Figure 13.5. Mu and Sigma correspond to the mean and standard deviation of a normally distributed natural logarithm of the time variable. See “Exponential, Weibull, and Lognormal Plots and Fits” on page 356.

Fitted Distribution Plots  Use in conjunction with the fit options to show three plots corresponding to the fitted distributions: Survival, Density, and Hazard. If you have not performed a fit, no plot appears. See “Fitted Distribution Plots” on page 360.

Competing Causes  Performs an estimation of the Weibull model using the specified causes to indicate a failure event and other causes to indicate censoring. The fitted distribution appears as a dashed line in the Survival Plot. See “Competing Causes” on page 361.

Estimate Survival Probability  Estimates survival probabilities for the time values that you specify.

Estimate Time Quantile  Estimates a time quantile for each survival probability that you specify.

Save Estimates  Creates a data table containing survival and failure estimates, along with confidence intervals, and other distribution statistics.

Exponential, Weibull, and Lognormal Plots and Fits

For each of the three supported distributions in the Survival platform, there is a plot command and a fit command. Use the plot command to see whether the event markers seem to follow a straight line. The markers tend to follow a straight line when the distributional fit is suitable for the data. Then, use the fit commands to estimate the parameters.
The following table shows what to plot to make a straight line fit for that distribution:

**Table 13.1 Straight Line Fits for Distribution**

</tr>
</tbody>
</table>

**Note:** S = product-limit estimate of the survival distribution.
Exponential

The exponential distribution is the simplest distribution for modeling time-to-event data. The exponential distribution has only one parameter, theta. It is a constant-hazard distribution, with no memory of how long it has survived to affect how likely an event is. The parameter theta is the expected lifetime.

Weibull

The Weibull distribution is the most popular distribution for modeling time-to-event data. The Weibull distribution can have two or three parameters. The Survival platform fits the two-parameter Weibull distribution. Authors parameterize this distribution in many different ways (Table 13.2). JMP reports two of these parameterizations: the Weibull alpha-beta parameterization and a parameterization based on the smallest extreme value distribution.

The alpha-beta parameterization, shown in the Weibull Parameter Estimates report, is widely used in the reliability literature (Nelson 1990). The alpha parameter is interpreted as the quantile at which 63.2% of the units fail. The beta parameter determines how the hazard rate changes over time. If beta > 1, the hazard rate increases over time; if beta < 1, the hazard rate decreases over time; and if beta = 1, the hazard rate is constant over time. A Weibull distribution with a constant hazard function is equivalent to an exponential distribution.

The lambda-delta extreme value parameterization is shown in the Extreme-Value Parameter Estimates report. This parameterization is sometimes desirable in a statistical sense because it places the Weibull distribution in a location-scale setting (Meeker and Escobar 1998, p. 86). The location parameter is lambda, and the scale parameter is delta. In relation to the alpha-beta parameterization, lambda is equal to the natural log of alpha, and delta is equal to the reciprocal of beta. Therefore, the delta parameter determines how the hazard rate changes over time. If delta > 1, the hazard rate decreases over time; if delta < 1, the hazard rate increases over time; and if delta = 1, the hazard rate is constant over time. A Weibull distribution with a constant hazard function is equivalent to an exponential distribution.

</table>
The lognormal distribution is also very popular for modeling time-to-event data. The lognormal distribution is equivalent to the distribution where if you take the log of the values, the distribution is normal. If you want to fit a normal distribution to your data, you can take the exp() of it and model your data with a lognormal distribution. See “Additional Examples of Fitting Parametric Survival” on page 383 in the “Fit Parametric Survival” chapter.

**Additional Options**

To see additional options for the exponential, Weibull, and lognormal fits, press Shift, click the red triangle next to Product-Limit Survival Fit, and select the desired fit.

Use these options to do the following tasks:

- Set the confidence level for the limits.
- Set the constrained value for theta (in the case of an exponential fit), sigma (in the case of a lognormal fit) or beta (in the case of a Weibull fit). See “WeiBayes Analysis” on page 360.
- Obtain a Confidence Contour Plot for the Weibull and lognormal fits (when there are no constrained values).
WeiBayes Analysis

JMP can constrain the values of the Theta (Exponential), Beta (Weibull), and Sigma (LogNormal) parameters when fitting these distributions. This feature is needed in WeiBayes situations, for example:

- Where there are few or no failures
- There are existing historical values for beta
- There is still a need to estimate alpha

For more information about WeiBayes situations, see Abernethy (1996).

With no failures, the standard technique is to add a failure at the end. Then, the estimates reflect a type of lower bound on the alpha value, rather than a real estimate. However, the WeiBayes feature allows for a true estimation.

Fitted Distribution Plots

Use the Fitted Distribution Plots option to see Survival, Density, and Hazard plots for the exponential, Weibull, and lognormal distributions. The plots share the same axis scaling so that the distributions can be easily compared.
These plots can be transferred to other graphs through the use of graphic scripts. To copy the graph, right-click in the plot to be copied and select Edit > Copy Frame Contents. Right-click in the destination plot and select Edit > Paste Frame Contents.

**Competing Causes**

Sometimes there are multiple causes of failure in a system. For example, suppose that a manufacturing process has several stages and the failure of any stage causes a failure of the whole system. If the different causes are independent, the failure times can be modeled by an estimation of the survival distribution for each cause. A censored estimation is undertaken for a given cause by treating all the event times that are not from that cause as censored observations.

The Competing Causes red triangle menu contains the following options:

- **Omit Causes**  Removes the specified cause value and recalculates the survival estimates.
**Save Cause Coordinates**  Adds a new column to the current table called log(–log(Surv)). This information is often used to plot against the time variable with a grouping variable, such as the code for type of failure.

**Weibull Lines**  Adds Weibull lines to the plot.

**Hazard Plot**  Adds a Hazard Plot.

**Simulate**  Creates a new data table containing time and cause information from the Weibull distribution, as estimated by the data.

---

### Additional Examples of the Survival Platform

- “Example of Survival Analysis”
- “Example of Competing Causes”
- “Example of Interval Censoring”

### Example of Survival Analysis

The failure of diesel generator fans was studied by Nelson (1982, p. 133) and Meeker and Escobar (1998, app. C1).

1. Select **Help > Sample Data Library** and open Reliability/Fan.jmp.
2. Select **Analyze > Reliability and Survival > Survival.**
3. Select Time and click **Y, Time to Event.**
4. Select Censor and click **Censor.**
5. Select the check box for **Plot Failure instead of Survival.**
6. Click **OK.**
Notice that the probability of failure increases over time. Often the next step is to explore distributional fits, such as a Weibull model. Click the red triangle next to Product-Limit Survival Fit and select **Weibull Plot** and **Weibull Fit**.
Because the fit is reasonable and the Beta estimate is near 1, you can conclude that this looks like an exponential distribution, which has a constant hazard rate. Click the Weibull Plot red triangle and select **Fitted Distribution Plots**. Three views of the Weibull fit appear.

### Example of Competing Causes

Nelson (1982) discusses the failure times of a small electrical appliance that has a number of causes of failure. One group (Group 2) of the data is represented in the JMP sample data table `Appliance.jmp`.

1. Select **Help > Sample Data Library** and open `Reliability/Appliance.jmp`. 

---

**Figure 13.9 Weibull Output for Fan Data**

![Weibull Plot](image)

**Figure 13.10 Fitted Distribution Plots**

![Fitted Distributions](image)
2. Select **Analyze > Reliability and Survival > Survival**.
3. Select Time Cycles and click **Y, Time to Event**.
4. Click **OK**.
5. Click the red triangle next to Product-Limit Survival Fit and select **Competing Causes**.
6. Click Cause Code, and click **OK**.
7. Click the Competing Causes red triangle and select **Hazard Plot**.

**Figure 13.11** Competing Causes Report and Hazard Plot

The survival distribution for the whole system is simply the product of the survival probabilities. The Competing Causes table shows the Weibull estimates of Alpha and Beta for each failure cause.

In this example, most of the failures were due to cause 9. Cause 1 occurred only once and could not produce good Weibull estimates. Cause 15 happened for very short times and resulted in a small beta and large alpha. Recall that alpha is the estimate of the 63.2% quantile of failure time, which means that causes with early failures often have very large alphas. If these causes do not result in early failures, then these causes do not usually cause later failures.

Figure 13.12 shows the Fit Y by X plot of Time Cycles by Cause Code with the Quantiles option in effect. This plot further illustrates how the alphas and betas relate to the failure distribution.
In this example, recall that cause 9 was the source of most of the failures. If cause 9 was corrected, how would that affect the survival due to the remaining causes? Select the Omit Causes option to remove a cause value and recalculate the survival estimates.

Figure 13.13 shows the survival plots with all competing causes and without cause 9. You can see that the survival rate (represented by the dashed line) without cause 9 does not improve much until 2,000 cycles. It then becomes much better and remains improved, even after 10,000 cycles.

**Figure 13.13 Survival Plots with Omitted Causes**
Example of Interval Censoring

With interval censored data, you know only that the events occurred in some time interval. The Turnbull method is used to obtain nonparametric estimates of the survival function.

In this example from Nelson (1990, p. 147), microprocessor units are tested and inspected at various times and the failed units are counted. Missing values in one of the columns indicate that you do not know the lower or upper limit, and therefore the event is left or right censored, respectively.

1. Select Help > Sample Data Library and open Reliability/Microprocessor Data.jmp.
2. Select Analyze > Reliability and Survival > Survival.
3. Select start time and end time and click Y, Time to Event.
4. Select count and click Freq.
5. Select the check box next to Plot Failure instead of Survival.
6. Click OK.
7. Click the red triangle next to Product-Limit Survival Fit and select LogNormal Fit.

Figure 13.14  Interval Censoring Output
The resulting Turnbull estimates are shown. Turnbull estimates might have gaps in time where the survival probability is not estimable. In this example, such gaps occur between 6 and 12, 24 and 48, 48 and 168, and so on.

At this point, select a distribution to see its fitted estimates — in this case, a Lognormal distribution is fit. Notice that the failure plot shows very small failure rates for these data.

**Statistical Reports for Survival Analysis**

For data that is not interval censored, the initial reports show Summary and Quantiles data (Figure 13.15). The Summary data shows the number of failed and number of censored observations for each group (when there are groups) and for the whole study. The mean and standard deviations are also adjusted for censoring. For computational details about these statistics, see the LIFETEST Procedure chapter in SAS Institute Inc. (2020).

The Quantiles data shows time to failure statistics for individual and combined groups. These include the median survival time, with upper and lower 95% confidence limits. The median survival time is the time (number of days) at which half the subjects have failed. The quartile survival times (25% and 75%) are also included.

**Figure 13.15** Summary Statistics for the Univariate Survival Analysis

![Summary Statistics for the Univariate Survival Analysis](image)

The Summary report gives estimates for the mean survival time, as well as the standard error of the mean. The estimated mean survival time is defined as follows:

\[
\hat{\mu} = \frac{\sum_{i=1}^{D} S(t_{i-1})(t_i - t_{i-1})}{m - 1} \\
\text{with a standard error of } \hat{\sigma}(\hat{\mu}) = \sqrt{\frac{m}{m - 1} \sum_{i=1}^{D - 1} \frac{A_i^2}{n_i(n_i - d_i)}}
\]
where

\[ \hat{S}(t_i) = \prod_{j=1}^{D-1} \left( 1 - \frac{d_j}{n_j} \right) \]

\[ A_i = \sum_{j=i}^{D-1} \hat{S}(t_j)(t_j + 1 - t_j) \]

\[ m = \sum_{j=1}^{D} d_j \]

\( \hat{S}(t_i) \) is the survival distribution at time \( t_i \)

\( D \) is the number of distinct event times

\( n_i \) is the number of surviving units just prior to \( t_i \)

\( d_i \) is the number of units that fail at \( t_i \)

\( t_0 \) is defined to be 0

When there are multiple groups, the Tests Between Groups table provides statistical tests for homogeneity among the groups. Kalbfleisch and Prentice (1980, ch. 1), Hosmer and Lemeshow (1999, ch. 2), and Klein and Moeschberger (1997, ch. 7) discuss statistics and comparisons of survival curves.

**Figure 13.16** Tests between Groups

<table>

<td>0.0772</td>
</tr>
<tr>
<td>Wilcoxon</td>
<td>2.0510</td>
<td>1</td>
<td>0.1035</td>
</tr>
</tbody>
</table>

**Test** Names two statistical tests of the hypothesis that the survival functions are the same across groups.

**Chi-Square** Provides the Chi-square approximations for the statistical tests.

The **Log-Rank** test places more weight on larger survival times and is more useful when the ratio of hazard functions in the groups being compared is approximately constant. The hazard function is the instantaneous failure rate at a given time. It is also called the *mortality rate* or *force of mortality*.

The **Wilcoxon** test places more weight on early survival times and is the optimum rank test if the error distribution is logistic. See Kalbfleisch and Prentice (1980).

**DF** Provides the degrees of freedom for the statistical tests.
**Prob>ChiSq** Lists the probability of obtaining a Chi-square value greater than the one computed if the survival functions are the same for all groups.

Figure 13.17 shows an example of the product-limit survival function estimates for one group.

**Note:** When the final time recorded is a censored observation, the report indicates a biased mean estimate. The biased mean estimate is a lower bound for the true mean.
Survival times can be expressed as a function of one or more variables. When this is the case, use a regression platform that fits a linear regression model while taking into account the survival distribution and censoring. The Fit Parametric Survival platform fits the time to event $Y$ (with censoring) using linear regression models that can involve both location and scale effects. The fit is performed using the Weibull, lognormal, exponential, Fréchet, loglogistic, smallest extreme value (SEV), normal, largest extreme value (LEV), and logistic distributions.

**Note:** The Fit Parametric Survival platform is a slightly customized version of the Fit Model platform. You can also fit parametric survival models using the Nonlinear platform.

Overview of the Fit Parametric Survival Platform

Survival times can be expressed as a function of one or more variables. When this is the case, use a regression platform that fits a linear regression model while taking into account the survival distribution and censoring. The Fit Parametric Survival platform fits the time to event \( Y \) (with censoring) using linear regression models that can involve both location and scale effects. The fit is performed using the Weibull, lognormal, exponential, Fréchet, loglogistic, SEV, normal, LEV, and logistic distributions.

Example of Parametric Regression Survival Fitting

The data table Comptime.jmp contains data on the analysis of computer program execution time whose lognormal distribution depends on the effect Load.

**Note:** The data in Comptime.jmp comes from Meeker and Escobar (1998, p. 434).

1. Select *Help > Sample Data Library* and open Reliability/Comptime.jmp.
2. Select *Analyze > Reliability and Survival > Fit Parametric Survival*.
3. Select ExecTime and click *Time to Event*.
4. Select Load and click *Add*.
5. Change the *Distribution* from *Weibull* to *Lognormal*.
6. Click *Run*.
Figure 14.2 Computing Time Output

When there is only one effect, a plot of the survival quantiles for three survival probabilities are shown as a function of the effect.

Time quantiles are desired for when 90% of jobs are finished under a system load of 5. See Meeker and Escobar (1998, p. 438).

7. Click the Parametric Survival Fit red triangle and select **Estimate Quantile**.
8. Type 5 in the first row beneath **Load**.
9. Type 0.9 in the first row beneath **p**.
10. Click **Go**.
Figure 14.3 Estimates of Time Quantile

<table>
<thead>
<tr>

<th>Upper 95%</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>571.21575</td>
<td>813.0482</td>
</tr>
</tbody>
</table>

The report estimates that 90% of the jobs will be done by 571 seconds of execution time under a system load of 5.

Launch the Fit Parametric Survival Platform

Launch the Fit Parametric Survival platform by selecting **Analyze > Reliability and Survival > Fit Parametric Survival**.

Figure 14.4 The Fit Parametric Survival Launch Window

Tip: To change the alpha level, click the Model Specification red triangle and select **Set Alpha Level**.

For more information about the options in the Select Columns red triangle menu, see **Using JMP**.
The Fit Parametric Survival launch window contains the following options:

**Time to Event**  Contains the time to event or time to censoring. With interval censoring, specify two Y variables, where one Y variable gives the lower limit and the other Y variable gives the upper limit for each unit.

**Censor**  Specifies a column with indicators to identify right-censored observations. Select the value that identifies right-censored observations from the Censor Code menu. The Censor column is used only when one Time to Event column is entered.

**Freq**  Specifies a column that contains the frequencies or counts of observations for each row when there are multiple units recorded.

**Cause**  Specifies a column that contains multiple failure causes. This column is particularly useful for estimating competing causes. A separate parametric fit is performed for each cause value. Failure events can be coded with either numeric or categorical (labels) values.

**By**  Performs a separate analysis for each level of a classification or grouping variable.

**Location and Scale Effects**  Specifies location and scale effects. For more information about the Construct Model Effects options, see *Fitting Linear Models*.

**Personality**  Indicates the fitting method. Parametric Survival should always be selected.

**Distribution**  Choose the desired response distribution that is appropriate for your data. Choose the All Distributions option to fit all the distributions and compare the fits. If you choose All Distributions, the report shows a comparison of the distribution fits. See “The Parametric Survival - All Distributions Report” on page 378.

---

**Note:** By default, the All Distributions option fits a model for the log-location-scale distributions that appear above All Distributions in the Distribution menu. Select Preferences > Platforms > Fit Parametric Survival > Include location-scale distributions in All Distributions to change the behavior of the All Distributions option to also include the location-scale distributions.

**Censor Code**  Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.
The Parametric Survival Fit Report

If you select All Distributions in the launch window, a Parametric Survival Fit report appears for each distribution. If you specify a Cause column in the launch window, a Parametric Survival Fit report appears for each cause. Otherwise, only one Parametric Survival Fit report appears. Each Parametric Survival Fit report contains the following:

**Effect Summary**  Shows an interactive report that enables you to add or remove effects from the model. See *Fitting Linear Models*.

**Model Fit Details**  The Time to event shows which Y column is specified, and the Distribution shows which distribution is fit. AICc, BIC, and -2Loglikelihood are all measures of the model fit. These measures allow for comparisons to other model fits. Observation Used and Uncensored Values are summary statistics for the data. See *Fitting Linear Models*.

**Whole Model Test**  Compares the complete fit with an intercept-only fit. If there is only an intercept term, the fit is the same as that from the Life Distribution platform.

**Parameter Estimates**  Shows the estimates of the regression parameters.

A link to launch the Generalized Regression platform appears below the Parameter Estimates table. The link enables you to perform variable selection using the Generalized Regression platform and appears under the following circumstances:

- The model has no scale effects.
- No Cause column is specified in the launch window.
- The Distribution specified in the launch window is Normal, Lognormal, or Weibull.

**Alternate Parameterization**  (Available only for the Weibull distribution.) Shows the parameter estimates for the $\alpha$ and $\beta$ parameterization of the Weibull distribution. For more information about this parameterization, see “Weibull” on page 85 in the “Life Distribution” chapter.

**Wald Tests**  Shows a Wald Chi-square test for each term in the model.

**Effect Likelihood Ratio Tests**  Compare the log-likelihood from the fitted model to one that removes each term from the model individually.

**Plot Survival Quantiles**  Shows the data points plotted with the 0.1, 0.5, and 0.9 quantiles.
**The Parametric Survival - All Distributions Report**

The Parametric Survival - All Distributions report appears only when you select All Distributions in the launch window. By default, this report contains a Model Comparison report and Distribution Overlay plot. The Quantile Function Overlay plot is available in the red triangle menu next to Parametric Survival - All Distributions.

**Model Comparison** Table that lists fit statistics (AICc and BIC) for the fitted distributions. The distributions with the smallest AICc and BIC values are labeled in the right-most column. If one distribution has the smallest value for both AICc and BIC, that distribution is labeled “Best”. The Parametric Survival Fit report corresponding to the distribution with
the smallest AICc is open by default. For more information about these statistics, see *Fitting Linear Models*.

**Distribution Overlay**  Plot of overlaid distribution functions for the fitted distributions at specified values of the effects.

**Quantile Function Overlay**  Plot of overlaid quantile functions for the fitted distributions at specified values of the effects.

Both the Distribution Overlay and Quantile Function Overlay plots show curves for each of the fitted distributions overlaid on the same graph. By default, each curve has a shaded Wald-based confidence interval. To the right of each plot, there is legend, an option to show shading of confidence intervals, and controls that enable you to specify different values of the effects. Figure 14.6 shows an example of a Distribution Overlay plot.

**Note:** You can change the $\alpha$ level for the shaded confidence intervals by selecting Set Alpha Level from the red triangle menu in the Fit Model launch window. The default $\alpha$ level is 0.05.

**Figure 14.6** Distribution Overlay Plot
Parametric Competing Cause Report

If you specify a Cause column in the launch window, the Parametric Competing Cause report appears. If you also specify All Distributions in the launch window, this report is labeled Parametric Competing Cause - All Distributions. The Parametric Competing Cause report contains the following:

**Summary by Cause**  Table that lists fit statistics (AICc and BIC) for each cause. If All Distributions is selected for the Distribution option in the launch window, this table includes fit statistics for each cause within each distribution fit.

**Model Comparison**  (Available only when All Distributions is selected for the Distribution option in the launch window.) Shows a table that lists fit statistics (AICc and BIC) for the fitted distributions. The distributions with the smallest AICc and BIC values are labeled in the right-most column. If one distribution has the smallest value for both AICc and BIC, that distribution is labeled “Best”. The Parametric Survival Fit report corresponding to the distribution with the smallest AICc is open by default.

For more information about the AICc and BIC statistics, see *Fitting Linear Models*.

Fit Parametric Survival Options

The Parametric Survival Fit red triangle menu contains the following options:

**Likelihood Ratio Tests**  Produces tests that compare the log-likelihood from the fitted model to one that removes each term from the model individually.

**Wald Tests**  Produces chi-square test statistics and p-values for Wald tests of whether each parameter is zero.

**Likelihood Confidence Intervals**  Specifies the type of confidence intervals shown in the Parameter Estimates table for each parameter. When this option is selected, a profile likelihood confidence interval appears. Otherwise, a Wald interval is shown. In the report, the interval type is noted below the Parameter Estimates table. This option is on by default when the computational time for the profile likelihood confidence intervals is not large.

**Note:** You can change the α level for the confidence intervals by selecting Set Alpha Level from the red triangle menu in the Fit Model launch window. The default α level is 0.05.

**Correlation of Estimates**  Produces a correlation matrix for the model effects with each other and with the parameter of the fitting distribution.
Covariance of Estimates  Produces a covariance matrix for the model effects with each other and with the parameter of the fitting distribution.

Estimate Survival Probability  Estimates the failure and survival probabilities for the given time values. Specify effect values and one or more time values. JMP then calculates the survival and failure probabilities with 95% confidence limits for all possible combinations of the entries.

Estimate Quantile  Estimates the quantiles for the given probabilities. Specify effect values and one or more quantile probabilities. JMP then calculates the time quantiles and 95% confidence limits for all possible combinations of the entries.

Note: For the Estimate Survival Probability and Estimate Quantile options, you can change the alpha level from the default of 0.05.

Residual Probability Plot  Shows a probability plot of the standardized residuals.

Save Residuals  Saves the residuals to a new column in the data table. For interval-censored observations, two columns of residuals are saved to the data table.

Distribution Profiler  Shows the response surfaces of the failure probability versus individual explanatory and response variables.

Quantile Profiler  Shows the response surfaces of the response variable versus the explanatory variable and the failure probability.

Distribution Plot by Level Combinations  Shows three probability plots for assessing model fit. The plots show different lines for each combination of the X levels.

Separate Location  A probability plot assuming equal scale parameters and separate location parameters. This is useful for assessing the parallelism assumption.

Separate Location and Scale  A probability plot assuming different scale and location parameters. This is useful for assessing if the distribution is adequate for the data. This plot is not shown for the Exponential distribution.

Regression  A probability plot for which the distribution parameters are functions of the X variables.

Save Probability Formula  Saves the estimated probability formula to a new column in the data table.

Save Quantile Formula  Saves the estimated quantile formula to a new column in the data table. Selecting this option displays a pop-up window, asking you to enter a probability value for the quantile of interest.
Publish Probability Formula  Creates a probability formula and saves it as a formula column script in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See *Predictive and Specialized Modeling*.

Publish Quantile Formula  Creates a quantile formula and saves it as a formula column script in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See *Predictive and Specialized Modeling*.

Model Dialog  Relaunches the launch window.

Effect Summary  Shows the interactive Effect Summary report that enables you to add or remove effects from the model. See *Fitting Linear Models*.

See *Using JMP* for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Nonlinear Parametric Survival Models

Use the Nonlinear platform for survival models in the following instances:

- The model is nonlinear.
- You need a distribution other than Weibull, lognormal, exponential, Fréchet, loglogistic, SEV, normal, LEV, or logistic.
- You have censoring that is not the usual right, left, or interval censoring.

With the ability to estimate parameters in specified loss functions, the Nonlinear platform becomes a powerful tool for fitting maximum likelihood models. For complete information about the Nonlinear platform, see *Predictive and Specialized Modeling*. 
To fit a nonlinear model when data are censored, you must first use the formula editor to create a parametric equation that represents a loss function adjusted for censored observations. Then use the Nonlinear platform to estimate the parameters using maximum likelihood.

### Additional Examples of Fitting Parametric Survival

- “Arrhenius Accelerated Failure LogNormal Model”
- “Interval-Censored Accelerated Failure Time Model”
- “Analyze Censored Data Using the Nonlinear Platform”
- “Left-Censored Data”
- “Weibull Loss Function Using the Nonlinear Platform”
- “Fitting Simple Survival Distributions Using the Nonlinear Platform”

### Arrhenius Accelerated Failure LogNormal Model

In the Devalt.jmp data, units are stressed by heating, in order to make them fail soon enough to obtain enough failures to fit the distribution.

**Note:** The data in Devalt.jmp comes from Meeker and Escobar (1998, p. 493).

1. Select **Help > Sample Data Library** and open Reliability/Devalt.jmp.
   - First, use the Bivariate platform to see a plot of hours by temperature using the log scale for time.
2. Select **Analyze > Fit Y by X**.
3. Select **Hours** and click **Y, Response**.
4. Select **Temp** and click **X, Factor**.
5. Click **OK**.
Next, use the survival platform to produce a LogNormal plot of the data for each temperature.

6. Select **Analyze > Reliability and Survival > Survival.**
7. Select Hours and click **Y, Time to Event.**
8. Select Censor and click **Censor.**
9. Select Temp and click **Grouping.**
10. Select Weight and click **Freq.**
11. Click **OK.**
12. Click the red triangle next to Product-Limit Survival Fit and select **LogNormal Plot** and **LogNormal Fit.**
13. Click **OK.**

**Figure 14.8** Lognormal Plot
Next, use the Fit Parametric Survival platform to fit one model using an effect for temperature.

14. Select **Analyze > Reliability and Survival > Fit Parametric Survival**.
15. Select Hours and click **Time to Event**.
16. Select x and click **Add**.
17. Select Censor and click **Censor**.
18. Select Weight and click **Freq**.
19. Change the **Distribution** type to **Lognormal**.
20. Click **Run**.
The result shows the regression fit of the data:

- If there is only one effect and it is continuous, then a plot of the survival as a function of the effect is shown. Lines are at 0.1, 0.5, and 0.9 survival probabilities.

- If the effect column has a formula in terms of one other column, as in this case, the plot is done with respect to the inner column. In this case, the effect was the column $x$, but the plot is done with respect to Temp, of which $x$ is a function.

Finally, get estimates of survival probabilities extrapolated to a temperature of 10 degrees Celsius for the times 30000 and 10000 hours.
21. Click the Parametric Survival Fit red triangle and select **Estimate Survival Probability**.

22. Enter the values shown in Figure 14.10 into the Dialog to Estimate Survival.

The Arrhenius transformation of 10 degrees is 40.9853, the effect value.

**Figure 14.10** Estimating Survival Probabilities

23. Click **Go**.

**Figure 14.11** Survival Probabilities

The Estimates of Survival report shows the estimates and a confidence interval.

**Interval-Censored Accelerated Failure Time Model**

The ICdevice02.jmp data shows failures that were found to have happened between inspection intervals. The model uses two $y$-variables, containing the upper and lower bounds on the failure times. Right-censored times are shown with missing upper bounds.

**Note:** The data in ICdevice02.jmp comes from Meeker and Escobar (1998, p. 640).

1. Select **Help > Sample Data Library** and open Reliability/ICdevice02.jmp.
2. Select **Analyze > Reliability and Survival > Fit Parametric Survival**.
3. Select HoursL and HoursU and click **Time to Event**.
4. Select Count and click **Freq**.
5. Select $x$ and click **Add**.
6. Click **Run**.
The resulting regression shows a plot of time by degrees.

**Analyze Censored Data Using the Nonlinear Platform**

You can analyze left-censored data using the Nonlinear platform. For the left-censored data, zero is the censored value because it also represents the smallest known time for an observation.
Note: The Tobit model is popular in economics for responses that must be positive or zero, with zero representing a censored point.

Note the following about the Tobit2.jmp data table:

- The response variable is a measure of the durability of a product and cannot be less than zero (Durable, is left-censored at zero).
- Age and Liquidity are independent variables.
- The table also includes the model and Tobit loss function. The model in residual form is \( \text{durable} - (b_0 + b_1 \times \text{age} + b_2 \times \text{liquidity}) \). To see the formula associated with Tobit Loss, right-click the column and select Formula.

Fit the Tobit model:

1. Select Help > Sample Data Library and open Reliability/Tobit2.jmp.
2. Select Analyze > Specialized Modeling > Nonlinear.
3. Select Model and click X, Predictor Formula.
4. Select Tobit Loss and click Loss.
5. Click OK.
6. Click Go.
7. Click Confidence Limits.

Figure 14.13 Solution Report
Left-Censored Data

The Tobit model from the previous section assumes a normal distribution that is censored at zero. An observation of zero is considered to be left-censored. In the Fit Parametric Survival platform, left-censored observations are specified using two response columns. In this example, you create a new column that indicates observations for which left censoring has occurred. For left-censored observations, the new column contains a missing value. Otherwise, it contains the observed value of durable. The new column is then used as the left side of interval-censored observations, and the existing column durable is used as the right side of the intervals.

1. Select Help > Sample Data Library and open Reliability/Tobit2.jmp.

Create the Left Censoring Column:

2. Select Cols > New Columns.
3. Type durable0 for Column Name.
4. Select Column Properties and click Formula.
5. Select Conditional > If and select durable.
6. Select Comparison > a == b, type 0, and press Enter.
7. Select the box labeled “else clause” and select durable.

Figure 14.14 shows the completed formula.

Figure 14.14 Column Formula for durable0

8. Click OK.
9. Click OK.

Fit the Tobit Model:

10. Select Analyze > Reliability and Survival > Fit Parametric Survival.
11. Select durable0 and click Time to Event.
12. Select durable and click Time to Event.

You must use two response columns to specify left-censored observations. The direction of censoring is determined by the order of the columns in the Time to Event role.
13. Select age and liquidity and click Add.
15. Click Run.

**Figure 14.15** Tobit Model Results

The report shows the estimated Tobit model fit. Note in the upper right part of the report that there are 13 left-censored observations. This is a good way to check that you have correctly specified the left censoring.

**Weibull Loss Function Using the Nonlinear Platform**

In this example, models are fit to the survival time using the Weibull, lognormal, and exponential distributions. Model fits include a simple survival model containing only two effects, a more complex model with all the effects, and the creation of dummy variables for the discrete effect Cell Type to be included in the full model.

Nonlinear model fitting is often sensitive to the initial values that you give to the model parameters. In this example, one way to find reasonable initial values is to first use the Nonlinear platform to fit only the linear model. When the model converges, the solution values for the parameters become the initial parameter values for the nonlinear model.

1. Select Help > Sample Data Library and open VA Lung Cancer.jmp.
   The first model and all the loss functions have already been created as formulas in the data table. The Model column has the following formula:
   \[
   \log(:Time) - (b0 + b1 * \text{Age} + b2 * \text{Diag Time})
   \]
2. Select Analyze > Specialized Modeling > Nonlinear.
3. Select Model and click \textbf{X, Predictor Formula}.
4. Click \textbf{OK}.
5. Click \textbf{Go}.

**Figure 14.16** Initial Parameter Values in the Nonlinear Fit Control Panel

The report computes the least squares parameter estimates for this model.

6. Click \textbf{Save Estimates}.

The parameter estimates in the column formulas are set to those estimated by this initial nonlinear fitting process.

The Weibull column contains the Weibull formula, explained in “Weibull Loss Function” on page 397.

To continue with the fitting process:

7. Select \textbf{Analyze} > \textbf{Specialized Modeling} > \textbf{Nonlinear} again.
8. Select Model and click \textbf{X, Predictor Formula}.
9. Select Weibull loss and click \textbf{Loss}.
10. Click **OK**.

The Nonlinear Fit Control Panel on the left in Figure 14.17 appears. There is now the additional parameter called sigma in the loss function. Because it is in the denominator of a fraction, a starting value of 1 is reasonable for sigma. When using any loss function other than the default, the **Loss is Neg LogLikelihood** box on the Control Panel is checked by default.

11. Click **Go**.

The fitting process converges as shown on the right in Figure 14.17.

**Figure 14.17** Nonlinear Model with Custom Loss Function

The fitting process estimates the parameters by maximizing the negative log of the Weibull likelihood function.

12. (Optional) Click **Confidence Limits** to show lower and upper 95% confidence limits for the parameters in the Solution table.

**Figure 14.18** Solution Report
Fit Parametric Survival
Additional Examples of Fitting Parametric Survival Reliability and Survival Methods

**Note:** Because the confidence limits are profile likelihood confidence intervals instead of the standard asymptotic confidence intervals, they can take time to compute.

You can also run the model with the predefined exponential and lognormal loss functions. Before you fit another model, reset the parameter estimates to the least squares estimates, as they might not converge otherwise. To reset the parameter estimates:

13. (Optional) Click the Nonlinear Fit red triangle and select **Revert to Original Parameters**.

**Fitting Simple Survival Distributions Using the Nonlinear Platform**

The following examples show how to use maximum likelihood methods to estimate distributions from time-censored data when there are no effects other than the censor status.

The Loss Function Templates folder has templates with formulas for exponential, extreme value, loglogistic, lognormal, normal, and one-and two-parameter Weibull loss functions. To use these loss functions, copy your time and censor values into the Time and censor columns of the loss function template. To run the model, select **Nonlinear** and assign the loss column as the **Loss** variable. Because both the response model and the censor status are included in the loss function and there are no other effects, you do not need a prediction column (model variable).

**Exponential, Weibull, and Extreme-Value Loss Function**

The Fan.jmp data table can be used to illustrate the Exponential, Weibull, and Extreme value loss functions discussed in Nelson (1982). The data are from a study of 70 diesel fans that accumulated a total of 344,440 hours in service. The fans were placed in service at different times. The response is failure time of the fans or run time, if censored.

**Tip:** To view the formulas for the loss functions, in the Fan.jmp data table, right-click the Exponential, Weibull, and Extreme value columns and select **Formula**.

1. Select **Help > Sample Data Library** and open Reliability/Fan.jmp.
2. Select **Analyze > Specialized Modeling > Nonlinear**.
3. Select Exponential and click **Loss**.
4. Click **OK**.
5. Make sure that the Loss is Neg LogLikelihood check box is selected.
6. Click **Go**.
7. Click **Confidence Limits**.
8. Repeat these steps, but select Weibull and Extreme value instead of Exponential.
Lognormal Loss Function

The Locomotive.jmp data can be used to illustrate a lognormal loss. The lognormal distribution is useful when the range of the data is several powers of \( e \).

**Tip:** To view the formula for the loss function, in the Locomotive.jmp data table, right-click the `logNormal` column and select **Formula**.

The lognormal loss function can be very sensitive to starting values for its parameters. Because the lognormal distribution is similar to the normal distribution, you can create a new variable that is the natural log of `Time` and use **Distribution** to find the mean and standard deviation of this column. Then, use those values as starting values for the Nonlinear platform. In this example, the mean of the natural log of `Time` is 4.72 and the standard deviation is 0.35.

1. Select **Help > Sample Data Library** and open Reliability/Locomotive.jmp.
2. Select **Analyze > Specialized Modeling > Nonlinear**.
3. Select **logNormal** and click **Loss**.
4. Click **OK**.
5. Type 4.72 in the box next to Mu.
6. Type 0.35 in the box next to sigma.
7. Click **Go**.
8. Click **Confidence Limits**.

**Figure 14.20 Solution Report**

The maximum likelihood estimates of the lognormal parameters are 5.11692 for Mu and 0.7055 for Sigma. The corresponding estimate of the median of the lognormal distribution is the antilog of 5.11692, \(e^{5.11692}\), which is approximately 167. This represents the typical life for a locomotive engine.
Statistical Details for the Fit Parametric Survival Platform

This section contains statistical details for the Fit Parametric Survival platform.

Loss Formulas for Survival Distributions

The following formulas are for the negative log-likelihoods to fit common parametric models. Each formula uses the calculator if conditional function with the uncensored case of the conditional first and the right-censored case as the Else clause. You can copy these formulas from tables in the Loss Function Templates folder in Sample Data and paste them into your data table.

Exponential Loss Function

In the exponential loss function shown here, \( \sigma \) represents the mean of the exponential distribution and \( \text{Time} \) is the age at failure.

\[
\begin{align*}
\text{Censor} & = 0 \Rightarrow - \log(\sigma) - \frac{\text{Time}}{\sigma} \\
\text{else} & \Rightarrow - \left( \frac{\text{Time}}{\sigma} \right)
\end{align*}
\]

A characteristic of the exponential distribution is that the instantaneous failure rate remains constant over time. This means that the chance of failure for any subject during a given length of time is the same regardless of how long a subject has been in the study.

Weibull Loss Function

The Weibull density function often provides a good model for the lifetime distributions. You can use the Survival platform for an initial investigation of data to determine whether the Weibull loss function is appropriate for your data.

\[
\begin{align*}
\text{Censor} & = 0 \Rightarrow \frac{\text{Model}}{\sigma} - \exp \left( \frac{\text{Model}}{\sigma} \right) - \log(\sigma) \\
\text{else} & \Rightarrow - \exp \left( \frac{\text{Model}}{\sigma} \right)
\end{align*}
\]

There are examples of one-parameter, two-parameter, and extreme-value functions in the Loss Function Templates folder.
Lognormal Loss Function

The formula shown below is the lognormal loss function where Normal Distribution(model/sigma) is the standard normal distribution function. The hazard function has value 0 at $t = 0$, increases to a maximum, and then decreases. The hazard function approaches zero as $t$ becomes large.

$$\begin{cases} 
    \text{censor} = 0 & \Rightarrow -0.5 \cdot \log\left(\frac{\text{Model}}{\text{sigma}}\right)^2 - 0.5 \cdot \log\left(2 \cdot \text{pi}\right) - \log(\text{sigma}) \\
    \text{else} & \Rightarrow \log\left(1 - \text{Normal Distribution}\left(\frac{\text{Model}}{\text{sigma}}\right)\right)
\end{cases}$$

Loglogistic Loss Function

If $Y$ is distributed as the logistic distribution, $\exp(Y)$ is distributed as the loglogistic distribution.

$$\begin{cases} 
    \text{censor} = 0 & \Rightarrow \frac{\text{Model}}{\text{sigma}} - 2 \cdot \log\left(1 + \exp\left(\frac{\text{Model}}{\text{sigma}}\right)\right) - \log(\text{sigma}) \\
    \text{else} & \Rightarrow -\log\left(1 + \exp\left(\frac{\text{Model}}{\text{sigma}}\right)\right)
\end{cases}$$
The Fit Proportional Hazards platform fits the Cox proportional hazards model, which assumes a multiplying relationship between covariates (predictors) and the hazard function.

Proportional hazards models are popular regression models for survival data with covariates. This model is semiparametric. The linear model is estimated, but the form of the hazard function is not. Time-varying covariates are not supported.

**Note:** The Fit Proportional Hazards platform is a slightly customized version of the Fit Model platform.

Overview of the Fit Proportional Hazards Platforms

The proportional hazards model is a special semiparametric regression model proposed by D. R. Cox (1972) to examine the effect of explanatory variables on survival times. The survival time of each member of a population is assumed to follow its own hazard function.

The proportional hazards model is nonparametric in the sense that it involves an unspecified arbitrary baseline hazard function. It is parametric because it assumes a parametric form for the covariates. The baseline hazard function is scaled by a function of the model’s (time-independent) covariates to give a general hazard function. Unlike the Kaplan-Meier analysis, proportional hazards computes parameter estimates and standard errors for each covariate. The regression parameters (β) associated with the explanatory variables and their standard errors are estimated using the maximum likelihood method. A conditional risk ratio (or hazard ratio) is also computed from the parameter estimates.

The survival estimates in proportional hazards are generated using an empirical method. See Lawless (1982). They represent the empirical cumulative hazard function estimates, \( H(t) \), of the survivor function, \( S(t) \), and can be written as \( S_0 = \exp(-H(t)) \). The hazard function is defined as follows:

\[
H(t) = \sum_{j: t_j < t} \frac{d_j}{\sum_{l \in R_j} e^{x_l \beta}}
\]

When there are ties in the response, meaning there is more than one failure at a given time event, the Breslow likelihood is used.

Example of the Fit Proportional Hazards Platform

This example illustrates one nominal effect with two levels. For an example with multiple effects and multiple levels, see “Example Using Multiple Effects and Multiple Levels” on page 408.

1. Select Help > Sample Data Library and open Rats.jmp.
2. Select Analyze > Reliability and Survival > Fit Proportional Hazards.
3. Select days and click Time to Event.
4. Select Censor and click Censor.
5. Select Group and click Add.
6. Click Run.
In the Rats.jmp data, there are only two groups. Therefore, in the Parameter Estimates report, a confidence interval that does not include zero indicates an alpha-level significant difference between groups. Also, in the Effect Likelihood Ratio Tests report, the test of the null hypothesis for no difference between the groups shown in the Whole Model Test table is the same as the null hypothesis that the regression coefficient for Group is zero.
Risk Ratios for One Nominal Effect with Two Levels

To show risk ratios for effects, select the Risk Ratios option from the red triangle menu. In this example, there is only one effect, and there are only two levels for that effect. The risk ratio for Group 2 is compared with Group 1 and appears in the Risk Ratios for Group report. See Figure 15.3. The risk ratio in this table is determined by computing the exponential of the parameter estimate for Group 2 and dividing it by the exponential of the parameter estimate for Group 1.

Note the following:

- The Group 1 parameter estimate appears in the Parameter Estimates table (Figure 15.2).
- The Group 2 parameter estimate is calculated by taking the negative value for the parameter estimate of Group 1.
- Reciprocal shows the value for 1/Risk Ratio.

Tip: To see the Reciprocal values, right-click in the Risk Ratios report and select Columns > Reciprocal.

For this example, the risk ratio for Group2/Group1 is calculated as follows:

\[ \frac{\exp[-(-0.2979479)]}{\exp(-0.2979479)} = 1.8146558 \]

This risk ratio value suggests that the risk of death for Group 2 is 1.81 times that for Group 1.

Figure 15.3  Risk Ratios for Group Table

For information about calculating risk ratios when there are multiple effects, or categorical effects with more than two levels, see “Risk Ratios for Multiple Effects and Multiple Levels” on page 410.
Launch the Fit Proportional Hazards Platform

Launch the Fit Proportional Hazards platform by selecting Analyze > Reliability and Survival > Fit Proportional Hazards.

**Figure 15.4** The Fit Proportional Hazards Launch Window

**Tip:** To change the alpha level, click the Model Specification red triangle and select **Set Alpha Level**.

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

The Fit Proportional Hazards launch window contains the following options:

**Time to Event**  Contains the time to event or time to censoring.

**Censor**  Nonzero values in the censor column indicate censored observations. (The coding of censored values is usually equal to 1.) Uncensored values must be coded as 0.

**Caution:** The Censor column role does not honor the Missing Value Code column property.

**Freq**  Column whose values are the frequencies or counts of observations for each row when there are multiple units recorded.

**By**  Performs a separate analysis for each level of a classification or grouping variable.
**Construct Model Effects**  Enters effects into your model. For more information about the Construct Model Effects options, see *Fitting Linear Models*.

**Personality**  Indicates the fitting method. Proportional Hazard should always be selected.

**Censor Code**  Identifies the value in the Censor column that designates right-censored observations. After a Censor column is selected, JMP attempts to automatically detect the censor code and display it in the box. To change this, you can click the red triangle and select from a list of values. You can also enter a different value in the box. If the Censor column contains a Value Labels column property, the value labels appear in the list of values. Missing values are excluded from the analysis.
The Fit Proportional Hazards Report

Finding parameter estimates for a proportional hazards model is an iterative procedure. When the fitting is complete, the report in Figure 15.5 appears.

Figure 15.5 The Proportional Hazards Fit Report

**Iteration History**  Lists iteration results occurring during the model calculations.

**Whole Model**  Shows the negative of the log-likelihood function (–LogLikelihood) for the model with and without the covariates. Twice the positive difference between them gives a chi-square test of the hypothesis that there is no difference in survival time among the effects. The degrees of freedom (DF) are equal to the change in the number of parameters between the full and reduced models. See *Fitting Linear Models*. 
Parameter Estimates  Shows the parameter estimates for the covariates, their standard errors, and 95% upper and lower confidence limits. A confidence interval for a continuous column that does not include zero indicates that the effect is significant. A confidence interval for a level in a categorical column that does not include zero indicates that the difference between the level and the average of all levels is significant.

Effect Likelihood Ratio Tests  Shows the likelihood ratio chi-square test of the null hypothesis that the parameter estimates for the effects of the covariates is zero.

Baseline Survival at mean  Plots the baseline function estimates at each event time in the data. The values in the Table report are plotted here.

Fit Proportional Hazards Options

The Proportional Hazards Fit red triangle menu contains the following options:

Likelihood Ratio Tests  Produces tests that compare the log-likelihood from the fitted model to one that removes each term from the model individually.

Wald Tests  Produces chi-square test statistics and p-values for Wald tests of whether each parameter is zero.

Likelihood Confidence Intervals  Specifies the type of confidence intervals shown in the Parameter Estimates table for each parameter. When this option is selected, a profile likelihood confidence interval appears. Otherwise, a Wald interval is shown. In the report, the interval type is noted below the Parameter Estimates table. This option is on by default when the computational time for the profile likelihood confidence intervals is not large.

Note: You can change the \( \alpha \) level for the confidence intervals by selecting Set Alpha Level from the red triangle menu in the Fit Model launch window. The default \( \alpha \) level is 0.05.

Risk Ratios  Shows the risk ratios for the effects. For continuous columns, unit risk ratios and range risk ratios are calculated. The Unit Risk Ratio is \( \exp(\text{estimate}) \) and the Range Risk Ratio is \( \exp[\text{estimate} \times (x_{\text{Max}} - x_{\text{Min}})] \). The Unit Risk Ratio shows the risk change over one unit of the regressor, and the Range Risk Ratio shows the change over the whole range of the regressor. For categorical columns, risk ratios are shown in separate reports for each effect. Note that for a categorical variable with \( k \) levels, only \( k - 1 \) design variables, or levels, are used.

Tip: To see Reciprocal values in the Risk Ratio report, right-click in the report and select Columns > Reciprocal.

Model Dialog  Shows the completed launch window for the current analysis.
Example Using Multiple Effects and Multiple Levels

This example uses a proportional hazards model for the sample data, VA Lung Cancer.jmp. The data were collected from a randomized clinical trial, where males with inoperable lung cancer were placed on either a standard or a novel (test) chemotherapy (Treatment). The primary interest of this trial was to assess if the treatment type has an effect on survival time; special interest is given to the type of tumor (Cell Type). See Prentice (1973) and Kalbfleisch and Prentice (2002) for more information about this data set.

For the proportional hazards model, covariates include the following:

- Whether the patient had undergone previous therapy (Prior)
- Age of the patient (Age)
- Time from lung cancer diagnosis to beginning the study (Diag Time)
- A general medical status measure (KPS)

Age, Diag Time, and KPS are continuous measures and Cell Type, Treatment, and Prior are categorical (nominal) variables. The four nominal levels of Cell Type include Adeno, Large, Small, and Squamous.

This example illustrates the results for a model with more than one effect and a nominal effect with more than two levels. Risk ratios are also demonstrated, with example calculations for risk ratios for a continuous effect and risk ratios for an effect that has more than two levels.

1. Select Help > Sample Data Library and open VA Lung Cancer.jmp.
2. Select Analyze > Reliability and Survival > Fit Proportional Hazards.
3. Select Time as **Time to Event**.
4. Select censor as **Censor**.
5. Select Cell Type, Treatment, Prior, Age, Diag Time, and KPS and click **Add**.
6. Click **Run**.
7. (Optional) Click the disclosure icon on the Baseline Survival at mean title bar to close the plot, and click the disclosure icon on Effect Summary to close the report.

**Figure 15.6** Report Window for Proportional Hazards Model with Multiple Effects and Levels

Note the following about the results:

- In the Whole Model report, the low Prob>Chisq value (<.0001) indicates that there is a difference in survival time when at least one of the effects is included in the model.
- In the Effect Likelihood Ratio Tests report, the Prob>ChiSq values indicate that KPS and at least one of the levels of Cell Type are significant; however, the Treatment, Prior, Age, and Diag Time effects are not significant.

