If the first argument evaluates to a character value or list, the result is that many copies.

`Repeat( "abc", 2 );`
Chapter 6
Types of Data

Scripting Guide
Work with Character Functions

"abcabc"
Repeat( {"A"}, 2 );
{"A", "A"}
Repeat( {1, 2, 3}, 2 );
{1,2,3,1,2,3}

If the first argument evaluates to a number or matrix, the result is a matrix. The second argument is the number of row repeats, and a third argument can specify the number of column repeats. If only two arguments are specified, the number of column repeats is 1.

Repeat( [1 2, 3 4], 2, 3 );
[ 1 2 1 2 1 2,
 3 4 3 4 3 4,
 1 2 1 2 1 2,
 3 4 3 4 3 4]
Repeat( 9, 2, 3 );
[ 9 9 9,
 9 9 9]

The repeat function is compatible with the function of the same name in the SAS/IML language, but is incompatible with the SAS character DATA step function, which repeats one more time than this function.

Substitute and Substitute Into

The Substitute() function returns a copy of a string with a replacement expression. The Substitute Into() function changes the original string with a replacement expression.

For example, consider the following script:

str1 = str2 = "All things considered";

// str3 holds the result of the Substitute, and str1 is not changed
str3 = Substitute( str1, "All", "Some" );

/*/ Substitute Into returns nothing, so str4 is missing, and str2 is changed and now holds the result of Substitute Into */
str4 = Substitute Into( str2, "All", "Some" );
Show( str1, str2, str3, str4 );

This script returns the following output:

str1 = "All things considered";
str2 = "Some things considered";
str3 = "Some things considered";
str4 = .;
Regular Expressions

A regular expression is a specification of a pattern frequently used to clean up or extract pieces of data. You can search for a pattern and replace it with a different string or extract specific parts of the string. Define the pattern in the `Regex()` or `Regex Match()` function.

- “Regex”
- “Regex Match”
- “Special Characters in Regular Expressions”
- “Escaped Characters in Regular Expressions”
- “Greedy and Reluctant Regular Expressions”
- “Backreferences and Capturing Groups”
- “Lookaround Assertions”

Regex

`Regex()` searches for a pattern within a source string and returns a string. It simply identifies a pattern in a string or transforms a string into another string.

```plaintext
Regex(source, pattern, (<replacement string>, <GLOBALREPLACE>), <format>, <IGNORECASE>);
```

IGNORECASE disregards case. GLOBALREPLACE repeats the match until the entire string is processed. format is a backreference to the matched group. `Regex()` returns missing if the match fails.

Example of Matching a String

`bus | car` is the regular expression (in quotation marks because it is a string). The expression means match “bus” or “car”.

```plaintext
sentence = "I took the bus to work.";
vehicle = Regex( sentence, "bus|car" );
"bus"
```

Examples of Replacing a String

The third optional argument in `Regex()` is a specification of the result string. The default value, \0, is a backreference to everything that was matched by the regular expression. In the preceding example, the word “bus” is matched in `sentence`. The default third argument, \0, replaces the entire sentence with “bus”.

A more interesting variation uses parentheses to create additional backreferences.
sentence = "I took the bus to work."

Regex( sentence, "(.*) bus (.*)", "\1 car \2" );
"I took the car to work."

The (.*) before and after bus are part of the regular expression. The parentheses create a capturing group. The . matches any character. The * matches zero or more of the previous expression. As a result, the first parenthesis pair matches everything before bus, and the second parenthesis pair matches everything after bus. The third argument, \1 car \2, reassembles the text; it leaves out bus and substitutes car.

See “Backreferences and Capturing Groups” on page 181.

**Example of Global Replacement**

GLOBALREPLACE changes the behavior of Regex(). If the match succeeds, the entire source string is returned with substitutions made for each place where the pattern matches. If there are no matches, an unchanged source string is returned.

sentence = "I took the red bus followed by the blue bus to get to work today."

Regex( sentence, "bus", "car", GLOBALREPLACE);
"I took the red car followed by the blue car to get to work today."

You can also use backreferences. This example starts with a different sentence.

sentence = "I took the red bus followed by the blue car to get to work today."

Regex(
    sentence,
    "(\w*) (bus|car)",
    "bicycle (not \2) that was \1",
    GLOBALREPLACE
);
"I took the bicycle (not bus) that was red followed by the bicycle (not car) that was blue to get to work today."

The \w* matches zero or more word characters and becomes backreference 1 because of the parentheses. bus|car becomes backreference 2 because of the parentheses. The third argument, bicycle (not \2) that was \1, describes how to build the substitution text for the part of the source text that was matched.

Notice how the backreferences can be used to swap data positions. This might be useful for swapping the position of first names and last names.
### Regex Match

Regex Match() returns an empty list with zero elements if the match fails. If the match succeeds, the first list is the text of the entire match (backreference 0). The second list is the text that matches backreference 1, and so on.

\[
\text{Regex Match(source, pattern, <replacement>|<MATCHCASE>, <NULL>)}
\]

Unlike Regex(), Regex Match() is case insensitive. Include MATCHCASE for a case-sensitive match. Include NULL if you want to match case but there is no replacement text.

#### Example of Parsing Name-Value Pairs

The following example parses pairs of names and values.

\[
\text{Regex Match(}
\]

```
"person=Fred id=77 friend= favorite=tea",
"\(\w+\)=\(\S*\) \(\w+\)=\(\S*\) \(\w+\)=\(\S*\) \(\w+\)=\(\S*\)"
```

```
;
\{"person=Fred id=77 friend= favorite=tea", "person", "Fred", "id", "77",
"friend", "", "favorite", "tea"\}
```