8. Click the Proportional Hazards Fit red triangle and select **Risk Ratios**.
**Figure 15.7 Risk Ratios Report**

![Risk Ratios Report](image)

**Risk Ratios for Multiple Effects and Multiple Levels**

Figure 15.7 shows the Risk Ratios for the continuous effects (Age, Diag Time, KPS) and the nominal effects (Cell Type, Treatment, Prior). For illustration, focus on the continuous effect, Age, and the nominal effect with four levels (Cell Type) for the VA Lung Cancer.jmp sample data.

For the continuous effect, Age, in the VA Lung Cancer.jmp sample data, the risk ratios are calculated as follows:

**Unit Risk Ratios**

\[ \exp(\beta) = \exp(-0.0085494) = 0.991487 \]
Range Risk Ratios

\[ \exp[\beta(x_{\text{max}} - x_{\text{min}})] = \exp(-0.0085494 \times 47) = 0.669099 \]

For the nominal effect, Cell Type, all pairs of levels are calculated and are shown in the Risk Ratios for Cell Type table. Note that for a categorical variable with \( k \) levels, only \( k - 1 \) design variables, or levels, are used. In the Parameter Estimates table, parameter estimates are shown for only three of the four levels for Cell Type (Adeno, Large, and Small). The Squamous level is not shown, but it is calculated as the negative sum of the other estimates. Here are two example Risk Ratios for Cell Type calculations:

\[
\begin{align*}
\text{Large/Adeno} &= \exp(\beta_{\text{Large}})/\exp(\beta_{\text{Adeno}}) = \exp(-0.2114757)/\exp(0.57719588) = 0.4544481 \\
\text{Squamous/Adeno} &= \exp[-(\beta_{\text{Adeno}} + \beta_{\text{Large}} + \beta_{\text{Small}})]/\exp(\beta_{\text{Adeno}}) \\
&= \exp[-(0.57719588 + (-0.2114757) + 0.24538322)/\exp(0.57719588) = 0.3047391
\end{align*}
\]

Reciprocal shows the value for 1/Risk Ratio.

Introduction to Consumer Research
Overview of Customer and Behavioral Research Methods

Consumer Research provides a full suite of tools for analyzing consumer and behavioral research data. You collect information about how customers use products or services, how satisfied they are with your offerings, and what new features they might desire. The resulting insights let you create better products and services, happier customers, and more revenue for your organization. Tools for analyzing these consumer research activities are located in the Consumer Research menu. Use the following platforms to analyze your data:

- The Categorical platform enables you to tabulate, plot, and compare categorical responses in your data, including multiple response data. You can use this platform to analyze data from surveys and other categorical response data, such as defect records and study participant demographics. Using the Categorical platform, you can analyze responses from data tables that are organized in many different ways. See Chapter 3, “Categorical Response Analysis”.

- The Choice platform is designed for use in market research experiments, where the ultimate goal is to discover the preference structure of consumers. Then, this information is used to design products or services that have the attributes most desired by consumers. See Chapter 4, “Choice Models”.

- The MaxDiff platform is an alternative to using standard preference scales to determine the relative importance of items being rated. A MaxDiff experiment forces respondents to report their most and least preferred options, thereby forcing respondents to rank options in terms of preference. See Chapter 5, “MaxDiff”.

- The Uplift platform enables you to maximize the impact of your marketing budget by sending offers only to individuals who are likely to respond favorably. It can do this even when you have large data sets and many possible behavioral or demographic predictors. You can use uplift models to make such predictions. This method has been developed to help optimize marketing decisions, define personalized medicine protocols, or, more generally, to identify characteristics of individuals who are likely to respond to some action. See Chapter 6, “Uplift”.

- The Multiple Factor Analysis platform enables you to analyze agreement among panelists in sensory data analysis. You can use MFA to analyze studies where items are measured on the same or different attributes by different instruments, individuals, or under different circumstances. See Chapter 7, “Multiple Factor Analysis”.
The Categorical platform enables you to tabulate, chart, and compare categorical response data, including multiple response data. You can analyze data from surveys and other categorical response data, such as defect records and study participant demographics. Many different data types and formats are supported.

Example of the Categorical Platform

This example uses the Color Preference Survey.jmp sample data table, which contains survey data on color preferences. You can use the Categorical platform to summarize results from different question types:

- A single response question
- Three aligned ranking questions
- A multiple response question
- A single response question segmented by a secondary question

You will set up four analyses (one for each type of question) in the Categorical launch window. Alternatively, you can use one launch tab at a time.

2. Select Analyze > Consumer Research > Categorical.
3. Select What is your favorite color? (select one) and click Responses.
4. Select What is your gender? and click X, Grouping Category.

**Note:** If you want to run the single analysis of favorite color by gender, click OK now.

**Figure 3.2** Completed Simple Tab in the Categorical Launch Window
5. Select the **Related** tab.
6. Select I like the color blue. through I like the color orange. and click **Aligned Responses**.
   This enters three questions with rating scales to be analyzed together. The gender grouping category applies to this analysis.
7. Select the **Multiple** tab.
8. Select Red: What colors do you like? (check all that you like) through None of the above: What colors do you like? (check all that you like) and click **Multiple Response**.
   This enters the multiple response question “What colors do you like?” where each response is in an individual column for analysis. The gender grouping category applies to this analysis.
9. Select the **Structured** tab.
10. Drag What is your favorite color? (select one) to the Side green arrow and drag How old are you? to the Top green arrow.

**Figure 3.3** Structured Tab in Categorical Launch Window

11. Click **Add**.

The What is your gender? column specified in the X. Grouping Category role does not apply to the structured analysis.

**Tip:** Click on the green arrows in the structured tab for a column list, where you can click to add a column. You can nest multiple columns by using the down arrow on the top or the right arrow on the side.
12. Click **OK**.

The results for each analysis are stacked vertically in a single report window.

**Simple Tab Report**

The first section shows the results for the simple response survey question, “What is your favorite color?”, grouped by gender. Each respondent was asked to select one color from the list: Red, Blue, Green, Orange, Yellow, Pink, Purple, or None of the above.

**Figure 3.5 Simple Response: Favorite Color by Gender**

The analysis shows that blue is the favorite color for both genders. For males, the frequency of the 43 male respondents selecting blue is 19. This corresponds to a share of 44.2% or 19/43. For females, 11 of 37 female respondents (frequency) or 29.7% (share) selected blue.
Tip: You can define the colors in the charts using the Value Colors column property. See *Using JMP*.

Related Tab Report

The second section of the report shows the results for three related questions that asked respondents to rank how much they liked a color. The responses to these questions are aligned, because the questions used the same rating scale of Strongly agree to Strongly disagree.

Figure 3.6 Aligned Response: Ranking Colors by Gender

The analysis shows that blue is the color with the highest rankings for both males and females. Orange has a high number of neutral results for both genders as compared to red and blue. The value colors column property is used to define the colors used in the share chart.

Note: If you analyze aligned questions individually using the Simple tab, you obtain three individual reports containing the same information as the related report. Using the Related tab aligns the reports so that the results are easier to compare to one another.

Multiple Tab Report

The third section in the report shows the results from a multiple choice survey question grouped by gender. The question was “What colors do you like? (check all that you like)”. Each possible response was collected in an individual column. If the subject selected a response, there is a value in the corresponding column. Otherwise, the column is empty.
Figure 3.7  Multiple Response: Colors Liked by Gender

From the results, we observe that blue and green are highly liked by both genders. Females like pink and purple at higher rates than males.

In a multiple response question, more than one answer is allowed. A case represents a single responder, and Total Cases is the total number of responders. In our data, we have 37 female cases and 43 male cases. The total number of cases responding are the number of cases who selected one or more responses (which in our data, was everyone).

The Total Responses column lists the total number of selections made. For females, there were 146 colors selected by the 37 females. For males, there were 180 colors selected by the 43 male responders. The tabulation includes the number of responders selecting each color, the share or the percent of the total responses, and the rate or the percent of the total cases.

Structured Tab Report

The final section shows the table generated from the structured tab where you set the favorite color question as the response of interest grouped by the age group. In the structured format, the levels of the primary response of interest form the rows of the table and the levels of the grouping variable form the columns.
Figure 3.8 Structured: Favorite Color by Age

The 10 to 19 age group has two responders with pink as their favorite color. No other age groups have responders with pink as their favorite color. You can see from the bottom row of the table that the number of responders in each age group is small. You could gather more data to draw conclusions about the favorite colors across age groups.
Launch the Categorical Platform

Launch the Categorical platform by selecting Analyze > Consumer Research > Categorical.

Figure 3.9  Categorical Platform Launch Window for the Simple Tab

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Response Roles

The launch window includes tabs for three groups of response roles (Simple, Related, and Multiple) and a Structured tab where you can create custom data summaries. The response role corresponds to the type of responses you want to analyze. Options on each tab correspond to how the responses are organized in your data table.

Simple Tab

Use the Simple tab to analyze a single response, such as a survey question where only a single answer is allowed. The data to be analyzed is contained in a single column.

Responses  Summarizes data from a single column. If multiple columns are selected, the categorical report contains a separate report for each individual column.
**Related Tab**

Use the Related tab to analyze a set of related responses across multiple columns.

**Figure 3.10** Categorical Platform Launch Window Related Tab

**Aligned Responses** Summarizes data from multiple columns that have the same response levels in a single report. This option is useful for survey data where you have many questions with the same set of responses. You can quickly summarize and compare response trends for all of the questions at once.

**Repeated Measures** Summarizes data from multiple columns where each column contains responses to the same question made at different time points. If an individual responds at multiple time points, the samples are called overlapping. When there are overlapping samples, the Kish correction is used. See Kish (1965, sec. 12.4).

**Rater Agreement** Summarizes data from multiple columns where each column is a rating for the same question or item, but is given by a different individual (rater).

**Multiple Tab**

Use the Multiple tab to analyze multiple responses where the responses are recorded in one or more columns. The options on the Multiple tab are specific to how the data is organized in your data table. A set of multiple responses could be from a survey where the response set allows for more than one choice (check-all-that apply questions), or from a set of defect data where an item can have multiple defects.
Figure 3.11  Categorical Platform Launch Window Multiple Tab

![Categorical Platform Launch Window](image)

**Multiple Response**  Summarizes data from multiple responses where each possible response is recorded in its own individual column. Each column can contain blanks, which correspond to the item not being selected.

**Figure 3.12  Multiple Response Column Format**

![Multiple Response Column Format](image)

**Multiple Response by ID**  Summarizes data from multiple responses where the data are recorded in a stacked format. There is a single column of responses with a second column containing an ID for the subject.

**Figure 3.13  Multiple Response by ID Format**

![Multiple Response by ID Format](image)

**Multiple Delimited**  Summarizes data from multiple responses where the responses are in a single column and each response is separated by a comma, semicolon, or tab.
Tip: Use the Multiple Responses column property for columns that contain delineated multiple responses. See Using JMP.

Indicator Group Summarizes multiple responses that are stored in indicator columns. The data table contains a column for each possible response, and each column is an indicator (for example, 0 and 1). A blank value indicates a missing response. See “Indicator Group” on page 72.

Response Frequencies Summarizes multiple responses that are stored in columns that contain frequency counts. This data format is the summarized version of the Indicator Group format. See “Response Frequencies” on page 73.

Free Text Summarizes text data. The Free Text option launches a Text Explorer report inside the Categorical report window. See Basic Analysis.
Structured Tab

Use the Structured tab to construct custom cross tabulations.

**Figure 3.15** Categorical Platform Launch Window for the Structured Tab

The Structured tab has three drop zones for assigning columns to roles. Drag column names to the green drop zone arrows. Alternatively, click the green arrows for a column list to select columns. The resulting structured table considers the innermost terms on the side of the table as responses and all other terms as grouping factors.

**Drop Zones**

**Top** Assigns one or more data table columns to the columns of the cross tabulation table. After one column has been assigned, use the down arrows to nest additional columns within already assigned columns or use the right arrows to add additional column groups.

**Side** Assigns one or more data table columns to the rows of the cross tabulation table. After one column has been assigned, use the right arrows to nest additional columns nested within already assigned rows or use the down arrows to add additional row groups.

**Multiple Aligned** Assigns two or more columns with aligned response.
Controls

**Undo**  Click to undo column assignments.

**Redo**  Click to redo the most recent assignment that was undone.

**Clear**  Click to remove all assignments in the drop zones.

**Add=>**  Click to add the constructed table to the structured table list.

**<=Edit**  Click to make changes to the selected table from the structured table list.

Columns Roles

The categorical platform launch window has the following column roles:

**X, Grouping Category**  (Not applicable for the Structured tab.) Assigns a column as a grouping category. The responses are summarized for each group. If more than one grouping column is used, then the tabulation is nested by default. Use the Grouping Option in the launch window to change the summarization.

**Sample Size**  Assigns a column whose values define the number of individual units in the group to which that frequency is applicable. The sample size is used for multiple response roles with summarized data. See “Example of the Multiple Responses” on page 69.

**Freq**  Assigns a column whose values define a frequency to each row for the analysis. The frequency role is used for summarized data.

**ID**  Assigns a column that identifies the respondent. This option is required when Multiple Response by ID is selected, and it is not used for any other response types.

**By**  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Other Launch Window Options

Additional options are located in the lower left of the launch window. Alternatively, these options can be selected from the Categorical red triangle menu in the platform report window.

**Grouping Option**  Defines how to use grouping variables in the analysis when more than one grouping column is specified.

**Combinations**  Analyzes the response for combinations of the grouping variables. The first column in the grouping list is the outermost group in the cross tabulation table.

**Each Individually**  Analyzes the response for each grouping variable individually.
Both  Provides reports for combinations of the grouping variables as well as for each grouping variable individually.

Unique Occurrences within ID  Limits the counts to unique response levels within a participant. Specify a column as the ID using the ID role. This option is applicable only when Multiple Response by ID is selected, and it is not used for any other response types.

Count Missing Responses  Specifies that missing values be included as a category. Missing values can be either empty cells or a defined missing code in the Missing Value Codes column property. If a column contains only missing values, the missing values are counted regardless of this option. For multiple responses, a response is considered missing if all response categories are missing or for indicators, if all are zero.

Note: If this option is not selected, missing values are excluded from the analysis.

Order Response Levels High to Low  Orders the responses from high to low. (The default ordering is low to high.) This option applies only to the response, and does not apply to grouping categories.

Tip: Use the Value Order column property to define a specific category ordering. See Using JMP.

Shorten Labels  Shortens value labels by removing prefixes and suffixes that are common to all labels.

Note: This option applies only to value labels, and does not apply to column names.

Include Responses Not in Data  Specifies that categories with no responses be included in the report. The categories with no responses must be specified in the Value Labels column property. This option applies only to responses. For grouping variables tabulations, include only categories with responses.

Include Response Categories in Excluded Rows  Specifies that response categories that appear only in excluded rows be included in the report. The counts for these categories are zero.
The initial Categorical report shows a cross tabulation and a share chart for each set of selected responses.

**Figure 3.16** The Initial Categorical Report

<table>
<thead>

<td>2</td>
<td>1</td>
<td>3</td>
<td>5</td>
<td>0</td>
</tr>
</tbody>
</table>

The upper left corner of the table lists the quantities (Freq, Share, and Rate when applicable) that are included in each cell of the table. Remove or add these quantities using the options in the Categorical red triangle menu.

- **The Frequencies count** (labeled Freq) is provided for each category with the total frequency (Total Responses) at the right of the table. When there are multiple responses, the summary columns at the right of the table also include the number of cases or the number of rows (Total Cases) and the number of responders (Total Cases Responding).
- **The Share of Responses** (Share) is determined by dividing each count (Freq) by the total number of responses.
- **The Rate** is the frequency of response (Freq) divided by the total number of cases (Total Cases). This quantity appears only for multiple responses and is not shown in Figure 3.16.

In Figure 3.16, the number of responses to the question What is your favorite color? are tabulated by gender. Consider the first row of the table with the results for females:

- The first cell of the table contains 11 responses. This is the count of the female respondents who selected blue as their favorite color.
- There are 37 total responses for females. Of the 37 female responses, 29.7% (11/37) selected blue as their favorite color.
Categorical Platform Options

The Categorical red triangle menu contains options that enable you to customize the report and request various statistical tests. The specific options that are available are determined by the response roles, the use of grouping categories, and the options selected in the launch window.

- “Report Options”
- “Statistical Testing Options”
- “Additional Categorical Platform Options”
- “Crosstab Table Options”

Report Options

The following options enable you to customize the appearance of the report:

Cross Tabulation Options

Frequencies  Shows or hides the frequency (labeled Freq) in the Crosstab table. The frequency is the count of the responses in each category.

Share of Responses  Shows or hides the share of responses (labeled Share) in the Crosstab table. The share of responses is the percent of responses in each category.

Rate Per Case  (Available only for multiple responses.) Shows or hides the rate per case (labeled Rate) in the Crosstab table. The rate per case is the percent of responses in each category based on the total number of cases (regardless of whether they were a respondent).

Rate per Case Responding  (Available only for multiple responses.) Shows or hides the Rate per Case Responding in the Crosstab table. The rate per case responding is the percent of responses in each category based on the cases that responded.

Chart Options

Share Chart  Shows or hides a divided bar chart. The bar length is proportional to the percentage of responses for each type. The column on the right shows the number of responses in each grouping category. If no grouping category is used, the column on the right shows the total number of responses.

Frequency Chart  Shows or hides a Frequency Chart. The bars reflect the frequency of responses within each group. The scale is consistent across the chart. The gray bars at the far right represent the total number of responses in each grouping category.
Transposed Freq Chart  Shows or hides a transposed Frequency Chart. The bars reflect the frequency of responses within each group. The responses are the rows, and the grouping levels are the columns in chart. The totals for each grouping level are represented by gray bars in the bottom row of the chart.

Tip: You can change the colors in the share chart using the Value Colors column property. See Using JMP.

Crosstab Viewing Options

Crosstab  Shows or hides the Crosstab table. The Crosstab table displays the response categories as column headings and the grouping levels (when used) as row labels. The upper left cell of the table shows the labels for the items in each cell of the table (Freq, Share, Rate, and Rate per Case Responding). If the report contains a transposed Crosstab table, this option also removes the transposed Crosstab table from the report.

Crosstab Transposed  Shows or hides a transposed Crosstab table. The transposed Crosstab table displays the response categories as row labels and the grouping levels (when used) as column headings. The upper left cell of the table shows the labels for the items in each cell of the table (Freq, Share, Rate, and Rate per Case Responding). If the report contains a Crosstab table, this option also removes the Crosstab table from the report.

Statistical Testing Options

The statistical testing options that are available depend on the response roles and the use of grouping variables in the analysis. Options include tests for multiple responses, response homogeneity, association, relative risk, and agreement. Options depend on both the response data type and the grouping variable (X, Grouping Category) data type.

Test Multiple Response  (Available only for multiple response data with one or more grouping categories.) See “Example of the Multiple Response Test” on page 52. Contains tests for independence of responses across each grouping category:

Count Test, Poisson  Shows or hides a test of independence of rates that uses Poisson regression. The frequency per unit is modeled by the sample categorical variable. The result is a likelihood ratio chi-square test of whether the rate of each individual response differs across grouping levels.

Homogeneity Test, Binomial  Shows or hides the likelihood ratio chi-square test of independence for each individual response level. Each response category has a binomial distribution (selected or not selected).
Exclude Nonresponses  Excludes nonresponses for count and homogeneity tests of multiple response categories. If a row is missing data in all response categories, it is treated as a nonresponse.

Test Response Homogeneity  (Available only for response variables that do not have a multiple response modeling type and when one or more groupings variables are specified.) Shows or hides a report that contains tests for response homogeneity that depend on your grouping variable:

- When the grouping variable is not a multiple response, then one tests for independence of the response across the grouping variable levels. The likelihood ratio and Pearson chi-square tests are provided. See “Example of the Test for Response Homogeneity” on page 51.
- When the grouping variable is a multiple response, then one tests for independence of the response across each of the grouping variable levels. A Rao-Scott Chi-square test is provided.

Cell Chisq  Shows or hides $p$-values for each cell in the table for a chi-square test of independence. A small $p$-value indicates a cell with an observed value that is larger or smaller than expected under the assumption that the rows are independent of the columns. The $p$-values are colored and shaded according to whether the count is larger or smaller than expected. See “Example of the Cell Chisq Test” on page 58.

Compare Each Sample  (Available only for single responses with one or more grouping variables.) Shows or hides a report that contains pairwise likelihood ratio and Pearson chi-square tests for independence of responses across levels of a grouping variable. See “Example of Compare Each Sample with Comparison Letters” on page 59.

Compare Each Cell  (Available only for single and multiple responses with one or more grouping variables.) Shows or hides pairwise likelihood ratio chi-square, Pearson chi-square, and Fisher’s exact tests for independence of each level of the response versus all other levels combined across levels of a grouping variable. See “Example of Compare Each Cell with Comparison Letters” on page 60.

Relative Risk  (Available when the grouping variable has two levels and either the response has two levels or is a multiple response and the Unique occurrences within ID option has been selected.) Shows or hides the relative risks for a two-level grouping variable for each level of the response. See “Example of Conditional Association and Relative Risk” on page 65.

Conditional Association  (Available only when the Unique occurrence within ID option has been selected.) Shows or hides the conditional probability of one response level given a second response level. See “Example of Conditional Association and Relative Risk” on page 65.
Agreement Statistic  (Available only for Rater Agreement responses.) Shows or hides the Kappa coefficient of agreement and the Bowker test of symmetry. See “Example of Rater Agreement” on page 67.

Transition Report  (Available only for Repeated Measures responses.) Shows or hides transition counts and rates matrices for changes in responses across time. See “Example of Repeated Measures” on page 68.

Test Options  Options available in this menu depend on your selected analysis.

ChiSquare Test Choices  Specifies which chi-square tests of homogeneity are calculated for single responses. You can choose between Both LR and Pearson, LR Only, or Pearson Only, where LR refers to likelihood ratio.

Show Warnings  Shows warnings for small sample sizes in chi-square tests.

Order by Significance  Reorders the reports so that the most significant reports are at the top.

Hide Nonsignificant  Suppresses reports that are non-significant.

FDR Adjusted PValues  Shows or hides false discovery rate p-values based on the method of Benjamini and Hochberg (1995).

Additional Categorical Platform Options

The following options enable you to add summary statistics to the report, save reports, and set report formats.

Summary Statistics Options

Total Responses  Shows or hides the sum of the frequency counts for the response in crosstab tables and share charts. When a grouping variable is specified, the total is across each grouping category.

Response Levels  Shows or hides the categories for the response column in crosstab tables and share charts.

Show Supercategories  (Available only when one or more supercategories is defined.) Shows or hides columns for supercategories in the crosstab table and the Frequency Chart. For more information about supercategories, see “Supercategories” on page 50.

Tip: This option shows or hides the Supercategories. To hide the individual categories within the supercategory, use the Hide option in the Supercategories column property. Alternatively, use the Response Levels option to hide all response levels so that only Supercategories remain unhidden.
**Total Cases**  (Available only for multiple response columns.) Shows or hides a column in the crosstab table that contains the number of cases (participants) in each group.

**Total Cases Responding**  (Available only for multiple response columns.) Shows or hides a column in the crosstab table that contains the number of cases (participants) who responded at least once. Participants who did not respond at all are not included. The total cases responding is less than or equal to the total cases.

**Mean Score**  Shows or hides a column in the crosstab table and share chart that contains the overall mean of the response or the mean for each grouping category. The mean is calculated based on a numerical value assigned to each response category.

- For numeric categories, the numeric value is the actual value.
- For non-numeric categories the value is the value assigned to the categories by the Value Scores column property.
- For categories without value scores, the value is based on a default assignment of 1 to the number of categories.

See “Example of Mean Score with Comparison Letters” on page 74.

**Mean Score Comparisons**  Shows or hides the Compare Means column in the crosstab table. This column compares the mean scores across grouping categories using the unpoled Satterthwaite $t$ test for pairwise comparisons. See the TTEST Procedure chapter in SAS Institute Inc. (2020). The results of the comparison are shown using letters. For more information about comparison letters, see “Comparison Letters” on page 48. For more information about specifying comparison groups, see “Example of User-Specified Comparison with Comparison Letters” on page 62.

**Std Dev Score**  Shows or hides a column in the crosstab table that contains the overall standard deviation of the response or the standard deviation of each grouping category.

**Order by Mean Score**  (Appears only when more than one response is specified and there are no grouping variables in the analyses.) Orders the response reports by the mean score.

**Save Options**

**Save Tables**  Contains options to save specific portions of the reports to a new data table. Each option creates an individual data table for each report. The options available in this menu depend on your selected analysis. The saved tables all include a Source script.

**Note:** Supercategories are not included in the new tables.

**Save Frequencies**  Saves the frequency counts from the crosstab table to a new data table.
Save Share of Responses  Saves the share of responses from the crosstab table to a new data table.

Save Contingency Table  Saves the complete crosstab table to a new data table.

Save Rate Per Case  Saves the rates per case from the crosstab table to a new data table.

Save Transposed Frequencies  Saves the transposed frequency counts from the crosstab table to a new data table.

Save Transposed Share of Responses  Saves the transposed share of responses from the crosstab to a new data table.

Save Transposed Rate Per Case  Saves the transposed rates per case from the crosstab table to a new data table.

Save Test Rates  Saves the results of the Test Multiple Response option to a new data table.

Save Test Homogeneity  Saves the results of the Test Response Homogeneity option to a new data table.

Save Mean Scores  Saves the mean scores for each sample group to a new data table.

Save tTests and pValues  Save t tests and p-values from the Mean Score Comparisons report to a new data table.

Save Excel File  (Available only on Windows.) Creates a Microsoft Excel spreadsheet with the structure of the crosstab table. This option maps all of the tables to one sheet, with the response categories as rows, the sample levels as columns, and sharing the headings for sample levels across multiple tables. When there are multiple elements in each table cell, you have the option to make them multiple or single cells in Microsoft Excel.

Report Format Options

Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Contents Summary  Shows or hides a Contents Summary report at the top of the Categorical report. The Contents Summary report contains all of the tests and mean scores in a summary that has links to the associated report.

Show Columns Used in Report  (Available only with SPSS or SAS names.) Shows or hides Columns Used in Report information. This option affects only columns that have an SPSS or SAS Name or SPSS or SAS Label column property.
Tip: When you import survey data from SAS or SPSS, the Name and Label column properties are automatically added to your JMP table. You can add a SAS or SPSS Name or Label column property using the Other column property. For example, if you use the SAS or SPSS Name column property to store a survey question, the column name can be a short name.

Format Elements  Enables you to specify formats for Frequencies, Shares, Rates, and Means.

Arrange in Rows  Enables you to arrange multiple reports across the window. Enter the number of reports that you want to view across the window.

Set Preferences  Enables you to set preferences for future launches of the Categorical platform in the current JMP session and in future JMP sessions. See “Set Preferences” on page 80.

Category Options  Contains options (Grouping Option, Count Missing Responses, Order Response Levels High to Low, Shorten Labels, and Include Responses Not in Data) that are also available on the launch window. If these options are selected here, the platform updates with the new setting. For more information about the Category Options, see “Other Launch Window Options” on page 38.

Force Crosstab Shading  Forces shading on Crosstab reports even if the preference is set to no shading. If this option is not selected, the Crosstab reports are shaded according to the current setting of the Shade Alternate Table Rows preference.

Relaunch Dialog  Enables you to return to the launch window and edit the specifications for an analysis.

See Using JMP for more information about the following options:

Local Data Filter  Shows or hides the local data filter that enables you to filter the data used in a specific report.

Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.
Crosstab Table Options

**Show Letters**  Shows or hides the column letter IDs in the Crosstab table. These letters are used in many of the tests of homogeneity and are displayed automatically for those tests.

**Specify Comparison Groups**  Enables you to specify specific comparison groups for tests of homogeneity. Use group comparison letters separated by a slash to represent each group. Separate multiple groups by commas. For example, to test A with E, B with D, and C with F, specify the groups as “A/E, B/D, C/F”. A Compare Each Cell report is provided for the defined comparison groups. See “Example of User-Specified Comparison with Comparison Letters” on page 62.

**Remove**  Removes the report from the report window.

**Caution:** The Remove option cannot be undone.

Comparison Letters

The Compare Each Cell, Compare Each Sample, and Mean Score Comparisons options use comparison letters to identify sample levels. For more than 26 levels, numbers are appended to the letters. The letters are shown to the right of the sample level headings of the crosstab table when a comparison option is turned on. These letters are used to identify levels in the Compare column.

Figure 3.17  Crosstab Table with Comparison Letters
A letter in the Compare column indicates a difference between two levels. The row containing the letter is one level and the letter in the Compare column indicates the second level. When two sample levels are significantly different, the letter of the sample level with a smaller share of responses is placed into the comparison cell of the other level. An uppercase letter indicates a stronger difference between levels than a lowercase letter. The default alpha level (significance level) for an uppercase letter is 0.05 and 0.10 for a lowercase letter. For example, in Figure 3.17, notice the following:

- The first row of the table for Family cars has a B in the Compare column. The letter B is associated with Sporty cars. This indicates that there is a difference in the country of origin for Sporty and Family cars at the 0.05 significance level. The B is in the row for Family cars because the total responses for Sporty cars (100) is less than the total responses for Family cars (155).

- The c in the Compare column of the Sporty row indicates a significant difference at the 0.10 level between the country of origin when comparing Sporty to Work cars. The c is in the row for Sporty cars because the total responses for Sporty cars (100) is greater than the total responses for Work cars (48).

Warnings for small counts are indicated by asterisks in the comparison cells. One asterisk indicates that the level has fewer than 100 responses. Two asterisks indicate fewer than 30 responses. In Figure 3.17, notice that the row for Work has an asterisk in the Compare column. This warning that the count of responses is small appears because the total responses for Work cars (48) is less than 100.

You can change the alpha levels and thresholds for the warning counts in the Categorical platform preferences. For more information about changing preferences, see “Set Preferences” on page 80.

**Tip:** If you want only one set of comparison letters in your report, set the **Lowercase Alpha Level** to 0 in the preferences.

The following examples illustrate the use of comparison letters:

- “Example of Compare Each Sample with Comparison Letters” on page 59
- “Example of Compare Each Cell with Comparison Letters” on page 60
- “Example of Mean Score with Comparison Letters” on page 74
Supercategories

The term *supercategories* refers to the aggregation of response categories. For example, when using a five-point rating scale, you might want to know the percent of responses from the top two ratings (top two boxes). Use the Supercategories column property to define groups of responses.

When you add a Supercategories column property to a response column, no additional columns are added to your data table. Instead, the Supercategories column property adds an additional category column to crosstab tables and Frequency Charts in the Categorical platform report. You can create multiple supercategories for a single response column. Share Charts do not show supercategories, and supercategories are not applied to grouping columns.

To create a supercategory:

1. Select a column in your data table that contains categories that you would like to aggregate.
2. Select *Cols > Column Info*.
3. Click *Column Properties* and select *Supercategories*.
4. (Optional) To change the default name of the supercategory, enter a Supercategory Name.
5. Select one or more categories from the Column’s Categories list.
6. Click *Add*.
7. (Optional) Select the supercategory and click the Supercategories red triangle for additional options.

**Supercategories Options**

The following options are available in the Supercategories red triangle menu in the Column Properties window:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hide</strong></td>
<td>Hides categories within a supercategory in the crosstab table and frequency chart.</td>
</tr>
</tbody>
</table>

**Tip:** If you want the flexibility to show or hide the individual categories in your reports, then do not use the Hide option. Use the Response Level option in the Categorical red triangle menu.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Net</strong></td>
<td>(Available only for a multiple response column.) Prevents individual respondents from being counted twice when they appear in more than one supercategory.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add Mean</strong></td>
<td>Includes mean statistics in the report.</td>
</tr>
</tbody>
</table>
Add Std Dev  Includes standard deviation statistics in the report.

Add All  Includes total responses in the report. By default, the Total Responses column is always included.

Note: Supercategories are supported for all response effects except Repeated Measures and Rater Agreement.

---

- “Example of the Multiple Responses”
- “Example of Mean Score with Comparison Letters”
- “Example of a Structured Report”
- “Example of a Multiple Response with Nonresponse”

---

**Example of the Test for Response Homogeneity**

This example uses the Car Poll.jmp sample data table, which contains data collected from a survey about car ownership. The data include demographics about the individuals polled and information about their car. You want to explore the relationship between marital status and the origin of the car. You also want to test for the homogeneity of the responses. That is, you want to test to see whether the distribution of the origin of cars is the same for married and single respondents.

1. Select Help > Sample Data Library and open Car Poll.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select country and click **Responses** on the Simple tab.
4. Select marital status and click **X, Grouping Category**.
5. Click **OK**.
6. Click the Categorical red triangle and select **Test Response Homogeneity**.

**Figure 3.18 Test Response Homogeneity**

The Share Chart indicates that the married group is evenly split between ownership of American and Japanese cars. In the single group, Japanese cars are the most frequently owned.

The test for response homogeneity provides results from two versions of the test. The Pearson Test and the Likelihood Ratio Test both have chi-square test statistics and associated \( p \)-values. The test for response homogeneity has a \( p \)-value of about 0.08 for either method.

**Example of the Multiple Response Test**

This example uses the Consumer Preferences.jmp sample data table. This table contains data from a survey about people’s attitudes and opinions, as well as questions concerning oral hygiene. You can use the Test Multiple Response option to test if the response rates for each brushing time (Brush Delimited) are the same across groups (Brush). The groups are defined by the frequency that responders brush their teeth.

1. Select **Help > Sample Data Library** and open Consumer Preferences.jmp.
2. Scroll to the right until you see the Brush Delimited column.
Figure 3.19  Consumer Preferences Data Table

<table>
<thead>
<tr>
<th>Brush After Waking Up</th>
<th>Brush After Meal</th>
<th>Brush Before Sleep</th>
<th>Brush Another Time</th>
<th>Brush Other</th>
<th>Brush Delimited</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Wake</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>After Meal</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>Wake, Before Sleep,</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>After Meal</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>Wake, Before Sleep,</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>Wake, After Meal, Before Sleep,</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>Wake, After Meal, Before Sleep,</td>
</tr>
</tbody>
</table>

Note that the Brush Delimited column contains the responses to a multiple response question. Each response is separated by a comma. The four columns preceding Brush Delimited contain the same information in a different data format. Each column (Brush after Waking Up, Brush After Meal, Brush Before Sleep, and Brush Another Time) contains one response. If the response was selected the column value is a 1, and otherwise it is 0.

4. Select the Multiple tab.
5. Select Brush Delimited and click Multiple Delimited on the Multiple tab.

Tip: Alternatively, you can select Brush after Waking Up, Brush After Meal, Brush Before Sleep, and Brush Another Time and click Indicator Group on the Multiple tab.

6. Select Brush and click X, Grouping Category.
7. Click OK.
8. Click the Categorical red triangle and select Test Multiple Response > Count Test, Poisson.
The p-values show that the response rates for After Meal, Before Sleep, and Other are significantly different across brushing groups. Wake is not significantly different across brushing groups. The bar graph to the right of the Prob>ChiSq column plots the p-values on a -Log10(p) scale. From the crosstab table, you can see that most people brush their teeth when they wake up regardless of how frequently they brush their teeth.

9. Click the Categorical red triangle and select Test Multiple Response > Homogeneity Test, Binomial.

**Figure 3.21** Test Multiple Response, Binomial
The Homogeneity Test, Binomial option always produces a larger test statistic (and therefore a smaller $p$-value) than the Count Test, Poisson option. The binomial distribution compares not only the rate at which the response occurred (the number of people who reported that they brush upon waking) but also the rate at which the response did not occur (the number of people who did not report that they brush upon waking).

In this example, the proportion of responders for each response (After Meal, Before Sleep, Wake, and Other) differs across the groups. The $p$-value for each response is less than 0.05.

**Tip:** JMP detects a multiple response column by the Multiple Response modeling type or the Multiple Response column property.

---

**Example of Supercategories**

This example uses the Color Preference Survey.jmp sample data table, which contains survey data on people’s color preferences. This example illustrates the use of supercategories.

2. Select the column I like the color orange. Right-click the column heading and select Column Properties > Supercategories.
3. Under Supercategories, select Agree and Strongly agree for the column’s categories.
4. Under Supercategory Name, enter Top 2 Box.
5. Click Add.

**Tip:** Click on the triangle to the left of the name to show the categories included in the supercategory.

6. Under Supercategories, select Disagree and Strongly disagree for the column’s categories.
7. Under Supercategory Name, enter Bottom 2 Box.
8. Click Add.
9. Click **OK**.

10. Select **Analyze > Consumer Research > Categorical**.

11. Select the **Structured** tab.

12. Click the Side green triangle and select I like the color orange.

13. Click the Top green triangle and select What is your gender?

14. Click **Add=>** and then click **OK**.

15. Click the Categorical red triangle and select **Transposed Freq Chart**.
The crosstab table includes two additional rows, one for each supercategory. The supercategories are also included in the Frequency Chart. Note that the frequency counts in the Top 2 Box row are the sums of the counts in the Agree and Strongly agree categories. The frequency counts in the Bottom 2 Box row are the sums of the counts in the Disagree and Strongly disagree categories.

16. Click the Categorical red triangle and deselect **Response Levels**.

By removing the response levels, your output now contains only the supercategories. Note that the totals are for all levels. In this example, the neutral responses are not included in the supercategories.
Example of the Cell Chisq Test

This example uses the Consumer Preferences.jmp sample data table. This table contains survey data about people’s attitudes and opinions, as well as questions concerning oral hygiene. You explore the distribution of responses to the statement “I am working on my career” across age groups.

1. Select Help > Sample Data Library and open Consumer Preferences.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select I am working on my career and click Responses on the Simple tab.
4. Select Age Group and click X, Grouping Category.
5. Click OK.
6. Click the Categorical red triangle and select Crosstab Transposed.
7. Click the Categorical red triangle and select Cell Chisq.

Figure 3.25 Cell Chisq

Small p-values indicate that there is a significant difference between the observed cell count and the expected cell count. The p-values are colored by significance level from dark red for cells with significantly higher counts than expected to dark blue for cells with significantly lower counts than expected. The expected cell count is based on the observed row and column totals. The expected cell count is calculated as the row total times the column total divided by the overall count.
For example, the expected number of responses under the null hypothesis that the rates are equal in the 25 - 29 group who agree is \((287*113)/448 = 72.4\); the observed value was 95. This observed value, with a \(p\)-value of 0.00788, is significantly larger than the expected value. The number of responses in the 25 - 29 group who agree with “I am working on my career” is higher than expected if the response to this question was independent of age.

**Example of Compare Each Sample with Comparison Letters**

This example uses the Consumer Preferences.jmp sample data table. This table contains survey data about people’s attitudes and opinions, as well as questions concerning oral hygiene. You explore the distribution of responses to the statement “I am working on my career” between each age group.

1. Select **Help > Sample Data Library** and open Consumer Preferences.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select “I am working on my career” and click **Responses** on the Simple tab.
4. Select “Age Group” and click **X, Grouping Category**.
5. Click **OK**.
6. Click the Categorical red triangle and select **Compare Each Sample**.

**Figure 3.26  Compare Each Sample**
The crosstab table summarizes the statement “I am working on my career” across age groups. The cells of the table contain the frequency (count) and share (percent) of those who agree or disagree with the statement for each age group. In addition, the crosstab includes comparison letters. Each group is labeled with a letter in the Compare column, which is to the right of the group label. The letters in the Compare column enable you to interpret the outcomes of the statistical test of independence among groups.

The Compare Each Sample report provides $p$-values from the pairwise Pearson and Chi-square likelihood ratio chi-square tests. The $p$-values are reported in symmetric matrices labeled by the comparison letters.

For this example we make the following observations:

- The comparison column for the 25 - 29 group contains all letters b through g. Thus, the 25 - 29 group has significantly different response rates to the statement “I am working on my career” as compared to all other groups. Because the letter b is lowercase, the difference between the 25 - 29 group and the 30 - 34 group is significant at the 0.10 level. All other letters are uppercase, which indicate differences that are significant at the 0.05 level.

- The >54 group, denoted by letter G, is significantly different from the 30 - 34 group, denoted by B. The letter for the comparison is in the cell for group G because group G has a higher number of responders (71 versus 68) than group B.

- The single asterisks in the comparison cells are small sample size warnings. A single asterisk indicates that a group has more than 30 but fewer than 100 responses.

- A double asterisk, not observed in this example, would indicate a group size of fewer than 30.

**Example of Compare Each Cell with Comparison Letters**

This example uses the Consumer Preferences.jmp sample data table. This table contains survey data about people’s attitudes and opinions, as well as questions concerning oral hygiene. You explore the distribution of the responses about job satisfaction between employee tenure groups.

1. Select **Help > Sample Data Library** and open Consumer Preferences.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select **Job Satisfaction** and click **Responses** on the Simple tab.
4. Select **Employee Tenure** and click **X, Grouping Category**.
5. Click **OK**.
6. Click the Categorical red triangle and select **Compare Each Cell**.
7. Click the **Compare Each Cell - Details** gray disclosure icon.
Figure 3.27 Compare Each Cell

The $p$-values for pairwise likelihood ratio chi-square, Pearson chi-square, and Fisher’s exact tests for independence are provided in tables. The tables are labeled by comparison letters. The comparison letters are shown in the crosstab table to the right of the group labels. Response rates that differ between groups are indicated with a comparison letter in the crosstab table cells.
Employees with fewer than 5 years of tenure are somewhat satisfied at a greater rate than those with 20 years of tenure. This finding is noted by the letter d in the Somewhat satisfied cell in the first row of the Crosstab table. In addition, the employees with fewer than 5 years of tenure are Extremely satisfied at a lower rate than the group with 20 years of tenure. This finding is noted by the letter a in the Extremely satisfied cell of the last row of the crosstab table. The letters are placed in the cell with the highest share of responses.

**Example of User-Specified Comparison with Comparison Letters**

This example uses the Consumer Preferences.jmp sample data table. This table contains survey data about people’s attitudes and opinions. You define specific comparison groups across which to compare the responses to the statement “I am working on my career”.

1. Select Help > Sample Data Library and open Consumer Preferences.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select I am working on my career and click Responses on the Simple tab.
4. Select Employee Tenure and click X, Grouping Category.
5. Click OK.
6. Click the red triangle next to I am working on my career By Employee Tenure and select Show Letters.
7. Click the red triangle next to I am working on my career By Employee Tenure and select Specify Comparison Groups.
8. Enter A/B, B/C, C/D and click OK.
9. Click the Categorical red triangle and select Test Response Homogeneity.
The test of response homogeneity compares Group A to Group B, Group B to Group C, and Group C to Group D. Group B (5 to 10 years) respondents agree with the statement “I am working on my career” more often than those in Group C (10 to 20 years). The Pearson $p$-value for this difference in agreement rates is 0.0136.

**Example of Aligned Responses**

This example uses the Consumer Preferences.jmp sample data table. This table contains survey data about attitudes and opinions.

1. Select **Help > Sample Data Library** and open Consumer Preferences.jmp.
2. Scroll to see the column I am working on my career.
Figure 3.29 Consumer Preferences Data Table (Partial Table)

Note that there are six columns, all with the same responses: Agree and Disagree. The responses for these six columns are aligned. For this example, we analyze the columns I am working on my career and I want to see the world. First, use standardize attributes to set the value colors, value order, and modeling type for these two columns:

3. Select the column headings I am working on my career and I want to see the world. Right-click and select **Standardize Attributes**.

4. Select **Column Properties > Value Colors**. Right-click the Agree color oval and set it to green and set Disagree to red.

5. Select **Column Properties > Value Order**. Click **Reverse**.

6. Select **Attributes > Modeling Type** and **Modeling Type > Ordinal**.

7. Click **OK**.

Next, use the Categorical platform to analyze these two columns.

8. Select **Analyze > Consumer Research > Categorical**.

9. Select I am working on my career and I want to see the world.

10. Select the **Related** tab, and then click **Aligned Responses** on the Related tab.

   **Tip:** To do the same thing using the Structured tab, drag the two columns into the Multiple Aligned drop zone (green arrow).

11. Click **OK**.

Figure 3.30 Aligned Response Report
Notice that the Share Chart is a directional bar chart. The type of bar chart you see depends on the modeling type of the columns:

- Ordinal columns result in a directional bar chart. The columns in this example are both ordinal.
- Nominal columns result in a stacked bar chart.

**Example of Conditional Association and Relative Risk**

This example uses the AdverseR.jmp sample data table, which contains adverse reactions from a clinical trial. Use this data to explore the conditional association of adverse events and then the relative risk of the events in the treatment group as compared to the control.

1. Select Help > Sample Data Library and open AdverseR.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select the Multiple tab.
4. Select ADVERSE REACTION and click Multiple Response by ID on the Multiple tab.
5. Select TREATMENT GROUP and click X, Grouping Category.
6. Select PATIENT ID and click ID.
7. Under the other launch window options, select Unique Occurrences within ID and click OK.
8. Click the Categorical red triangle and select Conditional Association.
The conditional association matrix provides the conditional probability of one adverse reaction given the presence of another reaction. The probabilities are across all groups. The probability of abnormal vision given that a patient has abdominal pain is 0.0323.

**Tip:** Hover over the heat map for conditional probabilities.

9. Click the Categorical red triangle and select **Relative Risk**.
10. Select PBO in the window and click **OK**.
    Right-click the Relative Risk Report in the window and select **Sort by Column**.
11. Select Relative Risk and click **OK**.
Figure 3.32 Relative Risk Report (Partial Report)

The Relative Risk option computes relative risks of different responses as the ratio of the risk for each level of the grouping variable. The default Relative Risk report lists the response name, the risk (rate) for each level of the grouping variable, a plot of the relative risk with 95% confidence intervals, and the relative risk estimate. Here you can compare the relative risk of the adverse reactions by treatment group. The relative risk of an infection is 5.7 times greater for PBO relative to ST_DRUG. However, the confidence interval is very wide and includes a relative risk of 1.0. A relative risk of 1.0 occurs when the risk is equal for each level of the grouping variable.

Right-click and select Columns > Lower 95% and Columns > Upper 95% to add 95% confidence intervals on the relative risk estimates to the report table.

Example of Rater Agreement

This example uses the Attribute Gauge.jmp sample data, which has the ratings (0/1) from three operators rating 50 parts three times.

1. Select Help > Sample Data Library and open Attribute Gauge.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select the Related tab.
4. Select A, B, and C, and click Rater Agreement on the Related tab.
5. Click OK.
The rater agreement is strong as shown by the Kappa statistics. The Kappa statistic can take on a value between 0 (no agreement) to 1.0 (perfect agreement). The details section provides 2x2 tables for each pair of raters. The Bowker test of symmetry tests the null hypothesis that cell proportions are symmetric for all pairs of cells ($p_{ij} = p_{ji}$ for all $i, j$). Here, $p$-values for the Bowker test are all greater than 0.05, indicating no strong evidence of asymmetry between raters.

**Example of Repeated Measures**

This example uses the Presidential Elections.jmp sample data table, which contains United States presidential election results for each state from 1980 through 2012. Use this data table to explore repeated measures where we consider the election results as repeated measures.

1. Select **Help > Sample Data Library** and open Presidential Elections.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select the Related tab.
5. Click **OK**.
6. Near the bottom of the report window, click the gray Transition Report disclosure icon to open the Transition Report.

**Figure 3.34** Repeated Measures Transition Report

The Transition Report is unique to the repeated measures analysis. This report includes counts and rates of differences between subsequent time points. Between 1980 and 1984, there were 5 Democratic states that transitioned to Republican states at a rate of 0.8333 or 5 out of 6 states. In 1980, they voted Democratic but voted Republican in 1984. Between 2008 and 2012, there were 2 out of 28 Democratic states that transitioned to Republican at a rate of 0.0714. All other states voted the same way in both the 2008 and 2012 elections.

**Example of the Multiple Responses**

The examples in this section use sample data tables that contain the same information organized in five different data table layouts. The data come from testing a fabrication line on three different occasions under two different conditions. Each set of operating conditions (or batch) yielded 50 units for inspection. Inspectors recorded seven types of defects. Each unit could have zero, one, or more than one defect. A unit could have more than one defect of the same kind.
Multiple Response

The Failure3MultipleField.jmp sample data table has a row for each unit and multiple columns for defects, where defects are entered one per column. In this example, there are three columns for defects. Thus, any one unit had at most three defects.

1. Select Help > Sample Data Library and open Quality Control/Failure3MultipleField.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select the Multiple tab.
4. Select Failure1, Failure2, and Failure3, and click Multiple Response on the Multiple tab.
5. Select clean and date and click X, Grouping Category.
6. Click OK.

**Figure 3.35 Multiple Response Report**

- **OCT 2**
- **OCT 3**

**Failure Chart**

- **contamination**
- **corrosion**
- **doping**
- **metallization**
- **miscellaneous**
- **oxide defect**
- **silicon defect**
The crosstab table has a row for each batch and a column for each defect type. The frequency, share, and rate of each defect within each batch are shown in the table cells. For example, for the batch after cleaning on OCT 1, there were 12 contamination defects representing 12/23 or 52.2% of the defects for that batch. The 12 contamination defects were from 50 units. For each clean and date combination, there were 50 total units. Each unit could have one or more defects. Therefore, the rate of contamination per unit was 24%. For the batch before cleaning on OCT 1, the Total Cases Responding is 28. The Total Responses count is 31, because three of the cases reported two defects.

**Multiple Response by ID**

The Failure3ID.jmp sample data table has a row for each defect type within each batch, a column for the number of occurrences of each defect type, and an ID column for each batch.

**Figure 3.36  Failure3ID Data Table (Partial Table)**

1. Select **Help > Sample Data Library** and open Quality Control/Failure3ID.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select the Multiple tab.
4. Select failure and click **Multiple Response by ID** on the Multiple tab.
5. Select clean and date and click **X, Grouping Category**.
6. Select SampleSize and click **Sample Size**.
7. Select N and click **Freq**.
8. Select ID and click **ID**.
9. Click **OK**.

The resulting report is the same as the report shown in Figure 3.35 with the exception of the Total Cases Responding column in the crosstab table. Here, the defect counts were summarized. From the summarized table, there is no record of the number of units with zero defects. Thus, the Total Cases Responding is the full batch size of 50 for each batch.
Multiple Delimited

The Failures3Delimited.jmp sample data table has a row for each unit with a single column in which the defects are recorded, delimited by a comma. Note in the partial data table, shown in Figure 3.37, that some units did not have any observed defects, so the failures column is empty.

![Figure 3.37 Failure3Delimited.jmp Data Table (Partial Table)](image)

1. Select **Help > Sample Data Library** and open Quality Control/Failures3Delimited.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select the Multiple tab.
4. Select failures and click **Multiple Delimited** on the Multiple tab.
5. Select clean and date and click **X, Grouping Category**.
6. Click **OK**.

When you click **OK**, you also get the report shown in Figure 3.35.

**Note:** If you specify more than one delimited column, separate analyses are produced for each column.

Indicator Group

The Failures3Indicators.jmp sample data table has a row for each unit and an indicator column for each defect type. The data entry in each defect column is a 0 if that defect was not observed and a 1 if the defect was observed for the unit.

![Figure 3.38 Faliure3Indicators.jmp Data Table (Partial Table)](image)

1. Select **Help > Sample Data Library** and open Quality Control/Failures3Indicators.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select the Multiple tab.
4. Select contamination through silicon defect and click **Indicator Group** on the Multiple tab.
5. Select clean and date and click **X, Grouping Category**.
6. Click **OK**.

When you click **OK**, you get the report shown in Figure 3.35.

**Response Frequencies**

The Failure3Freq.jmp sample data table has a row for each batch, a column for each defect type, and a column for the batch size. The data entries in the defect columns are the number of occurrences of each defect in the batch.

**Figure 3.39** Failure3Freq.jmp Data Table

1. Select **Help > Sample Data Library** and open Quality Control/Failure3Freq.jmp.
2. Select **Analyze > Consumer Research > Categorical**.
3. Select the Multiple tab.
4. Select the frequency variables (contamination through silicon defect).
5. On the Multiple tab, click **Response Frequencies**.
6. Select clean and date and click **X, Grouping Category**.
7. Select Sample Size and click **Sample Size**.
8. Click **OK**.
The resulting output is the same as that in Figure 3.35 with the exception of the Total Cases Responding column in the crosstab table. Here, the defect counts were summarized. From the summarized table, there is no record of the number of units with zero defects. Thus, the Total Cases Responding is the full batch size of 50 for each batch.

**Example of Mean Score with Comparison Letters**

This example uses the Consumer Preferences.jmp sample data table to explore the relationship between employee tenure and having school age children. The Employee Tenure column is a numeric column with values 1, 2, 3, and 4. These values have been assigned Value Labels using the Value Labels column property. To evaluate an average employee tenure using the Mean Score option in the categorical platform, assign Value Scores to the column values. For more information about column properties, see *Using JMP*.

1. Select **Help > Sample Data Library** and open Consumer Preferences.jmp.
2. In the data table, right-click the Employee Tenure column heading and select **Column Properties > Value Scores**.
3. Enter 1 for **Value** and 3 for **Score** and click **Add**.
4. Enter 2 for **Value** and 7.5 for **Score** and click **Add**.
5. Enter 3 for **Value** and 15 for **Score** and click **Add**.
6. Enter 4 for **Value** and 25 for **Score** and click **Add**.
7. Click **OK**.
8. Select **Analyze > Consumer Research > Categorical**.
9. Select **Employee Tenure** and click **Responses** on the Simple tab.
10. Select **School Age Children** and click **X, Grouping Category**.
11. Click **OK**.
12. Click the Categorical red triangle and select **Mean Score**.
13. Click the Categorical red triangle and select **Mean Score Comparisons**.

**Figure 3.41**  Categorical Report with Mean Scores

The mean employee tenure for those with school age children is 10.17 and 9.53 for those without school age children. Because the means are not statistically different, the Compare Means column in the Crosstab table is empty. If there were a difference, a letter would indicate the difference. If you had not used value scores, then the mean for those with school age children would be 2.20 and 2.057 for those without school age children.

**Tip:** Be aware of how your data are recorded when using the mean score option. If your data are recorded as coded numeric data with value labels, the mean value calculations are based on the numeric data. If the numeric values do not have meaning, use the Value Score column property to assign meaningful values to the response levels.
Example of a Structured Report

This example uses the Consumer Preferences.jmp sample data table to compare job satisfaction and salary against gender by age group and position tenure. Use the Structured tab to create the report.

1. Select Help > Sample Data Library and open Consumer Preferences.jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Select the Structured tab.
4. Drag Gender to the green drop zone at the Top of the table on the Structured tab.
5. Drag Age Group to the green drop zone just below Gender.
6. Drag Position Tenure to the green drop zone at the Top of the table next to Gender.
7. Drag Job Satisfaction to the green drop zone at the Side of the table.
8. Drag Salary Group to the green drop zone at the Side of the table under Job Satisfaction.

Tip: Click on the green drop zone arrows to select columns.

Figure 3.42 Structured Tab Report Setup

9. Click Add=>.
10. Click OK.
11. Click the Categorical red triangle and select Test Response Homogeneity.
Figure 3.43 Structured Tab Report Example

The structured tab report contains the table that you specified in the Structured tab. The tests for response homogeneity are for each combination of grouping variables. We see that, for males, there is no difference in job satisfaction across age groups (Pearson $p$-value = 0.9703). For females, there is a difference in job satisfaction across age groups (Pearson $p$-value = 0.0149). The middle-aged females tend to be the least satisfied with their jobs. Share and frequency charts can be added to your report to visualize your results.

Example of a Multiple Response with Nonresponse

This example uses the Color Preference Survey jmp sample data table, which contains survey data about people’s color preferences. You can use the Categorical platform to summarize results from a multiple response question with nonresponses. A nonresponse is a participant who did not answer the question. Surveys often use “none of the above” or “not applicable” as a response choice. This provides a method for distinguishing responders who do not see an appropriate response from those who did not answer the question.

1. Select Help > Sample Data Library and open Color Preference Survey jmp.
2. Select Analyze > Consumer Research > Categorical.
3. Click the Structured tab.
4. Select What colors do you like? (with nonresponse) and drag it to the green arrow drop zone at the Side of the table.
**Note:** This column contains multiple response data where the response levels are delimited with commas. There are three rows that contain no responses. This column was constructed for this example and does not align with the responses in the individual “What colors do you like” columns.

5. Click the **Top** green arrow and select *What is your gender?*
6. Click **Add=>**.
7. Click **OK**.

**Figure 3.44** Initial Cross Tabulation

<table>
<thead>
<tr>
<th>What colors do you like? (with nonresponse) By What is your gender?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Freq Share Rate</strong></td>
</tr>
<tr>
<td>Blue</td>
</tr>
<tr>

</tr>
<tr>
<td>None of the above</td>
</tr>
<tr>
<td>Orange</td>
</tr>
<tr>
<td>Pink</td>
</tr>
<tr>
<td>Purple</td>
</tr>
<tr>
<td>Red</td>
</tr>
<tr>
<td>Yellow</td>
</tr>
<tr>
<td>Total Responses</td>
</tr>
<tr>
<td>Total Cases</td>
</tr>
<tr>
<td>Total Cases Responding</td>
</tr>
</tbody>
</table>

Note that the number of total cases is higher than the number of total cases responding. There are 37 Females who filled out the survey but only 36 responded to this question.

8. Click the Categorical red triangle and select **Test Multiple Responses > Exclude Nonresponses**.
9. Click the Categorical red triangle and select **Test Multiple Responses > Homogeneity Test, Binomial**.
Figure 3.45: Binomial Homogeneity Test Results

The analysis supports that blue and yellow have similar preference levels across genders while other colors tend to be favored more or less across genders. For example, Red appears to be liked more by males than by females. The p-value for the test is 0.0044, which supports a conclusion that there is a difference in preference across genders. From the crosstab in Figure 3.44 you find that 76.7% of the males liked the color red as compared to 48.6% of the females.

The note at the top of the output indicates that nonresponse rows are excluded from the analysis. The note at the bottom of the output indicates that it is assumed that the multiple response is a check all that applies type question. This means that a respondent can select more than one response to the question. The tests are performed using only those rows with responses. The three rows that did not have responses for the question are not included.

Tip: You can obtain the same output using the Multiple tab. Select "What colors do you like? (with nonresponse)" as a Multiple Delimited response and "What is your Gender?" as a grouping variable.
Set Preferences

The Categorical red triangle menu has a Set Preferences option to enable you to specify settings and preferences.

Figure 3.46 Set Preferences Window

Select the **Set** box for the options that you want to set. Select the option box if you want the option to appear by default, or deselect the option box if you do not want the option to appear by default. To submit the changes that you make to the platform preferences, select the **Submit Platform Preferences** box. To save the changes that you make as a preference script, select the **Create Platform Preference Script** box. When the Categorical platform is launched, the preferences associated with the current preference set are used to create the Categorical report.

Running the saved script submits the preferences to the platform preferences. You can use the platform preference script to share a preference set among multiple users, or to save the settings for specific projects.
Statistical Details for the Categorical Platform

This section contains statistical details for the Categorical platform.

Rao-Scott Correction

The Rao-Scott correction is applied to the test of response homogeneity for multiple responses. See Lavassani et al. (2009).

In the case of a multiple response, you can have overlapping samples, meaning a single participant can provide more than one response. The Pearson chi-square test is not appropriate for multiple responses, because the multiple responses violate the Pearson chi-square test assumption of independence. In addition, expected values calculated using the marginal totals are influenced by the multiple responses because the totals are larger than if multiple responses were not allowed.

The Rao-Scott chi-square statistic is defined as follows:

$$\chi_C^2 = \frac{\chi^2}{\delta}$$

where

$$\chi^2$$ is the standard Pearson Chi-squared statistic

$$\delta = 1 - \frac{m_{++}}{n_+C}$$ is the correction factor

The correction factor contains the following quantities:

- $$m_{++}$$ is the total count of the multiple responses
- $$n_+$$ is the total number of participants and
- $$C$$ is the number of response levels (number of columns in the Crosstab table).

The degrees of freedom are $$(R-1)C$$ or the number of rows minus 1 times the number of columns.
Chapter 4
Choice Models
Fit Models for Choice Experiments

Use the Choice platform to analyze the results of choice experiments conducted in the course of market research. Choice experiments are used to help discover which product or service attributes your potential customers prefer. You can use this information to design products or services that have the attributes that your customers most desire.

The Choice platform enables you to do the following:

- Use information about subject (customer) traits as well as product attributes.
- Analyze choice experiments where respondents were allowed to select “none of these”.
- Integrate data from one, two, or three sources.
- Use the integrated profiler to understand, visualize, and optimize the response (utility) surface.
- Obtain subject-level scores for segmenting or clustering your data.
- Estimate subject-specific coefficients using a Bayesian approach.
- Use bias-corrected maximum likelihood estimators (Firth 1993).

Overview of the Choice Modeling Platform

Choice modeling, pioneered by McFadden (1974), is a powerful analytic method used to estimate the probability of individuals making a particular choice from presented alternatives. Choice modeling is also called conjoint choice modeling, discrete choice analysis, and conditional logistic regression.

A choice experiment studies customer preferences for a set of product or process (in the case of a service) attributes. Respondents are presented sets of product attributes, called profiles. Each respondent is shown a small set of profiles, called a choice set, and asked to select the preference that he or she most prefers. Each respondent is usually presented with several choice sets. Use the Choice platform to analyze the results of a choice experiment.

Note: You can design your choice experiment using the Choice Design platform. See the Design of Experiments Guide.

Because customers vary in how they value attributes, many market researchers view market segmentation as an important step in analyzing choice experiments. Otherwise, you risk designing a product or process that pleases the “average” customer, who does not actually exist, and ignoring the preferences of market segments that do exist.

For background on choice modeling, see Louviere et al. (2015), Train (2009), and Rossi et al. (2005).

The Choice Platform

The Choice Modeling platform uses a form of conditional logistic regression to estimate the probability that a configuration is preferred. Unlike simple logistic regression, choice modeling uses a linear model to model choices based on response attributes and not solely upon subject characteristics. In choice modeling, a respondent might choose between two cars that are described by a combination of ten attributes, such as price, passenger load, number of cup holders, color, GPS device, gas mileage, anti-theft system, removable-seats, number of safety features, and insurance cost.

The Choice platform allows respondents to not make a choice from among a set of profiles. The no choice option is treated as a product with a single attribute (“Select none of these”) that respondents are allowed to select. The parameter estimate for the No Choice attribute can then be interpreted in many ways, depending on the assumptions of the model. The Choice platform also enables you to obtain subject-level information, which can be useful in segmenting preference patterns.
You can obtain bias-corrected maximum likelihood estimators as described by Firth (1993). This method has been shown to produce better estimates and tests than MLEs without bias correction. In addition, bias-corrected MLEs improve separation problems that tend to occur in logistic-type models. See Heinze and Schemper (2002) for a discussion of the separation problem in logistic regression.

**Note:** The Choice platform is not appropriate to use for fitting models that involve ranking, scoring, or nested hierarchical choices. You can use PROC MDC in SAS/ETS for these analyses.

**Choice Designs in Developing Products and Services**

Although customer satisfaction surveys can disclose what is wrong with a product or service, they fail to identify consumer preferences with regard to specific product attributes. When engineers design a product, they routinely make hundreds or thousands of small design decisions. If customer testing is feasible and research participants (subjects) are available, you can use choice experiments to guide some design decisions.

Decreases in survey deployment, modeling, and prototyping costs facilitate the customer evaluation of many attributes and alternatives as a product is designed. Choice modeling can be used in Six Sigma programs to improve consumer products, or, more generally, to make the products that people want. Choice experiments obtain data on customer preferences, and choice modeling analysis reveals such preferences.

**Segmentation**

Market researchers sometimes want to analyze the preference structure for each subject separately in order to see whether there are groups of subjects that behave differently. However, there are usually not enough data to do this with ordinary estimates. If there are sufficient data, you can specify the subject identifier as a “By groups” in the Response Data or you could introduce a subject identifier as a subject-side model term. This approach, however, is costly if the number of subjects is large.

If there are not sufficient data to specify “By groups;” you can segment in JMP by clustering subjects using the Save Gradients by Subject option. The option creates a new data table containing the average Hessian-scaled gradient on each parameter for each subject. For an example, see “Example of Segmentation” on page 124. For more information about the gradient values, see “Gradients” on page 142.

In JMP Pro, you can request that the Choice platform use a Hierarchical Bayes approach in order to facilitate market segmentation. Bayesian modeling provides subject-specific estimates of model parameters (also called part-worths). These parameters i can be analyzed with hierarchical clustering or some other type of cluster analysis to reveal market segments.
Examples of the Choice Platform

In a study of pizza preferences, each respondent is presented with four choice sets, each containing two profiles. The Choice platform can analyze data that is in a one table format or a multiple data format. In the multiple table format, information about responses, choice sets, and subjects is saved in different data tables. In the one table format, that information is contained in a single data table.

- “One Table Format with No Choice” on page 87 shows how to analyze a subset of the available data in a one table format.
- “Multiple Table Format” on page 90 shows how to bring together information from different tables into one Choice analysis

One Table Format with No Choice

In this example, some respondents do not express a preference for either profile. The respondent makes “no choice”. When a respondent does not express a preference, the respondent’s choice indicator is entered as missing.

1. Select Help > Sample Data Library and open Pizza Combined No Choice.jmp.
   Choice sets are defined by the combination of Subject and Trial. Notice that there are missing values in the Indicator column for some choice sets.
2. Select Analyze > Consumer Research > Choice.
   The One Table, Stacked data format is the default.
3. Click Select Data Table.
4. Select Pizza Combined No Choice and click OK.
5. Complete the launch window:
   - Select Indicator and click Response Indicator.
   - Select Subject and click Subject ID.
   - Select Trial and click Choice Set ID.
   - Select Crust, Cheese, and Topping and click Add in the Construct Profile Effects panel.
   - Select Gender and click Add in the Construct Subject Effects (Optional) panel.
Figure 4.2  Completed Launch Window

6. Check the box next to **Respondent is allowed to select “None” or “No Choice”**.
7. Click **Run Model**.
The Effect Summary report shows the effects in order of significance. Cheese is the most significant effect, followed by the No Choice Indicator, which is treated as a model effect. The subject effect interactions Gender*Topping and Gender*Crust are also significant, indicating that preferences for Topping and Crust depend on Gender market segments.

To get some insight on the nature of the No Choice responses, select and view those choice sets that resulted in No Choice.

8. In the data table, right-click in a cell in the Indicator column where the response is missing and select Select Matching Cells.

9. In the Rows panel, right-click Selected and select Data View.
In the table in Figure 4.4, consider the profiles in the first seven choice sets, which are defined by the Subject and Trial combinations in rows 1 to 14. The only difference within each choice set is the Cheese. There is an indication that some respondents might not be able to detect the difference in cheeses. However, the analysis takes the No Choice Indicator into account and concludes that, despite this behavior, Cheese is significant.

To see how to further analyze data of this type, see “Find Optimal Profiles” on page 95.

**Multiple Table Format**

In this example, you examine pizza choices where three attributes, with two levels each, are presented to the respondents. The study was designed such that the respondents had to make a choice. The analysis uses three data tables: Pizza Profiles.jmp, Pizza Responses.jmp, and Pizza Subjects.jmp. Although you can always arrange your data into a single table, a multi-table approach can be more convenient than a one table analysis when you have additional profile and subject variables that you want to include in your analysis.

   - The profile data table, Pizza Profiles.jmp, lists all the pizza choice combinations that you want to present to the subjects. Each choice combination is given an ID.
   - The responses data table, Pizza Responses.jmp, contains the design and results. For the experiment, each subject is given four choice sets, where each choice set consists of two...
choice profiles (Choice1 and Choice2). The subject selects a preference (Choice) for each choice set. For information about how to construct a choice design, see the Design of Experiments Guide. Notice that each value in the Choice column is an ID value in the Profile data table that contains the attribute information.

– The subjects data table, Pizza Subjects.jmp, includes a Subject ID column and a single characteristic of the subject, Gender. Each value of Subject in the Pizza Subjects.jmp data table corresponds to values in the Subject column in the Pizza Responses.jmp data table.

2. Select Analyze > Consumer Research > Choice to open the launch window.

   Note: This can be done from any of the three open data tables.

3. From the Data Format menu, select Multiple Tables, Cross-Referenced.

   There are three separate sections, one for each of the data sources.

4. Click Select Data Table under Profile Data.

   A Profile Data Table window appears, which prompts you to specify the data table for the profile data.

5. Select Pizza Profiles and click OK.

6. Select ID and click Profile ID.

7. Select Crust, Cheese, and Topping and click Add.

Figure 4.5 Profile Data
8. Click the disclosure icon next to Response Data to open the outline and click Select Data Table.

9. Select Pizza Responses and click OK.

10. Enter Profile ID selections:
   - Select Choice and click Profile ID Chosen.
   - Select Choice1 and Choice2 and click Profile ID Choices.
   - Select Subject and select Subject ID.

**Figure 4.6** Response Data Window

Choice1 and Choice2 are the profiles presented to a subject in each of four choice sets. The Choice column contains the chosen preference between Choice1 and Choice2.

11. Click the disclosure icon next to Subject Data to open the outline and click Select Data Table.

12. Select Pizza Subjects and click OK.

13. Select Subject and click Subject ID.

14. Select Gender and click Add.
15. Click **Run Model**.
Six effects are entered into the model. The effects Crust, Cheese, and Topping are product attributes. The interaction effects, Gender*Crust, Gender*Cheese, and Gender*Topping are subject-effect interactions with the attributes. These interaction effects enable you to construct products that meet market-segment preferences.

Note: For Choice models, subject effects cannot be entered as main effects. They appear only as interaction terms.

The Effect Summary and Likelihood Ratio Tests reports show strong interactions between Gender and Crust and between Gender and Topping. Notice that the main effects of Crust and Topping are not significant. If you had not included subject-level effects, you might have overlooked important information relative to market segmentation.
Find Optimal Profiles

Next, you use the Utility Profiler to explore your results and find optimal settings for the attributes.

1. Click the Choice Model: Choice red triangle and select **Utility Profiler**.
   
   The Subject Terms menu beneath the profiler indicates that it is showing results for females.

2. Click the Utility Profiler red triangle and select **Optimization and Desirability > Desirability Functions**.

**Figure 4.9** Utility Profiler with Desirability Function

A desirability function that maximizes utility is added to the profiler. See *Profilers*.

3. Click the Utility Profiler red triangle and select **Optimization and Desirability > Maximize Desirability**.
Figure 4.10 Utility Profiler with Optimal Settings for Females

The optimal settings for females are a thin crust, Mozzarella cheese, and no topping.

4. From the Subject Terms menu, select M.
5. Click the Utility Profiler red triangle and select **Optimization and Desirability > Maximize Desirability**.

Figure 4.11 Utility Profiler with Male Level Factor Setting

The optimal settings for males are a thick crust, Mozzarella cheese, and a Pepperoni topping.

In this example, understanding the preferences of gender-defined market segments enables you to provide two pizza choices that appeal to two segments of customers.
Launch the Choice Platform

Launch the Choice platform by selecting **Analyze > Consumer Research > Choice.**

Your data for the Choice platform can be combined in a single data table or it can reside in two or three separate data tables. In the Choice launch window specify whether you are using one or multiple data tables in the Data Format list.

### One Table, Stacked

For the One Table, Stacked format, the data are in a single data table. There is a row for every profile presented to a subject and an indicator of whether that profile was selected. The **Pizza Combined No Choice.jmp** sample data table contains the results of a choice experiment in a single table format. See “One Table Format with No Choice” on page 87.

For more information about the launch window for this format, see “Launch Window for One Table, Stacked” on page 98.

### Multiple Tables, Cross-Referenced

For the Multiple Tables, Cross-Referenced format, the data are in two or three separate data tables. A profile data table and a response data table are required. A subject data table is optional. Note the following:

- The profile data table must contain a column with a unique identifier for each profile and columns for the profile level variables. The profile identifier is used in the response data table to identify the profiles presented and the profile selected.

- The optional subject data table must contain a column with a unique subject identifier for each subject and columns for the subject level variables. The subject identifier is used in the response table to identify the subjects.

The launch window for this format contains three sections: Profile Data, Response Data, and Subject Data. Each section corresponds to a different data table. You can expand or collapse each section as needed.

The **Pizza Profiles.jmp, Pizza Responses.jmp, and Pizza Subjects.jmp** sample data tables contain the results of a choice experiment using three tables. There is one table for the profiles, one for the responses, and one for the subject information. See “Multiple Table Format” on page 90.

For more information about the launch window for this format, see “Launch Window for Multiple Tables, Cross-Referenced” on page 100.
Launch Window for One Table, Stacked

Figure 4.12 Launch Window for One Table, Stacked Data Format

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Select Data Table  Select or open the data table that contains the combined data. Select Other to open a file that is not already open.

Response Indicator  A column that contains values that indicate the preferred choice. A 1 indicates the preferred profile and a 0 indicates the other profiles. If respondents are given an option to select no preference, enter missing values for choice sets where no preference is indicated. See “Respondent is allowed to select “None” or “No Choice”” on page 99.

Subject ID  An identifier for the study participant.

Choice Set ID  An identifier for the choice set presented to the subject for a given preference determination.

Grouping  A column which, when used with the Choice Set ID column, uniquely designates each choice set. For example, if a choice set has Choice Set ID = 1 for Survey = A, and another choice set has Choice Set ID = 1 for Survey = B, then Survey should be used as a Grouping column.

By  Produces a separate report for each level of the By Variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Construct Profile Effects  Add effects constructed from the attributes in the profiles.
For information about the Construct Profile Effects panel, see *Fitting Linear Models*.

**Note:** The choice model observes the column coding property of continuous profile and subject effects.

**Construct Subject Effects (Optional)** Add effects constructed from subject-related factors.

For information about the Construct Subject Effects panel, see *Fitting Linear Models*.

**Firth Bias-adjusted Estimates** Computes bias-corrected MLEs that produce better estimates and tests than MLEs without bias correction. These estimates also improve separation problems that tend to occur in logistic-type models. See Heinze and Schemper (2002) for a discussion of the separation problem in logistic regression.

**Hierarchical Bayes** Uses a Bayesian approach to estimate subject-specific parameters. See “Bayesian Parameter Estimates” on page 108.

**Number of Bayesian Iterations** (Applicable only if Hierarchical Bayes is selected.) The total number of iterations of the adaptive Bayes algorithm used to estimate subject-specific parameters. This number includes a burn-in period of iterations that are discarded. The number of burn-in iterations is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Respondent is allowed to select “None” or “No Choice”** Enters a No Choice Indicator into the model for response rows containing missing values. For the One Table, Stacked data format, the No Choice rows must contain (numeric) missing values in the Response Indicator column. The option appears at the bottom of the launch window.
Launch Window for Multiple Tables, Cross-Referenced

Figure 4.13  Launch Window for Multiple Tables, Cross-Referenced Data Format

Figure 4.13 shows the launch window for Multiple Tables, using Pizza Profiles.jmp as the Profile table.

In the case of Multiple Tables, Cross-referenced, the launch window has three sections:

- **“Profile Data”** on page 100
- **“Response Data”** on page 102
- **“Subject Data”** on page 104

**Profile Data**

The profile data table describes the attributes associated with each choice. Each attribute defines a column in the data table. There is a row for each profile. A column in the table contains a unique identifier for each profile. Figure 4.14 shows the Pizza Profiles.jmp data table and a completed Profile Data panel.
Figure 4.14 Profile Data Table and Completed Profile Data Outline

Select Data Table Select or open the data table that contains the profile data. Select Other to open a file that is not already open.

Profile ID Identifier for each row of attribute combinations (profile). If the Profile ID column does not uniquely identify each row in the profile data table, you need to add Grouping columns. Add Grouping columns until the combination of Grouping and Profile ID columns uniquely identify the row, or profile.

Grouping A column which, when used with the Profile ID column, uniquely designates each choice set. For example, if Profile ID = 1 for Survey = A, and a different Profile ID = 1 for Survey = B, then Survey would be used as a Grouping column.

Construct Profile Effects Add effects constructed from the attributes in the profiles. For information about the Construct Profile Effects panel, see Fitting Linear Models.
**Note:** The choice model observes the column coding property of continuous profile and subject effects.

**Firth Bias-adjusted Estimates**  Computes bias-corrected MLEs that produce better estimates and tests than MLEs without bias correction. These estimates also improve separation problems that tend to occur in logistic-type models. See Heinze and Schemper (2002) for a discussion of the separation problem in logistic regression.

**Hierarchical Bayes**  Uses a Bayesian approach to estimate subject-specific parameters. See “Bayesian Parameter Estimates” on page 108.

**Number of Bayesian Iterations**  (Applicable only if Hierarchical Bayes is selected.) The total number of iterations of the adaptive Bayes algorithm used to estimate subject effects. This number includes a burn-in period of iterations that are discarded. The number of burn-in iterations is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Response Data**

The response data table includes a subject identifier column, columns that list the profile identifiers for the profiles in each choice set, and a column containing the preferred profile identifier. There is a row for each subject and choice set. Grouping variables can be used to distinguish choice sets when the data contain more than one group of choice sets. Figure 4.15 shows the Pizza Responses.jmp data table and a completed Response Data panel.

Grouping variables can be used to align choice indices when more than one group is contained within the data.

**Select Data Table**  Select or open the data table that contains the response data. Select Other to open a file that is not already open.

**Profile ID Chosen**  The Profile ID from the Profile data table that represents the subject’s selected profile.

**Grouping**  A column which, when used with the Profile ID Chosen column, uniquely designates each choice set.

**Profile ID Choices**  The Profile IDs of the set of possible profiles. There must be at least two profiles.

**Subject ID**  An identifier for the study participant.
**Freq**  A column containing frequencies. If \( n \) is the value of the Freq variable for a given row, then that row is used in computations \( n \) times. If it is less than 1 or missing, then JMP does not use it to calculate any analyses.

**Weight**  A column containing a weight for each observation in the data table. The weight is included in analyses only when its value is greater than zero.

**By**  Produces a separate report for each level of the By Variable. If more than one By variable is assigned, a separate analysis is produced for each possible combination of the levels of the By variables.

**Respondent is allowed to select “None” or “No Choice”**  Enters a No Choice Indicator into the model for response rows containing missing values. For the Multiple Tables, Cross-Referenced data format, the No Choice rows must contain (categorical) missing values in the Profile ID Chosen column in the Response Data table. The option appears at the bottom of the Response Data panel.

### Subject Data

The subject data table is optional and depends on whether you want to model subject effects. The table contains a column with the subject identifier used in the response table, and columns for attributes or characteristics of the subjects. You can put subject data in the response data table, but you should specify the subject effects in the Subject Data outline. Figure 4.16 shows the Pizza Subjects.jmp data table and a completed Subject Data panel.
Select Data Table  Select or open the data table that contains the subject data. Select Other to open a file that is not already open.

Subject ID  Unique identifier for the subject.

By  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Construct Model Effects  Add effects constructed from columns in the subject data table.

For information about the Construct Model Effects panel, see Fitting Linear Models.
Choice Model Report

- “Effect Summary”
- “Parameter Estimates”
- “Likelihood Ratio Tests”
- “Bayesian Parameter Estimates”

Effect Summary

The Effect Summary report appears if your model contains more than one effect and if it can be calculated quickly. (If the report does not appear, select Likelihood Ratio Tests from the red triangle menu to make both reports appear.) It lists the effects estimated by the model and gives a plot of the LogWorth (or FDR LogWorth) values for these effects. The report also provides controls that enable you to add or remove effects from the model. The model fit report updates automatically based on the changes made in the Effects Summary report. See Fitting Linear Models.

Note: The Effect Summary report is not applicable to models fit with Hierarchical Bayes.

Effect Summary Table Columns

The Effect Summary table contains the following columns:

**Source**  Lists the model effects, sorted by ascending p-values.

**LogWorth**  Shows the LogWorth for each model effect, defined as -log10(p-value). This transformation adjusts p-values to provide an appropriate scale for graphing. A value that exceeds 2 is significant at the 0.01 level (because -log10(0.01) = 2).

**FDR LogWorth**  Shows the False Discovery Rate LogWorth for each model effect, defined as -log10(FDR PValue). This is the best statistic for plotting and assessing significance. Select the FDR check box to replace the LogWorth column with the FDR LogWorth column.

**Bar Chart**  Shows a bar chart of the LogWorth (or FDR LogWorth) values. The graph has dashed vertical lines at integer values and a blue reference line at 2.

**PValue**  Shows the p-value for each model effect. This is the p-value corresponding to the significance test displayed in the Likelihood Ratio Tests report.

**FDR PValue**  Shows the False Discovery Rate p-value for each model effect calculated using the Benjamini-Hochberg technique. This technique adjusts the p-values to control the false
discovery rate for multiple tests. Select the **FDR** check box to replace the **PValue** column with the **FDR PValue** column.

For more information about the FDR correction, see Benjamini and Hochberg (1995). For more information about the false discovery rate, see *Predictive and Specialized Modeling* or Westfall et al. (2011).

**Effect Summary Table Options**

The options below the summary table enable you to add and remove effects:

**Remove**  
Removes the selected effects from the model. To remove one or more effects, select the rows corresponding to the effects and click the Remove button.

**Add Profile Effect**  
Opens a panel that contains a list of all columns in the data table for the OneTable, Stacked data format, and for the columns in the Profile Data table for the Multiple Tables, Cross-Referenced data format. Select columns that you want to add to the model, and then click Add below the column selection list to add the columns to the model. Click Close to close the panel.

**Add Subject Effect**  
Opens a panel that contains a list of all columns in the data table for the OneTable, Stacked data format, and for the columns in the Subject Data table for the Multiple Tables, Cross-Referenced data format. Select columns that you want to add to the model, and then click Add below the column selection list to add the columns to the model. Click Close to close the panel.

**Parameter Estimates**

The Parameter Estimates report gives estimates and standard errors of the coefficients of utility associated with the effects listed in the Term column. The coefficients associated with attributes are sometimes referred to as *part-worths*. When the Firth Bias-Adjusted Estimates option is selected in the launch window, the parameter estimates are based on the Firth bias-corrected maximum likelihood estimators. These estimates considered to be more accurate than MLEs without bias correction. For more information about utility, see “Utility and Probabilities” on page 141.

**Comparison Criteria**

The AICc (corrected Akaike’s Information Criterion), BIC (Bayesian Information Criterion), \(-2\)Loglikelihood, and \(-2\)Firth Loglikelihood fit statistics are shown as part of the report and can be used to compare models. See *Fitting Linear Models*. 
The \(-2\text{Firth Loglikelihood fit statistic}\) is included in the report when the Firth Bias-Adjusted Estimates option is selected in the launch window. Note that this option is checked by default. The decision to use or not use the Firth Bias-Adjusted Estimates does not affect the AICc score or the \(-2\text{Loglikelihood results}\.\)

**Note:** For each of these statistics, a smaller value indicates a better fit.

### Likelihood Ratio Tests

The Likelihood Ratio Test report appears by default if the model is fit in less than five seconds. If the report does not appear, you can select the Likelihood Ratio Tests option from the Choice Model red triangle menu. The report gives the following:

- **Source** Lists the effects in the model.
- **L-R ChiSquare** The value of the likelihood ratio ChiSquare statistic for a test of the corresponding effect.
- **DF** The degrees of freedom for the ChiSquare test.
- **Prob>ChiSq** The \(p\)-value for the ChiSquare test.
- **Bar Graph** Shows a bar chart of the L-R ChiSquare values.

### Bayesian Parameter Estimates

(Available only for Hierarchical Bayes.) The Bayesian Parameter Estimates report gives results for model effects. The estimates are based on a Hierarchical Bayes fit that integrates the subject-level covariates into the likelihood function and estimates their effects on the parameters directly. The subject-level covariates are estimated using a Bayesian procedure combined with the Metropolis-Hastings algorithm. See Train (2001). Posterior means and variances are calculated for each model effect. The algorithm also provides subject-specific estimates of the model effect parameters. See “Save Subject Estimates” on page 112.

During the estimation process, each individual is assigned his or her own vector of parameter estimates, essentially treating the estimates as random effects and covariates. The vector of coefficients for an individual is assumed to come from a multivariate normal distribution with arbitrary mean and covariance matrix. The likelihood function for the utility parameters for a given subject is based on a multinomial logit model for each subject’s preference within a choice set, given the attributes in the choice set. The prior distribution for a given subject’s vector of coefficients is normal with mean equal to zero and a diagonal covariance matrix with the same variance for each subject. The covariance matrix is assumed to come from an inverse Wishart distribution with a scale matrix that is diagonal with equal diagonal entries.
For each subject, a number of burn-in iterations at the beginning of the chain is discarded. By default, this number is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Figure 4.17 Bayesian Parameter Estimates Report**

<table>
<thead>

</tbody>
</table>

**Term**  The model term.

**Posterior Mean**  The parameter estimate for the term’s coefficient. For each iteration after the burn-in period, the mean of the subject-specific coefficient estimates is computed. The Posterior Mean is the average of these means.

**Tip:** Select the red triangle option Save Bayes Chain to see the individual estimates for each iteration.

**Posterior Std Dev**  The standard deviation of the means of the subject-specific estimates over the iterations after burn-in.

**Subject Std Dev**  The standard deviation of the subject-specific estimates.

**Tip:** Select the red triangle option Save Subject Estimates to see the individual estimates.

**Total Iterations**  The total number of iterations performed, including the burn-in period.

**Burn-In Iterations**  The number of burn-in iterations. This number is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Number of Respondents**  The number of subjects.

**Avg Log Likelihood After Burn-In**  The average of the log-likelihood function, computed on values obtained after the burn-in period.
Choice Platform Options

Choice Model red triangle menu contains the following options.

**Note:** When you use Hierarchical Bayes, the subject-level estimates are based on Monte Carlo sampling. For this reason, results obtained for the options below vary from run to run.

- **Likelihood Ratio Tests**  See “Likelihood Ratio Tests” on page 108.
- **Show MLE Parameter Estimates**  (Available for Hierarchical Bayes) Shows non-Firth maximum likelihood estimates and standard errors for the coefficients of model terms. These estimates are used as starting values for the Hierarchical Bayes algorithm.
- **Joint Factor Tests**  (Not available for Hierarchical Bayes) Tests each factor in the model by constructing a likelihood ratio test for all the effects involving that factor. For more information about Joint Factor Tests, see Fitting Linear Models.
- **Confidence Intervals**  (Not available for Hierarchical Bayes) Shows or hides a confidence interval for each parameter in the Parameter Estimates report.
- **Confidence Limits**  (Available for Hierarchical Bayes) Shows or hides confidence limits for each parameter in the Bayesian Parameter Estimates report. The limits are constructed based on the 2.5 and 97.5 quantiles of the posterior distribution.
- **Correlation of Estimates**  If Hierarchical Bayes was not selected, shows the correlations between the maximum likelihood parameter estimates.
  
  For Hierarchical Bayes, shows the correlation matrix for the posterior means of the parameter estimates. The correlations are calculated from the iterations after burn-in. The posterior means from each iteration after burn-in are treated as if they are columns in a data table. The Correlation of Estimates table is obtained by calculating the correlation matrix for these columns.
- **Effect Marginals**  Shows or hides marginal probabilities and marginal utilities for each main effect in the model. The marginal probability is the probability that an individual selects attribute A over B with all other attributes set to their mean or default levels.
  
  In Figure 4.18, the marginal probability of any subject choosing a pizza with mozzarella cheese, thick crust and pepperoni, over that same pizza with Monterey Jack cheese instead of mozzarella, is 0.9470.
Figure 4.18  Example of Marginal Effects

Utility Profiler  Shows or hides the predicted utility for different factor settings. The utility is the value predicted by the linear model. See “Find Optimal Profiles” on page 95 for an example of the Utility Profiler. For more information about utility, see “Utility and Probabilities” on page 141. For more information about the Utility Profiler options, see Profilers.

Probability Profiler  Enables you to compare choice probabilities among a number of potential products. This predicted probability is defined as follows:

\[
\frac{\exp(U)}{\exp(U) + \exp(U_b)}
\]

where \(U\) is the utility for the current settings and \(U_b\) is the utility for the baseline settings. This implies that the probability for the baseline settings is 0.5. See “Utility and Probabilities” on page 141.

See “Comparisons to Baseline” on page 120 for an example of using the Probability Profiler. For more information about the Probability Profiler options, see Profilers.

Multiple Choice Profiler  Provides the number of probability profilers that you specify. This enables you to set each profiler to the settings of a given profile so that you can compare the probabilities of choosing each profile relative to the others. See “Multiple Choice Comparisons” on page 122 for an example of using the Multiple Choice Profiler. For more information about the Multiple Choice Profiler options, see Profilers.

Comparisons  Performs comparisons between specific alternative choice profiles. Enables you to select the factors and the values that you want to compare. You can compare specific configurations, including comparing all settings on the left or right by selecting the Any check boxes. If you have subject effects, you can select the levels of the subject effects to compare. Using Any does not compare all combinations across features, but rather all combinations of comparisons, one feature at a time, using the left settings as the settings for the other factors.
**Willingness to Pay** Requires that your model includes a continuous price column. Calculates the maximum price increase (decrease) that a customer is willing to pay for a new feature over the baseline feature cost. The result is calculated using the Baseline settings for each background setting.

**Save Utility Formula** When the analysis is on multiple data tables, creates a new data table that contains a formula column for utility. The new data table contains a row for each subject and profile combination, and columns for the profiles and the subject effects. When the analysis is on one data table, a new Utility Formula column is added.

**Save Gradients by Subject** (Not available for Hierarchical Bayes.) Constructs a new table that has a row for each subject containing the average (Hessian-scaled-gradient) steps for the likelihood function on each parameter. This corresponds to using a Lagrangian multiplier test for separating that subject from the remaining subjects. These values can later be clustered, using the built-in script, to indicate unique market segments represented in the data. See “Gradients” on page 142. For an example, see “Example of Segmentation” on page 124.

**Save Subject Estimates** (Available for Hierarchical Bayes.) Creates a table where each row contains the subject-specific parameter estimates for each effect. The distribution of subject-specific parameter effects for each effect is centered at the estimate for the term given in the Bayesian Parameter Estimates report. The Subject Acceptance Rate gives the rate of acceptance for draws of new parameter estimates during the Metropolis-Hastings step. Generally, an acceptance rate of 0.20 is considered to be good. See “Bayesian Parameter Estimates” on page 108.

**Save Bayes Chain** (Available for Hierarchical Bayes.) Creates a table that gives information about the chain of iterations used in computing subject-specific Bayesian estimates. See “Save Bayes Chain” on page 115.

**Model Dialog** Shows the Choice launch window, which can be used to modify and re-fit the model. You can specify new data sets, new IDs, and new model effects.
See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo** Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

**Save Script** Contains options that enable you to save a script that reproduces the report to several destinations.

**Save By-Group Script** Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

### Willingness to Pay

The term *willingness to pay* refers to the price that a customer is willing to pay for new features, calculated to match a customer’s utility for baseline features. For example, suppose that a customer is willing to pay $1,000 for a computer with a 40 GB hard drive. Willingness to Pay for an 80 GB hard drive is calculated by setting the Hard drive feature to 80 GB and then solving for the price that delivers the same utility as the $1000 40 GB hard drive.

### Willingness to Pay Launch Window Options

When you select the Willingness to Pay option, the Willingness to Pay launch window is shown. The launch window in Figure 4.20 is obtained by selecting the Willingness to Pay option in the report that results from running the *Choice* data table script in Laptop Profile.jmp.

**Factor** The variables from the analysis. These can be product features or subject-specific attributes.

**Baseline** The baseline setting for each factor. If the factor is categorical, select the baseline value from a list. If the factor is numeric, enter the baseline value.

**Role** The type of factor.

- **Feature Factor** A product or service feature from the experiment that you want to price.

- **Price Factor** A price factor in the experiment. The price factor must be continuous, and there can be only one specified price factor for each Willingness to Pay analysis.

- **Background Constant** A factor that you want to hold constant in the Willingness to Pay calculation. Generally, these are subject-specific variables.
**Background Variable**  A factor that you want to hold constant, at each of its levels, in the Willingness to Pay calculation. Generally, these are subject-level factors. Specifying a subject factor as a Background Variable rather than a Background Constant provides Willingness to Pay estimates for all levels of the variable.

**Include baseline settings in report table**  Adds the baseline settings with a price change of zero to the Willingness to Pay report.

**Tip:** If you make an output table, use this option to display all the baseline settings as well as the attribute settings.

**Output data table also**  Creates a data table containing the Willingness to Pay report.

**Figure 4.20**  Willingness to Pay Launch Window

Once you complete your first Willingness to Pay calculation, the platform remembers the baseline values and assigned roles that you selected. This enables you to do multiple Willingness to Pay comparisons without having to re-enter the baseline information. If there is no factor called Price, but there is a continuous factor used in the analysis, the continuous factor is automatically assigned as the Price factor in the Willingness to Pay window. Common cost variables that are not prices in the traditional sense include factors such as travel time or distance.

**Willingness to Pay Report**

The Willingness to Pay report displays the baseline value for each factor, as well as baseline utility values. For each factor, the report shows the feature setting, estimated price change, and new price. If there are no interaction or second-order effects, standard errors and confidence intervals are also shown. These are calculated using the delta method.
Save Bayes Chain

(Available for models fit with Hierarchal Bayes.) You can use the Bayes Chain data table to determine whether your estimates have stabilized. The table that is created has a number of rows equal to the Number of Bayesian Iterations (specified on the launch window) plus one. The first row, Iteration 1, gives the starting values. Subsequent rows show the results of the iterations, in order. The table has a column for the iteration counts, the model Log Likelihood, and columns corresponding to each model effect:

**Iteration**  Gives the iteration number, where the first row shows starting values.

**Log Likelihood**  The log-likelihood of the model for that iteration. You can plot the Log Likelihood against Iteration to view behavior over the burn-in and tuning periods.

**Adaptive Sigma for <model effect>**  Gives the estimate of the square root of the diagonal entries of the inverse Wishart distribution scale matrix for the corresponding effect.

**Acceptance for <model effect>**  Gives the sampling acceptance rate for the corresponding effect.

**Mean of <model effect>**  Gives the estimated mean for the corresponding effect.

**Variance of <model effect>**  Gives the estimated variance for the corresponding effect.
Additional Examples

- “Example of Making Design Decisions”
- “Example of Segmentation”
- “Example of Logistic Regression Using the Choice Platform”

- “Example of Transforming Data to Two Analysis Tables”
- “Example of Transforming Data to One Analysis Table”

Example of Making Design Decisions

You can use the Choice Modeling platform to determine the relative importance of product attributes. Even if the attributes of a particular product that are important to the consumer are known, information about preference trade-offs with regard to these attributes might be unknown. By gaining such information, a market researcher or product designer is able to incorporate product features that represent the optimal trade-off from the perspective of the consumer. This example illustrates the advantages of this approach to product design.

It is already known that four attributes are important for laptop design: hard-disk size, processor speed, battery life, and selling price. The data gathered for this study are used to determine which of four laptop attributes (Hard Disk, Speed, Battery Life, and Price) are most important. It also assesses whether there are Gender or Job effects associated with these attributes.

This example is described in four sections:

- “Complete the Launch Window” on page 116
- “Analyze the Model” on page 118
- “Comparisons to Baseline” on page 120
- “Multiple Choice Comparisons” on page 122

Complete the Launch Window

1. Select Help > Sample Data Library and open Laptop Runs.jmp.

Note: If you prefer not to follow the manual steps in this section, click the green triangle next to the script Choice with Gender to run the model, and go to “Analyze the Model” on page 118.

2. Click the green triangle next to the Open Profile and Subject Tables script.

   The script opens the Laptop Profile.jmp and Laptop Subjects.jmp data tables.
3. Select **Analyze > Consumer Research > Choice**.

   **Note:** This can be done from any of the three open data tables.

4. From the Data Format list, select **Multiple Tables, Cross-Referenced**.
5. Click **Select Data Table** under Profile Data and select Laptop Profile. Select Choice ID and click Profile ID.
6. Select Hard Disk, Speed, Battery Life, and Price and click **Add**.
7. Select Survey and Choice Set and click **Grouping**.

**Figure 4.22** Profile Data Window for Laptop Study

8. Open the **Response Data** outline.
9. From the **Select Data Table** list, select Laptop Runs.
10. Complete the Response Data table:
    - Select Response and click **Profile ID Chosen**.
    - Select Choice1 and Choice2 and click **Profile ID Choices**.
    - Select Survey and Choice Set and click **Grouping**
    - Select Person and click **Subject ID**.
Figure 4.23  Response Data Window for Laptop Study

11. Open the **Subject Data** outline.
12. From the **Select Data Table** list, select Laptop Subjects.
13. Select Person and click **Subject ID**.
14. Select Gender click **Add**.

Figure 4.24  Subject Data Window for Laptop Study

**Analyze the Model**

1. Click **Run Model**.
Figure 4.25  Laptop Effect Summary

The Effect Summary report shows that Hard Disk is the most significant effect. You can reduce the model by removing terms with a \( p \)-value greater than 0.15. This process should be done one term at a time. Here, Gender*Speed is the least significant effect, with a \( p \)-value of 0.625.

2. In the Effect Summary report, select Gender*Speed and click Remove.

Figure 4.26  Laptop Results
Once Gender*Speed is removed from the model, all effects have a $p$-value of 0.15 or less. Therefore, you use this as your final model.

3. Click the Choice Model: Response red triangle and select **Utility Profiler**.

**Figure 4.27** Laptop Profiler Results for Females

![Utility Profiler for Females](image)

**Tip:** If your utility profiler does not look like Figure 4.27, click the Utility Profiler red triangle and select **Appearance > Adapt Y Axis**.

4. From the list next to Subject Terms, select **M**.

**Figure 4.28** Laptop Profiler Results for Males in Development

![Utility Profiler for Males](image)

The interaction effect between Gender and Hard Disk is highly significant, with a $p$-value of 0.0033 (Figure 4.26 on page 119). In the Utility Profilers, check the slope for Hard Disk for both levels of Gender. You see that the slope is steeper for females than for males.

**Comparisons to Baseline**

Suppose you are developing a new product. You want to explore the likelihood that a customer selects the new product over the old product, or over a competitor’s product. Use the Probability Profiler to compare profiles to a baseline profile.
In this example, your company is currently producing laptops with 40 GB hard drives, 1.5 GHz processors, and 6-hour battery life, that cost $1,000. You are looking for a way to make your product more desirable by changing as few factors as possible. You set the current product configuration as the baseline. JMP adjusts the probabilities so that the probability of preference for the baseline configuration is 0.5. Then you compare the probabilities of other configurations to the baseline probability.

1. Do one of the following:
   - Follow the steps in “Complete the Launch Window” on page 116. Then complete step 1 and step 2 in “Analyze the Model” on page 118.
   - In the Laptop Runs.jmp sample data table, click the green triangle next to the Choice Reduced Model script.

2. Click the Choice Model: Response red triangle and select Probability Profiler.
   Note that the Probability Profiler is for Gender = F. You can change this later.

3. Using the menus and text box below the profiler, in the Baseline area, specify the Baseline settings as 40 GB, 1.5 GHz, 6 hours, and 1000.

4. Now set these as the values in the Probability Profiler. To set the Price at $1000, click $1242 above Price under the rightmost profiler cell, and type 1000. Then click outside the text box.

Figure 4.29 Probability Profiler with Text Entry Area for Price

This configuration has probability 0.5.

5. In the Probability Profiler, move the slider for HardDisk to 80 GB.
   Notice that, with this change, the probability is relatively insensitive to increases in Price.

6. Click the $1000 label above the Price cell in the profiler, type $1,200, and click outside the text box.
An increase in Hard Disk size from 40 GB to 80 GB and an increase in price to $1200 coincides with an increased probability of preference, from 0.50 to 0.90 for females. Change the Gender effect in the Baseline to M. The probability of preference is 0.71.

**Multiple Choice Comparisons**

Use the Multiple Choice Profiler to compare product profiles.

- You currently produce a low-end laptop with a small hard drive, a slow processor, and low battery life. You charge $1000.
- Company A produces a product with a fast processor speed and high battery life at a reasonable price of $1200.
- Company B makes the biggest hard drives with the fastest speed, but at a high price of $1500 and low battery life.

You want to gain market share by increasing only one area of performance, and price.

1. Do one of the following:
   - Follow the steps in “Complete the Launch Window” on page 116. Then complete step 1 and step 2 in “Analyze the Model” on page 118.
   - In the Laptop Runs.jmp sample data table, click the green triangle next to the Choice Reduced Model script.
2. Click the Choice Model: Response red triangle and select **Multiple Choice Profiler**.
   A window appears, asking for the number of alternative choices to profile. Accept the default number of 3.
3. Click **OK**.
   Three Alternative profilers appear. Notice that the profilers are set for Gender = F.
Each factor in each profiler is set to its default values. Alternative 1 indicates the product that you want to develop. Alternative 2 indicates Company A’s product. Alternative 3 indicates Company B’s product.

4. For Alternative 1, set Hard Disk to 40 GB, Speed to 1.5 GHz, Battery Life to 4 hours, and Price to $1,000.

5. For Alternative 2, set Hard Disk to 40 GB, Speed to 2.0 GHz, Battery Life to 6 hours, and Price to $1,200.

6. For Alternative 3, set Hard Disk to 80 GB, Speed to 2.0 GHz, Battery Life to 4 hours, and Price to $1,500.

**Figure 4.31  Multiple Choice Profiler for Females**
You can see that Company B has the greatest Share of 0.5630. It is obvious that with your company’s settings, very few females buy your product.

You want to increase your market share by upgrading your company’s laptop in one of the performance areas while increasing price. The slope of the line in Alternative 1’s Hard Disk profile suggests increasing hard disk space increases market share the most.

7. For Alternative 1, set Hard Disk to **80 GB** and Price to **$1,200**.

**Figure 4.32** Multiple Choice Profiler with Improved Laptop

By increasing hard disk space, you can increase the price of your laptop and expect a market share among females of about 43%. This share exceeds that of Company B’s high-performance laptop and is much better than the market share with the initial low-end settings seen in Figure 4.31.

Explore the settings that increase your market share for males. If you increase both Hard Disk size and Speed, you can capture a 44% market share among males.

**Example of Segmentation**

In this example, you attempt to identify market segments for pizza preferences.

To see how to complete the launch window for this example, see step 1 to step 15 in the example “Multiple Table Format” on page 90. Otherwise, follow the instructions below.

**Define Clusters**

1. Select **Help > Sample Data Library** and open Pizza Responses.jmp.
2. Click the green triangle next to the **Choice** script.
3. Click the Choice Model: Choice red triangle and select **Save Gradients by Subject**.
A data table appears with gradient forces saved for each main effect and subject interaction.

**Figure 4.33** Gradients by Subject for Pizza Data, Partial View

</tbody>
</table>

4. Click the green triangle next to the **Hierarchical Cluster** script.

**Figure 4.34** Dendrogram of Subject Clusters for Pizza Data
The script runs a hierarchical cluster analysis on all columns in the gradient table, except for Subject. Click either diamond to see that the rows have been placed into three clusters.

5. Click the Hierarchical Clustering red triangle and select **Save Clusters**.

A new column called Cluster is added to the data table containing the gradients. Each subject has been assigned a Cluster value that is associated with other subjects having similar gradient forces. See *Multivariate Methods* for a discussion of other Hierarchical Clustering options.

You can delete the gradient columns because they were used only to obtain the clusters.

6. Select all columns except Subject and Cluster. Right-click the selected columns and select **Delete Columns**.

7. Click the green triangle next to the **Merge Data Back** script (Figure 4.33).

The cluster information is merged into the Subject data table. The columns in the Subject data table are now Subject, Gender, and Cluster.

</tr>
</tbody>
</table>

This table can now be used for further analysis.

**Explore the Clusters**

1. Click the icon to the left of the Cluster variable in the columns panel and select **Nominal**.
2. Select **Analyze > Fit Y by X**.
3. Select Gender and click **Y, Response**.
4. Select Cluster and click **X, Factor**.
5. Click **OK**.
Observe patterns in the clusters:

- Cluster 1 is evenly divided between males and females
- Cluster 2 consists of only females
- Cluster 3 consists of only males

If desired, you could now refit and analyze the model with the addition of the Cluster variable.
Example of Logistic Regression Using the Choice Platform

Use the Choice Platform

1. Select Help > Sample Data Library and open Lung Cancer Responses.jmp and Lung Cancer Choice.jmp.
   Notice Lung Cancer Responses.jmp has only one column (Lung Cancer) with two rows (Cancer and NoCancer).
2. Select Analyze > Consumer Research > Choice
3. Select Multiple Tables, Cross-Referenced from the list next to Data Format.
4. Click Select Data Table, select Lung Cancer Responses, and click OK.
5. Select Lung Cancer and click Profile ID.
7. Uncheck the Firth Bias-Adjusted Estimates box.

Figure 4.37 Completed Profile Data Panel

8. Open the Response Data outline.
9. Click Select Data Table, select Lung Cancer Choice, and click OK.
10. Complete the Response Data outline:
    - Select Lung Cancer and click Profile ID Chosen.
    - Select Choice1 and Choice2 and click Profile ID Choices.
– Select Count and click Freq.

**Figure 4.38** Completed Response Data Panel

11. Open the **Subject Data** outline.
12. Click Select Data Table, select Lung Cancer Choice, and click **OK**.
13. Select Smoker and click **Add**.

**Figure 4.39** Completed Subject Data Panel

14. Click **Run Model**.
Figure 4.40  Choice Modeling Logistic Regression Results

Use the Fit Model Platform

1. Select Help > Sample Data Library and open Lung Cancer.jmp.
2. Select Analyze > Fit Model.
   
   Because the data table contains a model script, the Model Specification window is automatically completed. The Nominal Logistic personality is selected.
3. Click Run.
Notice that the likelihood ratio chi-square test for Smoker*Lung Cancer in the Choice model matches the likelihood ratio chi-square test for Smoker in the Logistic model. The reports shown in Figure 4.40 and Figure 4.41 support the conclusion that smoking has a strong effect on developing lung cancer. See Fitting Linear Models.

Example of Logistic Regression for Matched Case-Control Studies

This section provides an example using the Choice platform to perform logistic regression on the results of a study of endometrial cancer with 63 matched pairs. The data are from the Los Angeles Study of the Endometrial Cancer Data reported in Breslow and Day (1980). The goal of the case-control analysis was to determine the relative risk for gallbladder disease, controlling for the effect of hypertension. The Outcome of 1 indicates the presence of endometrial cancer, and 0 indicates the control. Gallbladder and Hypertension data indicators are also 0 or 1.

For more information about performing logistic regression using the Choice platform, see “Logistic Regression” on page 141.

1. Select Help > Sample Data Library and open Endometrial Cancer.jmp.
2. Select Analyze > Consumer Research > Choice.
3. Check that the Data Format selected is One-Table, Stacked.
4. Click the Select Data Table button.
5. Select Endometrial Cancer as the profile data table. Click **OK**.
6. Select Outcome and click **Response Indicator**.
7. Select Pair and click **Grouping**.
8. Select Gallbladder and Hypertension and click **Add** in the Construct Profile Effects window.
9. Deselect the **Firth Bias-Adjusted Estimates** check box.
10. Click **Run Model**.
11. Click the Choice Model: Outcome red triangle and select **Utility Profiler**.

**Figure 4.42** Logistic Regression on Endometrial Cancer Data

Likelihood Ratio tests are given for each factor. Note that Gallbladder is nearly significant at the 0.05 level ($p$-value = 0.0532). Use the Utility Profiler to visualize the impact of the factors on the response.
Example of Transforming Data to Two Analysis Tables

Consider the data from Daganzo, found in Daganzo Trip.jmp. This data set contains the travel time for three transportation alternatives and the preferred transportation alternative for each subject.

Add Choice Mode and Subjects
1. Select Help > Sample Data Library and open the Daganzo Trip.jmp data table.

Figure 4.43  Partial Daganzo Trip Table

<table>
<thead>
<tr>
<th></th>
<th>Subway</th>
<th>Bus</th>
<th>Car</th>
<th>Choice</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>16.481</td>

</tbody>
</table>

Each Choice number listed must first be converted to one of the travel mode names. This transformation is easily done by using the Choose function in the formula editor:

2. Select Cols > New Columns.
3. Specify the Column Name as Choice Mode and the modeling type as Nominal.
4. Click the Column Properties and select Formula.
5. Click Conditional in the functions list, select Choose, and press comma twice to obtain additional arguments for the function.
6. Click Choice for the Choose expression (expr), and double-click each clause entry box to enter “Subway”, “Bus”, and “Car” (with the quotation marks).

Figure 4.44  Choose Function for Choice Mode Column of Daganzo Data

7. Click OK in the Formula Editor window.
8. Click OK in the New Column window.

The new Choice Mode column appears in the data table. Because each row contains a choice made by each subject, another column containing a sequence of numbers should be created to identify the subjects.

10. Specify the Column Name as Subject.
11. Click **Missing/Empty** next to Initialize Data and select **Sequence Data**.
12. Click **OK**.

**Figure 4.45** Partial Daganzo Trip Data with New Choice Mode and Subject Columns

</tr>
</tbody>
</table>

**Stack the Data**

In order to construct the Profile data, each alternative needs to be expressed in a separate row.

1. Select **Tables > Stack**.
2. Select Subway, Bus, and Car and click **Stack Columns**.
3. For the Output table name, type Stacked Daganzo. Type Travel Time for the Stacked Data Column and Mode for the Source Label Column.

**Figure 4.46** Stack Dialog for Daganzo Data

4. Click **OK**.
Make the Profile Data Table

For the Profile Data Table, you need the Subject, Mode, and Travel Time columns.

1. Select the Subject, Mode, and Travel Time columns and select **Tables > Subset**.
2. Select **All Rows** and **Selected Columns** and click **OK**.

A partial data table is shown in Figure 4.48. Note the default table name is Subset of Stacked Daganzo.

Make the Response Data Table

For the Response Data Table, you need the Subject and Choice Mode columns, but you also need a column for each possible choice.

3. From the Daganzo Trip.jmp data, select the Subject and Choice Mode columns.
4. Select **Tables > Subset**.
5. Select **All Rows** and **Selected Columns** and click **OK**.

Note that the default table name is Subset of Daganzo Trip.

6. Select **Cols > New Columns**.
7. For the Column prefix, type **Choice**.
8. Select **Data Type > Character**.
9. Enter 3 for the Number of columns to add.

10. Click **OK**.

The columns Choice 1, Choice 2, and Choice 3 have been added.

11. Type “Bus” (without quotation marks) in the first row of Choice 1. Right-click the cell and select **Fill > Fill to end of table**.

12. Type “Subway” (without quotation marks) in the first row of Choice 2. Right-click the cell and select **Fill > Fill to end of table**.

13. Type “Car” (without quotation marks) in the first row of Choice 3. Right-click the cell and select **Fill > Fill to end of table**.

**Figure 4.49** Partial Subset Table of Daganzo Data with Choice Set

</tbody>
</table>

**Fit the Model**

Now that you have separated the original Daganzo Trip.jmp table into two separate tables, you can run the Choice Platform.

1. Select **Analyze > Consumer Research > Choice**.
2. From the Data Format list, select **Multiple Tables, Cross-Referenced**.
3. Specify the model, as shown in Figure 4.50.
4. Click **Run Model**.

   The resulting parameter estimate now expresses the utility coefficient for **Travel Time**.
Figure 4.51  Parameter Estimate for Travel Time of Daganzo Data

![Parameter Estimate Table]

The negative coefficient implies that increased travel time has a negative effect on consumer utility or satisfaction. The likelihood ratio test result indicates that the Choice model with the effect of Travel Time is significant.

Example of Transforming Data to One Analysis Table

Rather than creating two or three tables, it can be more practical to transform the data so that only one table is used. For the one-table format, the subject effect is added as in the previous example. A response indicator column is added instead of using three different columns for the choice sets (Choice 1, Choice 2, Choice 3). Transform data for use with the one-table scenario:

1. Create or open Stacked Daganzo.jmp from the Stack the Data steps shown in “Example of Transforming Data to Two Analysis Tables” on page 133.
2. Select Cols > New Columns.
3. Type Response as the Column Name.
4. Click Column Properties and select Formula.
5. Select Conditional in the functions list and then select If.
6. Select the column Choice Mode for the expression (expr).
7. Enter “=” and select Mode.
8. Type 1 for the Then Clause and 0 for the Else Clause.
9. Click OK in the Formula Editor window. Click OK in the New Column window.

The completed formula should look like Figure 4.52.
Chapter 4  Choice Models 139
Consumer Research  Additional Examples

Figure 4.52  Formula for Response Indicator for Stacked Daganzo Data

\[
\begin{cases}
\text{Choice Mode} = \text{Mode} = 1 \\
\text{else} \\
\end{cases}
\]

10. Select the Subject, Travel Time, and Response columns and then select Tables > Subset.
11. Select All Rows and Selected Columns and click OK.

A partial listing of the new data table is shown in Figure 4.53.

Figure 4.53  Partial Table of Stacked Daganzo Data Subset

12. Select Analyze > Consumer Research > Choice to open the launch window and specify the model as shown in Figure 4.54.

Figure 4.54  Choice Dialog Box for Subset of Stacked Daganzo Data for One-Table Analysis

13. Click Run Model.
Notice that the result is identical to that obtained for the two-table model, shown earlier in Figure 4.51.

This chapter illustrates the use of the Choice Modeling platform with simple examples. This platform can also be used for more complex models, such as those involving more complicated transformations and interaction terms.

**Statistical Details for the Choice Platform**

- **“Special Data Table Rules“**
- **“Utility and Probabilities“**
- **“Gradients“**

**Special Data Table Rules**

**Default Choice Set**

If in every trial, you can choose any of the response profiles, you can omit the **Profile ID Choices** selection under **Pick Role Variables** in the Response Data section of the Choice launch window. The Choice Model platform then assumes that all choice profiles are available on each run.

**Subject Data with Response Data**

If you have subject data in the Response data table, select this table as the **Select Data Table** under the Subject Data. In this case, a **Subject ID** column does not need to be specified. In fact, it is not used. It is generally assumed that the subject data repeats consistently in multiple runs for each subject.
Logistic Regression

Ordinary logistic regression can be performed with the Choice Modeling platform.

**Note:** The Fit Y by X and Fit Model platforms are more convenient to use than the Choice Modeling platform for logistic regression modeling. This section is used only to demonstrate that the Choice Modeling platform can be used for logistic regression, if desired.

If your data are already in the choice-model format, you might want to use the steps given below for logistic regression analysis. However, three steps are needed:

- Create a trivial Profile data table with a row for each response level.
- Put the explanatory variables into the Response data.
- Specify the Response data table, again, for the Subject data table.

For examples of conducting Logistic Regression using the Choice Platform, see “Example of Logistic Regression Using the Choice Platform” on page 128 and “Example of Logistic Regression for Matched Case-Control Studies” on page 131.

Utility and Probabilities

Parameter estimates from the choice model identify consumer utility, or marginal utilities in the case of a linear utility function. Utility is the level of satisfaction consumers receive from products with specific attributes and is determined from the parameter estimates in the model.

The choice statistical model is expressed as follows:

\[
P_{ij[k]} = \frac{\exp(\beta'(X[k] \otimes Z[j]))}{\sum_{l=1}^{m} \exp(\beta'(X[k] \otimes Z[l]))}
\]

where:

- \(\otimes\) is the Kronecker rowwise product
- the numerator calculates for the \(j^{th}\) alternative actually chosen
- the denominator sums over the \(m\) choices presented to the subject for that trial
Gradients

The gradient values that you obtain when you select the Save Gradients by Subject option are the subject-aggregated Newton-Raphson steps from the optimization used to produce the estimates. At the estimates, the total gradient is zero, and \( \Delta = H^{-1}g = 0 \), where \( g \) is the total gradient of the log-likelihood evaluated at the MLE, and \( H^{-1} \) is the inverse Hessian function or the inverse of the negative of the second partial derivative of the log-likelihood.

But, the disaggregation of \( \Delta \) results in the following:

\[
\Delta = \sum_{ij} \Delta_{ij} = \sum H^{-1}g_{ij} = 0,
\]

Here \( i \) is the subject index, \( j \) is the choice response index for each subject, \( \Delta_{ij} \) are the partial Newton-Raphson steps for each run, and \( g_{ij} \) is the gradient of the log-likelihood by run.

The mean gradient step for each subject is then calculated as follows:

\[
\bar{\Delta}_i = \frac{\sum_j \Delta_{ij}}{n_i},
\]

where \( n_i \) is the number of runs per subject. The \( \bar{\Delta}_i \) are related to the force that subject \( i \) is applying to the parameters. If groups of subjects have truly different preference structures, these forces are strong, and they can be used to cluster the subjects. The \( \bar{\Delta}_i \) are the gradient forces that are saved. You can then cluster these values using the Clustering platform.
Use MaxDiff (maximum difference scaling) as an alternative to standard preference scales to determine the relative importance of items being rated. MaxDiff forces respondents to report their most and least preferred options. This often results in rankings that are more definitive than rankings obtained using standard preference scales.

The MaxDiff platform enables you to do the following:

- Use information about respondent (subject) traits as well as product attributes.
- Integrate data from one, two, or three sources.
- Obtain subject-level scores for segmenting or clustering your data.
- Estimate subject-specific coefficients using a Bayesian approach.
- Use bias-corrected maximum likelihood estimators (Firth 1993).

Overview of the MaxDiff Modeling Platform

MaxDiff, also known as best-worst scaling (BWS), is a choice-based measurement method. Rather than asking a respondent to report one favorite choice among several alternative profiles, MaxDiff asks a respondent to report both a best and a worst choice. The MaxDiff approach can provide more information about preferences than an approach where a respondent reports only a favorite choice. For background on MaxDiff studies, see Louviere et al. (2015). For background on choice modeling, see Louviere et al. (2015), Train (2009), and Rossi et al. (2005).

MaxDiff analysis uses the framework of random utility theory. A choice is assumed to have an underlying value, or utility, to respondents. The MaxDiff platform estimates these utilities. The MaxDiff platform also estimates the probabilities that a choice is preferred over other choices. This is done using conditional logistic regression. See McFadden (1974).

Note: One-factor MaxDiff studies can be designed using the MaxDiff Design platform. See the Design of Experiments Guide.

Segmentation and Bayesian Subject-Level Effects

Market researchers sometimes want to analyze the preference structure for each subject separately in order to see whether there are groups of subjects that behave differently. If there are sufficient data, you can specify “By groups” in the Response Data or you could introduce a Subject identifier as a subject-side model term. This approach, however, is costly if the number of subjects is large. Other segmentation techniques discussed in the literature include Bayesian and mixture methods.

If there are not sufficient data to specify “By groups,” you can segment in JMP by clustering subjects using response data and the Save Gradients by Subject option. The option creates a new data table containing the average Hessian-scaled gradient on each parameter for each subject. For an example, see “Example of Segmentation” on page 124 in the “Choice Models” chapter. For more information about the gradient values, see “Gradients” on page 142 in the “Choice Models” chapter.

MaxDiff also provides a Hierarchical Bayesian approach to estimating subject-level effects. This approach can be useful in market segmentation.
Examples of the MaxDiff Platform

Thirty respondents participated in a MaxDiff study to compare seven flavors of potato chips. Each choice set consisted of three profiles (potato chip flavors). For each choice set, a respondent’s favorite choice was recorded as 1 and his or her least favorite choice was recorded as -1. Intermediate choices were recorded as 0.

The MaxDiff platform can analyze data that is presented in a one-table format or in a multiple-table format. In the multiple table format, information about responses, choice sets, and subjects is saved in different data tables. In the one-table format, that information is contained in a single data table.

- “One Table Format” on page 146 shows how to analyze a subset of the available data in a one-table format. Note that you could add additional profile and subject data to the single table for a more complete analysis.
- “Multiple Table Format” on page 149 shows how to bring together information from different tables into one MaxDiff analysis.

One Table Format

1. Select Help > Sample Data Library and open Potato Chip Combined.jmp.
2. Select Analyze > Consumer Research > MaxDiff.
   Note that the default Data Format is set to One Table, Stacked.
3. Click Select Data Table.
4. Select Potato Chip Combined and click OK.
5. Assign roles to columns to complete launch dialog:
   - Select Response and click Response Indicator.
   - Select Respondent and click Subject ID.
   - Select Choice Set ID and click Choice Set ID.
   - Select ProfileID and click Add in the Construct Profile Effects panel.
Note that the setting for Worst choice changed to -1 when you specified the Response column as the Response Indicator variable.

6. Click Run Model.

The report indicates that Profile ID is significant, indicating that preferences for the various chip types differ significantly. The highest Marginal Utility is for Barbecue chips. The estimated probability that Barbecue chips are preferred to other chip types is 0.2895.

7. Click the MaxDiff Model red triangle and select All Levels Comparison Report.
Figure 5.4 All Comparisons Report

Each comparison is the difference in estimated utilities between the chip type labeling the row and the chip type labeling the column. Small $p$-values are colored with an intense blue or red color, depending on the sign of the difference. For example, based on the blue colors across the Gyro row, you can see that Gyro chips have significantly lower utility than all other chip types. Barbecue chips have higher utility than all other chip types, though they do not differ significantly from Southern Barbecue chips.

### Note:
Because the All Comparisons Report $p$-values are not corrected for multiple comparisons, use them as a guide.
Multiple Table Format

This version of the potato chip study uses three data tables: Potato Chip Profiles.jmp, Potato Chip Responses.jmp, and Potato Chip Subjects.jmp. Although you can always arrange your data into a single table, a multi-table approach can be more convenient than a one-table analysis when you have additional profile and subject variables that you want to include in your analysis.

Complete the Launch Window

1. Select Help > Sample Data Library and open the Potato Chip Responses.jmp sample data table.

   Note: If you prefer not to follow the steps for completing the launch window, click the green triangle next to the MaxDiff for Flavor script. Then proceed to “Explore the Model” on page 151.

2. Click the green triangle next to the Open Profile and Subject Tables script.
   - The profile data table, Potato Chip Profiles.jmp, lists all the potato chip types in the study (Flavor) along with information about the country of origin (Product Of). Each choice has a Profile ID.
   - The subjects data table, Potato Chip Subjects.jmp, lists the respondents. It also gives additional information about each respondent: Citizenship and Gender.
   - The responses data table, Potato Chip Responses.jmp, lists the respondents. For each respondent, the Survey ID and Choice Set ID for each set of profiles is listed, along with the Profile ID values for each choice set. The table also contains response data in the Best Profile and Worst Profile columns.

3. From any of the three data tables, select Analyze > Consumer Research > MaxDiff.
4. From the Data Format list, select Multiple Tables, Cross-Referenced.
   There are three separate outlines, one for each of the data sources.
5. Click Select Data Table under Profile Data.
   A Profile Data Table window appears, which prompts you to specify the data table for the profile data.
6. Select Potato Chip Profiles and click OK.
   The columns from this table appear in the Select Columns.
7. Select Profile ID from the Select Columns list and click Profile ID under Pick Role Variables.
8. Select Flavor and click Add under Construct Model Effects.
   Note that Product Of is another profile effect that you could add to the effects list.
9. Open the Response Data outline. Click Select Data Table.
10. Select Potato Chip Responses and click OK.
11. Assign roles to columns to complete the launch dialog:
   – Select Best Profile and click Best Choice.
   – Select Worst Profile and click Worst Choice.
   – Select Choice 1, Choice 2, and Choice 3 and click Profile ID Choices.
   – Select Respondent and click Subject ID.

Figure 5.6 Completed Response Data Outline
12. Open the Subject Data outline. Click **Select Data Table**.
13. Select Potato Chip Subjects and click **OK**.
14. Select Respondent and click **Subject ID**.
15. Select Citizenship and Gender and click **Add** under **Construct Model Effects**.

**Figure 5.7** Completed Subject Data Outline

---

**Explore the Model**

1. Click **Run Model**.

**Figure 5.8** MaxDiff Model Report

---

The Effect Summary report shows the terms in the model and gives $p$-values for their significance. Notice that Flavor is a profile effect, and that each of Citizenship*Flavor and Gender*Flavor is an interaction of a subject and a profile effect.

The Likelihood Ratio Tests report indicates that Flavor is significant.
Launch the MaxDiff Platform

Launch the MaxDiff platform by selecting Analyze > Consumer Research > MaxDiff.

Your data for the MaxDiff platform can be combined in a single data table or it can reside in two or three separate data tables. In the MaxDiff launch window, specify whether you are using one or multiple data tables in the Data Format list.

One Table, Stacked

For the One Table, Stacked format, the data are in a single data table. There is a row for every profile presented to a subject within a choice set and an indicator for the best and worst profiles in that choice set. The Potato Chip Combined.jmp sample data table contains the results of a MaxDiff experiment in a single table format. See “One Table Format” on page 146.

For more information about the launch window for this format, see “Launch Window for One Table, Stacked” on page 153.

Multiple Tables, Cross-Referenced

For the Multiple Tables, Cross-Referenced format, the data are in two or three separate data tables. A profile data table and a response data table are required. A subject data table is optional. Note the following:

- The profile data table must contain a column with a unique identifier for each profile and columns for the profile level variables. The profile identifier is used in the response data table to identify best and worst profile responses for each choice set.

- The optional subject data table must contain a column with a unique subject identifier for each subject and columns for the subject level variables. The subject identifier is used in the response data table to identify the subjects.

The launch window for this format contains three sections: Profile Data, Response Data, and Subject Data. Each section corresponds to a different data table. You can expand or collapse each section as needed.

The Potato Chip Profiles.jmp, Potato Chip Responses.jmp, and Potato Chip Subjects.jmp sample data tables contain the results of a MaxDiff experiment using three tables. See “Multiple Table Format” on page 149.

For more information about the launch window for this format, see “Launch Window for Multiple Tables, Cross-Referenced” on page 154.
Launch Window for One Table, Stacked

Launch the MaxDiff platform by selecting Analyze > Consumer Research > MaxDiff. For one table select One Table, Stacked from the Data Format menu.

Figure 5.9  Launch Window for One Table, Stacked Data Format

For more information about the options in the Select Columns red triangle menu, see Using JMP.

Select Data Table  Select or open the data table that contains the combined data. Select Other to open a file that is not already open.

Response Indicator  A column containing the preference data. Use two of the values 1, -1, or 0 for the Best and Worst choices, and the third value for profiles that are not Best or Worst. The default coding is a 1 to indicate the Best choice and a -1 for the Worst choice.

Subject ID  An identifier for the study participant.

Choice Set ID  An identifier for the set of profiles presented to the subject for a given preference determination.

Grouping  A column which, when used with the Choice Set ID, uniquely designates each choice set. For example, if a choice set has Choice Set ID = 1 for Survey = A, and another choice set has Choice Set ID = 1 for Survey = B, then Survey should be used as a Grouping column.

By  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of By variables.
**Construct Profile Effects**  Add effects constructed from the attributes for the profiles.

For information about the Construct Profile Effects panel, see *Fitting Linear Models*.

**Construct Subject Effects (Optional)**  Add effects constructed from subject-related factors.

For information about the Construct Subject Effects panel, see *Fitting Linear Models*.

**Firth Bias-adjusted Estimates**  Computes bias-corrected MLEs that produce better estimates and tests than MLEs without bias correction. These estimates also improve separation problems that tend to occur in logistic-type models. See Heinze and Schemper (2002) for a discussion of the separation problem in logistic regression.

**Hierarchical Bayes**  Uses a Bayesian approach to estimate subject-specific parameters. See “Bayesian Parameter Estimates” on page 162.

**Number of Bayesian Iterations**  (Applicable only if Hierarchical Bayes is selected.) The total number of iterations of the adaptive Bayes algorithm used to estimate subject effects. This number includes a burn-in period of iterations that are discarded. The number of burn-in iterations is equal to half of the Number of Bayesian Iterations specified on the launch window.

---

**Launch Window for Multiple Tables, Cross-Referenced**

Launch the MaxDiff platform by selecting **Analyze > Consumer Research > MaxDiff**. For multiple tables select **Multiple Tables, Cross-Referenced** form the Data Format menu.

**Figure 5.10**  Launch Window for Multiple Tables, Cross-Referenced Data Format
For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

In the case of Multiple Tables, Cross-Referenced, the launch window has three sections:

- **“Profile Data” on page 155**
- **“Response Data” on page 156**
- **“Subject Data” on page 157**

### Profile Data

The profile data table describes the attributes associated with each choice. Each choice can comprise many different attributes, and each attribute is listed as a column in the data table. There is a row for each possible choice, and each possible choice contains a unique ID.

**Select Data Table**  Select or open the data table that contains the profile data. Select Other to open a file that is not already open.

**Profile ID**  Identifier for each row of choice combinations. If the Profile ID column does not uniquely identify each row in the profile data table, you need to add Grouping columns. Add Grouping columns until the combination of Grouping and Profile ID columns uniquely identifies the row, or profile.

**Grouping**  A column which, when used with the Choice Set ID column, uniquely designates each choice set. For example, if Profile ID = 1 for Survey = A, and a different Profile ID = 1 for Survey = B, then Survey would be used as a Grouping column.

**Construct Profile Effects**  Add effects constructed from the attributes in the profiles.

For information about the Construct Profile Effects panel, see *Fitting Linear Models*.

**Firth Bias-adjusted Estimates**  Computes bias-corrected MLEs that produce better estimates and tests than MLEs without bias correction. These estimates also improve separation problems that tend to occur in logistic-type models. See Heinze and Schemper (2002) for a discussion of the separation problem in logistic regression.

**Hierarchical Bayes**  Uses a Bayesian approach to estimate subject-specific parameters. See “Bayesian Parameter Estimates” on page 162.

**Number of Bayesian Iterations**  (Applicable only if Hierarchical Bayes is selected.) The total number of iterations of the adaptive Bayes algorithm used to estimate subject effects. This number includes a burn-in period of iterations that are discarded. The number of burn-in iterations is equal to half of the Number of Bayesian Iterations specified on the launch window.
Response Data

Figure 5.11 shows the Response Data outline populated using Potato Chip Responses.jmp.

Figure 5.11  Response Data Outline

The response data table contains the study results. It gives the choice set IDs for each trial as well as the profiles selected as best and worst by the subject. The Response data are linked to the Profile data through the choice set columns and the choice response column. Grouping variables can be used to align choice indices when more than one group is contained within the data.

Select Data Table  Select or open the data table that contains the response data. Select Other to open a file that is not already open.

Best Choice  The Response table column containing the Profile ID of the profile that the study participant designated as Best.

Worst Choice  The Response table column containing the Profile ID of the profile that the study participant designated as Worst.

Profile ID Choices  The columns that contain the Profile IDs of the set of possible choices for each choice set. There must be at least three profiles.

Grouping  A column which, when used with the Profile ID Chosen column, uniquely designates each choice set.

Subject ID  A unique identifier for the study participant.

Freq  A column containing frequencies. If $n$ is the value of the Freq variable for a given row, then that row is used in computations $n$ times. If it is less than 1 or missing, then JMP does not use it to calculate any analyses.
Weight  A column containing a weight for each observation in the data table. The weight is included in analyses only when its value is greater than zero.

By  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of By variables.

Subject Data

Figure 5.12 shows the Subject Data outline populated using Potato Chip Subjects.jmp.

Figure 5.12  Subject Data Outline

Note: A subject data table is optional, depending on whether subject effects are to be modeled.

The subject data table contains the Subject ID and one or more columns of attributes or characteristics for each subject. The subject data table contains the same number of rows as subjects and has an identifier column that matches a similar column in the Response data table.

Note: You can include subject data in the response data table, but you need to specify subject effects in the Subject Data outline.

Select Data Table  Select or open the data table that contains the subject data. Select Other to open a file that is not already open.

Subject ID  Unique identifier for the subject.

By  Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of By variables.
**Construct Model Effects**  Add effects constructed from columns in the subject data table.

For information about the Construct Model Effects panel, see *Fitting Linear Models*.

---

**MaxDiff Model Report**

The MaxDiff Model window shows some of the following reports by default, depending on your selections in the launch window.

- “Effect Summary”
- “MaxDiff Results”
- “Parameter Estimates”
- “Bayesian Parameter Estimates”
- “Likelihood Ratio Tests”

For descriptions of the platform options, see “MaxDiff Platform Options” on page 164.

**Effect Summary**

The Effect Summary report appears if your model contains more than one effect. It lists the effects estimated by the model and gives a plot of the LogWorth (or FDR LogWorth) values for these effects. The report also provides controls that enable you to add or remove effects from the model. The model fit report updates automatically based on the changes made in the Effects Summary report. See *Fitting Linear Models*.

**Note:** The Effect Summary report is not applicable to models fit with Hierarchical Bayes.

Figure 5.13 shows the Effect Summary report obtained by running the script *MaxDiff for Flavor* in Potato Chip Responses.jmp.

**Figure 5.13** Effect Summary Report

![Effect Summary Table](image)

**Effect Summary Table Columns**

The Effect Summary table contains the following columns:

- **Source**  Lists the model effects, sorted by ascending *p*-values.
**LogWorth**  Shows the LogWorth for each model effect, defined as \(-\log_{10}(p\text{-value})\). This transformation adjusts \(p\)-values to provide an appropriate scale for graphing. A value that exceeds 2 is significant at the 0.01 level (because \(-\log_{10}(0.01) = 2\)).

**FDR LogWorth**  Shows the False Discovery Rate LogWorth for each model effect, defined as \(-\log_{10}(\text{FDR PValue})\). This is the best statistic for plotting and assessing significance. Select the FDR check box to replace the LogWorth column with the FDR LogWorth column.

**Bar Chart**  Shows a bar chart of the LogWorth (or FDR LogWorth) values. The graph has dashed vertical lines at integer values and a blue reference line at 2.

**PValue**  Shows the \(p\)-value for each model effect. This is the \(p\)-value corresponding to the significance test displayed in the Likelihood Ratio Tests report.

**FDR PValue**  Shows the False Discovery Rate \(p\)-value for each model effect calculated using the Benjamini-Hochberg technique. This technique adjusts the \(p\)-values to control the false discovery rate for multiple tests. Select the FDR check box to replace the PValue column with the FDR PValue column.

For more information about the FDR correction, see Benjamini and Hochberg (1995). For more information about the false discovery rate, see Predictive and Specialized Modeling or Westfall et al. (2011).

**Effect Summary Table Options**

The options below the summary table enable you to add and remove effects:

**Remove**  Removes the selected effects from the model. To remove one or more effects, select the rows corresponding to the effects and click the Remove button.

**Add Profile Effect**  Opens a column dialog that contains a list of all columns in the data table for the OneTable, Stacked data format, and for the columns in the Profile Data table for the Multiple Tables, Cross-Referenced data format. Select columns that you want to add to the model, and then click Add below the column selection list to add the columns to the model. Click Close to close the panel.

**Add Subject Effect**  Opens a column dialog that contains a list of all columns in the data table for the OneTable, Stacked data format, and for the columns in the Subject Data table for the Multiple Tables, Cross-Referenced data format. Select columns that you want to add to the model, and then click Add below the column selection list to add the columns to the model. Click Close to close the panel.

**MaxDiff Results**

Figure 5.14 shows the MaxDiff Results report obtained by running the script MaxDiff with No Subject Effects in Potato Chip Responses.jmp.
For each Profile effect specified in the launch window, the following are displayed:

**Marginal Utility**  An indicator of the perceived value of the corresponding level of the effect. Larger values suggest that the feature is of greater value.

**Marginal Probability**  The estimated probability that a subject expresses a preference for the corresponding level of the effect over all other levels. For each effect, the marginal probabilities sum to one.

**Bar Chart**  Shows a bar chart of the marginal probabilities.

**Effect Column**  Gives the name of the effect and a list of its levels. The levels define the features to which the Marginal Utility and Marginal Probability estimates apply.

### Parameter Estimates

This report gives details about parameter estimates, fit criteria, and the fitting algorithm.

Figure 5.15 shows the Parameter Estimates report obtained by running the script MaxDiff for Flavor in Potato Chip Responses.jmp.

Term  Lists the terms in the model.

Estimate  An estimate of the parameter associated with the corresponding term. In discrete choice experiments, parameter estimates are sometimes referred to as part-worths. Each part-worth is the coefficient of utility associated with the given term. By default, these estimates are based on the Firth bias-corrected maximum likelihood estimators and therefore are considered to be more accurate than MLEs without bias correction.

Std Error  An estimate of the standard deviation of the parameter estimate.

Comparison Criteria

The AICc (corrected Akaike’s Information Criterion), BIC (Bayesian Information Criterion), \(-2\)Loglikelihood, and \(-2\)Firth Loglikelihood fit statistics are shown as part of the report and can be used to compare models. See Fitting Linear Models for more information about the first three of these measures.

The \(-2\)Firth Loglikelihood value is included in the report only when the Firth Bias-adjusted Estimates check box is checked in the launch window. This option is checked by default.

For each of these statistics, a smaller value indicates a better fit.
Bayesian Parameter Estimates

(Appears only if Hierarchical Bayes is selected on the launch window.) The Bayesian Parameter Estimates report gives results for model effects. The estimates are based on a Hierarchical Bayes fit that integrates the subject-level covariates into the likelihood function and estimates their effects on the parameters directly. The subject-level covariates are estimated using a version of the algorithm described in Train (2001), which incorporates Adaptive Bayes and Metropolis-Hastings approaches. Posterior means and variances are calculated for each model effect. The algorithm also provides subject-specific estimates of the model effect parameters. See “Save Subject Estimates” on page 165.

During the estimation process, each individual is assigned his or her own vector of parameter estimates, essentially treating the estimates as random effects and covariates. The vector of coefficients for an individual is assumed to come from a multivariate normal distribution with arbitrary mean and covariance matrix. The likelihood function for the utility parameters for a given subject is based on a multinominal logit model for each subject’s preference within a choice set, given the attributes in the choice set. The prior distribution for a given subject’s vector of coefficients is normal with mean equal to zero and a diagonal covariance matrix with the same variance for each subject. The covariance matrix is assumed to come from an inverse Wishart distribution with a scale matrix that is diagonal with equal diagonal entries.

For each subject, a number of burn-in iterations at the beginning of the chain is discarded. By default, this number is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Term**  The model term.

**Posterior Mean**  The parameter estimate for the term’s coefficient. For each iteration after the burn-in period, the mean of the subject-specific coefficient estimates is computed. The Posterior Mean is the average of these means.

**Tip:** Select the red triangle option Save Bayes Chain to see the individual estimates for each iteration.
**Posterior Std Dev**  The standard deviation of the means of the subject-specific estimates over the iterations after burn-in.

**Subject Std Dev**  The standard deviation of the subject-specific estimates around the posterior mean.

**Tip:** Select the red triangle option Save Subject Estimates to see the individual estimates.

**Total Iterations**  The total number of iterations performed, including the burn-in period.

**Burn-In Iterations**  The number of burn-in iterations, which are discarded. This number is equal to half of the Number of Bayesian Iterations specified on the launch window.

**Number of Respondents**  The number of subjects.

**Avg Log Likelihood After Burn-In**  The average of the log-likelihood function, computed on values obtained after the burn-in period.

### Likelihood Ratio Tests

Figure 5.17 shows the Likelihood Ratio Tests report obtained by running the script MaxDiff for Flavor in Potato Chip Responses.jmp.

**Figure 5.17  Likelihood Ratio Tests**

**Source**  Lists the effects in the model.

**L-R ChiSquare**  The value of the likelihood ratio ChiSquare statistic for a test of the corresponding effect.

**DF**  The degrees of freedom for the ChiSquare test.

**Prob>ChiSq**  The p-value for the ChiSquare test.

**Bar Chart**  Shows a bar chart of the L-R ChiSquare values.
MaxDiff Platform Options

The MaxDiff Model red triangle menu contains the following options:

**Show MLE Parameter Estimates** *(Available for Hierarchical Bayes.)* Shows non-Firth maximum likelihood estimates and standard errors for the coefficients of model terms. These estimates are used as starting values for the Hierarchical Bayes algorithm.

**Joint Factor Tests** *(Not available for Hierarchical.)* Tests each factor in the model by constructing a likelihood ratio test for all the effects involving that factor. For more information about Joint Factor Tests, see *Fitting Linear Models*.

**Confidence Intervals** *(Not available for Hierarchical Bayes)* Shows or hides a confidence interval for each parameter in the Parameter Estimates report.

**Confidence Limits** *(Available for Hierarchical Bayes)* Shows or hides confidence limits for each parameter in the Bayesian Parameter Estimates report. The limits are constructed based on the 2.5 and 97.5 quantiles of the posterior distribution.

**Correlation of Estimates** If Hierarchical Bayes was not selected, shows or hides the correlations between the maximum likelihood parameter estimates.

For Hierarchical Bayes, shows or hides the correlation matrix for the posterior means of the parameter estimates. The correlations are calculated from the iterations after burn-in. The posterior means from each iteration after burn-in are treated as if they are columns in a data table. The Correlation of Estimates table is obtained by calculating the correlation matrix for these columns.

**Comparisons** Performs comparisons between specific alternative choice profiles. Enables you to select factor values and the values that you want to compare. You can compare specific configurations, including comparing all settings on the left or right by selecting the Any check boxes. Using Any does not compare all combinations across features, but rather all combinations of comparisons, one feature at a time, using the left settings as the settings for the other factors. See “Comparisons Report” on page 166.

**All Levels Comparison Report** Shows the All Levels Comparison Report, which contains a table with information about all pairwise comparisons of profiles. If you are modeling subject effects, you must specify a combination of subject effects and the table is specific to that combination of subject effects. Each cell of the table shows the difference in utilities for the row level and column level, the standard error of the difference, and a Wald $p$-value for a test of no difference.
**Caution:** The $p$-values are not corrected for multiple comparisons. Use these results as a guide.

The Wald $p$-values are colored. A saturated blue (respectively, red) color indicates that the Difference (Row - Column) is negative (respectively positive). The intensity of the red and blue coloring indicates the degree of significance.

**Save Utility Formula** When the analysis is on multiple data tables, creates a new data table that contains a formula column for utility. The new data table contains a row for each subject and profile combination, and columns for the profiles and the subject effects. When the analysis is on one data table, a new Utility Formula column is added.

**Save Gradients by Subject** (Not available for Hierarchical Bayes.) Constructs a new table that has a row for each subject containing the average (Hessian-scaled-gradient) steps for the likelihood function on each parameter. This corresponds to using a Lagrangian multiplier test for separating that subject from the remaining subjects. These values can later be clustered, using the built-in-script, to indicate unique market segments represented in the data. See “Example of Segmentation” on page 124 in the “Choice Models” chapter.

**Note:** When a subject gradient is non-estimable it is set to missing in the Gradient by Subject table.

**Save Subject Estimates** (Available for Hierarchical Bayes.) Creates a table where each row contains the subject-specific parameter estimates for each effect. The distribution of subject-specific parameter effects for each effect is centered at the estimate for the term given in the Bayesian Parameter Estimates report. The Subject Acceptance Rate gives the rate of acceptance for draws of new parameter estimates during the Metropolis-Hastings step. Generally, an acceptance rate of 0.20 is considered to be good. See “Bayesian Parameter Estimates” on page 162.

**Save Bayes Chain** (Available for Hierarchical Bayes.) Creates a table that gives information about the chain of iterations used in computing subject-specific Bayesian estimates. See “Save Bayes Chain” on page 167.

**Model Dialog** Shows the MaxDiff launch window that resulted in the current analysis, which can be used to modify and re-fit the model. You can specify new data sets, new IDs, and new model effects.

See *Using JMP* for more information about the following options:

**Local Data Filter** Shows or hides the local data filter that enables you to filter the data used in a specific report.
Redo  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.

Save Script  Contains options that enable you to save a script that reproduces the report to several destinations.

Save By-Group Script  Contains options that enable you to save a script that reproduces the platform report for all levels of a By variable to several destinations. Available only when a By variable is specified in the launch window.

Comparisons Report

The Comparisons report is shown when you specify pairwise comparisons. It contains the following columns:

Factor  Shows the levels of the subject factors that you specified.

Compared 1  Shows the factor and levels for the profile variables in the first component of the comparison.

Compared 2  Shows the factor and levels for the profile variables in the second component of the comparison.

Utility 1  Shows the estimated utility of the first component for the subjects specified in the Factor column.

Utility 2  Shows the estimated utility of the second component for the subjects specified in the Factor column.

Probability 1  Shows the predicted probability that the first component is preferred to the second for the subjects specified in the Factor column.

Probability 2  Shows the predicted probability that the second component is preferred to the first for the subjects specified in the Factor column.

Odds 1  Probability 1 divided by Probability 2.

Odds 2  Probability 2 divided by Probability 1.

Comparison Difference  Utility 1 minus Utility 2.

Standard Deviation  The sample standard error of the estimated Comparison Difference.
Save Bayes Chain

(Available for models fit with Hierarchal Bayes.) You can use the Bayes Chain data table to determine whether your estimates have stabilized. The table that is created has a number of rows equal to the Number of Bayesian Iterations (specified on the launch window) plus one. The first row, Iteration 1, gives the starting values. Subsequent rows show the results of the iterations, in order. The table has a column for the iteration counts, the model Log Likelihood, and columns corresponding to each model effect:

- **Iteration**  Giving the iteration number, where the first row shows starting values.
- **Log Likelihood**  The log-likelihood of the model for that iteration. You can plot the Log Likelihood against Iteration to view behavior over the burn-in and tuning periods.
- **Adaptive Sigma for <model effect>**  Gives the estimate of the square root of the diagonal entries of the inverse Wishart distribution scale matrix for the corresponding effect.
- **Acceptance for <model effect>**  Gives the sampling acceptance rate for the corresponding effect.
- **Mean of <model effect>**  Gives the estimated mean for the corresponding effect.
- **Variance of <model effect>**  Gives the estimated variance for the corresponding effect.
The Uplift platform is available only in JMP Pro.

Use uplift modeling to optimize marketing decisions, to define personalized medicine protocols, or, more generally, to identify characteristics of individuals who are likely to respond to an intervention. Also known as incremental modeling, true lift modeling, or net modeling, uplift modeling differs from traditional modeling techniques in that it finds the interactions between a treatment and other variables. It directs focus to individuals who are likely to react positively to an action or treatment.

Overview of the Uplift Platform

Use the Uplift platform to model the incremental impact of an action, or treatment, on individuals. An uplift model helps identify groups of individuals who are most likely to respond to the action. Identification of these groups leads to efficient and targeted decisions that optimize resource allocation and impact on the individual. See Radcliffe and Surry (2011).

The Uplift platform fits partition models. Although traditional partition models select splits to optimize classification, uplift models select splits to maximize treatment differences.

The uplift partition model accounts for the fact that individuals are grouped by a treatment factor. To determine splits, models are fit to all possible binary splits of each factor. The type of model that is fit is dependent on the type of response. A continuous response is modeled as a linear function of the split, the treatment, and the interaction of the split and treatment. A categorical response is expressed as a logistic function of the split, the treatment, and the interaction of the split and treatment. In either case, the interaction term measures the difference in uplift between the groups of individuals in the two splits. The most significant split is selected and the process repeats.

The Uplift platform selects the most significant split based on the significance of interaction terms in each of the binary split models. However, predictor selection based solely on p-values introduces bias in favor of predictors with many levels that result in many models for the single predictor. For this reason, JMP adjusts p-values to account for the number of levels or models considered. The correction used is based on Monte Carlo simulation. See Sall (2002). The splits are determined by the minimum adjusted p-values for tests of the significance of the interaction effect across models for all possible binary splits across all predictors. The logworth for each adjusted p-value, namely $-\log_{10}(\text{adj } p\text{-value})$, is reported.
Example of the Uplift Platform

The Hair Care Product.jmp sample data table results from a marketing campaign designed to increase purchases of a hair coloring product targeting both genders. For purposes of designing the study and tracking purchases, 126,184 “club card” members of a major beauty supply chain were identified. Approximately half of these members were randomly selected and sent a promotional offer for the product. Purchases of the product over a subsequent three-month period by all club card members were tracked.

The data table shows a Promotion column, indicating whether the member received promotional material. The column Purchase indicates whether the member purchased the product over the test period. For each member, Gender, Age, Hair Color (natural), U.S. Region, and Residence (whether the member is located in an urban area) was assembled. Also shown is a Validation column consisting of about 33% of the subjects.

For a categorical response, the Uplift platform interprets the first level in its value ordering as the response of interest. This is why the column Purchase has the Value Order column property. This property ensures that “Yes” responses are first in the ordering.

1. Select Help > Sample Data Library and open Hair Care Product.jmp.
2. Select Analyze > Consumer Research > Uplift.
3. From the Select Columns list:
   – Select Promotion and click Treatment.
   – Select Purchase and click Y, Response.
   – Select Gender, Age, Hair Color, U.S. Region, and Residence, and click X, Factor.
   – Select Validation and click Validation.
4. Click OK.
5. Below the Graph in the report that appears, click Go.

Based on the validation set, the optimal Number of Splits is determined to be three. Note that the left vertical scale is locked in order to maintain the overall rates of outcomes displayed on the right vertical axis.
Figure 6.2  Graph after Three Splits

The right hand vertical axis in the graph indicates that the proportion of purchases is small compared to non-purchases. The graph shows that uplift in purchases occurs for females with black, red, or brown hair and for younger females (Age < 42) with blond hair. For older blond-haired women (Age ≥ 42) and males, the promotion has a negative effect.

6. Click the Uplift Model for Purchase red triangle and select Uplift Graph.

Figure 6.3  Uplift Graph

Notice that for two groups of subjects (males and non-blond women in the Age ≥ 42 group), the promotion has a negative effect. The horizontal lines shown on the Uplift Graph delineate the graph for the validation set. Specifically, the decision tree is evaluated for the validation set and the Uplift Graph is constructed from the estimated uplifts.
Launch the Uplift Platform

Launch the Uplift platform by selecting Analyze > Consumer Research > Uplift.

**Figure 6.4 Uplift Platform Launch Window**

![Uplift Platform Launch Window](image)

For more information about the options in the Select Columns red triangle menu, see *Using JMP*.

**Y, Response** Assigns one or more columns to be analyzed.

**X, Factor** Assigns one or more columns to be used as factors.

**Treatment** Assigns a categorical treatment column. If the treatment column contains more than two levels, the first level is treated as one treatment level and the remaining levels are combined into a second treatment level.

**Weight** Assigns a numeric column that contains a weight for each observation in the data table. A row is included in the analysis only when its weight is greater than zero.

**Freq** Assigns a frequency variable to this role. This is useful for summarized data.

**Validation** Assigns a numeric column that defines the validation sets. This column should contain at most three distinct values:

- If there are two values, the smaller value defines the training set and the larger value defines the validation set.
- If there are three values, these values define the training, validation, and test sets in order of increasing size.
If the validation column has more than three levels, the rows that contain the smallest three values define the validation sets. All other rows are excluded from the analysis. The Uplift platform uses the validation column to train and tune the model or to train, tune, and evaluate the model. For more information about validation, see Predictive and Specialized Modeling.

If you click the Validation button with no columns selected in the Select Columns list, you can add a validation column to your data table. See Predictive and Specialized Modeling.

By Produces a separate report for each level of the By variable. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variable.

Validation Portion The portion of the data to be used as a validation set. Enter a value between 0 and 1.

Informative Missing If selected, enables missing value categorization for categorical predictors and informative treatment of missing values for continuous predictors.

Ordinal Restricts Order If selected, restricts consideration of splits to those that preserve the ordering.

**The Uplift Model Report**

- “Uplift Model Graph”
- “Uplift Report Options”

**Uplift Model Graph**

The graph represents the response on the vertical axis. The horizontal axis corresponds to observations, arranged by nodes. For each node, a black horizontal line shows the mean response. Within each split, there is a subsplit for treatment shown by a red or blue line. These lines indicate the mean responses for each of the two treatment groups within the split. The value ordering of the treatment column determines the placement order of these lines. As nodes are split, the graph updates to show the splits beneath the horizontal axis. Vertical lines divide the splits.

Beneath the graph are the control buttons: Split, Prune, and Go. The Go button appears only if there is a validation set. Also shown is the name of the Treatment column and its two levels, called Treatment1 and Treatment2. If more than two levels are specified for the Treatment column, all levels except the first are treated as a single level and combined into Treatment2.
To the right of the Treatment column information is a report showing summary values relating to prediction. (Keep in mind that prediction is not the objective in uplift modeling.) The report updates as splitting occurs. If a validation set is used, values are shown for both the training and the validation sets.

**RSquare**  The RSquare for the regression model associated with the tree. Note that the regression model includes interactions with the treatment column. An RSquare closer to 1 indicates a better fit to the data than does an RSquare closer to 0.

<table>
<thead>
<tr>
<th>Note:</th>
<th>A low RSquare value suggests that there might be variables not in the model that account for the unexplained variation. However, if your data are subject to a large amount of inherent variation, even a useful uplift model can have a low RSquare value.</th>
</tr>
</thead>
</table>

**RMSE**  The root mean square error (RMSE) for the regression model associated with the tree. RMSE is given only for continuous responses. See *Fitting Linear Models*.

**N**  The number of observations.

**Number of Splits**  The number of times splitting has occurred.

**AICc**  The Corrected Akaike Information Criterion (AICc), computed using the associated regression model. AICc is given only for continuous responses. See *Fitting Linear Models*.

### Uplift Decision Tree

The decision tree shows the splits used to model uplift. See Figure 6.5 for an example using the Hair Care Product.jmp sample data table. Each node contains the following information:

**Treatment**  The name of the treatment column is shown, with its two levels.

**Rate**  (Appears only for two-level categorical responses.) For each treatment level, the proportion of subjects in this node who responded.

**Mean**  (Appears only for continuous responses.) For each treatment level, the mean response for subjects in this node.

**Count**  The number of subjects in this node in the specified treatment level.

**t Ratio**  The $t$ ratio for the test for a difference in response across the levels of Treatment for subjects in this node. If the response is categorical, it is treated as continuous (values 0 and 1) for this test.

**Trt Diff**  The difference in response means across the levels of Treatment. This is the uplift, with the following assumptions:

- The first level in the treatment column’s value ordering represents the treatment.
- The response is defined so that larger values reflect greater impact.
**LogWorth**  The value of the logworth for the subsequent split based on the given node.

**Figure 6.5** Nodes for First Split

![Diagram of nodes and splits](image)

**Candidates Report**

Each node also contains a Candidates report with additional information:

**Term**  The model term.

**LogWorth**  The maximum logworth over all possible splits for the given term. The logworth corresponding to a split is $-\log_{10}$ of the adjusted $p$-value.

**F Ratio**  When the response is continuous, this is the F Ratio associated with the interaction term in a linear regression model. The regression model specifies the response as a linear function of the treatment, the binary split, and their interaction. When the response is categorical, this is the ChiSquare value for the interaction term in a nominal logistic model.

**Gamma**  When the response is continuous, this is the coefficient of the interaction term in the linear regression model used in computing the $F$ ratio. When the response is categorical, this is an estimate of the interaction constructed from Firth-adjusted log-odds ratios.

**Cut Point**  If the term is continuous, this is the point that defines the split. If the term is categorical, this describes the first (left) node.
Uplift Report Options

With the exception of the options described below, all of the red triangle options for the Uplift report are described in the documentation for the Partition platform. For more information about these options, see Predictive and Specialized Modeling.

Minimum Size Split

This option presents a window where you enter a number or a fractional portion of the total sample size to define the minimum size split allowed. To specify a number, enter a value greater than or equal to 1. To specify a fraction of the sample size, enter a value less than 1. The default value for the Uplift platform is set to 25 or the floor of the number of rows divided by 2,000, whichever value is greater.

Column Uplift Contributions

This table and plot address a column’s contribution to the uplift tree structure. A column’s contribution is computed as the sum of the F Ratio values associated with its splits. Recall that these values measure the significance of the treatment-by-split interaction term in the regression model.

Uplift Graph

Consider the observations in the training set. Define uplift for an observation as the difference between the predicted probabilities or means across the levels of Treatment for the observation’s terminal node. These uplift values are sorted in descending order. On its vertical axis, the Uplift Graph shows the uplift values. On its horizontal axis, the graph shows the proportion of observations with each uplift value.

Save Columns

Save Difference  Saves the estimated difference in mean responses across levels of Treatment for the observation’s node. This is the estimated uplift.

Save Difference Formula  Saves the formula for the Difference, or uplift.

Publish Difference Formula  Creates the difference formula and saves it as a formula column script in the Formula Depot platform. If a Formula Depot report is not open, this option creates a Formula Depot report. See Predictive and Specialized Modeling.
Multiple factor analysis (MFA) is an analytical method closely related to principal components analysis (PCA). MFA uses eigenvalue decomposition to transform multiple measurements on the same items into orthogonal principal components. These components can help you understand how the items are similar and how they are different. MFA uses multiple table or consensus PCA techniques.

Figure 7.1 Consensus Map in Multiple Factor Analysis

Overview of the Multiple Factor Analysis Platform

Multiple factor analysis (MFA) is an analytical method that is closely related to principal components analysis (PCA). However, MFA differs from PCA in that it combines measurements from more than one table. Such tables are sometimes called sub-tables or sub-matrices. Each sub-table has the same number of rows, which represent the items or products being tested. In JMP, sub-tables are represented as groups of columns in a single data table. Each column group is called a block. Note the following about blocks:

- The number of columns in a block can vary. For example, in sensory analysis, a block represents a panelist. Some panelists might rate fewer attributes of a product than other panelists.
- Each block of columns can represent different measurements entirely. MFA scales each block to enable global analysis of all measurements.

The primary goal of MFA is to find groupings of products (rows in a data table) that are similar. A secondary goal is to identify outlier panelists. An outlier panelist results are so different from the rest of the group that they change the study results. Supplementary variables can be used to investigate why items group together.

You can use MFA to analyze studies where items are measured on the same or different attributes by different instruments, individuals, or under different circumstances. MFA is frequently used in sensory analysis to account for different measurements among panelists. Traditional sensory analysis can entail hours of up-front training to ensure that panelists’ measurements are consistent with each other. For example, consider a juice product with sensory measurements described as “fruity”, “sweet”, and “refreshing”. In traditional sensory analysis, each panelist would have to be trained and tested to make sure reporting on distinct sensory measurements was consistent across panelists. MFA enables the researcher to perform a PCA-like analysis with untrained panelists.

When you use MFA, the same items are measured each time and the measurements can be arranged into internally consistent groups or blocks. For sensory analysis, the rows are the items measured, and the columns are the sensory aspects recorded by each panelist (there is a block for each panelist). Missing observations are replaced by the column mean.

For more information about multiple factor analysis, see Abdi et al. (2013).
Example of Multiple Factor Analysis

This example uses data from a simulated sensory panel study of wine characteristics. Participants rated 16 wines on a number of characteristics from 1 (no intensity) to 10 (prominent intensity). You want to better understand how the 16 wines are similar or different.

1. Select Help > Sample Data Library and open Wine Sensory Data.jmp.
2. Select Analyze > Consumer Research > Multiple Factor Analysis.
3. Select Vineyard and click Product ID.
4. Select Region and click Z, Supplementary.
5. Select all of the column groups from Carolyn to Jose and click Add Block.

**Note:** The columns in this data table are grouped into one block for each panelist. For ungrouped data, select the columns for a block, click Add Block, and repeat for each block.

6. Click Run Model.
Notice the following in the Summary Plots:

- In the plot of the factor scores in the first two dimensions, the wines tend to cluster together according to their regions.
- In the loading plot, the rays in the lower left quadrant correspond to Carolyn. They indicate a difference between Carolyn and the other raters.

7. In the legend next to the loading plot, click Carolyn to highlight her results.
Carolyn’s results differ from the other panelists. You might want to re-run the analysis without her results. See Figure 7.6 on page 188 for the results of the analysis without Carolyn.
Launch the Multiple Factor Analysis Platform

Launch the Multiple Factor Analysis Platform by selecting Analyze > Consumer Research > Multiple Factor Analysis.

**Figure 7.4 The Multiple Factor Analysis Launch Window**

For more information about the options in the Select Columns red triangle menu, see Using JMP.

**Product ID**  Specifies columns of items or products to be analyzed.

**Z, Supplementary**  Specifies the columns to be used as supplementary variables. These variables are those with which you are interested in identifying associations, but they are not included in the calculations.

**Freq**  Identifies one column whose numeric values assign a frequency to each row in the analysis.
By  A column or columns whose levels define separate analyses. For each level of the specified column, the corresponding rows are analyzed using the other variables that you have specified. The results are presented in separate reports. If more than one By variable is assigned, a separate report is produced for each possible combination of the levels of the By variables.

Add Block  Use to add one or more columns to a block:
- Adds individual columns as a single block.
- Adds a column group as a block.
- Adds individual columns to a selected block.

Tip: If you group the columns into blocks before running the platform, you can select multiple column groups and cast them as blocks in a single action. Otherwise, you must select each group of columns for each block and click Add Block, one block at a time. Double-click a block name to change it.

Data Format

The Multiple Factor Analysis platform uses a data table that contains column groups, or sub-tables. Each column group, referred to as a block, can have a different number of columns. Each block of columns can represent different measurements. The columns or blocks do not have to be in JMP column groups. However, the platform is easier to launch when the columns are grouped into blocks in the data table.

The data table rows represent the items that are being measured. Observations for each item must be in a single row. For example, Figure 7.5 shows a table that is measuring attributes of 16 wines from different vineyards. The column panel shows the column groups, or sub-tables, for each panelist. The Vineyards in rows 17 and 18 are not assigned a Region. The analysis could be used to explore which region the vineyards are most aligned to.

**Note:** Missing observations are replaced by the column mean. When missing observations result in no variation for a column, the column is excluded from the analysis. Missing rules are applied to all variables, including supplementary variables.
The Multiple Factor Analysis Report

The initial Multiple Factor Analysis report shows a table of eigenvalues, summary plots, and a consensus map.

Figure 7.6 Multiple Factor Analysis Report

Summary Plots

The Summary Plot report has three sections:

- The first section shows the eigenvalues of the consensus PCA with a plot of the cumulative percent of variance explained by each component. A consensus PCA is used to obtain a common representation of the blocks of data. Consensus PCA refers to the principal component solution of the weighted sub-tables and is used to obtain a common representation of the blocks of data.
• The middle section is a plot of factor scores with a marker for each row (item). If supplementary variables are used, there is a labeled marker for each level of the variables. Items that cluster together in this plot are considered to be similar.

• The third section is a loading plot of factor loadings for each block.

**Tip:** In the loading plot legend, click a block to highlight it in the plot.

**Select dimension**  Controls the dimensions plotted on the score and loading plots. The first control selects the horizontal dimension, and the second control selects the vertical dimension.

**Consensus Map**

The Consensus Map report contains a plot that overlays the individual panelist responses with the average response among all panelists for each item. You might use this map to investigate response consistency among panelists. For example, if a given panelist’s points fall consistently farther from the average of the other panelists, then that panelist might be a candidate to exclude from the analysis. Hover over a data point to view the block label for that point. Click a product ID in the legend to highlight it in the consensus map.

**Select dimension**  Controls the dimensions plotted on the consensus map. The first control selects the horizontal dimension, and the second control selects the vertical dimension.

**Highlight Product**  Controls the transparency of the items according to their inertia score. Small inertia indicates items that panelists have good agreement on. Large inertia indicates items that panelists do not agree on.

- **Small Inertia**  Highlights items with inertia less than or equal to the value in the text box. To adjust the cutoff for the inertia value, use the slider or enter a value in the text box.

- **Large Inertia**  Highlights items with inertia greater than or equal to the value in the text box. To adjust the cutoff for the inertia value, use the slider or enter a value in the text box.

- **Min and Max Inertia**  Highlights the items with the smallest and largest inertia. The text box and slider have no impact on the results when this option is selected.

**Multiple Factor Analysis Platform Options**

The Multiple Factor Analysis red triangle menu includes the following options.

**Block Weights**  Shows or hides the first eigenvalue for each block as well as the weight of that eigenvalue. The weight is the inverse of the square root of the first eigenvalue.
**Multiple Factor Analysis**  
**Chapter 7**  
**Multiple Factor Analysis Platform Options Consumer Research**

**Eigenvalues**  Shows or hides a table of eigenvalues that correspond to the consensus dimensions, in order, from largest to smallest.

**Eigenvectors**  Shows or hides a table of the eigenvectors for each of the consensus dimensions, in order, from left to right. Using these coefficients to form a linear combination of the original variables produces the consensus principal component variables.

**Variable Loadings**  Shows or hides the loadings for each column. As in principal components analysis, loadings represent correlations of variables with components. Values near zero indicate the variable has little effect on the consensus dimension.

**Variable Partial Contributions**  Shows or hides a table that contains the partial contributions of variables. The partial contributions represent the percentage of variance that each variable contributes to the consensus dimension.

**Variable Squared Cosines**  Shows or hides a table that contains the squared cosines of variables. The sum of the squared cosine values across consensus dimensions is equal to 1 (100%) for each variable. The squared cosines represent the overlap in variance between variables and dimensions.

**Tip:** For the variable loadings, variable partial contributions, and variable squared cosines, values near zero indicate the variable is weakly related to the consensus dimension. Values far from zero indicate a strong association. The degree of transparency for the table values highlights these effects.

**Summary Plots**  Shows or hides the summary plots. The summary plots include the plot of the eigenvalues or score plot and the loading plot.

**Consensus Map**  Shows or hides the consensus map. See “Consensus Map” on page 189.

**Biplot**  Shows or hides a plot that is an overlay of the score and loadings plots. Use the controls to select any two dimensions for the plot.

**Partial Axes Plot**  Shows or hides a partial axes plot. This plot displays correlations between PCA scores from separate block analyses and the consensus principal component. Use the controls to select any two dimensions for the plot. Click a block in the legend to highlight that block in the plot.

**Display Options**

**Arrow Lines**  Enables you to show or hide arrows on the loading plot, and the partial axes plot. Arrows are shown if the number of variables is 1000 or fewer. If there are more than 1000 variables, the arrows are off by default.

**Show Labels**  Shows or hides block name labels on all points in the consensus map and bi-plot. Shows or hides column name labels on all points in the partial axes plot.
Tip: Use row labels to identify centroids on the consensus map and data points on the loading plot.

**RV Correlations**  Shows or hides a matrix of squared correlation coefficients between blocks.

**Lg Coefficients**  Shows or hides a matrix of similarity measures between blocks.

**Block Partial and Consensus Correlations**  Shows or hides a matrix of correlation coefficients between block partial scores and consensus principal component scores. The matrix is rectangular because only correlations between concordant dimensions are displayed.

**Block Partial Contributions**  Shows or hides the sum of the variable contributions within the block.

**Block Partial Inertias**  Shows or hides the block contribution multiplied by the eigenvalue for the principal component and then divided by 100.

**Block Squared Cosines**  Shows or hides the block inertia squared and divided by the sum of squares used to calculate the eigenvalues. The values have a range between 0 and 1. The Block Squared Cosines can be considered as the percentage of the block variance explained by each principal component.

**Save Individual Scores**  Saves the item consensus principal components to new columns in the data table. If one or more categorical supplementary variables are used, this option also saves individual scores for each level of the supplementary variables to a new data table.

**Save Individual Squared Cosines**  Saves the item squared cosines to new columns in the data table. If one or more categorical supplementary variables are used, this option also saves categorical supplementary variable squared cosines to a new data table.

**Save Individual Partial Contributions**  Saves the item partial contributions to new columns in the data table. If one or more categorical supplementary variables are used, this option also saves categorical supplementary partial contributions to a new data table.

**Save Block Partial Scores**  Saves the block partial scores to a new data table.

**Save Partial Axes Coordinates**  Saves the partial axes coordinates to a new data table.

See *Using JMP* for more information about the following options:

**Local Data Filter**  Shows or hides the local data filter that enables you to filter the data used in a specific report.

**Redo**  Contains options that enable you to repeat or relaunch the analysis. In platforms that support the feature, the Automatic Recalc option immediately reflects the changes that you make to the data table in the corresponding report window.
Statistical Details for the Multiple Factor Analysis Platform

Multiple factor analysis combines information from sub-tables into a set of orthogonal columns that describe the items in the rows of the table. The basic procedure is as follows:

- Perform PCA on each sub-table.
- Record the first eigenvalue of each sub-table to create a matrix of weights.
- Concatenate the sub-tables side-by-side, center and normalize the matrix.
- Perform a generalized PCA on the concatenated table via the singular value decomposition. Generalized PCA is used to constrain the solution using the sub-table weights.

This results in three matrices of generalized right and left singular vectors and singular values. These are then used to derive component scores, eigenvalues, and component loadings for the consensus across sub-tables. These three matrices are the result of decomposing the many columns from the original measurements into a few interpretable dimensions that explain the similarities and differences between the objects being measured.

Calculations

For MFA, a singular value decomposition of the $X$ matrix can be defined as follows:

$$ X = P\Delta Q^T \quad \text{with the constraint} \quad p^T M p = q^T A q = I $$

The matrices use are as follows:

$X$ is an $n \times p$ centered and normalized matrix of sub-tables. In consumer research there are $n$ products and $p$ panelists’ ratings.

$Q$ is a $p \times q$ matrix of right singular vectors, which are weighted by the MFA singular values to obtain the loadings on $q$ principal components.

$\Delta$ is a $q \times q$ diagonal matrix of singular values from the generalized PCA. As with PCA, the magnitude of the squared singular values, or eigenvalues, represent the importance of each principal component in the combined analysis.

$P$ is an $n \times q$ matrix of left singular vectors, which are weighted by the MFA singular values to obtain the $q$ principal components of the compromise.

$M$ is the $n \times n$ diagonal matrix of mass weights.
A is the $p \times p$ diagonal matrix of block or panelist weights.

For more information about multiple factor analysis, see Abdi et al. (2013).

**Mass Weight**

JMP calculations use $N - 1$ for mass weight calculations. These calculations affect individual and block partial scores.

Get the Most from JMP

Whether you are a first-time or a long-time user, there is always something to learn about JMP.

Visit JMP.com to find the following:

• live and recorded webcasts about how to get started with JMP
• video demos and webcasts of new features and advanced techniques
• details on registering for JMP training
• schedules for seminars being held in your area
• success stories showing how others use JMP
• the JMP user community, resources for users including examples of add-ins and scripts, a forum, blogs, conference information, and so on

## Scripting Guide

1. **Learn about JMP**
   - **Documentation and Additional Resources**
     - Formatting Conventions in JMP Documentation .................................................. 23
     - JMP Help ........................................................................................................ 24
     - JMP Documentation Library .......................................................................... 24
     - Additional Resources for Learning JMP ......................................................... 30
       - JMP Tutorials .................................................................................................. 30
       - Sample Data Tables ...................................................................................... 30
       - Learn about Statistical and JSL Terms ......................................................... 31
       - Learn JMP Tips and Tricks ........................................................................... 31
       - JMP Tooltips .................................................................................................. 31
       - JMP User Community .................................................................................... 32
     - Free Online Statistical Thinking Course ....................................................... 32
     - JMP New User Welcome Kit ........................................................................... 32
     - Statistics Knowledge Portal .......................................................................... 32
     - JMP Training .................................................................................................... 32
     - JMP Books by Users ...................................................................................... 33
     - The JMP Starter Window ............................................................................... 33
     - JMP Technical Support .................................................................................... 33

2. **Introduction** ..................................................................................................... 35
   - **Welcome to the JMP Scripting Language**
     - What JSL Can Do for You ............................................................................... 37
     - Help with Learning JSL .................................................................................... 37
       - The Scripting Guide ....................................................................................... 37
       - The Scripting Index ....................................................................................... 38
         - Let JMP Teach You JSL ............................................................................ 38
     - Terminology ..................................................................................................... 41
     - Basic JSL Syntax ............................................................................................... 44
     - Book Conventions ............................................................................................. 45
3 Getting Started ................................................................. 47
   Let JMP Write Your Scripts ............................................. 47
      Capturing a Script for an Analysis Report ...................... 49
      Capturing a Script for a Data Table ............................. 50
      Capturing a Script to Import a File ............................. 51
      Gluing Scripts Together ............................................. 52

4 Scripting Tools ............................................................. 57
   Using the Script Editor, Log Window, Debugger and Profiler .... 57
      Work with the Script Editor ......................................... 59
         Introduction to the Script Editor ............................... 59
         Run a Script ....................................................... 60
         Stop a Script ..................................................... 61
         Edit a Script ..................................................... 61
         Color Coding and Themes ........................................ 61
         Autocomplete Functions .......................................... 62
         Tooltips ................................................................ 62
         Split a Window ...................................................... 63
         Match Parentheses, Brackets, and Braces ..................... 64
         Select a Rectangular Block of Text .............................. 65
         Select Fragmented Text ............................................ 66
         Drag and Drop Text ................................................ 66
         Find and Replace .................................................... 66
         Automatic Formatting .............................................. 67
         Errors Are Marked by Special Characters ....................... 67
         Typing in Multiple Rows at Once .................................. 67
         Add Code Folding Markers ......................................... 68
         Advanced Options .................................................. 69
         Set Preferences for the Script Editor .............................. 70
      Work with the Log ....................................................... 70
         Enhanced Log in JMP ................................................ 71
         Text Log in JMP ..................................................... 76
      Debug or Profile Scripts .............................................. 77
         Debugger and Profiler Window .................................... 78
         Work with Breakpoints ............................................. 82
         View Variables ...................................................... 85
         Work with Watches ................................................ 85
         Modify Preferences in Debugger ................................. 86
         Persistent Debugger Sessions ..................................... 87
         Examples of Debugging and Profiling Scripts ................. 87
5 JSL Building Blocks

Learning the Basics of JSL

JSL Syntax Rules .......................................................... 98
  Value Separators ......................................................... 98
  Numbers ................................................................. 101
  Names ................................................................. 101
  Comments .............................................................. 102
Operators ................................................................. 103
Boolean Values .......................................................... 107
Global and Local Variables ............................................. 108
  Local Namespaces ....................................................... 108
  Named Namespaces .................................................... 109
Show Symbols, Clear Symbols, and Delete Symbols ............... 109
Lock and Unlock Symbols .............................................. 110
Hide a Global Variable ................................................ 111
Rules for Name Resolution ............................................... 111
  Variable Names Used as Arguments .............................. 112
  Rules for Resolving Names ......................................... 112
Scoping Operators ..................................................... 114
Troubleshoot Variables and Column Names ....................... 117
Troubleshoot Variables and Keywords ............................ 118
Frequently Asked Questions about Name Resolution ............. 118
Alternatives for Gluing Expressions Together ..................... 119
Iterate .......................................................................... 120
  For ............................................................................. 120
  While ........................................................................... 121
Summation ................................................................. 122
  Product ...................................................................... 123
Break and Continue ..................................................... 124
Conditional Functions ................................................... 126
  If .............................................................................. 126
  Match ....................................................................... 128
  Choose ..................................................................... 130
  Interpolate .............................................................. 131
  Step ......................................................................... 133
Compare Incomplete or Mismatched Data ......................... 133
  Missing Values .......................................................... 135
Inquiry Functions ......................................................... 136
  General Element Types ............................................... 137
  Specific Element Types ............................................... 137
6 Types of Data ................................................................. 141

Working with Numbers, Strings, Dates, Currency, and More

Numbers and Strings ...................................................... 143
  Formatting Numbers .................................................... 144
  Unicode Characters ...................................................... 145
Path Variables ............................................................... 145
  Create and Customize Path Variables............................. 148
  Relative Paths ............................................................ 149
  File Path Separators .................................................... 149
Date-Time Functions and Formats .................................... 150
  Date-Time Values ........................................................ 150
  Program with Date-Time Functions ............................... 151
  Date-Time Values in Data Tables ................................. 158
  Custom Date-Time Formatting with Format Patterns .......... 162
Currency ........................................................................... 164
Hexadecimal and BLOB Functions .................................... 165
Work with Character Functions ....................................... 168
  Concat ......................................................................... 168
  Munger ....................................................................... 169
  Repeat ......................................................................... 170
  Substitute and Substitute Into ...................................... 171
Regular Expressions ....................................................... 172
  Regex .......................................................................... 172
  Regex Match ............................................................... 174
  Special Characters in Regular Expressions .................... 176
  Escaped Characters in Regular Expressions ................... 177
  Greedy and Reluctant Regular Expressions .................... 179
  Backreferences and Capturing Groups ......................... 181
  Lookaround Assertions ................................................ 182

Pattern Matching ........................................................... 183
  Parsing Strings in Fixed Fields ...................................... 184
  Patterns and Case ......................................................... 186
  Troubleshooting Patterns ............................................. 186

7 Data Structures ............................................................. 189

Working with Collections of Data

Lists ................................................................................. 191
### Evaluate Lists
- Assignments with Lists ................................................. 193
- Perform Operations in Lists ........................................... 193
- Find the Number of Items in a List ................................ 193
- Subscripts ........................................................................ 193
- Locate Items in a List ..................................................... 195
- List Operators and Functions ......................................... 196
- Iterate through a List ..................................................... 199
- Concatenate Lists .......................................................... 200
- Insert a Nested List in an Existing List ......................... 201
- Index into a List with Another List ................................. 201
- Send Messages to Lists ................................................. 201

### Matrices
- Construct Matrices ......................................................... 202
- Subscripts ........................................................................ 202
- Inquiry Functions ......................................................... 204
- Comparisons, Range Checks, and Logical Operators .......... 208
- Numeric Operations ...................................................... 209
- Concatenation .............................................................. 212
- Transpose ....................................................................... 212
- Indexing into a Matrix or List with Another Matrix or List ... 213
- Matrices and Data Tables .............................................. 214
- Matrices and Reports .................................................... 216
- Loc Functions ............................................................... 217
- Ranking and Sorting ...................................................... 219
- Special Matrices ............................................................ 219
- Inverse Matrices and Linear Systems .............................. 224
- Decompositions and Normalizations ............................... 228
- Build Your Own Matrix Functions .................................. 233
- Statistical Examples ...................................................... 234
- Associative Arrays ......................................................... 238
- Create Associative Arrays .............................................. 238
- Work with Associative Arrays ........................................ 241
- Applications for Associative Arrays ............................... 244
- Associative Arrays in Graph Theory ............................... 246
- Associative Arrays in Set Operations ............................. 249

### 8 Programming Methods

#### Complex Scripting Techniques and Additional Functions

- Lists and Expressions .................................................... 253
Expressions .......................................................... 253
Macros ................................................................. 265
Manipulating Lists .................................................. 265
Manipulating Expressions ....................................... 268
Advanced Scoping and Namespaces .............................. 272
Names Default To Here ........................................... 272
Scoped Names ....................................................... 276
Namespaces .......................................................... 280
Referencing Namespaces and Scopes ............................ 284
Resolving Named Variable References ............................ 287
Best Practices for Advanced Scripting ............................ 288
Advanced Programming Concepts ............................... 289
Throw and Catch Exceptions ..................................... 289
Functions ............................................................. 291
Recursion ............................................................. 294
Includes ............................................................... 294
Load and Save Text Files .......................................... 295
Run External Programs ........................................... 295
Classes ................................................................. 297
File and Directory Operations ..................................... 300
Select a Directory or File .......................................... 300
Get a List of Filenames ............................................ 301
Connect to a Network Directory ................................ 302
Scripting By Groups ............................................... 303
Encrypt and Decrypt Scripts ...................................... 304
Encryption and Global Variables ................................. 306
Encrypting Scripts in Data Tables ............................... 306
Working with Expressions in an Encrypted Script ............ 307
Additional Numeric Functions .................................... 308
Derivatives ............................................................ 308
Algebraic Manipulations .......................................... 310
Maximize and Minimize .......................................... 312
Identifying Differences Between Strings, Lines, or Sequences 313
Scheduling Actions .................................................. 315
Functions that Communicate with Users .......................... 316
Writing to the Log ................................................... 317
Send Information to the User .................................... 318
9 Data Tables

Working with Data Table Objects

Get Started with Data Tables ................................................................. 325
Basic Data Table Scripting ................................................................. 328
  Open a Data Table ................................................................. 328
  Create a New Data Table ....................................................... 330
  Import Data ............................................................................. 331
  Set the Current Data Table ................................................... 355
  Name a Data Table ............................................................... 356
  Save a Data Table ................................................................. 356
  Hide a Data Table ................................................................. 357
  Print a Data Table ................................................................. 358
  Resize a Data Table ............................................................... 358
  Close a Data Table ................................................................. 358
  Set and Get a Data Table ....................................................... 359
  Perform Actions on All Open Data Tables ....................... 359
  Create Journals ....................................................................... 360
  Create Excel Workbooks .......................................................... 361
  Prevent Changes to a Data Table ........................................ 362
Advanced Data Table Scripting .......................................................... 363
  Select Columns in a Data Table ............................................ 363
  Store Summary Statistics in Global Variables .................. 364
  Create a Table of Summary Statistics ................................. 367
  Subset a Data Table ................................................................. 369
  Add a Data Filter ................................................................. 370
  Sort a Data Table ................................................................. 376
  Stack Values in a Data Table .................................................. 377
  Split Values in a Stacked Data Table ................................. 378
  Transpose a Data Table .......................................................... 379
  Vertically Concatenate Data Tables ....................................... 380
  Horizontally Concatenate Data Tables .............................. 381
  Virtually Join Data Tables ...................................................... 382
  Replace Data in Data Tables .................................................. 385
  Create a Table Using Tabulate ............................................. 386
  Copy Data Tables ................................................................. 387
  Find Missing Data Patterns .................................................... 388
  Compare Data Tables ............................................................. 388
  Create a Summary Table ........................................................ 389
  Subscribe to a Data Table ...................................................... 390
  Move Data Between Matrices and Data Tables .................. 391

10 Scripting Platforms

Create, Repeat, and Modify Analyses

Example of Scripting a Platform
Send Messages to a Platform
Conventions for Messages and Arguments
Send Multiple Messages
Find Messages for Objects
Interpret the Show Properties List
Send Messages to an Object
Specify Which Columns to Analyze
Create Column References
Specify Multiple Column Names at Once
Enable Users to Specify Columns
Specify a By Variable
Filter by Value using a Where Statement
Enable User Input
Execute Embedded Red Triangle Options
Make Platforms Invisible
Specify Report Titles
Common Messages for Platform Windows
Scripting Considerations by Platform
Categorical
Control Charts
Distribution
DOE
Fit Model
Formula Depot
Graph Builder
Neural and Neural Net
Partial Least Squares and PLS
Process Capability
Scatterplot 3D
Text Explorer
Explore Outliers
Scripting-Only Messages and Arguments by Platform
Bivariate Script-Only Message
Choice Script-Only Message

Pre-Evaluated Statistics
Calculator Formulas
11 Display Trees

Create and Interact with Windows

Navigate JMP Reports .................................................. 519
Examples of Common Display Boxes .............................. 520
View the Display Tree .................................................. 521
Show Display Box Properties ................................. 523
Display Box Object References .............................. 524
Send Messages to Display Boxes .............................. 529
Example of Creating a Report ...................................... 536
Construct Custom Windows ...................................... 539
Example of Creating a Graph Box ......................... 539
Extract Values from a Window .................................. 540
Constructors for New Windows .............................. 542
Interact with a Closing Window ............................ 582
Update an Existing Display .................................. 584
Set Function and Set Script ................................ 588
Get and Set Selected Values of Display Elements That Return Lists ......................... 590
Send Messages to Constructed Displays ..................... 592
Construct Display Boxes That Contain Platforms .............................................. 593
Counting the Number of Child Boxes .......................................................... 595
Examples of Creating a Dashboard from Two Reports ..................................... 596
Example of Creating a Cluster Platform Launch Window ................................. 602
Example of Constructing a Custom Platform .................................................. 605
Example of Specifying Text and Background Colors ...................................... 608

Modal Windows ................................................................................................. 609
  Construct a Modal Window .............................................................................. 609
  Construct a Column Dialog ............................................................................ 611
  Comparison of Column Dialog and New Window .......................................... 613
  Constructors for Column Dialogs .................................................................... 614

Convert Deprecated Dialog to New Window ..................................................... 617
  New Window Example .................................................................................... 617
  Example of Deprecated Dialog ....................................................................... 618
  Differences Between New Window and the Deprecated Dialog ....................... 620
  Optional Scripts in New Window ..................................................................... 627

Scripting the Script Editor .................................................................................. 628
Technical Details ................................................................................................ 629
  Write Tab Box and Tab Page Box Scripts ....................................................... 629

12 Scripting Graphs ............................................................................................ 631
  Editing and Creating Two-Dimensional Graphs .............................................. 633
    Add Scripts to Graphs .................................................................................... 633
      Specify the Order of Graphical Elements .................................................. 634
    Create New Graphs from Scratch and Customize Them ............................... 640
      Customize Graphs .................................................................................... 641
      Create Shapes for a Bubble Plot ............................................................... 642
      How to Find Shapes .................................................................................. 645
    Add Lines, Arrows, Points, Shapes, and Text .............................................. 646
      Draw Lines .................................................................................................. 646
      Draw Arrows .............................................................................................. 648
      Draw Markers ............................................................................................. 650
      Draw Pies and Arcs ...................................................................................... 651
      Draw Regular Shapes: Circles, Rectangles, and Ovals ............................... 653
      Draw Irregular Shapes: Polygons and Contours ......................................... 655
    Add Text ........................................................................................................ 658
    Specify Colors ............................................................................................... 659
    Specify Transparency ..................................................................................... 663
    Add Fill Patterns ........................................................................................... 664
    Specify Line Types ......................................................................................... 667
13 Three-Dimensional Scenes

Scripting in Three Dimensions

About JSL 3-D Scenes ......................................................... 725
JSL 3-D Scene Boxes ......................................................... 725
Setting the Viewing Space ................................................... 728
  Setting Up a Perspective Scene ........................................ 729
  Setting up an Orthographic Scene ..................................... 730
Changing the View ........................................................... 731
  The Translate Command .................................................. 731
  The Rotate Command ..................................................... 731
  The Look At Command .................................................... 733
  The ArcBall ................................................................. 734
Graphics Primitives .......................................................... 735
  Primitives Example ....................................................... 738
  Controlling the Appearance of Primitives ......................... 739
  Other Uses of Begin and End .......................................... 745
Drawing Spheres, Cylinders, and Disks .................................. 745
  Construction ............................................................... 745
  Lighting ..................................................................... 746
  Lighting ..................................................................... 746
Drawing Text ...................................................................... 747
## Extending JMP

### External Data Sources, Analytical Tools, and Automation

- Real-Time Data Capture on Windows ........................................ 771
  - Create a Data Feed Object ............................................. 771
  - Read in Real-Time Data ................................................ 773
  - Manage a Data Feed with Messages .................................... 774
  - Examples of Data Feed .................................................. 776
- Dynamic Link Libraries (DLLs) ............................................. 778
- Use Sockets in JSL ............................................................ 780
  - Socket-Related Commands .............................................. 781
  - Messages for Sockets .................................................. 782
- Database Access .................................................................... 783
  - Run Query Builder Queries ............................................. 783
  - Open Database Function ................................................ 784
  - Creating a Database Connection and Executing SQL ............... 786
- Write a SQL Query .............................................................. 787
- Work with SAS ...................................................................... 788
  - Make a SAS DATA Step .................................................... 788
  - Create SAS DATA Step Code for Formula Columns ............... 788
  - SAS Variable Names ...................................................... 789
  - Connect to a SAS Metadata Server .................................... 789

The JMP Scripting Language, or JSL, lets you write scripts to re-create results in JMP. Power users often develop scripts to extend JMP’s functionality and automate a regularly scheduled analysis in production settings. If you do not want to learn JSL, JMP can write the scripts for you.

JSL is used to perform many actions:

- implements column formulas
- launches platforms
- interactively modifies platforms
- creates graphics

What JSL Can Do for You

JMP can automatically save scripts to reproduce any data table or analysis in its current state. You can pause anytime in your analysis to save a script to a script window (or script editor), in a data table, or in an analysis report. You can then modify the script as needed for future projects. When you are finished with your work, you can then save a script to reproduce your final results.

Here are some examples where JSL scripts can be helpful:

- Suppose you need to describe an analysis process in detail, from beginning to end. An example is to create an audit trail for a governing agency, or for peers reviewing your journal article.
- Suppose you have a set of analysis steps that should be followed routinely by your lab technicians.
- Suppose you fit the same model to new data every day, and the steps are always the same.

You can use JMP interactively as usual, save scripts to reproduce your work, and in the future run those scripts to reproduce your results.

There are a few things that JSL is not designed to do:

- JMP cannot record scripts while you are working. Though script-recording is a useful feature in some other scripting languages, it is less important for software like JMP, where the results are what matter. You cannot use script-recording to observe how a sequence of interactive steps is performed.
- JSL is not an alternative command-line interface for using the program.

Help with Learning JSL

There are several places within JMP to get help with writing or understanding a JSL script.

The Scripting Guide

The Scripting Guide begins with basic information (such as terminology and syntax) for JMP users who are not familiar with the scripting language. The Scripting Guide then progresses to more advanced information.

<table>
<thead>
<tr>
<th>Chapters 2 through 4</th>
<th>Includes information about learning JSL, producing basic scripts, and introduces you to the JSL scripting environment.</th>

**The Scripting Index**

The Scripting Index on the Help menu provides a brief description and the syntax for JSL functions, objects, and display boxes. Each entry includes an example that you can run and modify to test your own code. And an embedded log window lets you see messages as examples are run.
Notes:

- To display the Scripting Index entry for a function in a script, run the script, press Alt, and then double-click the function. You can also run the script, right-click the function, and select Help Scripting Index.
- To copy the syntax or description from the Scripting Index window, right-click the area that you want to copy and select Copy Text.

The Scripting Index window includes the following buttons:

- Click the Clear button to clear the search text box to begin a new search.
- Click the arrow to set search filter options and parameters.
- After you edit the sample script in the Scripting Index, click this button to revert to the original script.

Note: When you edit an example script, the changes persist when you view other entries in the Scripting Index. To revert the script, click Reset, which appears above the script after you edit it.

Search Filter Options

Click the down arrow button next to the search box to refine your search.

Contains Terms  Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.

Contains Phrase  Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).

Starts With Phrase  Returns items that start with the search criteria.

Ends With Phrase  Returns items that end with the search criteria.

Whole Phrase  Returns items that consist of the entire string. A search for “text box” returns entries that contain only “text box”.

Regular Expression  Enables you to use the wildcard (*) and period (.) in the search box. Searching for “get.*name” looks for items that contain “get” followed by one or more words. It returns “Get Color Theme Names”, “Get Name Info”, and “Get Effect Names”, and so on.

Invert Result  Returns items that do not match the search criteria.
**Match All Terms**  Returns items that contain both strings. A search for “t test” returns elements that contain either or both of the search strings: “Pat Test”, “Shortest Edit Script” and “Paired t test”.

**Ignore Case**  Ignores the case in the search criteria.

**Match Whole Words**  Returns items that contain each word in the string based on the Match All Terms setting. If you search for “data filter”, and Match All Terms is selected, entries that contain both “data” and “filter” are returned.

**Search Category and Item Names**  Returns category names (in the left column) and item names (in the middle column) that match the search criteria.

**Search Prototypes and Descriptions**  Returns prototypes (the JSL syntax) and descriptions that match the search criteria.

**Search Examples**  Returns examples that match the search criteria.

---

**Let JMP Teach You JSL**

The best JSL writer is JMP. You can work in JMP interactively and then save the results as a script to reuse later. With simple modifications, your script can serve as a template for speeding up routine tasks.

Because JSL is a very flexible language, you can reach your goals in many different ways. Here is an example. Typically, the script that JMP saves for you specifies every detail of your analysis, even if most of the details happen automatically by default. Does that mean that the scripts that you write have to be just as complete and detailed? Not at all. You usually need to specify only those details that you would select in the graphical user interface (GUI). For example, if you open Big Class.jmp from the sample data folder and want to launch Distribution for height, weight, and sex, the following script is all that is necessary:

```julia
Distribution( Y( :height, :weight, :sex ) );
```

Suppose you run the Distribution platform in the GUI and then select **Save Script > To Script Window** from the red triangle menu for the report. The following script appears:

```julia
Distribution(
    Continuous Distribution( Column( :height ) ),
    Continuous Distribution( Column( :weight ) ),
    Nominal Distribution( Column( :sex ) ),
);
```

Both scripts give the same result.

Feel free to experiment with JSL. If you think something ought to be possible, it probably is. Give it a try, and see what happens.
Terminology

Before you begin creating scripts, you should become familiar with basic JSL terms used throughout the *Scripting Guide*.

**Operators and Functions**

An *operator* is one- or two-character symbol (such as + or =) for features such as common arithmetic actions, scoping names, regular expressions, concatenating, and subscripting.

A *function* is a command that might contain additional information for the function to use.

Certain JSL functions work the same as operators but provide access to more complex actions. For example, the following two lines are equivalent:

```
2 + 3; // returns 5
Add( 2, 3 ); // returns 5
```

The first line uses the `+` operator. The second line uses the `Add()` function equivalent.

Although all JSL operators have function equivalents, not all functions have operator equivalents. For example, `Sqrt(a)` can be represented only by the `Sqrt()` function.

**Note:** In previous versions of JMP and its documentation, the terms *operators* and *functions* were used interchangeably. Now each term has a specific meaning.

**Objects and Messages**

An *object* is a dynamic entity in JMP, such as a data table, a data column, a platform results window, a graph, and so on. Most objects can receive messages that instruct the object to perform some action on itself.

A *message* is a JSL expression that is directed to an object. That object knows how to evaluate the message. In the following example, `dt` is the data table object. `<<` indicates that a message follows. In the following example, the message tells JMP to create a summary table with the specified variables.

```
dt << Summary( Group( :age ), Mean( :height ) )
```

In this expression, `dt` is the name of a variable that contains a reference to a data table. You could use any name for this variable. The *Scripting Guide* commonly uses `dt` to represent data table references. Here are some of the more common names used to represent references to certain objects:
These variables are not pre-assigned references. Each one must be assigned prior to its use. In the following example, the global variable named $A$ is assigned the value “Hello, World”. When the `Show(A)` command is processed, the result is the value of $A$.

```
A = "Hello, World";
Show(A);
A = "Hello, World";
```

**Arguments and Parameters**

An *argument* is additional information that you can provide to a function or message. For example, in `Root(25)`, 25 is an argument to the `Root()` function. `Root()` acts on the argument that you provide and returns the result: 5.

Programming and scripting books commonly talk about parameters as well. A *parameter* is a description of the argument that a function accepts. For example, the general specification for `Root()` might be `Root( number )`, where `number` is the parameter.

`Parameter` and `argument` express two perspectives of the same concept: information that a function needs.

For simplicity in the *Scripting Guide*, we use the word *argument* in both cases.

A *named argument* is an optional argument that you select from a predetermined set and explicitly define. For example, `title("My Line Graph")` in the `Graph Box()` function is a named argument because the title is explicitly defined as such.

```
Graph Box( title("My Line Graph"),
    Frame Size( 300, 500 ),
    Marker( Marker State( 3 ), [11 44 77], [75 25 50] );
    Pen Color( "Blue" );
    Line( [10 30 70], [88 22 44] ));
```

Note that the `Frame Size()` arguments 300 and 500 are not named. The position of these arguments implies meaning; the first argument is always the width, the second argument is always the height.
Optional Arguments

Functions and messages require certain arguments, and other arguments are optional. You can include them, but you do not have to. In specifications, optional arguments are enclosed in angle brackets. For example:

\[
\text{Root}( x, <n> )
\]

The \(x\) argument is required. The \(n\) argument is optional.

Optional arguments often have a default value. For example, for \(\text{Root}()\), the default value of \(n\) is 2:

<table>
<thead>
<tr>
<th>Code</th>
<th>Output</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{Root}(25))</td>
<td>5</td>
<td>Returns the square root of 25.</td>
</tr>
<tr>
<td>(\text{Root}(25, 2))</td>
<td>5</td>
<td>Returns the square root of 25.</td>
</tr>
<tr>
<td>(\text{Root}(25, 3))</td>
<td>2.92401773821287</td>
<td>Returns the cube root of 25.</td>
</tr>
</tbody>
</table>

Or and the Vertical Bar Symbol

A single vertical bar (\(|\)) represents a logical OR. For brevity, \(|\) represents the word \(or\) when referring to alternative values.

For example, a pathname can be either absolute or relative. When you see an argument such as \(\text{absolute}|\text{relative}\), this means that you enter \(either\) one of the following two options:

- \(\text{absolute}\) indicates an absolute pathname.
- \(\text{relative}\) indicates a relative pathname.

More than two options can also be strung together with a vertical bar in this way.

Script Formatting

Whitespace characters (such as spaces, tabs, and newlines) and capitalization are ignored in JSL. This means that the following two expressions are equivalent:

Expression 1:

\[
\text{sum} = 0; \\
\text{For}( i = 1, i <= 10, i++, \\
    \text{sum} += i; \\
    \text{Show}( i, \text{sum} ); \\
); 
\]

Expression 2:
You can format your script in any way that you like. However, the script editor can also format your script for you. The *Scripting Guide* uses the script editor’s default formatting for capitalization, spaces, returns, tabs, and so on. See “Work with the Script Editor” on page 59 in the “Scripting Tools” chapter for more information about using the script editor.

**Note:** The only white space exception is two-character operators (such as <= or ++). The operators cannot be separated by a space.

---

**Basic JSL Syntax**

A JSL script is a series of expressions. Each expression is a section of JSL code that accomplishes a task. JSL expressions hold data, manipulate data, and send commands to objects.

Many expressions are nested message names. Message contents are enclosed in parentheses:

```
Message Name( argument 1, argument 2, ... );
```

The meaning of JSL names depends on the context. The same name might mean one thing in a data table context and something entirely different in a function context. See “Rules for Name Resolution” on page 111 in the “JSL Building Blocks” chapter.

Almost anything that follows certain punctuation rules, such as matching parentheses, is a valid JSL expression. For example:

```
win = New Window( "Window Example", 
    <<Modal,
        Text Box( "Hello, World" ),
        Text Box( "-----" ),
        Button Box( "OK" )
    );
```

**Notes:**

- Names can have embedded spaces. See “Names” on page 101 in the “JSL Building Blocks” chapter.
- Message contents are enclosed in parentheses, which must be balanced. See “Parentheses” on page 98 in the “JSL Building Blocks” chapter.
• Items are separated by commas. See “Commas” on page 98 in the “JSL Building Blocks” chapter.
• JSL is not case sensitive; you can type “text box();” or “Text Box();”.
• Messages are commonly nested inside other messages.

---

**Book Conventions**

In the *Scripting Guide*, the function names that are case sensitive are capitalized as you must use them. Arguments that are placeholders for actual choices are in lowercase. For example, `Connect Color` is a function that you need to type as is, and `color` stands for some color choice that you make yourself.

```
Connect Color(color);
```

In this case, the argument in parentheses must be some color value (for example, a JMP color number, or a supported color name like "red", "blue", and so on, or an RGB value given as a list, such as `{.75, .50, .50}`). Sometimes alternatives like these are shown with the vertical bar (|) character for “or,” like this:

```
Connect Color( number | "color name" | {r,g,b} );
```

Syntax coloring is applied to scripts that you can paste into a script editor and then run.
Chapter 3

Getting Started
Let JMP Write Your Scripts

You often have to produce the same reports for the same data on a regular basis. This chapter shows you how to let JMP write scripts for common tasks like importing text data, opening Microsoft Excel files, and producing reports. A final tutorial shows you how to put it all together into a single script to open an Microsoft Excel file and produce three reports automatically.

The Scripting Guide is written for users who are familiar with JMP but might not be familiar with JSL. For more information about performing common tasks, see Using JMP. Discovering JMP is also a good resource for learning basic concepts and understanding the JMP workflow.
Contents

- Capturing a Script for an Analysis Report ......................................................... 49
- Capturing a Script for a Data Table ................................................................. 50
- Capturing a Script to Import a File ................................................................. 51
- Gluing Scripts Together .................................................................................. 52
Capturing a Script for an Analysis Report

Here are the basic steps for capturing a script to reproduce an analysis:

1. Launch a platform, such as Distribution.
2. Make any changes or additions that you need. For example, add tests and other graphs.
3. Capture the script to recreate your results.

You can save the script in the data table, so that if you send the data table to others, they can run your script and duplicate your reports.

Example

Follow these steps to produce a distribution report, capture the script to reproduce it, and save it to the data table.

1. Select Help > Sample Data Library and open Companies.jmp.
2. Select Analyze > Distribution to open the Distribution launch window.
3. Select Profits ($M) in the Select Columns box and click the Y, Columns button.
4. Click OK.
   The Distribution report window appears.
5. Click the Distributions red triangle and select Stack to make your report horizontal.
6. Click the red triangle next to Profits ($M) and deselect Outlier Box Plot to turn the option off.
7. Click the red triangle next to Profits ($M) and select Test Mean.
   The Test Mean window appears.
8. Type 500 in the Specify Hypothesized Mean box.
9. Click OK.
   The test for the mean is added to the report window.
   Now you have your customized report.

Note: The data tables that you use in examples are located in JMP’s Samples/Data folder.
10. Click the Distributions red triangle and select **Save Script > To Data Table**.

Your data table now has a script named Distribution saved to it. Right-click the Distribution script and select **Edit** to see the script.

**Figure 3.2** Distribution Script Saved to the Data Table

11. To run the script and reproduce your final report exactly, click the green triangle next to the script.

**Capturing a Script for a Data Table**

Here are the basic steps for capturing a script to reproduce a data table:

1. Open the data table.
2. Make any changes that you need. For example, add a script, correct values, add new columns.

3. Capture the script to recreate your data table.

**Example**

Use the data table from the previous example, where you saved a script to it.

1. In the data table, select the red triangle next to the data table’s name.
2. Select **Copy Table Script**.

**Figure 3.3 Copy the Table Script**

3. Open a script window by selecting **File > New > Script**.
4. Select **Edit > Paste**.

You now have a script that duplicates your data table. You can save this script and run it at any time to recreate your data table, with all its scripts attached.

---

**Capturing a Script to Import a File**

To capture a script that imports a file, you open the file in JMP. JMP automatically records the steps that occurred when you opened the file.

**Import a Text File**

1. Select **File > Open**.
Getting Started
Gluing Scripts Together

The Open Data File window appears.
2. Select **Text Files** from the list next to **File name**.
3. In the Open as section, select **Data (Best Guess)**.
   JMP formats the data based on tabs, commas, white space, and other characters in the text file.
4. Browse to select the file, and then select **Open**.
   The file is opened as a data table. The data table includes a script named Source. This JSL script imports your text file with the text import rules that you used.
5. Right-click the Source script and select **Edit**.
   You can copy this script, paste it into a new script window, and save it. Then you can run this script later to reimport the text file.

*Tip:* The import script is an Open() expression that specifies the text file and the import options to correctly import the file into JMP. The first part of this expression is the pathname to the specific file that you imported. If you save this script and want to run it a different place, you might need to edit the pathname so that it points to the text file. Pathnames are discussed in greater detail in “Path Variables” on page 145 in the “Types of Data” chapter.

---

**Gluing Scripts Together**

Suppose new data is saved out to an Microsoft Excel file once a week, and you need to produce the same reports every week. You could open the file and perform the same steps every week. However, creating a script that imports the new Microsoft Excel file into JMP and runs all analyses automatically is more efficient. The following example shows you how to set up your script and run it each week.

**Import the Microsoft Excel File**

1. Open a new script window (**File > New > Script**).
2. In your script window, enter the Open() expression to open the *Solubil.xlsx* sample import data file. The file is located in JMP’s Samples/Import Data folder.
   ```julia
dt = Open( "$SAMPLE_IMPORT_DATA/Solubil.xlsx" );
```
   Be sure to put the semicolon at the end of this expression, because you will add more expressions. The semicolon glues expressions together.
3. Run your script to import the Microsoft Excel file by selecting **Edit > Run Script**.
   The Microsoft Excel file opens as a data table.
Notes:

• You can also include the Excel Wizard argument in the Open() expression to preview the worksheet before importing it. See “Import Data from a Microsoft Excel File” on page 343 in the “Data Tables” chapter.

• You can specify an absolute or relative path to the file rather than using a path variable. For relative links, the script and file being opened must be in the same relative location each time you run the script. With absolute links, make sure that other users running the script have access to the file’s location. See “Path Variables” on page 145 in the “Types of Data” chapter for more information about using pathnames.

Run Your Reports and Capture Their Scripts

You have three reports to produce: a distribution report, a 3D scatterplot, and a multivariate report. Perform each one using the GUI, and add its script to the script window.

1. With your new data table open, select Analyze > Distribution.
2. Select all the columns except Labels and click Y, Columns.
3. Click OK.
4. Press Ctrl, click the eth red triangle, and then select Histogram Options > Show Counts. Bar counts are added to all six histograms.
5. In the Distribution window, click the Distributions red triangle and select Save Script > To Clipboard.
6. Click a line or two after your Open() expression and select Edit > Paste.
7. Type a semicolon after the last close parenthesis.
8. Select Graph > Scatterplot 3D.
9. Select all the columns except Labels and click Y, Columns.
10. Click OK.
11. Copy and paste the script for Scatterplot 3D into the script window just like you did for your Distribution report. Be sure to add the semicolon at the end.
13. Select all the columns except Labels and click Y, Columns.
14. Click OK.
15. Copy and paste the script for Multivariate into the script window just like you did for Distributions and Scatterplot 3D.

You should see the following script:

```
dt = Open( "$SAMPLE_IMPORT_DATA/Solubil.xlsx" );
Distribution(
    Continuous Distribution( Column( :eth ), Show Counts( 1 ) ),
```

Continuous Distribution( Column( :oct ), Show Counts( 1 ) ),
Continuous Distribution( Column( :cc14 ), Show Counts( 1 ) ),
Continuous Distribution( Column( :c6c6 ), Show Counts( 1 ) ),
Continuous Distribution( Column( :hex ), Show Counts( 1 ) ),
Continuous Distribution( Column( :chc13 ), Show Counts( 1 ) ),
);
Scatterplot 3D(
    Y( :eth, :oct, :cc14, :c6c6, :hex, :chc13 ),
    Frame3D( Set Grab Handles( 0 ), Set Rotation( -54, 0, 38 )
);
Multivariate(
    Y( :eth, :oct, :cc14, :c6c6, :hex, :chc13 ),
    Estimation Method( "Row-wise" ),
    Scatterplot Matrix( Density Ellipses( 0 ), Shaded Ellipses( 0 )
);

Save the Script
You now have a script that reproduces all of the steps that you performed manually. Save the script, and close your data table and all its report windows.
1. In the script window that contains your script, select File > Save or File > Save As.
2. Specify a filename (for example, Weekly Report).
3. Click Save.

Run the Script
As long as your weekly updated Microsoft Excel file is saved in the same place and contains the same columns, you can run your script and automatically produce all your reports.
1. Open the script that you saved.
2. Select Edit > Run Script.

Your Microsoft Excel file is opened in JMP, and all three of your reports appear.

You can send this script to others. As long as they have access to the same Microsoft Excel file in the same location, they can also run the script in JMP and see your reports.

Advanced Note: Auto-Submit
If you want a particular script to always be executed instead of opened into the script window, put the following command on the first line of the script:

//!
If this is not the very first line, with nothing else on the same line, this command does nothing.
You can override this command when opening the file.

1. Select **File > Open**.
2. Press Ctrl, select the JSL file, and then click **Open**.
   The script opens into a script window instead of being executed.

The command is also ignored when you right-click the file in the Home Window and select **Edit Script**.
JMP provides several programming tools for script writers. The script editor supports syntax coloring, autocompletes functions as you type, highlights matching braces, allows for code folding, and has additional features to help you develop scripts more quickly. Error messages and output are shown in the log window, which can be displayed inside the script editor. The JMP Scripting Language (JSL) Debugger and Profiler can help you troubleshoot your scripts.

Introduction to the Script Editor

The script editor provides a friendly environment for writing and reading JSL scripts. Figure 4.2 shows basic features such as syntax coloring, inline commenting, and automatic formatting. Other common programming options are described later in this section.

Script editor features are also available in the log window and anywhere else that you can edit or write a script (for example, in the Scripting Index or Application Builder).
Tip: Consider setting the *Autosave timeout* value in the General preferences to automatically save open scripts at the specified number of minutes. This autosave value also applies to data tables, journals, scripts, projects, and reports.

**Run a Script**

To run an entire script, select **Edit > Run Script**.

To run specific lines in a script, select those lines and then select **Edit > Run Script**.

To run specific lines that are not adjacent, press Ctrl, select the lines, and then select **Edit > Run Script**.

On Windows, you can also click in a line or select several lines and press Enter on your numeric keypad.

Run the script automatically when you open it by using one of the following methods:

- Type `//!` on the first line.
- Include `Run JSL(1)` in the `Open()` statement:
Stop a Script

To stop the script, press Esc on Windows (or Command-period on macOS). You can also select **Edit > Stop Script**. On macOS, **Edit > Stop Script** is available only when the script is running.

Edit a Script

To edit a script on Windows, press Insert. You can then type directly over (overwrite) any existing JSL code. Note that this feature is not available on macOS.

Color Coding and Themes

On Windows, the default font in the script editor is 10-point Consolas. On macOS, the default script editor font is 13-point Menlo.

JMP applies the following colors in the script window:

- black for text, identifiers (JSL functions), braces, and user macros
- white for the script editor background
- gray for the disabled background and guides
- green for comments
- purple for strings
- maroon for platform names

**Note:** If a platform name is used in a message, the JSL messages color is used.

- teal blue for numbers
- dark blue for operator symbols, the first keyword, and JSL messages
- medium blue for function names, second and third keywords, and macros
- red for unknown objects

You can customize colors and fonts in the Customize Styles section of the Script Editor preferences. Syntax coloring for JSL, the log, SAS code, JavaScript, Text, JMP Text Analytics, R, Matlab, Python, C, JSON, and SQL are supported. In addition, options for dark and light themes are provided.
**Autocomplete Functions**

If you do not remember the exact name of a function, use autocompletion to see a list of functions that match what you have typed so far. Type part of the name, and then press Ctrl+Space on Windows (Option+Esc on macOS).

Suppose that you want to clear your JSL variables, but do not remember the command. You can type `clear` and then press Ctrl+Space, to see a list of possible clear commands. Select the command that you want to insert.

Figure 4.3  Autocomplete Example

![Autocomplete Example](image)

**Tooltips**

If you are using a function and do not remember the syntax or need more information about it, place the cursor over it to see a brief explanation. This works only with JSL function names, not platform commands, messages, or user-created functions. JSL function names are colored blue in the script editor.

The tooltip shows the syntax, arguments, and a brief explanation of the function (Figure 4.4). The tip also appears in the script editor window status bar.

Figure 4.4  Tooltip for a JSL Function

![Tooltip for a JSL Function](image)

After running a script, you can also place the cursor over variable names to see their current value. To turn off variable tooltips, deselect `Preferences > Script Editor > Show Variable Value Tips`.

To turn off function tooltips, deselect `Preferences > Script Editor > Show Operator Tips`. 
Tip: In addition to showing the tooltip for a function, you can display its Scripting Index entry. Run the script, press Alt, and then double-click the function. A description, sample script, and information about syntax is provided. You can also read help for the topic by running the script, right-clicking the function, and selecting Help Browser.

Example of a Tooltip for a JSL Variable
1. Enter and run the following line in a script window:
   ```javascript
   my_variable = 8;
   ```
   2. Hover over the variable name after you run the line.
      A tooltip shows the name of the variable and its value: 8.
   3. Enter and run the following line:
      ```javascript
      my_variable = "eight";
      ```
   4. Hover over the variable name after you run the line.
      A tooltip shows the name of the variable and its value: “eight”.

Split a Window

You can split the Script Editor window into two vertical or horizontal windows. This feature enables you to independently scroll through your code in two different places and edit the contents in both. When you make a change in one window, the change is immediately reflected in the other window.

- To split an open Script Editor window, right-click in the window and select Split > Horizontal or Vertical.
- To revert to a single window, right-click and select Remove Split.
Match Parentheses, Brackets, and Braces

The script editor helps you match fences (or parentheses, square brackets, and braces) in the following ways:

- The matching closing fence is added when you type an opening fence.
- When you click next to either an opening or closing fence, the fence and its match are highlighted in blue. If the fence does not have a match, it is highlighted in red.
- If you double-click a fence, everything between the matching fence is selected (including the fences).
- If you put your cursor within an expression and press Ctrl+] on Windows (Command+B on macOS), the entire expression is selected. Fences that enclose the expression are included. Repeat this process to highlight the next-higher expression. Figure 4.6 shows an example.
Figure 4.6 Each Step in Matching Fences

When you type an opening brace, JMP adds the closing brace. Enter code between the braces, type the closing brace, and then your cursor automatically moves after the closing brace that JMP added. This prevents you from accidentally adding an unnecessary closing brace.

You can turn on and off the autocompletion of braces in the JMP preferences. See “Set Preferences for the Script Editor” on page 70.

Select a Rectangular Block of Text

To select a rectangular block of text, press Alt and drag your cursor from the starting point to the end of the block. You can either copy or cut the text enclosed in the block.

Suppose that you want to select all of the following code except for the comment marks.

```// Y( :Y ),
// X( :X ),
```

Select a rectangular portion beginning with `Y`. When you paste, you get the following code:

```Y( :Y ),
X( :X ),
```

The rectangular selection inserts returns where needed to maintain the structure of the text. Select `Get Menu Item State` on both lines in the following example.

```bb << Get Menu Item State(1),
bb << Get Menu Item State(2),
```

When you paste, a return is inserted at the end of each line.
Select Fragmented Text

To select text that is not contiguous, press Ctrl on Windows or Command on macOS and drag your cursor over the text. Continue this action for any other text that you want to select. You can then copy and paste your selection into a new script or you can run the selected text. Text will be pasted or run in the order it was selected.

Drag and Drop Text

You can drag and drop text within a script editor window or between windows or from a data table into a script editor window. On Windows, pressing Ctrl before dragging and dropping copies the text. On macOS, the text is copied by default.

Drag and drop text in any of these ways:

- Select a row or column, pause, and then drop it into the script editor window.
- Double-click text in a text field and then drop it into the script editor window. Examples are text in a data table cell and any other selectable text.

On Windows, you can also drag and drop text into a minimized window.

1. Drag the text over the Home Window button  in the lower right corner of the window. The Home Window appears.
2. In the Home Window list, drag the text over the destination window. That window appears.
3. Drop the text where you want it.

Find and Replace

Many find and replace options are available in the script editor, including the support of regular expressions. For example, searching with the following regular expression:

```
get.*name
```

returns messages such as “Get Button Name”, and “GetFontName”

Basic regular expressions such as ^ and $ (which match the start of line and end of line) and \n (which matches a carriage return) are also supported.

See Using JMP for more information about the Search options.
Automatic Formatting

The script editor can format a script for easier reading. Any generated script (for example, by saving a platform script) is automatically formatted with tabs and returns in appropriate places.

You can also reformat individual scripts that are difficult to read (for example, scripts in which all commands are strung together with no whitespace characters). From the Edit menu, select Reformat Script.

**Tip:** This command alerts you if your script is badly formed (for example, if your parentheses are not matched).

Errors Are Marked by Special Characters

After you run a script, the /*###*/ characters in the log indicate the location of an error in the script execution. The following example shows a script in which the height column name is misspelled.

```plaintext
Names Default To Here( 1 );
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt:heihgt[3]; // misspelled column name
```

After you run the script, the log reads:

```plaintext
Scoped data table access requires a data table column or variable in access or evaluation of 'dt:heihgt' , dt:heihgt/*###*/
```

In the following script, error marked by /*###*/

```plaintext
Names Default To Here( 1 );
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt:heihgt/*###*/[3];
```

/*###*/ directly follows the misspelled height argument.

Typing in Multiple Rows at Once

When you edit a script, you can type in multiple rows at once instead of manually updating the same code on multiple lines. For example, in the following script, you want to change the s variable to aString. You can easily change the first instance of s to aString. To change the other instances at once, hold down Alt and select the column of s variables. Type aString once.

```plaintext
s = "";
For( i = 1, i <= n, i++,
s += "Hello";
```

s += "Number"
    s += Char( i )
);

The script then looks like this:

    aString = "";
    For( i = 1, i <= n, i++,
        aString += "Hello";
        aString += "Number";
        aString += Char( i );
    );

Note: You can type in multiple rows at once, but you can type only in the same column. In the preceding example, the s variables are in the same column.

Add Code Folding Markers

You can add code folding markers that show the beginning and the end of the code block, enabling you to collapse and expand code inside stand-alone functions.

To turn on this feature, select Code folding in the Script Editor preferences. Then you can expand and collapse blocks of code by right-clicking on a script and selecting Advanced > Expand All or Collapse All.

Tip: To fold or expand all code in the entire script, press Shift+Ctrl and then click a code marker.

After you select this preference, Function and Expr expressions are foldable. See “Add More Folding Keywords” on page 69 for more information about adding folding markers to other expressions.

Figure 4.7 Code Folding Markers Shown in a Script

By default, code does not remain collapsed after you save the script and restart JMP. To save the state of the folded code, select Save and restore document state information in the Script Editor preferences.
Add More Folding Keywords

Custom code folding is supported for other stand-alone functions as shown in the following example:

```javascript
{"If", "For", "For Each Row", "While", "Try", "New Window", "V List Box", "H List Box"}
```

JMP supports multiple keyword lists. A system administrator can define a set of keywords in `jmpKeywords.jsl` and save the script in `C:/ProgramData/SAS/JMP/` or designated directory listed below. You save your version of `jmpKeywords.jsl` in your `C:/Users/<user>/Documents/` folder. JMP merges all keyword lists from the designated directories.

On Windows, the following directories are examined in the order listed:

- `C:/ProgramData/SAS/JMP/16/`
- `C:/ProgramData/SAS/JMP/`
- `C:/Users/<user>/AppData/Roaming/SAS/JMP/16/`
- `C:/Users/<user>/AppData/Roaming/SAS/JMP/`
- `C:/Users/<user>/Documents/`

On macOS, the following directories are examined in the order listed:

- `/Library/Application Support/JMP/16/`
- `/Library/Application Support/JMP/`
- `~/Library/Application Support/JMP/16/`
- `~/Library/Application Support/JMP/`
- `~/Documents/`

Note that `jmpKeywords.jsl` is stored in the designated JMP directory, even if you are using JMP Pro.

Notes:

- The list in `jmpKeywords.jsl` is case insensitive.
- Code folding is not supported for messages, platforms, user-defined functions, and comments.
- After you edit and save the list in `jmpKeywords.jsl`, turn the Allow additional code folding keywords preference off and then back on for the changes to take effect. Messages in the log indicate that the keywords were loaded.

Advanced Options

Right-clicking on selected text in the Script Editor provides the following Advanced options:

**Expand All** (Appears only if JSL code folding is on.) Expands all blocks of code.
**Scripting Tools**

**Chapter 4**

**Work with the Log**

The Log in JMP has two modes:

- “Enhanced Log in JMP” on page 71
- “Text Log in JMP” on page 76

You can switch between the two modes by selecting `File > Preferences > Script Editor` to further customize the editor. For more information about script editor preferences, see *Using JMP*.

**Note:** The log shows the steps you take during data cleanup. For example, if you add a column property or import the data into Excel, then the JSL expressions for those actions are captured in the log. This enables you to clean up the data more efficiently when you receive a new data set.

---

**Collapse All** (Appears only if JSL code folding is on.) Collapses all blocks of code.

**Comment Block** Makes the selected text comments.

**Uncomment Block** Uncomments the selected comments.

**Make Uppercase** Changes all selected text to uppercase.

**Make Lowercase** Changes all selected text to lowercase.

---

**Set Preferences for the Script Editor**

In the JMP preferences, customize the script editor settings such as the font, colors, and spacing options.

**Setting the Fonts**

1. Select `File > Preferences`.
2. Select the `Fonts` group.
3. Click `Mono` to set the font for the script editor.

For more information about font preferences, see *Using JMP*.

---

**Work with the Log**

The Log in JMP has two modes:

- “Enhanced Log in JMP” on page 71
- “Text Log in JMP” on page 76

You can switch between the two modes by selecting `File > Preferences > Log`.

**Note:** The log shows the steps you take during data cleanup. For example, if you add a column property or import the data into Excel, then the JSL expressions for those actions are captured in the log. This enables you to clean up the data more efficiently when you receive a new data set.
Enhanced Log in JMP

The Enhanced Log is a tabular view of the events in a JMP session. To view the JMP Log, select **View > Log** (**Window > Log** on macOS). By default, the log in JMP appears in Enhanced mode. The log window contains events, or actions, in the rows of the table and the corresponding JSL code and output in a separate text pane. This tabular view of the events is easy to navigate, displays errors and warnings, and can help you create a JSL script of the actions in a JMP session. For an example of using the log to generate a JSL script for recorded actions, see “Example of Recording Actions in the Enhanced Log” on page 75.

**Note:** When you used the embedded log in a script window, the embedded log does not use the Enhanced Log mode. Further, any script output from a script window with an embedded log does not appear in the Enhanced Log.

**Figure 4.8 Enhanced Log**

![Enhanced Log screenshot](image-url)
Each row of the tabular view contains information in the following columns:

**Type**  Contains an icon that represents message type. For more information about the types of messages, see “Filter” on page 73.

*Tip:* You can hover over an icon in the Type column to see the type of message that a particular icon represents.

**Message**  Contains a description of the event or result. Among other things, this could be a recorded action, JSL that was submitted, the result of JSL that was submitted, or an error message. Each description of a logged item or result is limited to three lines of text; longer items are denoted with an Ellipsis icon in the upper right corner of the Message section of the row. The full text for longer items appears in the text pane at the bottom of the log window.

**Origin**  Contains an icon that shows the type of JMP window from which the logged item or result was generated. If the Color by Window option is selected in the red triangle menu next to Filter, logged items generated by the same JMP window are specified by a common color. You can click on the icon in the Origin column to bring the corresponding window to the front.

*Note:* Not all rows in the log table have an icon in the Origin column.

**Result**  Contains an icon that shows the type of JMP window that contains the result. If the Color by Window option is selected, logged items generated by the same JMP window are specified by a common color. You can click on the icon in the Result column to bring the corresponding window to the front.

*Note:* Not all rows in the log table have an icon in the Result column.

**Timestamp**  Contains a date-time value that indicates when the logged item was generated.

### Enhanced Log Options

The red triangle menu in the Enhanced Log contains the following options:

**Go To**  (Available only when one or more rows of the log table are selected.) Brings the window corresponding to the selected row in the log table to the front. If an Origin window and a Result window both appear in the selected row, both windows are brought to the front with the Result window on top of the Origin window.

**Run Scripts**  (Available only when one or more rows of the log table that contain a scriptable action are selected.) Runs the JSL script that corresponds to the selected rows in the log table.
**Color by Window**  Specifies whether the rows in the log table are colored by the JMP window that created the row of the log output.

**Clear**  (Available only when one or more rows of the log table are selected.) Removes the selected row or rows from the log table.

*Caution:* This action cannot be undone.

**Clear Log**  Removes all rows from the log table.

*Caution:* This action cannot be undone.

**Filter**  Contains the following options to filter what types of logged events appear in the log table.

- **Result**  Shows or hides rows that correspond to the results of running JSL.
- **Script**  Shows or hides rows that correspond to submitted JSL.
- **Log**  Shows or hides rows that correspond to informational log messages.
- **Warning**  Shows or hides rows that correspond to warning messages in the log.
- **Error**  Shows or hides rows that correspond to error messages in the log.
- **Action**  Shows or hides rows in the log table that correspond to interactive JMP actions. These actions include data table operations, platform launches, and closing report windows. You can customize which actions are shown in the log table by selecting specific options in the Action Recording submenu.

**Action Recording**  Contains the following options to filter what types of interactive JMP actions appear in the log table.

- **Data Table Operations**  Shows or hides rows that correspond to manipulations of a data table. These actions can include row and column operations, as well as actions in the Tables, Rows, and Cols menus.
- **Platform Launch**  Shows or hides rows that correspond to launching a JMP platform.
- **Report Snapshot on Close**  Shows or hides rows that correspond to a JSL script that is saved when a report window is closed.

**Save Script**  Contains the following options that save a script that reproduces all selected rows in the log table. If no rows are selected, these options save a script to reproduce all events recorded in the log table.

- **To Script Window**  Saves the script to a script window.
To Clipboard  Saves the script to the clipboard.

Make Into Data Table  Creates a data table that contains all rows from the log table. If rows are selected in the log table, they are also selected in the data table that is created.

Filter the Results in the Enhanced Log

To the right of the red triangle menu, use the search field to filter the items in the log table view.

Click the down arrow button next to the search box to refine your search.

Contains Terms  Returns items that contain a part of the search criteria. A search for “ease oom” returns messages such as “Release Zoom”.

Contains Phrase  Returns items that contain the exact search criteria. A search for “text box” returns entries that contain “text” followed directly by “box” (for example, “Context Box” and “Text Box”).

Starts With Phrase  Returns items that start with the search criteria.

Ends With Phrase  Returns items that end with the search criteria.

Whole Phrase  Returns items that consist of the entire string. A search for “text box” returns entries that contain only “text box”.

Regular Expression  Enables you to use the wildcard (*) and period (.) in the search box. Searching for “get.*name” looks for items that contain “get” followed by one or more words. It returns “Get Color Theme Names”, “Get Name Info”, and “Get Effect Names”, and so on.

Invert Result  Returns items that do not match the search criteria.

Match All Terms  Returns items that contain both strings. A search for “t test” returns elements that contain either or both of the search strings: “Pat Test”, “Shortest Edit Script” and “Paired t test”.

Ignore Case  Ignores the case in the search criteria.

Match Whole Words  Returns items that contain each word in the string based on the Match All Terms setting. If you search for “data filter”, and Match All Terms is selected, entries that contain both “data” and “filter” are returned.
Example of Recording Actions in the Enhanced Log

You can use the Enhanced Log to record many of the interactive actions that you perform for data cleanup and analysis. In this example, the Enhanced Log is used to generate a JSL script for some data manipulation and analysis actions.

1. Select View > Log.
2. Click the red triangle next to the Filter box and select Clear Log.
4. Right-click Displacement in the Columns panel in the data table, and select Column Info.
5. Type Engine Size for the Column Name. Click OK.
6. Right-click Type in the Columns panel in the data table, and select Column Info.
7. Select Ordinal for the Modeling Type. Click OK.
8. Click Horsepower in the Columns panel in the data table and drag it above Weight.
9. Select Graph > Graph Builder.
10. Drag Horsepower to the Y drop zone.
11. Drag Engine Size to the X drop zone.
12. Close the Graph Builder window.
14. Select Type and Horsepower and click Y, Columns.
15. Click OK.
16. Click the red triangle next to Horsepower and select Continuous Fit > Fit Lognormal.
17. Close the Distribution window.
18. Select View > Log.
19. Press Ctrl and select the first, second, third, and last rows of the log table.

20. Click the red triangle next to the Filter box and select **Save Script > To Script Window**.

The script to reproduce the selected actions appears in a new script window. You can save this script to reuse later or use it as a starting point for a more complex analysis.

**Text Log in JMP**

The Text Log in JMP is a text-based log of JSL scripts that have been run during a JMP session and the results of those scripts. When the log is open, output appears in the log after you run a script. The script that was run is shaded in the log, and the corresponding output appears beneath it. To view the log in Text mode, select Text for the Mode preference after selecting **File > Preferences > Log**.

Syntax and compatibility errors are reported in the log, including the line number, script filename, and code that JMP could not process. Many interactive JMP actions are also recorded in the log.

**Tips:**

- To omit compatibility warnings from the log, deselect **Show log warnings for JSL compatibility changes in 12** in the JMP General preferences.
- To choose which actions are recorded in the log, you can use the Action Recording preferences after selecting **File > Preferences > Log**.
Show the Text Log in the Script Window

You can view the log inside the script window by right-clicking and selecting **Show Embedded Log**. To view the embedded log by default, select **Show embedded log on script window open** in the Script Editor preferences. This option makes it easy to edit and run a script, quickly see the results of your changes, and then continue to develop the script. The embedded log uses the Text log mode. See “Text Log in JMP” on page 76.

The embedded log always appears in the Scripting Index script window, but it is not available in Application Builder and the Debugger.

**Figure 4.10** The Script Window with an Embedded Text Log

```julia
1 A = "Hello, World";
2 Show( A );

//:
//:
A = "Hello, World";
Show( A );
//:
A = "Hello, World";
```

Debug or Profile Scripts

In an open script, click the **Debug Script** button (or select **Edit > Debug Script**) to show the script in the JSL Debugger window. You can also use a keyboard shortcut:

- Press Ctrl+Shift+R (Windows).
- Press Shift+Command+R (macOS).
The JSL Debugger helps identify the point at which a script causes an error or fails. Rather than commenting out portions of the script or adding `Print()` expressions, you can use the Debugger to find the problem.

Once the JSL Debugger appears, you can continue in this mode, or you can click the **Profile JSL Script** button to move into the JSL Profiler mode. The JSL Profiler helps with optimization. You can profile your scripts during execution to see how much time is spent executing particular lines or how many times a particular line is executed.

**Tip:** To debug a script automatically when you open it, include `Debug JSL(1)` in the `Open()` statement:

```
Open( "$SAMPLE_SCRIPTS/scoping.jsl", Debug JSL(1) );
```

**Debugger and Profiler Window**

The Debugger opens in a new instance of JMP (Figure 4.11). The original instance is inoperable until the script produces something that requires interaction. At that point, the Debugger window becomes inoperable until you perform whatever action is required. Then control is returned to the Debugger. Close the Debugger to work again in the original instance of JMP.

**Figure 4.11** The Debugger Window
Use the buttons at the top to control the Debugger or the JSL Profiler. One or more scripts that you are debugging or profiling are shown in tabs. If your script includes other scripts, each one opens in a new tab.

Tabs in the bottom portion of the Debugger provide options to view variables, namespaces, the log, and the current execution point; work with breakpoints; and set options.

**Tip:** To view or edit long values on a tab in the Debugger, right-click the value and select *Edit*. The code opens in a script editor.

### Using the Execution Buttons

Use the buttons at the top to control execution of the script within the Debugger or JSL Profiler.

**Table 4.1  Description of the Debugger Buttons**

<table>
<thead>
<tr>
<th>Button</th>
<th>Button Name</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="run.png" alt="Run" /></td>

</tr>
<tr>
<td><img src="image" alt="Show Profile by Percent" /></td>
<td>Show Profile by Percent</td>
<td>For line counts, shows the individual line count divided by the total line count. For time, shows the percentage of time spent on an individual line (line time/total time*100).</td>
</tr>
<tr>
<td><img src="image" alt="Time Units" /></td>
<td>Time Units</td>
<td>Sets the time unit to microseconds, milliseconds, or seconds. Available in the JSL Profiler after you click the Run profiler button ➤.</td>
</tr>
</tbody>
</table>

**Notes:**
- You can switch back and forth between the Debugger and JSL Profiler modes only prior to the start of the program.
- Some of the debugger buttons are disabled when profiling.
- All breakpoints are disabled when running in the JSL Profiler mode.
Variable Lists

The tabs on the bottom left of the Debugger let you examine global variables, local variables, watch variables, and variables within namespaces.

**Globals**  The Globals tab lists all global variables and updates their values as you step through the script. Each variable is added as it is initialized. If there are already global variables defined from running earlier scripts, they will be listed with their current values when you start the Debugger. See “View Variables” on page 85.

**Locals**  The Locals tab lists all variables by scope and updates their values as you step through the script. Select a scope in the menu. See “View Variables” on page 85.

**Watch**  If there is a particular variable or value of an expression whose values you want to watch as you step through the code, you can add them here. This is particularly useful if your script uses many variables that might be difficult to watch in the Globals or Locals lists. See “Work with Watches” on page 85.

**Namespaces**  As namespaces are defined, they are added to the menu. Select a namespace to view any variables and their values used within the namespace. See “View Variables” on page 85.

**Classes**  The Classes tab lists classes that are defined in the script. See “Classes” on page 297 in the “Programming Methods” chapter.

Debugger Options

The tabs on the bottom right of the Debugger let you view the call stack, work with breakpoints, set options, and view the log.

**Call Stack**  The call stack lists the current execution point in scripts and functions. The main script is always the first script listed. If you call a function, the function is added on top of the calling script. Likewise, any included files are added to the top of the list as you step through them. When you exit any function or script, it is removed from the list and you return to the next one in the list. The current line numbers are updated as you step through.

Double-click a row in the call stack to move the cursor to the specified line.

### Table 4.1  Description of the Debugger Buttons (Continued)

<table>
<thead>
<tr>
<th>Button</th>
<th>Button Name</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red</td>
<td>Color Theme</td>
<td>Sets the color of the shading for the JSL Profiler. Available in the JSL Profiler after you click the Run profiler button</td>
</tr>
</tbody>
</table>
Breakpoints  Add, edit, delete, and disable or enable breakpoints on lines. See “Work with Breakpoints” on page 82. You can also double-click a row on the Breakpoints tab to move the cursor to the specified line.

Data Breakpoints  Add, edit, delete, and disable or enable breakpoints in variables. Data breakpoints watch for changes in variables, unlike breakpoints, which watch for changes in lines.

Options  Set the Debugger preferences interactively on this tab. See “Modify Preferences in Debugger” on page 86.

Log  The log from the script that you are debugging is shown on this tab.

Work with Breakpoints

A breakpoint interrupts the execution of a script. Although you can step through a script line by line, this can be tedious and lengthy for a long or complex script. You can set breakpoints at places of interest and simply run the script in the Debugger. The script is run normally until a breakpoint is reached. At the breakpoint, the Debugger stops executing the script so that you can look at the values of variables or start stepping line by line.

Breakpoints that appear on the Breakpoints tab in the lower right corner watch for changes in a line. Breakpoints that appear on the Data Breakpoints tab watch for changes in variables.

JMP preserves breakpoints across sessions. So when you close and reopen JMP, the breakpoints still appear.

Tip: Turn on line numbers by right-clicking in the script and selecting Show Line Numbers. You can also show line numbers by default in all scripts by modifying the Script Editor preferences.

Create a Breakpoint

When creating a breakpoint, you can specify settings such as conditions and break behavior. To do so, click on the Breakpoints tab or Data Breakpoints tab, and then enter the breakpoint information.

Otherwise, create a quick breakpoint by doing one of the following:

- In the Debugger margin, click the appropriate line (to the right of the line number if displayed).
- In the Debugger margin, right-click in the margin where you want the breakpoint and select Set Breakpoint.

The red breakpoint icon appears where you inserted the breakpoint and on the Breakpoints tab.
Delete Breakpoints

Do one of the following:

- In the Debugger margin, click the breakpoint icon.
- In the Debugger margin, right-click the breakpoint icon and select Clear Breakpoint.
- On the Breakpoints tab, select the breakpoint and then click \(\times\).
- On the Breakpoints tab, click \(\times\) to delete all breakpoints (not just the selected breakpoints).

The red breakpoint icon is removed, and the breakpoint no longer appears on the Breakpoints tab.

Disable and Enable Breakpoints

Disabling a breakpoint is helpful when you potentially fix a problem and then want to see whether the script will run correctly past that breakpoint. You can then enable the breakpoint when necessary rather than re-creating it.

Do one of the following:

- In the Debugger margin, right-click the breakpoint icon and select Enable Breakpoint or Disable Breakpoint.
- On the Breakpoints tab, select or deselect the breakpoint’s check box.
- On the Breakpoints tab, click \(\text{}\) to disable or enable all breakpoints.

A disabled breakpoint turns white; enabled breakpoints are shaded red.

Specify and Clear Conditional Expressions on Breakpoints

Setting a condition on a breakpoint is an alternative to single-stepping through code. Rather than single-step and view the variables for each expression, you specify that the script break only when a condition is met. Then you can step through the code and figure out where the problem arises.

Suppose that a calculation in your script is incorrect, and you suspect the problem occurs when \(i==19\). Set a conditional breakpoint for \(i==18\). The Debugger will run until that condition is met, then you can step through the code to identify the problem.

Specify a Breakpoint Condition

1. Right-click the breakpoint icon and select Edit Breakpoint.
2. On the Condition tab, select Condition and enter the conditional expression.
3. Specify whether to break when the expression Is true or Has Changed.
4. Click OK.
Disable or Enable a Condition

1. Right-click the breakpoint icon and select **Edit Breakpoint**.
2. On the Condition tab, deselect or select **Condition**.

Delete a Condition

On the Breakpoints tab, click in the breakpoint’s Condition field and press Delete.

Specify Break Options

Right-clicking the breakpoint and selecting **Edit Breakpoint** provides a quick way to manage breakpoint behavior. Alternatively, select the breakpoint on the Breakpoints tab and click [ ]. Both methods display the Breakpoint Information window, where you customize settings on the Hit Count and Action tabs.

Change the Hit Count

You can control the number of times a breakpoint must be hit and when the break occurs. For example, to break when the condition is met twice, select **break when the hit count is equal to** and type 2 on the Hit Count tab.

Define an Action

You also have the option of defining a JSL expression or script that the Debugger executes when a breakpoint is hit and execution has stopped. This script is called an **action**. On the Action tab, enter the JSL expression to be executed.

Run the Script to the Cursor

When you right-click and select **Run To Cursor**, all expressions before the location of the cursor are executed. Select this option when you want to see values only up to the current line. To see values when each expression is executed, use the stepping options.

Tips for Setting Breakpoints

- If you do not want to watch for errors in a specific loop, set a breakpoint after the loop ends. The Debugger will hit the next breakpoint rather than stepping through each line of the loop.
- Avoid inserting a breakpoint in lines that do not trigger an action (such as comments, blank lines, and end parentheses). Debugger will not break on these lines.
- When you insert breakpoints, close Debugger, and edit the script, the breakpoints remain on the original line numbers. You might need to delete and then reinsert the breakpoints.
• Breakpoints are remembered across Debugger sessions. This means that your breakpoints list includes breakpoints that have been set in all scripts, not just the script that you are currently debugging.

• Breakpoints are remembered by the Debugger session, not by each script. This means that breakpoints are listed even for scripts that have been moved or deleted.

• On the Breakpoints tab, click \( \times \) to remove all breakpoints in scripts whether they are currently open or not, or for scripts that no longer exist.

**View Variables**

The variables lists are populated as they appear in the script. Their values are updated every time the script changes them. If you are uncertain why a variable has a particular value when you run your script, you can watch its value at every step to see what happens.

You can also assign the variables whatever value you want. For example, if you are stepping through a `For()` loop but are interested only in what happens starting with a particular iteration, you can assign your iterating variable that value. Step through the first part of the loop that initializes the iteration variable and then assign it the value that you want in the variable list at the bottom. Then when you step through, the loop begins executing at that point.

**Tips for Managing Variables**

• If you have run several scripts using the global scope, you might want to clear or delete global variables. This makes the list of variables in the Debugger shorter and relevant. Use the `Delete Symbols()` function to do so. You can also close JMP and restart to clear the space.

• If your script uses so many variables that they are difficult to find and watch in the variable lists, add watches for the specific variables in which you are interested.

• To view or edit long values on a tab in the Debugger, right-click the value and select **Edit**. The code opens in a script editor.

**Work with Watches**

JMP preserves the Watch variables across sessions. So when you close and reopen JMP, the Watch variables are still listed on the Watch tab.

**Create a Watch**

• On the Watch tab, click \( \) and enter the value in the window.
• In the Debugger, right-click the line that you want to watch, select **Add Watch**, and then enter the variable name in the window.

• In the Debugger, place the cursor in or next to a variable name (or select the variable name), right-click, and select **Add Watch**.

• On the Watch tab, enter the variable in an empty **Variable** field.

**Modify a Watch**

Do one of the following on the Watch tab to enter a new value:

• Select the watch and click ![enter value here](image).
• Click in the Variable field and enter a new value.

**Delete Watches**

Do one of the following on the Watch tab to delete watches:

• Select the watch and then click ![delete watch](image).
• Click ![delete all watches](image) to remove all watches.

**Modify Preferences in Debugger**

The Debugger lets you change preferences as you work in the Debugger. Select the Options tab to find the following settings:

- **Show Line Numbers**  Shows or hides the line numbers for the script in the Debugger.

- **Break on Multiple Statements Per Line**  Stops executing the script between each expression in a single line.

- **Break On Throw**  Breaks when the script executes the `Throw()` function. For example, `Throw()` might be enclosed in a `Try()` expression. The Debugger breaks on `Throw()` instead of continuing through the rest of the expression. This lets you identify where the problem occurred in the script and then return to debugging.

- **Break On Execution Error**  Stops executing the script when the error occurs rather than closing the Debugger.

- **Warn On Assignment In Condition**  Shows a warning when you enter a breakpoint condition that contains the assignment. For example, if you have a breakpoint on `x = 1` and add the condition `x = 1` to the breakpoint, you are prompted to verify the assignment of `x`.

- **Enter Debugger Upon Termination**  Keeps the Debugger open after a JSL program terminates execution. On by default, this option lets you examine attributes of the executed program.
**Break For Compatibility Warnings**  Breaks when a JSL compatibility issue is found.

**Persistent Debugger Sessions**

JMP saves all breakpoints and watches until you delete them. Other user-specific settings, such as column widths on the tabs and the Debugger window size, persist between sessions of JMP.

These settings are stored in a file named JMP.jdeb, the location of which is defined in the USER_APPDATA variable:

- Windows 7 and higher: 
  
  "C:/Users/<username>/AppData/Roaming/SAS/JMP/16/"

- macOS: 
  
  "/Users/<username>/Library/Application Support/JMP/16/"

As usual, the values of local variables, global variables, and namespaces clear when you close and reopen JMP.

**Note:** On Windows, the paths differ based on the JMP edition. In JMP Pro, the path refers to “JMPPro”.

**Examples of Debugging and Profiling Scripts**

This section includes examples of setting breakpoints to watch variables; stepping into, over, and out of expressions; watching variables in different scopes and namespaces; debugging interactive scripts; and profiling scripts with the JSL Profiler.

Example scripts are located in the Samples/Scripts folder.

**Tip:** Make sure that **Show Line Numbers** is selected on the Debugger Options tab before proceeding.

**Using Breakpoints and Watching Global Variables**

The following example shows how to set a breakpoint in a loop and watch variables change through each iteration of the loop.

1. Open the string.jsl sample script and click the **Debug Script** button.
2. Click in the margin for line 12 to add a breakpoint.
   
   You should have a breakpoint for the following expression inside the For() loop:
   
   ```
   stringFunction(i);
   ```
3. Click **Run**.

The first two expressions are evaluated:

- `stringFunction` is defined as a function.
- `str` is defined as an empty string.

Both variables and their types and values have been added to the Globals list. In addition, the `For()` loop has been evaluated up to the line with the breakpoint, shown in Figure 4.12.

- `i` has been assigned to 0.
- `i` and its value and type have been added to the Globals list.
- `i` has been determined to be less than or equal to 9.
- `stringFunction()` has not yet been called.

**Figure 4.13  View the Initial Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>i</code></td>
<td>10</td>
<td>Number</td>
</tr>
<tr>
<td><code>str</code></td>
<td>&quot;0123456789&quot;</td>
<td>String</td>
</tr>
<tr>
<td><code>stringFunction</code></td>
<td>Function( {i}, {y}, y = Char(i); str = str</td>
<td></td>
</tr>
</tbody>
</table>

**Tip:** The initial value of `i` is 10 because the script was run before entering the Debugger; it’s showing the value of `i` after running the script (10). Start a new instance of JMP, open the script without running it, and enter the Debugger immediately.

4. Click **Run** again.

The script runs until it hits the breakpoint. The results are shown in Figure 4.14.

- `stringFunction()` is called, evaluated, and returns to the loop.
- `i` is incremented and determined to be less than or equal to 9.
– In the Globals list, \(i\) is now 1 and \(str\) is now “0”.

**Figure 4.14** Global Variables at First Breakpoint

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>1</td>
<td>Number</td>
</tr>
<tr>
<td>str</td>
<td>“0”</td>
<td>String</td>
</tr>
<tr>
<td>stringFunct.</td>
<td>Function((i), (y)), (y = \text{Char}(i); \ str = str | y;)</td>
<td>Function</td>
</tr>
</tbody>
</table>

5. Click **Run** again.

The script runs until it hits a breakpoint. The results are shown in Figure 4.15.

– \(\text{stringFunction()}\) is called, evaluated, and returns to the loop.
– \(i\) is incremented and determined to be less than or equal to 9.

In the Globals list, \(i\) is now 2, and \(str\) is now “01”.

**Figure 4.15** Global Variables at Second Breakpoint

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>2</td>
<td>Number</td>
</tr>
<tr>
<td>str</td>
<td>“01&quot;</td>
<td>String</td>
</tr>
<tr>
<td>stringFunct.</td>
<td>Function((i), (y)), (y = \text{Char}(i); \ str = str | y;)</td>
<td>Function</td>
</tr>
</tbody>
</table>

You can continue to click **Run** and watch \(i\) and \(str\) change with each iteration of the loop. Or, click **Run without breakpoints** to complete running the script and exit the Debugger.

**Stepping Into, Over, and Out**

**Step Into, Step Over**, and **Step Out** offer flexibility when your script contains expressions, functions, or includes other JSL files.

1. Open the `scriptDriver.jsl` sample script and click the **Debug Script** button.
2. This script writes information to the log, so select the Log tab at the bottom of the Debugger to view the messages.
3. Click **Step Over**.

The first line in the script is evaluated.

4. Click **Step Over** again.

The current expression is evaluated, and the Debugger moves to the following line. In this case, the expression is a few lines long, and it assigns an expression to a variable.

5. Click **Step Over** again.

This expression is several lines long, and assigns a function to a variable.
Line 30 calls the expression that was created earlier.

6. Click **Step Over**.

The Debugger steps into the expression, running it line by line.

7. Continue clicking **Step Over** until the expression ends.

The Debugger returns to the line following the expression call.

Line 31 calls the function defined earlier.

8. Click **Step Over** to run the function without stepping into it. The Debugger runs the entire function, and returns to the line following the function call.

Line 33 includes another script.

9. Click **Step Into**.

The Debugger opens the script in another tab and waits.

10. Click **Step Over**.

The next line in the included script is run.

11. Click **Step Out**.

The Debugger runs the rest of the included script and returns to the line following the `Include()` function.

** Watching Variables in Different Scopes and Namespaces **

Tabs at the bottom of the Debugger window let you watch variables as they are created and changed. This example shows variables in several scopes and a namespace.

1. Open the `scoping.jsl` sample script and click the **Debug Script** button.

2. Click **Step Over**.

The fourth line turns off `Names Default To Here`. If you run this script again in the same JMP session, this line resets the scoping so that the first variable that is created is in the global scope.

3. Click **Step Over**.

A global variable named `x` is created. On the Globals tab, `x` has been added to the list, showing its value as 5 and its type as number.

4. Select the **Locals** tab, and then select **Global** from the list of scopes.

The global variable `x` is also shown here.

5. Click **Step Over** twice.

`Names Default To Here` is turned on, which places the rest of the script into a Here scope. Then a new variable `x` is created in that scope.

Notice that the value of the global variable `x` has not changed.
6. Select **Here** from the list on the Locals tab.
   The local $x$ is listed under **Here**, with its value and type.

7. Click **Step Over**.
   A Local **Here** scope is created. A second Here scope is shown in the Locals list.

8. Click **Step Over**.
   A new $x$ variable is created in this Here scope. On the Locals tab, select each of the three scopes from the list (**Here**, **Here**, and **Global**) to see three different $x$ variables.

9. Click **Step Over**.
   Look in the Debugger’s log to see the output. Notice that **here:**$x$ scopes to the local here, not the script window’s here.

10. Click **Step Over**.
    After writing an empty line to the log, the script exits the Local Here scope. The second Here, along with its’ $x$ variable, has disappeared from the Locals list.

11. Click **Step Over**.
    A namespace called “test” is created, with another variable named $x$. Select the **Namespaces** tab to see it.

12. Click **Step Over** and look at the log.

13. Click **Step Over** to exit the Debugger.

**Using the Debugger with Interactive Scripts**

When your script creates interactive elements, the Debugger hands control back to the main instance of JMP so that you can interact with it. When you are finished, control returns to the Debugger.

1. Open the interactive.jsl sample script and click the **Debug Script** button.
2. Click **Step Over** twice.
   The **New Window** expression is evaluated, and a modal window waiting for input is created. You might need to move the Debugger window to see the new modal window.

3. Enter two numbers in the Assign X and Y window and click **OK**.
   Control is given back to the Debugger.

4. Click **Step Over** three times and look at the log in the Debugger.
   The log shows the two new numbers that you entered in the window.

5. Click **Step Into** to exit the Debugger.
Using the JSL Profiler

Use the JSL Profiler to see how much time is spent executing particular lines or how many times a particular line is executed.

1. Open the string.jsl sample script.
2. Click the **Debug Script** button.
3. Click the **Profile JSL Script** button.

**Figure 4.16 Initial JSL Profiler Window**

- Click the **Run** button to start profiling.

The profiler collects information about the number of times a statement is executed and the time it takes to execute it. Time is cumulative and collected each time a JSL statement is executed.

**Figure 4.17 Profiled Script Window**
In the left margin, the selected statistics are displayed. Percent of time is displayed by default. Click the **Show Profile by Count** button \( \sum \) to switch to percent of statement counts instead. The left margin is color-coded to allow for quick identification of problematic performance areas.
Studying the syntax and basics of JSL is crucial, whether you are a beginning or an advanced user. Some concepts (such as loops and variables) are common among many scripting languages, but punctuation rules differ in JSL.

**Figure 5.1 Example of a JSL Script**

```
6 // Compute the area of a circle.
7 radius = 2;
8 circle area = Pi() * radius * radius;
9 Print( "The area is " || Format( circle area, "Fixed", 2 ) );
```

This chapter introduces you to the basic concepts of JSL, from syntax rules and file path conventions to conditions and namespaces.

JSL Syntax Rules

All scripting and programming languages have their own syntax rules. JSL looks familiar if you have programmed in languages such as C and Java. However, rules for punctuation and spaces differ in JSL.

The following sections describe JSL syntax rules for the following basic components of the language.

Value Separators

Words in JSL are separated by parentheses, commas, semicolons, spaces, and various operators (such as +, –, and so on). This section describes the rules for using these separators and delimiters in JSL.

Commas

A comma separates items, such as items in a list, rows in a matrix, or arguments to a function.

```js
my list = {1, 2, 3};
your list = List( 4, 5, 6 );
my matrix = [3 2 1, 0 -1 -2];
If( Y < 20, X = Y );
Table Box( String Col Box( "Age", a ) );
```

**Note:** To glue a sequence of commands into a single argument inside a function, separate each sequence with a semicolon. See “Semicolons” on page 99.

Parentheses

Parentheses have several purposes in JSL:

- Parentheses group operations in an expression. The following parentheses group the operations in the If() expression.

  ```js
  y = 10;
  If(
      Y < 20, X = Y,
      X = 20
  );
  ```

- Parentheses delimit arguments to a function. In the following example, parentheses enclose the argument to the Open() function.

  ```js
  Open( "$SAMPLE_DATA/Big Class.jmp" );
  ```
• Parentheses also mark the end of a function name, even when arguments are not needed. For example, the Pi function has no arguments. However, the parentheses are required so that JMP can identify Pi as a function.

   Pi();

**Note:** Be careful that parentheses match. Every ( needs a ), or errors result.

The script editor can match fences (parentheses, brackets, and braces). Press Ctrl+] (Command+B on macOS) with your cursor in any part of a script. The editor searches for fences, highlighting the text between the first set of opening and closing fences that it finds. Repeat this process to highlight the next-higher fence. See “Match Parentheses, Brackets, and Braces” on page 64 in the “Scripting Tools” chapter for an example.

**Semicolons**

Expressions separated by a semicolon are evaluated in succession, returning the result of the last expression. In the following code, 0 is assigned to the variable i and then 2 is assigned the variable j.

   i = 0;
   j = 2;

You can also use semicolons to join arguments that are separated by commas as shown in the following If() expression.

   If( x < 5, y = 3; z++; );

The semicolon in other languages is used as an expression terminator character. In JSL, the semicolon is a signal to continue because more commands might follow. For more information about separating expressions with semicolons, see “Alternatives for Gluing Expressions Together” on page 119.

Semicolons at the end of a script or at the end of a line of arguments are harmless, so you can also think of semicolons as terminating characters. Trailing semicolons are allowed at the end of a script stream and after a closing parenthesis or closing curly brace. In fact, terminating each complete JSL expression with a semicolon helps avoid errors when you copy and paste small scripts into a larger one.

The semicolon is equivalent to the Glue() function. See “Operators” on page 103 for more information about semicolons and Glue().

**Double Quotes**

Double quotes enclose text strings. Anything inside double quotes is taken literally, including spaces and upper- or lower-case; nothing is evaluated. If you have "Pi () ^ 2" (inside double quotes), it is just a sequence of characters, not a value close to ten.
You do have to be careful with text strings. Extra spaces and punctuation do affect the output, because text strings inside double quotes are used literally, exactly as you enter them.

To have double quotes inside a quoted string, precede each quotation mark with the escape sequence `\!` (backslash-bang). For example, run the following script and look at the title of the window:

```javascript
New Window( "\!"Hello\!" is a quoted string."),
   Text Box( Char( Repeat( "*", 70 ) ) )
);
```

**Table 5.1** Escape Sequences for Quoted Strings

<table>
<thead>
<tr>
<th>!b</th>
<th>blank</th>
</tr>
</thead>
<tbody>
<tr>
<td>!t</td>
<td>tab</td>
</tr>
<tr>
<td>!r</td>
<td>carriage return only</td>
</tr>
<tr>
<td>!n</td>
<td>linefeed (newline) only</td>
</tr>
<tr>
<td>!N</td>
<td>inserts line breaking characters appropriate for the host environment\textsuperscript{a}</td>
</tr>
<tr>
<td>!f</td>
<td>formfeed (page break)</td>
</tr>
<tr>
<td>!0</td>
<td>null character</td>
</tr>
</tbody>
</table>

**Note:** The null character is dangerous to use, because it is typically treated as the end of the string. Be sure to type the number zero, not the letter O.

| \!\ backslash |
| \!" double quotation mark |

\textsuperscript{a} On macOS, this escape sequence is CR (carriage return character, hexadecimal \texttt{0D}). On Windows, this sequence is CR LF (carriage return followed by a linefeed, hexadecimal \texttt{0D0A}).

Sometimes, long passages require a lot of escaped characters. In these cases, use the notation `\[...\]` and everything between the brackets does not need or support escape sequences. Here is an example where `\[...\]` is used inside a double-quoted string.

```javascript
jslPhrase = "The JSL to do this is :
   a = "hello";
   b = a|| " world.";
   Show(b);
]\\ and you use the Submit command to run it.";
```
Spaces

JSL allows whitespace characters inside names; spaces, tabs, returns, and blank lines inside or between JSL words are ignored. This is because most JSL words come from the user interface, and most of those commands have spaces in them. For example, the JSL expression for the Fit Model platform is `Fit Model()` or `FitModel()`. Spaces inside an operator or between digits in a single number are not allowed. In these cases, the script generates errors. For example, you cannot put spaces between the two plus signs in `i++ (i + +)` or in numbers (4 3 is not the same as 43).

**Note:** Why does JSL allow whitespace characters inside names? For one reason, the names of commands and options match the equivalent commands in JMP menus and windows. Another reason is that data table column names often include spaces.

Numbers

Numbers can be written as integers, decimal numbers, dates, times, or date-time values. They can also be included in scientific notations with an E preceding the power of ten. For example, these are all numbers:

```
.   1   12   1.234   3E3   0.314159265E+1   1E-20   01JAN98
```

**Note:** A single period by itself is considered a missing numeric value (sometimes called \textit{NaN} for “not a number”).

For more information about dates, times, and date-time values, see “Date-Time Functions and Formats” on page 150 in the “Types of Data” chapter. See “Currency” on page 164 in the “Types of Data” chapter for more information about combining numbers with currency symbols.

Names

A name is simply something to call an item. When you assign the numeric value 3 to a variable in the expression `a = 3`, `a` is a name.

Commands and functions have names, too. In the expression `Log( 4 )`, `Log` is the name of the logarithmic function.

Names have a few rules:

- Names must start with an alphabetic character or underscore and can continue with the following:
  - alphabetic characters (a-z A-Z)
numeric digits (0-9)
whitespace characters (spaces, tabs, line endings, and page endings)
mathematical symbols in Unicode (such as the Greek small alpha letter α)
a few punctuation marks or special characters (apostrophes (‘), percent signs (%), periods (.), backslashes (\), and underscores (_))

- When comparing names, JMP ignores whitespace characters (such as spaces, tabs, and line endings). Upper case and lower case characters are not distinguished. For example, the names Forage and for age are equivalent, despite the differences in white space and case.

You can still have a name that is any other sequence of characters. If the name does not follow the rules above, it needs to be quoted and followed by "n". For example, to use a global variable with the name taxable income(2011), you must use "taxable income(2011)"n every time the variable appears in a script:

"taxable income( 2011 )"n = 456000;
tax = .25;
Print( tax * "taxable income( 2011 )"n );
114000

Note: Previously, the Name() parser directive wrapped the column name that contained illegal characters. Name() is deprecated.

For more information about how JMP interprets names, see “Rules for Name Resolution” on page 111.

Comments

Comments are notes in the code that are ignored by the JSL processor (or parser). You include comments to describe sections of the script. Comments are also convenient for removing portions of a script temporarily. For example, you can insert comment symbols around code that might be causing an error and then rerun the script.

Type the comment symbols around code that you want to comment. The following example shows code commented with /* */ in the middle of a line. When the script is run, JMP considers both expressions to be identical.

tax /*percentage*/ = .25;
tax = .25;
An operator is a one- or two-character symbol used to perform common arithmetic actions, compare values, construct lists, subscript into a data element, send messages, concatenate lists, scope names, glue expressions, and end expressions.

Arithmetic operators come in several varieties:

- **infix** (with arguments on either side, such as \( + \) in \( 3 + 4 \), or \( = \) in \( a = 7 \))
- **prefix** (with one argument on its right side, such as \( !a \) for logical negation)
- or **postfix** (with one argument on its left side, such as \( a++ \) for incrementing \( a \))

To make writing expressions easier, JSL uses certain special character operators that are alternatives to using functions. These operators have the same meaning as if the phrase had been written as a function. For example, the following two expressions are equivalent.

\[
\text{Net Income After Taxes} = \text{Net Income} - \text{Taxes}; \\
\text{Assign( Net Income After Taxes, Subtract( Net Income, Taxes ) );}
\]

The assignment operation can be written either as the `Assign()` function or as an infix operator `=`. Similarly, subtraction can be done with the `Subtract()` function or the infix minus sign; they are equivalent inside JMP.
Another common operator is the semicolon (\;). You use the semicolon to:

- Separate yet join one expression to another in a programming sequence. The semicolon returns the result of its last argument, so \( a; b \) is the same as \( \text{Glue}(a, b) \).
- End an expression. Though the semicolon is permitted at the end of an expression, it is not the expression terminator used in other languages.

An expression can contain more than one operator. In these instances, the operators are grouped in order of precedence with decreasing priority. For example, * takes precedence over +:

\[ a + b * c \]

So \( b * c \) is evaluated first, and then the result is added to \( a \).

+ takes precedence over -:

\[ a + b * c - d \]

So \( b * c \) is evaluated, and then the result is added to \( a \). \( d \) is then subtracted from the result of \( a + b * c \).

Table 5.3 shows operators shaded in order of precedence and each operator's function equivalent.

</table>

**Boolean Values**

A Boolean value enables or disables an option. To enable the option, use `1`, `true`, or `yes` as the argument.

```plaintext
obj << Unequal Variances( 1 );
oj << Unequal Variances("true");
```
obj << Unequal Variances( "yes" );

**Note:** Quoting the value prevents it from being evaluated as a variable.

Omitting the argument also enables the option. This is the default for all but row state messages.

```julia
obj << Unequal Variances;
obj << Unequal Variances();
```

To disable the option, use `0`, `false`, or `no` as the argument.

To toggle an option (turn off an enabled option or turn on a disabled option), use `"toggle"`.

**Notes:**
- The quoted "`present"", "`absent"", "`on", "`off", "switch", and "`flip" are supported for backwards compatibility.
- For row state messages, an empty argument always toggles the option.

---

**Global and Local Variables**

*Variables* are names that hold values, which you reference later in scripts. There are two types of variables:

- **Global variables** are shared among all scripts that you run in a JMP session.
- **Local variables** apply only to the script context in which you define them. They can also be local to only a piece of a script, as with variables local to a particular function.

To limit the scope of variables, you can define them in a *namespace*, which is a collection of variables, functions, and other unique names. JMP has a single global variable namespace that all scripts use by default. When you use a name plainly, without a qualifying syntax, the name is an *unscoped* variable and therefore in the global namespace.

```julia
x = 1;
```

**Local Namespaces**

Putting variables in the global namespace can cause conflicts. When two scripts have variables with the same names, the value of the variable in the last script that you run last overwrites the variable’s value in the first script.

To prevent this problem, we recommend that you begin each script with the following line:

```julia
Names Default To Here( 1 );
```
The Names Default To Here(1); function makes all unscoped variables in the script local to that script and does not affect the global variable namespace. See “Advanced Scoping and Namespaces” on page 272.

Notes:

- The Names Default to Here setting is true by default for custom menus and toolbar buttons. A script that runs when you select a custom menu item or click a custom toolbar button does not affect global variables.
- The Names Default to Here setting is false by default for table scripts. If a table script specifies Names Default to Here(1), this setting lasts only as long as the table script runs. After the script finishes running, the setting is reset to whatever it was before the script ran.

Named Namespaces

You can also create a variable in a specific namespace. In the following example, the x variable is created in the aa namespace:

```
aa:x = 1;
```

Preceding local variables with the Local() function is another option. Both a and b are local variables in the following expression:

```
Local( {a = 1, b}, ... );
```

Scoping operators also distinguish a global variable from a local variable. See “Rules for Name Resolution” on page 111.

The following sections describe functions that help you manage variables.

Show Symbols, Clear Symbols, and Delete Symbols

The Show Symbols() function lists all variables and namespaces that are defined both globally and in the local script, along with their current values. Here is an example of Show Symbols() messages that are shown in the log:

```
Show Symbols();
// Here
a = 5;
b = 6;
// 2 Here
// Global
c = 10;
// 1 Global
```
Tip: The JSL debugger also shows you the values of variables and namespaces. See “Debug or Profile Scripts” on page 77 in the “Scripting Tools” chapter.

The Clear Symbols() function erases the values set for variables that are defined both globally and in the local script. For example, after you clear and then show symbols, the variables are empty.

```
Clear Symbols();
Show Symbols();
// Here
a = Empty;
b = Empty;
// 2 Here

// Global
c = Empty;
// 1 Global
```

Note: The older Show Globals() and Clear Globals() functions are aliases of the newer Show Symbols() and Clear Symbols() functions.

To remove all global variables and namespaces, use the function Delete Symbols(). After the last Show Symbols() in the following script is run, nothing shows up in the log. All variables have been completely removed from memory.

```
Delete Symbols();
Show Symbols();
```

To list variables in all namespaces, use Show Namespaces(). To delete only a specific namespace, use ns << Delete. Clear Symbols() and Delete Symbols() do not clear or delete variables in each namespace, although they do clear and delete variables that contain references to namespaces. See “Rules for Name Resolution” on page 111 for more information about unscoped variables.

Note: Clear Symbols() and Delete Symbols() break all scripts that are currently in use. These functions can be very useful in a programming and debugging environment, but do not include them in any script that you plan to distribute. If you include Names Default To Here(1) in your scripts, clearing and deleting global symbols is unnecessary.

Lock and Unlock Symbols

If you want to lock a variable to prevent it from being changed, use the Lock Symbols() function. (Lock Globals() is an alias.)

```
Lock Symbols( name1, name2, ... );
```
To release the lock and enable the global to be changed, use the `Unlock Symbols()` function. (`Unlock Globals()` is an alias.)

```
Unlock Symbols( name1, name2, ... );
```

The primary use of these two commands is to prevent inadvertent changes to variables. For example, locking a variable prevents `Clear Symbols()` from clearing a variable that is being used by another script.

**Note:** You cannot use `Lock Symbols()` to lock a namespace. Instead, use `ns <<Lock Namespace`.

### Hide a Global Variable

To hide (or protect) a global variable, put two underscores (__) before the name. Protecting a global variable means that it will be hidden and cannot be examined or shown. However, the behavior is different depending upon the context.

This example will not print the variable because it is protected:

```
Show(::__xyz);
```

This example returns a NULL value for the protected variable:

```
::a = Name Expr( ::__xyz );
```

This example does return a value for the protected variable:

```
Show( Eval( ::__xyz ) );
```

### Rules for Name Resolution

In JMP, you identify the following types of objects by a name:

- Columns and table variables in a data table
- Global variables, which hold values for the remainder of a JMP session
- Scriptable object types
- Arguments and local variables inside formulas

Most of the time, you can just use an object’s name directly to refer to the object. Consider the following example:

```
ratio = height / weight;
```
Depending on the complexity of your script, it might be obvious that ratio is a variable and height and weight are data table column names. But what if the meanings are ambiguous? A script might use ratio as a global variable and as column names.

Variable Names Used as Arguments

Message arguments are evaluated as a rule. In previous versions of JMP, some messages interpreted a variable name as a string value. For example, the following script results in a linear scale in the current version of JMP and a log scale in JMP 11.

```julia
Log = "Linear";
axis box << Scale( Log );
```

The syntax `Scale( "Log" )` is preferred for setting a string literal. To catch ambiguous instances, set the “Allow Unquoted Strings in JSL” General preference to “Yes (with a warning)” or “No”.

Rules for Resolving Names

JMP interprets object names using name resolution. The following rules are applied sequentially to unscoped names:

1. If the variable is followed by a pair of parentheses ( ), look it up as a function.
2. If the variable is prefixed by : scope operator or an explicit data table reference, look it up as a data table column or table variable.
3. If the variable is prefixed by :: scope operator, look it up as a global variable.
4. If the variable is an explicit scope reference (such as `group:vowel`), look it up in the user-defined group namespace.
5. If the variable is in a Local or Parameter function, look it up as a local variable. If it is nested, repeat until a function call boundary is found.
6. If the variable is in a user-defined function or method, look it up as a function or method argument or local variable.
7. Look the variable up in the current scope and its parent scope. Repeat until the Here scope is encountered.
8. Look the variable up as a variable in the Here scope.
9. Look the variable up as a global variable.
10. If Names Default to Here(1) is at the top of the script, stop looking. The scope is local.
11. Look the variable up as a data table column or table variable. Columns are preferred over table variables.
12. Look the variable up as an operator or a platform launch name (for example, Distribution, Bivariate, Chart, and so on).

13. When the name cannot be found:
   – If the name is used in a reference, print and error to the log.
   – If the name is used as the target of an assignment (as an L-value), test the following:
     - If the variable is preceded by :: scope operator, create and use a global variable.
     - If the variable is an explicit scope reference, create and use the variable in the specified namespace or scope.
     - If Names Default to Here(0) is at the top of the script, create a global variable.
     - If Names Default to Here(1) is at the top of the script, create a Here namespace variable.

Exceptions

- Some names are variables that refer to an object such as a data table, data column, or platform; they are not used for getting or setting a value. These names are passed through (or interpreted literally) rather than resolved.

- For function definitions, column formulas, and Nonlinear platform formulas, the scope is the same for each row in a column.

- If a name is a direct reference to a column in a data table that has been closed, the name is resolved again to that column when the table is reopened.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Show( :weight << Get As Matrix ); // weight resolves to a column name
Close( dt, NoSave );
Show( :weight << Get As Matrix ); // weight cannot be resolved

dt = Open( "$SAMPLE_DATA/Big Class.jmp" ); // reopen data table
Show( :weight << Get As Matrix ); // weight resolves to a column name
```

However, the following example does not resolve the variable to the second instance of the data table:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = Column( dt, 5); // col is Column( "weight" );
Close( dt, NoSave );
dt = Open( "$SAMPLE_DATA/Big Class.jmp" ); // reopen data table
Show( col << Get As Matrix ); // the reference to the first data table no longer exists
```

The following sections describe how JMP resolves the names of data table columns. For more information about name resolution, see “Advanced Scoping and Namespaces” on page 272 in the “Programming Methods” chapter.
Scoping Operators

Using scoping operators is an easy way to help JMP resolve ambiguous names (for example, when a name refers to both a variable and a column name).

In the following example, the prefix double-colon operator (::) identifies z as a global variable. The single-colon prefix operator (:) identifies x and y as column names.

::z = :x + :y;

Tip: The Names Default to Here(1) function also affects name resolution. See “Names Default To Here and Global Variables” on page 274 in the “Programming Methods” chapter.

Two JSL functions are interchangeable with scoping operators. Table 5.4 describes the functions and syntax.

<table>
<thead>
<tr>
<th>Operator and Equivalent Function</th>
<th>Function Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>:  As Column</td>
<td>:name</td>
<td>Forces name to be evaluated as a data table column. The optional data table reference argument, dt, sets the current data table. See “Scoped Column Names” on page 114 for examples.</td>
</tr>
<tr>
<td>: As Column</td>
<td>As Column(dt, name)</td>
<td></td>
</tr>
<tr>
<td>::  As Global</td>
<td>::name</td>
<td>Forces name to be evaluated as a global variable.</td>
</tr>
<tr>
<td>:: As Global</td>
<td>As Global(name)</td>
<td>Note: The double-colon is also used as an infix operator to represent ranges.</td>
</tr>
</tbody>
</table>

Scoped Column Names

Scoped column names is the simplest way to prevent conflicts with variable names. Use scoping operators to force names in a script to refer to columns.

1. The prefix colon (:) means that the name refers to a table column or table variable only, never a global variable. The prefix colon refers to the current data table context.

   :age;

2. The infix colon (: ) operator extends this notion by using a data table reference to specify which data table has the column. This is particularly important when multiple data tables are referenced in a script.
In the following example, the `dt` variable sets the data table reference to `Big Class.jmp`. The infix colon separates the data table reference and `age` column.

```julia
dt = Data Table( "Big Class.jmp" );
dt:age // The colon is an infix operator.
As Column() achieves the same results:
dt = Data Table( "Big Class.jmp" );
As Column( dt, age );
```

Therefore, the following expressions are equivalent when only `Big Class.jmp` is open:

```julia
:age;
As Column( dt, age );
dt:age;
```

The `Column` function can also identify a column. For `Big Class.jmp`, the following expressions all refer to `age`, the second column in the table:

```julia
Column( "age" );
Column( 2 );
Column( dt, 2 );
Column( dt, "age" );
```

### Prevent Column Name and Variable Name Conflicts

To avoid conflicts, use unique column and variable names or scope the names.

- When a global variable and a column have the same name, the global variable name takes precedence. In this situation, you must scope the column name.
  ```julia
  ::age = [];
age = :age << Get As Matrix;
  ```

- To avoid ambiguity between the global variable and column name, scope both variables.
  ```julia
  ::age = :age << Get As Matrix;
  ```

- If more than one data table might be open, assign data table references to variables. Scope your columns to the appropriate table.
  ```julia
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt2 = Open( "$SAMPLE_DATA/Students.jmp" );
::age = dt1:age << Get As Matrix;
::height = dt2:height << Get As Matrix;
  ```

Note that JMP evaluates column formulas through each consecutive cell of the column, so scoping the column name is usually unnecessary. However, if a variable assigned in a formula has the same name as a column, you must scope the column name. See “Scoped Names” on page 276 in the “Programming Methods” chapter.
**Tip:** The Names Default to Here(1) function also affects name resolution. See “Names Default To Here and Global Variables” on page 274 in the “Programming Methods” chapter.

### Unscoped Column Names

Sometimes an unscoped name gets or sets a value. JMP resolves it as a column in a data table (rather than a global variable) under these circumstances:

- if no global variable, local variable, or an argument using that name already exists,
- and the data table in context has a column of that name,
- and
  - either the current row is set to a positive value
  - or the name is subscripted (for example, the subscript \([1]\) in \(\text{weight}[1]\) selects the first value in the \(\text{weight}\) column).

**Exception**

In column formulas and Nonlinear formulas, column names take precedence over global variables.

### Set the Current Data Table Row

By default, the current row is 0, an illegal row number. So the following expression assigns a missing value to the `ratio` global variable:

\[
\text{ratio} = \text{height} / \text{weight};
\]

Specify the row number with the `Row()` function. In the following example, the row is set to 3. The height in that row is divided by the weight, and the result is assigned to the `ratio` global variable.

\[
\text{Row()} = 3; \\
\text{ratio} = \text{height} / \text{weight};
\]

Another possibility is to use subscripts to specify the row number. The following expression divides the height in row 3 by the weight in row 4.

\[
\text{ratio} = \text{height}[3] / \text{weight}[4];
\]

Specifying the row number is unnecessary when the script iterates a row at a time down the whole column. The following example creates the `ratio` column. For each row, the height is divided by the weight.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "ratio" );
For Each Row( :ratio = height / weight );
```
JMP evaluates formulas and calculates pre-evaluated statistics iteratively down a column. In these instances, identifying the row number is also unnecessary. (Pre-evaluated statistics are single numbers computed from the data table, as discussed in “Pre-Evaluated Statistics” on page 466 in the “Data Tables” chapter.)

**Name Resolution in Automatically Run Scripts**

In an `Open()` function, you can specify that the script run automatically when it’s opened.

```javascript
Open( "$MY_SCRIPTS/A.jsl", Run JSL( 1 ) );
Open( "$MY_SCRIPTS/B.jsl", Run JSL( 1 ) );
```

You can also type `//!` on the first line of the script to run the script automatically.

In these instances, the only shared names between `A.jsl` and `B.jsl` are globals and namespaces (not here and not local).

To apply the names in `A.jsl` to `B.jsl`, include `B.jsl` in `A.jsl` instead of opening and running both scripts.

```javascript
Include( "$MY_SCRIPTS/B.jsl" );
```

**Troubleshoot Variables and Column Names**

When you reference a column name using `As Name()`, and `Names Default To Here( 1 )` is set, JMP returns a variable reference. That reference is then processed using the standard reference rules.

In the following example, there is no `height` variable in the `Here:` scope, so JMP returns an error.

```javascript
Names Default To Here( 1 );
Open( "$SAMPLE_DATA/Big Class.jmp" );
As Name( "height" )[3]; // converts height to a variable reference
As Name( "height" ) /*###*/[3];
```

The `/*###*/` characters in the log indicate the location of an error in the script execution.

To prevent this problem, use one of the following methods:

- **Use `As Column()` instead of `As Name()`**:
  ```javascript
  Names Default To Here( 1 );
  Open( "$SAMPLE_DATA/Big Class.jmp" );
  As Column( "height" )[3]; // converts height to a data column reference
  ```

- **Explicitly scope `height` with `As Name()`**:
  ```javascript
  Names Default To Here( 1 );
  dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
  dt:( As Name( "height" ) )[3]; // scopes height as a data column reference
  ```
These scripts return 55, the value of `height` in the third row of Big Class.jmp.

### Troubleshoot Variables and Keywords

Name resolution errors can also occur when a variable and unquoted keyword have the same name. For example, one argument for `<<Preselect Role()` is “Y”. Quote this argument if your script also uses Y as a variable.

### Frequently Asked Questions about Name Resolution

#### Should you always scope?

Yes. When in doubt, scope. Scoping is especially important in scripts that might be used by many people on a variety of data tables; you will not necessarily know whether a name is used in two contexts (such as for both a global variable and column name).

If you are writing such scripts, consider using explicit scoping and namespaces. See “Advanced Scoping and Namespaces” on page 272 in the “Programming Methods” chapter.

Prefix scope operators do not take run-time overhead after the first resolution. Infix scope operators, which follow data table references, always take run-time overhead.

#### What is the difference between a column reference and a column referred to by name? If I have a column reference in a global variable, how do I assign a value to a cell in the column?

With a column reference, you can send messages to change specific characteristics of the column or to access its values (for example, coloring cells or setting a formula).

When a column has been assigned to a global variable, assign a value to a cell in the column using a subscript. Suppose that the name of the column `height` has been assigned to the `x` variable:

```julia
x = Column( "height" );
```

Assign a value to the third row in the `height` column:

```julia
x[3] = 64 // sets the third row of height to 64
```
Which Has Precedence When Scoping, ".:" or "[ ]"?

Scoping occurs before subscripting. This means that these two lines of code are equal:

```
dataTable:colName[i]
(dataTable:colName)[i]
```

Alternatives for Gluing Expressions Together

You can separate expressions with a semicolon, either on the same line or on different lines. JMP then evaluates each expressions in succession, returning the result of the last one. Here is an expression that first sets `a` to 2 and then sets `b` to 3:

```
a = 2;
b = 3;
```

The semicolon joins the two expressions and returns the value of the last one. So if `x = (a = 2; b = 3)`, the value of `x` is 3.

The `Glue()` function returns the result of the last expression. This function is equivalent to using semicolons. The following expressions both return 3:

```
Glue( a = 2, b = 3 );
a = 2; b = 3;
```

The `First()` function also evaluates each argument sequentially but returns the result of the first expression. The following expression returns 2:

```
First( a = 2, b = 3 );
```

Example

What does `First()` do in the following script?
x = 1000;
First( x, x = 2000 );

The First() function returns the value of x (1000). 2000 is then assigned to x.

Iterate

JSL provides the For(), While(), Summation(), and Product() functions to repeat (or iterate) actions according to the conditions that you specify.

Note: A similar function called For Each Row() is for iterating actions over rows of a data table. See “If” on page 126 for an example. “Additional Ways to Access Data Values” on page 459 in the “Data Tables” chapter also describes iterating through table rows.

• “For”
• “While”
• “Summation”
• “Product”
• “Break and Continue”

For

The For() function expects four arguments separated by commas. The first three arguments are rules for how many times to repeat the loop, and the fourth is what to do each time the loop is executed.

Here is the basic syntax for For():

For( initialization, while, iteration, body );

For example, the following script sums the numbers from 0 to 20:

s = 0;
For( i = 0, i <= 20, i++, s += i );

The script works like this:

<table>
<thead>
<tr>
<th>x = 1000;</th>
<th>First( x, x = 2000 );</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the $s$ variable to 0. This variable holds the sum.</td>
<td>Begins the For() loop.</td>
</tr>
<tr>
<td>i = 0,</td>
<td>Sets the initialization variable (i) to 0. This expression is performed only once.</td>
</tr>
</tbody>
</table>
Infinite Loops

For loops that always evaluate as true create an infinite loop, which never stops. To stop the script, press Esc on Windows (or Command+period on macOS). You can also select Edit > Stop Script. On macOS, Edit > Stop Script is available only when the script is running.

Comparing For Loops in JSL to C and C++

The JSL For() loop works just like it does in the C (and C++) programming language, although the punctuation is different.

Tip: If you know C, watch out for the difference between JSL and C in the use of semicolons and commas. In JSL, For() is a function where commas separate arguments and semicolons join expressions. In C, for is a special clause where semicolons separate arguments and commas join them.

While

A related function is While(), which repeatedly tests the condition and evaluates its body script as long as the condition is true. The syntax is:

While( condition, body );

For example, here are two different programs that use a While() loop to find the least power of 2 that is greater than or equal to x (287). The result of both programs is 512.

```
x = 287;

// loop 1:
y = 1;
While( y < x, y *= 2 );
Show( y );
```
The scripts work like this:

<table>
<thead>
<tr>
<th>x = 287;</th>
<th>Sets x to 287.</th>
</tr>
</thead>
<tbody>
<tr>
<td>// loop 1</td>
<td></td>
</tr>
<tr>
<td>y = 1;</td>
<td>Sets y to 1.</td>
</tr>
<tr>
<td>While( y &lt; x,</td>
<td>Begins the While() loop.</td>
</tr>
<tr>
<td>y *= 2</td>
<td>As long as y is less than x, continues evaluating the loop.</td>
</tr>
<tr>
<td>);</td>
<td>Ends the loop.</td>
</tr>
<tr>
<td>Show(y);</td>
<td>Shows the value of y (512).</td>
</tr>
<tr>
<td>// loop 2</td>
<td></td>
</tr>
<tr>
<td>k = 0;</td>
<td>Sets k to 0.</td>
</tr>
<tr>
<td>While( 2 ^ k &lt; x,</td>
<td>Begins the While() loop.</td>
</tr>
<tr>
<td>k++</td>
<td>Raises 2 to the exponent power of k and continues evaluating the loop as long as the result is less than 287.</td>
</tr>
<tr>
<td>);</td>
<td>Ends the loop.</td>
</tr>
<tr>
<td>Show(2 ^ k);</td>
<td>Shows the value of 2 ^ k (512).</td>
</tr>
</tbody>
</table>

As with For() loops, While() loops that always evaluate as true create an infinite loop, which never stops. To stop the script, press Esc on Windows (or Command-period on macOS). You can also select Edit > Stop Script. On macOS, Edit > Stop Script is available only when the script is running.
**Summation**

The `Summation()` function adds the body results over all \( i \) values. The syntax is:

\[
\text{Summation( initialization, limitvalue, body );}
\]

For example:

\[
s = \text{Summation( } i = 1, 10, i );
\]

returns 55, the result of \( 1+2+3+4+5+6+7+8+9+10 \).

The script works like this:

\[
\begin{array}{l}
s = \text{Sets the variable to the value of the function.} \\
\text{Summation( } \text{Begins the Summation() loop.} \\
i = 1, \text{Sets } i \text{ to 1.} \\
10, \text{Sets the limit of } i \text{ to 10.} \\
i \text{All values of } i \text{ from 1 to 10 are added together, resulting in 55.} \\
)\; ; \text{Ends the loop.}
\end{array}
\]

This behavior is similar to \( \Sigma \) in the Formula Editor. The following expression:

\[
\text{Summation( } i = 1, \text{N Row(), } x ^ 2 );
\]

is equivalent to the following formula in the Formula Editor:

\[
\sum_{i=1}^{\text{NRow}} x^2
\]

**Product**

The `Product()` function is similar to `Summation()` except that it multiplies the body results rather than adding them. The syntax is the same as for `Summation()`. For example:

\[
p = \text{Product( } i = 1, 5, i );
\]

returns 120, the result of \( 1*2*3*4*5 \).

In this example, the initial value of \( i \) is 1, the upper limit is 5, then all integer values of \( i \) up to 5 are multiplied.

Here is the equivalent in the Formula Editor:
Break and Continue

The Break() and Continue() functions give you more control over looping. Break() immediately stops the loop and proceeds to the next expression that follows the loop. Continue() is a gentler form of Break(). It immediately stops the current iteration of the loop and continues with the next iteration of the loop.

Break

Break() is typically used inside a conditional expression. For example:

```javascript
For( i = 1, i <= 5, i++,
    If( i == 3, Break() );
    Print( "i=" || Char( i ) );
);
```

results in:

```
"i=1"
"i=2"
```

The script works like this:

<table>
<thead>
<tr>
<th>For(</th>
<th>Begins the For() loop.</th>
</tr>
</thead>
<tbody>
<tr>
<td>i = 1,</td>
<td>Sets i to 1.</td>
</tr>
<tr>
<td>i &lt;= 5,</td>
<td>As long as i is less than or equal to 5, continues evaluating the loop.</td>
</tr>
<tr>
<td>i++,</td>
<td>Increments i by 1. Note that this step is done after the If loop is evaluated.</td>
</tr>
<tr>
<td>If(</td>
<td>Begins the If() loop.</td>
</tr>
<tr>
<td>i == 3, Break()</td>
<td>If i is equal to 3, breaks the loop.</td>
</tr>
<tr>
<td>)</td>
<td>Ends the loop.</td>
</tr>
<tr>
<td>Print(</td>
<td>When i is not equal to 3, opens the Print() loop.</td>
</tr>
<tr>
<td>&quot;i=&quot;</td>
<td>Prints the string &quot;i=&quot; to the log.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Note that when the `If()` and `Break()` expressions follow `Print()`, the script prints the values of `i` from 1 to 3, because the loop breaks after "i=3" is printed.

```
"i=1"
"i=2"
"i=3"
```

### Continue

As with `Break()`, `Continue()` is typically used inside a conditional expression. For example:

```julia
For( i = 1, i <= 5, i++,
    If( i < 3, Continue() );
    Print( "i=" || Char( i ) );
);```

results in:

```
"i=3"
"i=4"
"i=5"
```

The script works like this:

<table>
<thead>
<tr>
<th><code>For()</code></th>
<th>Begins the <code>For()</code> loop.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>i = 1,</code></td>
<td>Sets i to 1.</td>
</tr>
<tr>
<td><code>i &lt;= 5,</code></td>
<td>Evaluates 1 as less than or equal to 5.</td>
</tr>
<tr>
<td><code>i++,</code></td>
<td>Increments i by 1. Note that this step is done after the <code>If</code> loop is evaluated.</td>
</tr>
<tr>
<td><code>If()</code></td>
<td>Begins the <code>If()</code> loop.</td>
</tr>
<tr>
<td><code>i &lt; 3, Continue()</code></td>
<td>Evaluates i as 1 and continues as long as i is less than 3.</td>
</tr>
<tr>
<td><code>);</code></td>
<td>Ends the <code>If()</code> loop.</td>
</tr>
</tbody>
</table>
JSL provides five functions to evaluate an expression conditionally:

- "If"
- "Match"
- "Choose"
- "Interpolate"
- "Step"

**If**

The If() function evaluates the first result expression when its condition evaluates as true (a nonzero or nonmissing value). Otherwise, it evaluates the second result expression.

The syntax is:

If ( condition, result1, result2 );

For example, the following script returns "Young" when the age is less than 12. Otherwise, the script returns "Young at Heart".

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "age group", "Character" );
For Each Row(
   :age group = If( :age <= 12,
   "Young",
   "Young at Heart"
   )
);
```
You can also string together multiple conditions and results. The syntax is:

\[
\text{If( condition1, result1, condition2, result2, ..., resultElse );}
\]

In the preceding example, if condition1 is not true, the function continues evaluating until it finds a true condition. Then that condition’s result is returned.

The last result is returned when all conditions are false. And when a value is missing, the missing value is returned. For these reasons, it’s very important to include a default result at the end of the expression. Consider the following example, which recodes gender abbreviations in Big Class.jmp:

\[
dt = \text{Open( "$SAMPLE\_DATA/Big Class.jmp" );}
\text{For Each Row( sex =}
\text{  If(}
\text{    sex == "F", "Female",}
\text{    sex == "M", "Male",}
\text{    "Unknown"
\text{  );
\text{  );
\text{Ends the loop.}
\)
\]

The script works like this:

<table>
<thead>
<tr>
<th>For Each Row( sex =</th>
<th>For each row in the table, sex is the column that is recoded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>If(</td>
<td>Begins the If() loop.</td>
</tr>
<tr>
<td>sex == &quot;F&quot;, &quot;Female&quot;,</td>
<td>If the value of sex is F, replaces the value with Female.</td>
</tr>
<tr>
<td>sex == &quot;M&quot;, &quot;Male&quot;,</td>
<td>If the value of sex is M, replaces the value with Male.</td>
</tr>
<tr>
<td>&quot;Unknown&quot; );</td>
<td>If neither of the above conditions are true, replaces the value with Unknown. If this result were omitted and the value of sex were missing, the script would return a missing value.</td>
</tr>
<tr>
<td></td>
<td>Ends the loop.</td>
</tr>
</tbody>
</table>

You can also put actions and assignments in the result expression. The following example assigns 20 to \( x \), because the first condition \( y < 20 \) is false:

\[
y = 25;
z = \text{If( } y < 20, \ x = y, \ x = 20 \ );
\]
Note: Be careful to use two equal signs (==) for equality tests, not one equal sign (=). An `If` with an argument such as `name=value` assigns rather than tests the value.

Avoiding Memory Issues with Multiple If Statements

Running a script that contains dozens of If() Statements can cause memory problems. We recommend reducing the If() nesting. Suppose that your script contains 100 If() statements in this format:

```
If( val, If( val, If( val, If( val,
  If( val, If( val, If( val, If( val,
    ... ))))))));
```

Rewrite the script:

```
If( val, val1, If( val, val2, If( val, val3,
  If( val, val4, If( val, val5, If( val, val6, ...) ) ) ) ) );
```

You can also try setting the maximum call depth. The Maximum Call Depth preference sets the default for the maximum call depth (or stack size) in which JSL built-in functions, user-defined functions, or `Recurse()` function calls can be made. By default, the maximum call depth is set to 256.

In JMP, your JSL script has a limited amount of physical runtime stack memory in which to perform JSL function calls. By default, this size is set to 2MB. Increasing the maximum call depth can cause a physical runtime stack overflow, so incrementally increase this preference in small amounts until you find the best value that works for your JSL script.

```
Preferences[1] << Set( Maximum JMP call depth( 64 ) );
```

Match

You can use the `Match()` function to make several equality comparisons without needing to rewrite the value to be compared. The syntax is:

```
Match( x, value1, result1, value2, result2, ..., resultElse );
```

For example, the following script recodes gender abbreviations in Big Class.jmp:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( sex =
  Match(
    sex,
    "F", "Female",
    "M", "Male",
    "Unknown"));
```
The script works like this:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>For Each Row</code></td>
<td>sex =</td>
</tr>
<tr>
<td><code>Match()</code></td>
<td>Begins the <code>Match()</code> loop.</td>
</tr>
<tr>
<td><code>sex,</code></td>
<td>Specifies <code>sex</code> as the match argument.</td>
</tr>
<tr>
<td>&quot;F&quot;, &quot;Female&quot;,</td>
<td>If the value matches &quot;F&quot; replace it with “Female”.</td>
</tr>
<tr>
<td>&quot;M&quot;, &quot;Male&quot;,</td>
<td>If the value matches &quot;M&quot;, replace it with &quot;Male&quot;.</td>
</tr>
<tr>
<td>&quot;Unknown&quot; );</td>
<td>If F or M are not matched, replaces the value with &quot;Unknown&quot;.</td>
</tr>
<tr>
<td>);</td>
<td>Ends the loop.</td>
</tr>
</tbody>
</table>

This `Match()` example is a simplified version of the example in “If” on page 126. The advantage of `Match()` is that you define the comparison value once rather than repeat it in each condition. The disadvantage is that you cannot use expressions with operators as you can with `If`; the argument `sex == "F"` returns an error in a `Match()` expression.

With more groups of conditions and results, the value of `Match()` becomes more apparent. The following script would require many additional lines of code with `If()`.

```julia
dt = Open( "$SAMPLE_DATA/Travel Costs.jmp" );
For Each Row(
    )
);```

Be careful with the data type of the condition and result. In the preceding example, the conditions and results are both character data. If the data types do not match, JMP automatically changes the column’s data type. The results might not be what you want.
Note: The Match() function explicitly checks to see if the compare expression $x$ is missing and if the value of $value1$ is missing, then it returns the value of $result1$; otherwise it continues to compare the expression $x$ to each $valueN$ value in each $valueN/resultN$ pair, ignoring any missing values. If the expression $x$ is equal to any of the $valueN$ value, then the corresponding $resultN$ value is returned. If no matching $valueN$ value is found, then the $resultElse$ value is returned.

Choose

The Choose() function shortens scripts even more than Match(), provided the arguments are tested against integers. The syntax is:

```
Choose( expr, result1, result2, result3, ..., resultElse );
```

Suppose you have a data table with a group column of numeric values from 1 through 7. If the first cell contains the number 1, the following script returns $x = "Low"$.

```
x = ( Choose( group[1], "Low", "Medium", "High", "Unknown" ); );
Show( x );
```

The script works like this:

<table>
<thead>
<tr>
<th>x = Creates the x variable.</th>
<th>Choose( Begins the Choose() loop.</th>
</tr>
</thead>
<tbody>
<tr>
<td>group[1],</td>
<td>Evaluates the value of group in the first row.</td>
</tr>
<tr>
<td>&quot;Low&quot;,</td>
<td>If the value of group is 1, return &quot;Low&quot;.</td>
</tr>
<tr>
<td>&quot;Medium&quot;,</td>
<td>If the value of group is 2, return &quot;Medium&quot;.</td>
</tr>
<tr>
<td>&quot;High&quot;,</td>
<td>If the value of group is 3, return &quot;High&quot;.</td>
</tr>
<tr>
<td>&quot;Unknown&quot;</td>
<td>Otherwise, return &quot;Unknown&quot;.</td>
</tr>
<tr>
<td>)</td>
<td>Ends the loop.</td>
</tr>
<tr>
<td>);</td>
<td>Closes the x variable.</td>
</tr>
<tr>
<td>Show( x );</td>
<td>Returns the value of x.</td>
</tr>
</tbody>
</table>

If the expression evaluates to an out-of-range integer (such as 7 when only 4 replacement values are listed), the last result is returned. In the preceding example, "Unknown" is returned.
Notice that If() and Match() require more code to achieve the same results as the Choose function:

```julia
If( 
    group[1] == 1, "Low", 
    group[1] == 2, "Medium", 
    group[1] == 3, "High", 
    "Unknown"
);
Match( group, 1, "Low", 2, "Medium", 3, "High", "Unknown" );
```

**Note:** If the data types in the expression do not match, JMP automatically changes the column’s data type.

### Interpolate

The Interpolate() function performs linear interpolation for continuous data or bilinear interpolation for two-dimensional continuous data.

In the simplest case, the function finds the \( y \) value that corresponds to a given \( x \) value between two sets of points. You might use Interpolate() to calculate missing values between data points.

The data points can be specified as alternating ordered arguments:

```julia
Interpolate( x, x1, y1, x2, y2, ... );
```

or as matrices containing the \( x \) and \( y \) values:

```julia
Interpolate( x, xmatrix, ymatrix );
```

Suppose that your data set includes the height of individuals from age 20 through 25. However, there is no data point for age 23. To estimate the height for 23-year-olds, use interpolation. The following example shows the value that you want to evaluate (age 23), followed by matrices for ages (20 through 25) and heights (59 through 75).

```julia
Interpolate( 23, [20 21 22 24 25], [59 62 56 69 75] );
```

returns:

```
62.5
```

The value 62.5 is halfway between the \( y \) values 56 and 69, just as 23 is halfway between the \( x \) values 22 and 24.

You can also interpolate multiple points by specifying a matrix or list of values in the first argument.

```julia
Interpolate( [23, 24.5], [20 21 22 24 25], [59 62 56 69 75] );
```
returns:

\[ [62.5, 72] \]

**Bilinear Interpolation**

You can also interpolate in two-dimensions:

\[
\text{Interpolate( \{x, y\}, xvector, yvector, zmatrix \);} 
\]

Here, the first argument is a list of two points, the second and third arguments are vectors that define the grid of \(x\) and \(y\) values, and the fourth argument is a matrix of data points. The function then finds the interpolated \(z\) value within the appropriate quadrant of the \(z\) matrix. The appropriate quadrant is found by comparing the \(x\) and \(y\) values to the \(x\)vector and \(y\)vector arguments.

Suppose you have a 2x3 matrix and you want to interpolate a point that is halfway between the first and second rows of points and halfway between the second and third columns of points.

\[
\text{Interpolate( \{0.5, 0.75\}, [0 1], [0 0.5 1], [10 15 20, 12 16 18] \);} 
\]

returns:

17.25

Note that 0.5 is halfway between 0 and 1 for the \(x\) values (corresponding to the rows of the matrix) and 0.75 is halfway between 0.5 and 1 for the \(y\) values (corresponding to the columns of the matrix). You can find the bilinear interpolation in two steps:

1. Find the halfway points between the second and third columns for each row of the matrix:
   - Row 1: 17.5 is halfway between 15 and 20.
   - Row 2: 17 is halfway between 16 and 18.
2. Find the halfway point between the two points in the previous step: 17.25.

**Notes:**

- The \(x\) values must be in ascending order. For example, \text{Interpolate(2,1,1,3,3)} returns 2. However, \text{Interpolate(2,3,3,1,1)} returns a missing value (\).
- \text{Interpolate(\)} is best used for continuous data, but \text{Step(\)} is designed for discrete data. See “Step” on page 133.

Scripting Guide

Compare Incomplete or Mismatched Data

Compare Incomplete or Mismatched Data

Comparing data that contains missing values can return misleading results unless you specify a condition that is always true or use functions such as Is Missing() or Zero Or Missing(). Comparisons of data with mismatched types (numeric versus character) or data in matrices can also be confusing.

Table 5.5 shows examples of such comparisons and matrices and explanations of the results. For a review of operators used in comparisons, see “Operators” on page 103. For an overview of comparing data, see the JSL Syntax Reference.

Note: Matrices must include the same number of columns or rows.

</thead>
<tbody>
<tr>
<td>Any([2 2]==[1 2])</td>
<td>1</td>
<td>Summarizes elementwise comparisons; returns 1 if any comparison is true and returns 0 otherwise.</td>
</tr>
</tbody>
</table>

Missing Values

In a comparison, missing values typically return missing, not true or false. For this reason, it is very important to include a result that is always true. Suppose that a data table column contains the values 1, 2, 3, and a missing value in column A. A formula in column B sets up the comparison.

```julia
New Table( "Testing Comparisons",
  Add Rows( 4 ),
  New Column( "A",
    Numeric,
    "Continuous",
    Format( "Best", 10 ),
    Set Values( [1, 2, 3, .] )
  ),
  New Column( "B", Character, "Nominal", Formula( If( :A, "true", 1, "false" ) ) )
);
```

The following values are stored in column B:

"true"
"true"
"true"
"false"

The script works like this:

```julia
If( :A, "true", 1, "false" )
```

<table>
<thead>
<tr>
<th>If( :A, &quot;true&quot;, 1, &quot;false&quot; )</th>
<th>Begins the comparison.</th>
</tr>
</thead>
<tbody>
<tr>
<td>:A, &quot;true&quot;,</td>
<td>If the value of A is nonmissing and nonzero, the result is &quot;true&quot;. This comparison is true for the first three rows.</td>
</tr>
<tr>
<td>1, &quot;false&quot;</td>
<td>The value of 1 is always true, so the missing value returns &quot;false&quot;.</td>
</tr>
<tr>
<td>);</td>
<td>Closes the comparison.</td>
</tr>
</tbody>
</table>
Notes:

• When a cell contains a non-empty string, the comparison fails with the first comparison. The following script returns a missing value if a is a string. It works for numeric values.

```
a = "a";
If( a, "true", "false" );
```

• When one value is false and another one is missing, Or() returns missing. Use OrMZ() to return false instead. See the JSL Syntax Reference.

• When one value is true and another one is missing, And() returns missing. Use AndMZ() to return false instead. See the JSL Syntax Reference.

• MatchMZ() is similar to Match() except that missing values are treated as 0.

• IfMZ() is similar to If() except that missing values are treated as 0.

Is Missing

If you know that some values are missing, you can also compare with Is Missing(). The comparison in the preceding example can be rewritten to return "missing" for missing values:

```
If( :A, "true", Is Missing( :A ), "missing", "false" );
```

The preceding expression returns "true" when A is nonmissing and nonzero, "missing" when A is missing, and "false" otherwise.

Zero Or Missing

If the missing value could be 0, use the Zero Or Missing() function instead:

```
Zero Or Missing( A );
```

This expression returns 1 when A is 0 or missing.

Tip: You cannot compare a known value with an explicitly defined missing value, only with variables, matrices, or other things that could contain missing values.

Inquiry Functions

Inquiry functions identify the type of an element, such as a string, list, or matrix. You can then write a script specific to that element type.

JMP also uses inquiry functions to determine the writability of a directory or file and to identify a computer’s operating system and the JMP version.
Chapter 5
Scripting Guide

**General Element Types**

The `Type()` function returns a string naming the type of the resulting value. For example:

```javascript
Show( Type( 1 ), Type( "hi" ), Type( {"a", 2} ), Type( [10 24 325] ) );
```

results in:

```
Type(1) = "Integer"
Type("hi") = "String"
Type( {"a", 2} ) = "List"
Type([10 24 325]) = "Matrix";
```

**Specific Element Types**

Other inquiry functions (such as `Is Matrix()`, `Is List()`, `Is Scriptable()`, and so on) let you test for specific types of objects. In the following example, `Is Matrix()` evaluates as true, then the specified calculations are run:

```javascript
a = [2 3];
b = [1, 1];
c = a * b;
If( Is Matrix( c ),
   (c[^]a) / (a * b),
   Print( "c is not a matrix." )
);
[5 25]
```

`Is Scriptable()` returns 1 when the object is scriptable. Four variables in the following example refer to a data table, column, platform, and report. All four objects are scriptable, so `Is Scriptable()` returns 1 for each example.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = Column( "weight" );
plat = Bivariate( Y( :weight ), X( :height ) );
rep = Report( plat );
Show( Is Scriptable( dt ) );
   Is Scriptable(dt) = 1;
Show( Is Scriptable( col ) );
   Is Scriptable(col) = 1;
Show( Is Scriptable( plat ) );
   Is Scriptable(plat) = 1;
Show( Is Scriptable( rep ) );
   Is Scriptable(rep) = 1;
```

`Is Empty()` tests to see whether a variable has a value, a function, an expression, or a reference to an object. It returns 1 if the variable is undefined or holds the `Empty()` value. Otherwise, you get errors when referring to something that has not been created or assigned a value yet. Programmers call this an *uninitialized variable.*
Here is an example of a test to see whether a data table is opened and therefore assigned to the \( dt \) variable. If a data table is not opened, the \( \text{Open()} \) function prompts the user to open the table.

\[
\text{If( Is Empty( } dt = \text{Current Data Table()} \text{),}
\]

\[
\text{dt = Open()}
\]

\);

You can use \( \text{Is Empty()} \) for any variable (such as global variable, local variable, and columns).

Table 5.6 shows functions that identify object types.

**Table 5.6 Inquiry Functions That Identify Object Types**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Associative Array( (x) )</td>
<td>Returns 1 if the evaluated argument is an associative array or 0 otherwise.</td>
</tr>
<tr>
<td>Is Directory( (x) )</td>
<td>Returns 1 if the ( x ) argument is a directory and 0 otherwise.</td>
</tr>
<tr>
<td>Is Empty( (\text{global}) )</td>
<td>Returns 1 if the global variable, data table, or data column does not have a value (is uninitialized) or 0 otherwise.</td>
</tr>
<tr>
<td>Is Expr( (x) )</td>
<td>Returns 1 if the evaluated argument is an expression or 0 otherwise.</td>
</tr>
<tr>
<td>Is File( (x) )</td>
<td>Returns 1 if the ( x ) argument is a file and 0 otherwise.</td>
</tr>
<tr>
<td>Is List( (x) )</td>
<td>Returns 1 if the evaluated argument is a list or 0 otherwise.</td>
</tr>
<tr>
<td>Is Matrix( (x) )</td>
<td>Returns 1 if the evaluated argument is a matrix or 0 otherwise.</td>
</tr>
<tr>
<td>Is Name( (x) )</td>
<td>Returns 1 if the evaluated argument is a name or 0 otherwise. See “Retrieve a Stored Expression Rather than its Result” on page 257.</td>
</tr>
<tr>
<td>Is Namespace( (x) )</td>
<td>Returns 1 if the evaluated argument is a namespace or 0 otherwise.</td>
</tr>
<tr>
<td>Is Number( (x) )</td>
<td>Returns 1 if the evaluated argument is a number or missing numeric value or 0 otherwise.</td>
</tr>
<tr>
<td>Is Scriptable( (x) )</td>
<td>Returns 1 if the evaluated argument is a scriptable object or 0 otherwise.</td>
</tr>
<tr>
<td>Is String( (x) )</td>
<td>Returns 1 if the evaluated argument is a string or 0 otherwise.</td>
</tr>
<tr>
<td>Type( (x) )</td>
<td>Returns a string naming the type of ( x ).</td>
</tr>
</tbody>
</table>
Object Attributes

JMP provides the following functions to determine whether a file or directory is writable before attempting to write to them. Use these functions in combination with `Is Directory(path)` and `Is File(path)` to verify a script destination and attribute. See the *JSL Syntax Reference* for additional information.

The `Is Directory Writable(path)` function returns 1 if the directory specified in the path argument is writable and 0 otherwise.

The `Is File Writable(path)` function returns 1 if the file specified in the path argument is writable and 0 otherwise.

For example, the following code verifies the path refers to a directory and then checks to ensure the directory is writable:

```js
If( Is Directory( "$SAMPLE_DATA/Loss Function Templates" ),
    If( Is Directory Writable( "$SAMPLE_DATA/Loss Function Templates" ),
        "Directory is writable."
        "Directory is read only!"
    ),
    "Is a read only directory."
);
```

Host Information

The `Host Is()` inquiry function identifies the current operating system. Then actions specific to that operating system can be performed.

The following example specifies text sizes in reports for different operating systems. If you commonly write your scripts on Windows and share them with macOS users, the results can look different from what you intended. For example, the following expression sets the text to a larger size (12) on macOS and a smaller size (10) on Windows:

```js
textsize = If( Host is( "Mac" ), 12, 10 );
```

Version Information

The `JMP Version()` inquiry function returns the JMP version as a string. You might use this function to determine the JMP version and then run a script compatible with that version.

```js
JMP Version(); // returns "16.0.0" in JMP 16
JMP Version(); // returns "9.0.0" in JMP 9
```

Notice that a leading blank is inserted before versions less than 10.0.0. This blank helps when comparing version numbers. Without the leading blank, 9.0.0 is interpreted as greater than 10.0.0.
This chapter discusses basic data types:

- numbers and strings
- paths, which are a special type of string
- dates and times, which can be either special numbers or special strings
- currency
- hexadecimal values and blobs

At the end of the chapter are two sections that show more advanced methods of interacting with strings and pattern matching with regular expressions.

Numbers and Strings

Numbers can be written as integers, decimal numbers, in scientific notation with an E preceding the power of ten, and as date-time values. A single period by itself is the missing numeric value.

For example, these are all numbers:

.   1   12   1.234  3E3  0.314159265E+1  1E-20

One or more characters placed within double quotation marks constitute a string. For example, these are all strings:

"Green" "Hello,\nWorld!" "54"

Notice that if a number is in quotation marks, it is a string, not a number. There are two functions you can use to change a number into a string or a string into a number.

- Use `Num()` to convert a string into a number. For example:
  ```
  Num( "54" );
  54
  ```
  
  **Note:** `Num()` cannot convert non-numeric characters, so it produces a missing value.

  ```
  Num( "Hello" );
  .
  ```

- Use `Char()` to convert a number into a string. For example:
  ```
  Char( 54 );
  "54"
  Char( 3E3 )
  "3000"
  ```

To preserve locale-specific numeric formatting in `Num()` or `Char()` output, include the `<<UseLocale(1)` option as shown in the following example:

  ```
  Char( 42, 5, 2, << UseLocale( 1 ) );
  // results in the character value "42,00" in the French locale
  ```

To look at each character in a string, use the `Substr()` function. This example looks for the letter “a” in the string and prints a message to the log:

  ```
  ch = Substr( "alphabetic", 1, 1 ); // start and end with the first character
  If( ch == "a",
  Print( "First letter is a." )
  );
  "First letter is a."
  ```
Formatting Numbers

The `Format()` function provides options for formatting numbers with thousands separators, decimal points, geographic symbols, \( p \)-values, and so on. The following example shows a basic format for a fixed decimal column.

```plaintext
Format( x, "Fixed Dec", 10, 2, "Use thousands separator" );
```

The format starts with the number to be formatted. Then you can specify the width of the number, the number of decimal places, and whether to use a thousands separator.

Here are other examples:

```plaintext
Format( x, "Currency", 20, <<Use Locale(0) ); // ignores computer locale and uses a period for the decimal separator
Format( x, "Currency", 20, "Use thousands separator" );
Format( x, "m/d/y", 10 );
Format( x, "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole digits" );
Format( x, "Latitude DDD", "PUNDIR" ); // "PUN" for punctuation, "DIR" for direction, PUNDIR for both
Format( x, "Custom", Formula( Abs( value ) ), 15 );
```

The syntax for `Function()` arguments is shown in the JSL Syntax Reference. You can also find the argument names and options in the data table Column Info window.

See “Date-Time Functions and Formats” on page 150 and “Currency” on page 164 for more information about formatting date-time values and currency.

**Note:** If the date format is unknown, an error is written to the log.

**Matrix Box, Number Col Box, Number Col Edit Box, Number Edit Box**

To format numbers in `Matrix Box()`, `Number Col Box()`, `Number Col Edit Box()`, and `Number Edit Box()`, send the `Set Format` message to the display box. You can then specify the same arguments as for the `Format()` function, such as the following:

```plaintext
<<Set Format( 10, 2, "Use thousands separator" );
<<Set Format( "Currency", "EUR", 20 );
```

The syntax for `Set Format` arguments is shown in the JSL Syntax Reference. You can also find the argument names and options in the data table Column Info window.

**Note:** If you specify the number of decimal places, that number must be preceded with the width.
### Unicode Characters

JMP supports both Unicode UTF-8 and UTF-16 standards for encoding and representing text for most of the world languages. See the The Unicode Consortium for code charts and more information on the Unicode standard.

To display Unicode characters in JMP, precede the Unicode code for the character with ‘\!’. For example:

- Greek letter sigma (σ) in Unicode = U+03C3; in JMP, use \!U03C3
- Greek letter mu (μ) in Unicode = U+03BC; in JMP, use \!U03BC

To use Unicode to express superscripts and subscripts:

- subscript 1 (₁) in Unicode = U+2081; in JMP, use \!U2081
- superscript 2 (²) in Unicode = U+00B2; in JMP, use \!U00B2

To express x² in Unicode, in JMP, use \!U0078\!U00B2.

To use Unicode surrogate pairs, specify the Unicode escape sequence twice. If you specify an emoji Unicode character, you might need to change the font for it to appear correctly. The following example shows how to include an emoji in a text box.

```julia
New Window( "Emoji Example",
   V List Box( 
      Text Box( "Surrogate Pair with space: \!UD83D \!UDE00", Set Font( "Segoe UI Emoji" ) ),
      Text Box( "Surrogate Pair without space: \!UD83D\!UDE00", Set Font( "Segoe UI Emoji" ) )
   )
);
```

### Path Variables

*Path variables* are shortcuts to directories or files. Rather than enter the entire path to the directory or file, you use the path variable in a script. A path variable is a special type of string and is always contained within double quotation marks.

One common predefined path variable in JMP is $SAMPLE_DATA. This variable points to the sample data folder in your JMP or JMP Pro installation folder. The following example opens the Big Class.jmp sample data table.

```julia
Open( "$SAMPLE_DATA/Big Class.jmp" );
```

Several path variables are predefined in JMP. The following table shows the definitions for the current JMP version. Variables in previous versions of JMP might differ.
Table 6.1 Predefined Path Variable Definitions

Types of Data
Path Variables

Chapter 6
Scripting Guide

Path variable definitions are updated automatically based on the version of JMP you are using. For example, when you run a JMP 14 script in JMP 16, the JMP 16 path variable definitions are used.

To see the definition of any path variable, use the function Get Path Variable:

```plaintext
Get Path Variable( "HOME" );
"/C:/Users/<username>/AppData/Roaming/SAS/JMP/16/
```

Note that you don't include a dollar sign for Set Path Variable() or Get Path Variable(). But you must include the dollar sign when using the variable in a script.

**Trailing Slashes**

Make sure to include a trailing slash after the path variable. In the following example, the root name "Big Class" is assigned to the dtName variable. The Open() expression evaluates $SAMPLE_DATA and the trailing slash and then appends the dtName value along with the file extension .jmp.

```plaintext
dtName = "Big Class";
dt = Open( "$SAMPLE_DATA/" || dtName || ".jmp" );
```

The path is interpreted as:

`C:/Program Files/SAS/JMP/16/Samples/Data/Big Class.jmp`

Without the slash that follows $SAMPLE_DATA, the path is interpreted as:

`C:/Program Files/SAS/JMP/16/Samples/DataBig Class.jmp`

**Create and Customize Path Variables**

You can create your own path variables or override some of the built-in variables with the Set Path Variable(). In the following example, the path variable is called `root`. The variable points to the `c:/` directory.

```plaintext
Set Path Variable( "root", "c:/" );
```
To get the value of the new variable, use `Get Path Variable()`.

```
Get Path Variable( "root" );
"c:/"
```

Use your path variable as you would other variables. The following expression opens the `myimportdata.txt` file in the `c:/` directory.

```
Open( "$root/myimportdata.txt" );
```

As with getting path variables, omit the dollar sign when setting path variables.

## Relative Paths

If you plan to use relative paths in variables, you must set the default directory. Then any path not preceded by a drive letter is relative to the default directory. Here is an example:

```
Set Default Directory( "c:/users/smith/data" );
```

To return the value of the default directory, use `Get Default Directory()`.

```
Get Default Directory(); // returns "c:/users/smith/data"
```

So the following expression resolves as `C:/users/smith/data/cleansers.jmp`:

```
Open("cleansers.jmp");
```

## File Path Separators

In JMP, the preferred file path format is the Portable Operating System Interface (POSIX), or UNIX, format with forward slashes (`/`) as separators. This means that you do not have to identify the current operating system in scripts run on both Windows and macOS. However, each host still accepts its native format for compatibility.

You can convert file path format from Windows to POSIX (and vice versa) using `Convert File Path()`. Converting from a POSIX to a Windows path might be useful when you need to output a path to a file or to another application. The syntax is:

```
Convert File Path (path, <absolute|relative>, <POSIX|windows>, <base(path)>);
```

For example, the following script converts a POSIX path to a Windows path:

```
Convert File Path( "c:/users/smith", windows);
c:\users\smith
```

You can substitute a path variable (such as `$HOME`) for the path inside quotes.
Date-Time Functions and Formats

A date-time value consists of any portion of a date or time. The value can be seconds (3388594698), a complete date (such as “Wednesday, May 18, 2011”), the date and time (“05/18/2011 8:18:18 PM”), the week number (3), and so on.

JMP lets you convert date-time values to common formats, perform arithmetic on the values, and manipulate the data in a number of ways.

**Tip:** For descriptions of all date-time functions and their arguments, see the JSL Syntax Reference.

Date-Time Values

Date-time values are stored and calculated as the number of seconds since midnight, January 1, 1904. For example:

```javascript
Today(); // returns 3388649872 on May 19, 2011 at 12:00:00 AM
```

As with `Today()`, the `Date DMY()` and `Date MDY()` functions also return month, day, and year arguments as seconds. For example, if it were 12:00:00 a.m. on May 19, 2011, all of the following statements would return the same value:

```javascript
Date DMY( 19, 5, 2011 );
Date MDY( 5, 19, 2011 );
Today();
3388608000
```

The `As Date()` function takes the number of seconds and displays it as a date or duration.

- Values that represent one year or more are returned as dates:
  ```javascript
  As Date( 3388608000 );
  19May2011
  ```
- Values that represent less than a year are returned as durations.
  ```javascript
  As Date( 50000 );
  :0:13:53:20
  ```

You can use date-time values in two ways:

- a literal value, for example `19May2011:10:10`
- a string, for example "Thursday, May 19, 2011"

You can perform arithmetic with date-time literals, which use the number of seconds as the base number.

```javascript
As Date( 19May2011 + 1 );
```
Chapter 6
Types of Data

19May2011:00:00:01

Program with Date-Time Functions

Table 6.2 shows functions that convert seconds into date-time values and date-time values into seconds.

<table>
<thead>
<tr>
<th>Function</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbrev $\text{Date}(date)$</td>
<td>Returns a string representation for the $date$ supplied. The format is based on your computer’s regional setting. So for the English (United States) locale, the date is formatted like &quot;02/29/2004&quot;. Even if you are running JMP in English with a different locale, the locale format is applied.</td>
</tr>
<tr>
<td>$\text{As Date}(expression)$</td>
<td>Formats a number or expression so that it shows as a date or duration in a text window. For example, values that represent one year or more are returned as dates.</td>
</tr>
<tr>
<td>$x = \text{As Date}(8\text{Dec2000} + \text{In Days}(2));$</td>
<td>shows as:</td>
</tr>
<tr>
<td>$10\text{Dec2000}$</td>
<td>Values that represent less than a year are returned as durations.</td>
</tr>
<tr>
<td>$\text{As Date}(50000);$</td>
<td>shows as:</td>
</tr>
<tr>
<td>$:0:13:53:20$</td>
<td></td>
</tr>
<tr>
<td>$\text{Date DMY}(\text{day, month, year})$</td>
<td>Returns the specified date expressed as the number of seconds since midnight, 1 January 1904. For example, the second Leap Day of the third millennium is $\text{DateDMY}(29,2,2004)$, which returns 3160857600.</td>
</tr>
<tr>
<td>$\text{Date MDY}(\text{month, day, year})$</td>
<td>Returns the specified date expressed as the number of seconds since midnight, 1 January 1904. For example, the second Leap Day of the third millennium is $\text{DateMDY}(2,29,2004)$, which returns 3160857600.</td>
</tr>
<tr>
<td>$\text{Day Of Week}(date)$</td>
<td>Returns an integer representation for the day of the week of the $date$ supplied. Weeks are Sunday–Saturday.</td>
</tr>
</tbody>
</table>
Table 6.2 Date-Time Functions (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day Of Year(date)</td>
<td>Returns an integer representation for the day of the year of the date supplied.</td>
</tr>
<tr>
<td>Day(date)</td>
<td>Returns an integer representation for the day of the month of the date supplied.</td>
</tr>
<tr>
<td>Format(date, &quot;format&quot;)</td>
<td>Returns the value in the format specified in the second argument. Most typically used for formatting datetime values from a number of seconds to a formatted date. Format choices are those shown in the Column Info dialog box. Also see Table 6.3 “How JMP Interprets Two-Digit Years” on page 157.</td>
</tr>
<tr>
<td>Hour(datetime)</td>
<td>Returns an integer representation for the hour part of the date-time value supplied.</td>
</tr>
<tr>
<td>In Days(n)</td>
<td>These functions return the number of seconds per n minutes, hours, days, weeks, or years. Divide by these functions to express an interval in seconds as an interval in other units.</td>
</tr>
<tr>
<td>In Hours(n)</td>
<td></td>
</tr>
<tr>
<td>In Minutes(n)</td>
<td></td>
</tr>
<tr>
<td>In Weeks(n)</td>
<td></td>
</tr>
<tr>
<td>In Years(n)</td>
<td></td>
</tr>
<tr>
<td>Long Date(date)</td>
<td>Returns a string representation for the specified date. The format is based on your computer’s regional setting. So for the English (United States) locale, the date is formatted like &quot;Sunday, February 29, 2004&quot;. Even if you are running JMP in English with a different locale, the locale format is applied.</td>
</tr>
<tr>
<td>MDYHMS(date)</td>
<td>Returns a string representation for the date supplied, formatted like &quot;2/29/2004 00:02:20 AM&quot;.</td>
</tr>
<tr>
<td>Minute(date-time)</td>
<td>Returns an integer representation for the minute part of the date-time value supplied.</td>
</tr>
<tr>
<td>Month(date)</td>
<td>Returns an integer representation for the month of the date supplied.</td>
</tr>
<tr>
<td>Num(date-time)</td>
<td>Returns an integer representation for the date-time value supplied.</td>
</tr>
<tr>
<td>InFormat(string, &quot;format&quot;)</td>
<td>Parses a string of a given format and returns datetime value expressed as if surrounded by As Date(), returning the date in DdMOnyy format.</td>
</tr>
</tbody>
</table>
Table 6.2 Date-Time Functions  *(Continued)*

<table>
<thead>
<tr>
<th>Function</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second(<em>date-time</em>)</td>
<td>Returns an integer representation for the second part of the <em>date-time</em> value supplied.</td>
</tr>
<tr>
<td>Short Date(<em>date</em>)</td>
<td>Returns a string representation for the <em>date</em> supplied, in the format MM/DD/YYYY, regardless of locale (for example, &quot;02/29/2004&quot;).</td>
</tr>
<tr>
<td>Time Of Day(<em>date</em>)</td>
<td>Returns an integer representation for the time of day of the <em>date-time</em> supplied.</td>
</tr>
<tr>
<td>Today()</td>
<td>Returns the current date and time expressed as the number of seconds since midnight, 1 January 1904. No arguments are accepted, but the parentheses are still needed.</td>
</tr>
</tbody>
</table>
| Week Of Year(*date*, <rule_n>) | Returns the week of the year as a date-time value. Three rules determine when the first week of the year begins.  
  • With rule 1 (the default), weeks start on Sunday, with the first Sunday of the year being week 2. Week 1 is a partial week or empty.  
  • With rule 2, the first Sunday begins with week 1, with previous days being week 0.  
  • With rule 3, the ISO-8601 week number is returned. Weeks start on Monday. Week 1 is the first week of the year with four days in that year. It is possible for the first or last three days of the year to belong to the neighboring year's week number. |
| Year(*date*)         | Returns an integer representation for the year of the specified *date*.                                                                      |

**Examples of Common Date-Time Functions**

You can use any function that returns seconds within a function that returns a date-time.

For example, if today is May 19, 2011 and the time is 11:37:52 AM, `Today()` returns the number of seconds, and the functions that follow show that number of seconds since the base time in different date-time formats:

```plaintext
Today()
3666955847
Short Date( Today() );
"03/13/2020"
```
Long Date( Today() );
   "Friday, March 13, 2020"
Abbrev Date( Today() );
   "3/13/2020"
MDYHMS( Today() );
   "03/13/2020 2:50:17 PM"

The date argument in parentheses can be seconds (or any function that returns seconds), or any date-time literal value. For example, both of the following expressions return the same value:

Long Date( 3388649872 );
Long Date( 19May2011 );
   "Friday, March 13, 2020"

Note: Long Date() and Abbrev Date() values are formatted according to your computer’s regional settings.

Extract Parts of Dates

You can extract parts of date values using the functions Month(), Day(), Year(), Day Of Week(), Day Of Year(), Week Of Year(), Time Of Day, Hour(), Minute(), and Second(), which all return integers. If today is May 24th, 2011, each of the following examples returns the 144th day of the year:

Day of Year( Today() );
Day of Year( 24May2011 );
Day of Year( Date MDY( 5, 24, 2011 ) );
   144

Example

A data table column named Date contains date-time values that are formatted as "m/d/y". You want to create a column that shows only the time. In the following script, the second column’s formula extracts the time of day from the Date value in the first column.

New Table( "Assembly Tests",
   Add Rows( 1 ),
   New Column( "Date",
      Numeric, Continuous,
      Format( "m/d/y" ),
      Set Values( [3389083557] )
   ),
   New Column( "Time",
      Numeric, Continuous,
      Formula( Format( Time Of Day( :Date ), "h:m:s") )
   );
Figure 6.1 shows the result. Note that the time of day does not appear in the Date column, because the Format function applies the “m/d/y” format.

**Figure 6.1** Example of Extracting the Time

<table>
<thead>
<tr>
<th>Date</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>05/24/2011</td>
<td>12:05:57 PM</td>
</tr>
</tbody>
</table>

**Rules for Determining the Week of the Year**

Week of Year() returns the week of the year as a date-time value. Three rules determine when the first week of the year begins.

- With rule 1 (the default), weeks start on Sunday, with the first Sunday of the year being week 2. Week 1 is a partial week or empty.
  
  Week Of Year( Date DMY( 19, 6, 2013 ), 1 );
  
  25

- With rule 2, the first Sunday begins with week 1, with previous days being week 0.
  
  Week Of Year( Date DMY( 19, 6, 2013 ), 2 );
  
  24

- With rule 3, the ISO-8601 week number is returned. Weeks start on Monday. Week 1 is the first week of the year with four days in that year. It is possible for the first or last three days of the year to belong to the neighboring year’s week number.
  
  Week Of Year( Date DMY(19, 6, 2013), 3 );
  
  25

**Arithmetic on Dates**

You can perform the usual arithmetic operations with date-time data as with any other numeric data. One option is simple arithmetic, such as subtracting a number from a date-time value.

Another option is writing a formula to perform the arithmetic.

**Example**

The Date column in your data table shows when a customer uses his credit card to buy gas. You want to know how many days elapse between purchases. The following script creates a Days elapsed column. The formula in that column subtracts the Date value in the current row from that of the previous row.

```
New Table( "Gas Purchases",
    Add Rows( 3 ),
    New Column( "Date",
```
Figure 6.2 shows the result.

**Figure 6.2** Example of Calculating Date-Time Values

<table>
<thead>
<tr>
<th>Date</th>
<th>Days elapsed</th>
</tr>
</thead>
<tbody>
<tr>
<td>07/01/2011</td>
<td></td>
</tr>
<tr>
<td>07/15/2011</td>
<td>14</td>
</tr>
<tr>
<td>07/30/2011</td>
<td>15</td>
</tr>
</tbody>
</table>

**Time Intervals**

The *In Minutes*, *In Hours*, *In Days*, *In Weeks*, and *In Years* functions are used to express time intervals in units rather than seconds. Each of these functions returns the number of seconds associated with a particular period of time. For example, the following expression returns the number of weeks between now and July 4, 2012.

\[
\frac{(\text{Date DMY}(04, 07, 2012) - \text{Today}())}{\text{In Weeks}()};
\]

\[-208.22544775132\]

When the argument for the interval function is empty, JMP counts by 1. You can enter another number to change the count. For example, *In Years* (10) converts the interval to decades. The following expression returns the number of decades between now and December 31, 2037.

\[
\frac{(\text{Date DMY}(31, 12, 2037) - \text{Today}())}{\text{In Years}(10)};
\]

\[2.18927583529799\]
Two-Digit and Four-Digit Years

JMP applies its own algorithms for interpreting and displaying datetime strings rather than supporting operating system-specific datetime formats. However, JMP uses the date-time separators selected in the Region and Language control panel (Windows) or the Date & Time preferences (macOS) to interpret and display dates.

Two-digit years are interpreted according to the current system clock year and JMP rules. For example, when the year in a script is 11, and you run the script after 1990, the year shows as 2011.

```plaintext
Long Date( 25May11 );
"Wednesday, May 25, 2011"
```

To avoid ambiguity, enter four-digit years. The following expression returns 1911 (rather than 2011) as indicated:

```plaintext
Long Date( 25May1911 );
"Thursday, May 25, 1911"
```

Table 6.3 explains how JMP interprets two-digit years.

### Table 6.3 How JMP Interprets Two-Digit Years

<table>
<thead>
<tr>
<th>Two-Digit Year Value</th>
<th>When it is Evaluated</th>
<th>Result</th>
<th>Examples</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>00–10</td>
<td>before 1990 (on Windows)</td>
<td>19__</td>
<td>enter 5 in year</td>
<td>1905</td>
</tr>
<tr>
<td></td>
<td>before or during 1990 (on macOS)</td>
<td></td>
<td>1979</td>
<td></td>
</tr>
<tr>
<td></td>
<td>during or after 1990 (on Windows)</td>
<td>20__</td>
<td>enter 5 in year</td>
<td>2005</td>
</tr>
<tr>
<td></td>
<td>after 1990 (on macOS)</td>
<td></td>
<td>1991</td>
<td></td>
</tr>
<tr>
<td>11–89 (on Windows)</td>
<td>any time</td>
<td>current century</td>
<td>enter 13 in year</td>
<td>1913</td>
</tr>
<tr>
<td>11–90 (on macOS)</td>
<td>any time</td>
<td>current century</td>
<td>enter 13 in year</td>
<td>2013</td>
</tr>
<tr>
<td>90–99 (on Windows)</td>
<td>before 2011</td>
<td>19__</td>
<td>enter 99 in year</td>
<td>1999</td>
</tr>
<tr>
<td>91–99 (on macOS)</td>
<td>during or after 2011</td>
<td>20__</td>
<td>enter 99 in year</td>
<td>2099</td>
</tr>
</tbody>
</table>
Note: JMP always displays four-digit years regardless of the regional settings. If you need to show two-digit years, use character string functions. See the “Types of Data” chapter on page 141.

Date-Time Values in Data Tables

Change Date-Time Input and Display Formats

In data tables, JMP can accept the input of date-time values in one format (the input format), store them internally as the number of seconds since the base date, and display them in a different date-time format. The Informat() and Format() functions give you this control.

- **Informat()** takes a string date-time value, defines the date format used in that string, and returns the date in ddMonyyyy format.

  ```
  Informat( "19May2011 11:37:52 AM", "ddMonyyy h:m:s" );
  19May2011:11:37:52
  ```

- **Format()** takes the number of seconds since the base date (or a date-time function that returns that number) and returns the date in the specified format.

  ```
  Format( 3388649872, "ddMonyyy h:m:s" );
  "19May2011 11:37:52 AM"
  Format( Today(), "ddMonyyy h:m:s" );
  "19May2011 11:37:52 AM"
  ```

Suppose that you are entering dates into a column using the d/m/y h:m format, but you want to see the dates in the m/d/y format. **Input Format** defines the input format, and **Format** defines the display format. For example,

```
New Table( "Widget Assembly",
  Add Rows( 1 ),
  New Column( "Date",
    Numeric,
    "Continuous",
    Format( "m/d/y" ),
    Input Format( "d/m/y h:m" ),
    Set Values( [3126917100] )
  )
);
```

The **Format** and **Input Format** values are shown in the data table’s column properties (Figure 6.3). Note that when you click in the cell to edit it, the date-time value appears in the input format. When you edit the value, or add a new value, the format specified in the data table column Format list is used to display the value.
**Figure 6.3** Example of Date-Time Display and Input Values

![Example of Date-Time Display and Input Values](image)

**Notes:**
- In a script that converts a column from character to numeric, specify `Format()` and `Informat()` to prevent missing values. See “Convert Character Dates to Numeric Dates” on page 902 in the “Common Tasks” chapter.
- The date-separator character on your computer might differ from the forward slash (/) character shown in the *Scripting Guide*.
- You can enter time values in 24-hour format (military time) or with AM or PM designators.

Table 6.4 describes the formats used as arguments in date-time functions or as data table formats. You can also use the formats for the `format` argument to a `Format` message to a data column. See “Set or Get Formats” on page 416 in the “Data Tables” chapter.

For descriptions of specific date-time functions, see the *JSL Syntax Reference*.

**Notes:**
- Date-time formats in which a colon or T separate the date and time always use a 24-hour format. Other formats use your computer’s regional settings.
- If the format is unknown, an error is written to the log.

<td>reads thirty-seven minutes and 4 seconds</td>
</tr>
</tbody>
</table>

**Note:** The following formats display the date-time according to your computer’s regional settings. They are available only for the display of dates, not for date input in a data table. Examples are shown for the United States locale.

<table>
<thead>
<tr>
<th>Abbreviated date</th>
<th>&quot;Date Abbrev&quot;</th>
<th>(Display only) “01/02/1999”</th>
</tr>
</thead>
<tbody>
<tr>
<td>Long date</td>
<td>&quot;Date Long&quot;</td>
<td>(Display only) &quot;Saturday, January 02, 1999&quot;</td>
</tr>
<tr>
<td>Locale date</td>
<td>“Locale Date”</td>
<td>(Display only) “01/02/1999”</td>
</tr>
</tbody>
</table>
Custom Date-Time Formatting with Format Patterns

Format patterns are strings that define a date-time format. Here’s one example:

\(<YYYY></><MM></><DD> <hh><:><mm><:><ss><ampm>\n
The parts of the pattern in angle brackets are called field descriptors. They represent a value (such as \(<YYYY>\), which is a four-digit year) or other date-time text (such as \(</>\), which is a locale-specific date separator).

The conversion of a date-time value to a string and a string converted to a date-time value work as follows:

- When a date-time value is converted to a string, the field descriptors are replaced by the appropriate value or symbols.
- When a string is converted to a date-time value, a value is or matching symbols are expected to be found where each field descriptor is. Anything outside a format descriptor is treated as literal text. The literal text is replaced as-is when it is converted to a string, and is expected to be found where specified when converting from a string.

<table>
<thead>
<tr>
<th>Type</th>
<th>Format argument</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locale date and time</td>
<td>&quot;Locale Date Time h:m&quot;</td>
<td>(Display only) “01/02/1999 13:01“ or “01/02/1999 01:01 PM“</td>
</tr>
<tr>
<td></td>
<td>&quot;Locale Date Time h:m:s&quot;</td>
<td>(Display only) “01/02/1999 13:01:02“ or “01/02/1999 01:01:02 PM“</td>
</tr>
</tbody>
</table>

Note: \(<Day>\) is the day count, used as the most significant field of a duration. \(<Hour>\) and \(<Minute>\) field descriptors are also available.
Example of Outputting the Date-Time Value to the Log

The following script uses Informat() to read a string date-time value, defines the format pattern used in that string, and returns the date in ddMonyyy format. The script then outputs the date-time value to the log.

```plaintext
dateVal = Informat( "June 16, 2016", "Format Pattern", "<Month> <D>, <YYYY>" );
16Jun2016
```

Here's another way to specify the format pattern:

```plaintext
date2 = 16Jun2021;

dayofwk2 = Format( date2, "Format Pattern", "<DayOfWeek>" );
monthnew2 = Format( date2, "Format Pattern", "<Months>" );

YYYYMMDD = Format( date2, "Format Pattern", "<YYYY>//<MM>//<DD>" );
YMMDD = Format( date2, "Format Pattern", "<YY>//<MM>//<DD>" );
"21/Jul/16"
```

Example of Changing the Input Format of a Column

The following script shows how to change the input format of a column. The Input Format appears when you edit the value in a data table.

```plaintext
New Table( "temp_date",
  Add Rows( 2 ),
  New Column( "date1",
    Numeric,
    "Continuous",
    // specify how the value appears in the data table
    Format( "Format Pattern", "<Month> <D>, <YYYY>", 35 ),
    // specify how the value appears when you edit the value
    Input Format( "Format Pattern", "<YYYY>*<MM>*<DD>" ),
    Set Values( {"2018*10*31", "2018*09*09"} )
  ),
  New Column( "date2",
    Numeric,
    "Continuous",
    Format( "Format Pattern", "<YYYY>*<MM>*<DD>", 10 ),
    Set Values( {"2018*02*05", "2018*07*03"} )
  )
);
```
Currency

JMP displays numbers as currency using the `Format()` function, which uses the following syntax:

```
Format(x,"Currency", <"currency code">, <decimal>, < << Use Locale(Boolean)));
```

Where:

- `x` is a column or a number
- "currency code" is an International Standards Organization (ISO) 4217 code
- `decimal` is the number of decimal places

To illustrate the `Format` function:

```
Format( 12345.6, "Currency", "GBP", 3 );
"£12,345.600"
```

By default, the operating system locale is used for the currency if the currency code symbol is omitted. For example, running the following script in a Japanese operating system formats the number with the yen symbol.

```
Format( 12345.6, "Currency", 3);
"¥12,345.600"
```

To ignore the computer’s locale and use a period for the decimal separator, include the `Use Locale(0)` argument:

```
Format( 12345.6, "Currency", 3, <<Use Locale(0));
```

**Tip:** If you change the region when JMP is open, restart JMP for the `Use Locale` setting to work properly.

If the currency code is not supported by JMP, the currency code string appears before the number.

```
Format( 12345.6, "Currency", "BBD", 3 );
"BBD 12,345.600"
```

Table 6.6 lists the currencies supported in JMP.

For more information about how to format currency, see “Formatting Numbers” on page 144.

Hexadecimal and BLOB Functions

JMP can also handle binary (large) objects, commonly called BLOBs. The functions below convert between hexadecimal values, numbers, characters, and BLOBs. Some of the functions are covered in more detail following Table 6.7.

See the JSL Syntax Reference for more information.

Table 6.7 Hexadecimal and BLOB Functions

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hex(“text”)</td>
<td>Returns the hexadecimal codes for the characters in text, number, or blob.</td>
</tr>
<tr>
<td>Hex(“num”)</td>
<td></td>
</tr>
<tr>
<td>Hex(“blob”)</td>
<td>Char To Hex is an alias.</td>
</tr>
<tr>
<td>Hex To BLOB(“hexstring”)</td>
<td>Returns a BLOB representation of the hexadecimal code supplied as a quoted string.</td>
</tr>
</tbody>
</table>
Table 6.7 Hexadecimal and BLOB Functions (Continued)

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hex To Char</strong>(&quot;hexstring&quot;, &quot;encoding&quot;)</td>
<td>Returns a character string that corresponds to the hexadecimal code supplied as a quoted string. The default encoding for the character string is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and euc-jp are also supported.</td>
</tr>
<tr>
<td><strong>Hex to Number</strong></td>
<td>Returns the number that corresponds to the hexadecimal code supplied as a quoted string.</td>
</tr>
<tr>
<td><strong>Char To BLOB</strong>(&quot;string&quot;)</td>
<td>Converts a character string into a binary (BLOB). The default encoding for the blob is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and euc-jp are also supported.</td>
</tr>
<tr>
<td><strong>BLOB To Char</strong>(&quot;blob&quot;)</td>
<td>Converts binary data to a character string. The default encoding for the character string is utf-8. utf-16le, utf-16be, us-ascii, iso-8859-1, ascii~hex, shift-jis, and euc-jp are also supported.</td>
</tr>
<tr>
<td><strong>BLOB Peek</strong>(&quot;blob&quot;, offset, length)</td>
<td>Returns a new BLOB that is a subset of the given BLOB that is length bytes long and begins at the offset. Note that the offset is 0-based.</td>
</tr>
<tr>
<td><strong>Matrix to BLOB</strong>(matrix, type, bytesEach, endian)</td>
<td>Makes a BLOB from a matrix by converting the matrix elements to 1-byte, 2-byte, or 4-byte signed or unsigned integers or 4-byte or 8-byte floating point numbers.</td>
</tr>
<tr>
<td><strong>BLOB to Matrix</strong>(blob, &quot;type&quot;, bytes, &quot;endian&quot;, &lt;nCols&gt;)</td>
<td>Creates a matrix by converting each byte in the blob to numbers.</td>
</tr>
</tbody>
</table>

**Hex**(string) returns the hexadecimal codes for each character in the argument. For example,

```cpp
Hex( "Abc" );
```

returns

```
"416263"
```
since 41, 62, and 63 are the hexadecimal codes (in ASCII) for “A”, “b”, and “c”.

**Hex to Char**(string) converts hexadecimal to characters. The resulting character string might not be valid display characters. All the characters must be in pairs, in the ranges 0-9, A-Z, and a-z. Blanks and commas are allowed, and skipped. For example,
Hex To Char( "4142" );
returns
"AB"
since 41 and 42 are the hexadecimal equivalents of “A” and “B”.

Hex and Hex To Char are inverses of each other, so

    Hex To Char( Hex( "Abc" ) );
returns
"Abc"

Hex To BLOB(string) takes a string of hexadecimal codes and converts it to a binary object.

    a = Hex To BLOB( "6A6B6C" );
    Show( a );
    a = Char To BLOB("jkl", "ascii~hex")

BLOB Peek(blob,offset,length) extracts bytes as defined by the arguments from a blob.

    b = BLOB Peek( a, 1, 2 );
    Show( b );
    b = Char To BLOB("kl", "ascii~hex")
    b = BLOB Peek( a, 0, 2 );
    Show( b );
    b = Char To BLOB("jk", "ascii~hex")
    b = BLOB Peek( a, 2 );
    Show( b );
    b = Char To BLOB(1", "ascii~hex")

Hex(blob) converts a blob into hexadecimal.

    c = Hex( a );
    Show( c );
    c = "6A6B6C"
    d = Hex To Char( c );
    Show( d );
    d = "jkl"

Concat(blob1,blob2) or blob1 || blob2 concatenates two blobs.

    e = Hex To BLOB( "6D6E6F" );
    Show( e );
    f = a||e;
    Show( f );
    e = Char To BLOB("mno", "ascii~hex")
    f = Char To BLOB("jklmno", "ascii~hex")

Length(blob) returns the number of bytes in a blob.

    g = Length( f );
Show( g );
g = 6

Note: When blobs are listed in the log, they are shown with the constructor function Char To BLOB("...").

Any hex code outside the ASCII range (space to }, or hex 20 - 7D) is encoded as the three-character sequence [-][hexdigit][hexdigit]. For example,

h = Hex To BLOB( "19207D7E" );
Show( h );
i = Hex( h );
Show( i );
  h = Char To BLOB("~19 ~7E", "ascii~hex")
  i = "19207D7E"

Char To BLOB(string) creates a blob from a string, converting ~hex codes.
BLOB To Char(blob) creates a string with ~hex codes to indicate non-visible and non-ASCII codes.

---

Work with Character Functions

This section shows how to use some of the more complex character functions that are described in the JSL Syntax Reference.

Concat

In the Concat function, expressions yielding names are treated like character strings, but globals that have the name values are evaluated. The following example demonstrates that if you have a stored name value, you need to either use Char before storing it in a global, or Name Expr on the global name.

n = {abc};
c = n[1] || "def";
Show( c );
  "abcdef"

m = Expr( mno );
c = m || "xyz";
Show( c );
  Name Unresolved: mno in access or evaluation of 'mno', mno/*###*/
  // The /**##*/ characters indicate the location of an error in the script execution.

m = Expr( mno );
c = Name Expr( m ) || "xyz";
Show( c );
"mnoxyz"

m = Char( Expr( mno ) );
c = m || "xyz";
Show( c );
"mnoxyz"

Concat Items() converts a list of string expressions into a single string, with each item separated by a delimiter. If unspecified, the delimiter is a blank. Its syntax is

resultString = Concat Items ({list of strings}, <"delimiter string">);

For example,
a = {"ABC", "DEF", "HIJ"};
result = Concat Items(a, "/");
returns
"ABC/DEF/HIJ"
Alternatively,
result = Concat Items( a );
returns
"ABC DEF HIJ"

**Munger**

Munger works many different ways, depending on what you specify for its arguments:

Munger(string, offset, find | length, <replace>);

**Table 6.8** Munger behaviors for various types of arguments

<table>
<thead>
<tr>
<th>Find, length, and replace arguments</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify a string as the find and specify no replace string, Munger returns the position (after offset) of the first occurrence find string.</td>
<td>Munger(&quot;the quick brown fox&quot;, 1, &quot;quick&quot;); 5</td>
</tr>
<tr>
<td>If you specify a positive integer as the length and specify no replace string, Munger returns the characters from offset to offset + length.</td>
<td>Munger(&quot;the quick brown fox&quot;, 1, 5 ); &quot;the q&quot;</td>
</tr>
</tbody>
</table>
Table 6.8 Munger behaviors for various types of arguments (Continued)

<table>
<thead>
<tr>
<th>Find, length, and replace arguments</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify a string as the find and specify a replace string, Munger replaces the first occurrence after offset of text with replace.</td>
<td>Munger( &quot;the quick brown fox&quot;, 1, &quot;quick&quot;, &quot;fast&quot; ); &quot;the fast brown fox&quot;</td>
</tr>
<tr>
<td>If you specify a positive integer as the length and specify a replace string, Munger replaces the characters from offset to offset + length with replace.</td>
<td>Munger( &quot;the quick brown fox&quot;, 1, 5, &quot;fast&quot; ); &quot;fastuick brown fox&quot;</td>
</tr>
<tr>
<td>If you specify a positive integer as the length, and offset + length exceeds the length of text, Munger either returns text from offset to the end or replaces that portion of text with the replace string, if it exists.</td>
<td>Munger( &quot;the quick brown fox&quot;, 5, 25); &quot;quick brown fox&quot; Munger( &quot;the quick brown fox&quot;, 5, 25, &quot;fast&quot; ); &quot;the fast&quot;</td>
</tr>
<tr>
<td>If you specify zero as the length and specify no replace string, Munger returns a blank string.</td>
<td>Munger( &quot;the quick brown fox&quot;, 1, 0 ); &quot;&quot;</td>
</tr>
<tr>
<td>If you specify zero as the length and specify a replace string, the string is inserted before the offset position.</td>
<td>Munger( &quot;the quick brown fox&quot;, 1, 0, &quot;see &quot; ); &quot;see the quick brown fox&quot;</td>
</tr>
<tr>
<td>If you specify a negative integer as the length value and specify no replace string, Munger returns all characters from the offset to the end of the string.</td>
<td>Munger( &quot;the quick brown fox&quot;, 5, -5 ); &quot;quick brown fox&quot;</td>
</tr>
<tr>
<td>If you specify a negative integer for length and specify a replace string, Munger replaces all characters from the offset to the end with the replace string.</td>
<td>Munger( &quot;the quick brown fox&quot;, 5, -5, &quot;fast&quot; ); &quot;the fast&quot;</td>
</tr>
</tbody>
</table>

**Repeat**

The Repeat() function makes copies of its first argument into a result. The second (and sometimes a third) argument is the number of repeats, where 1 means a single copy.
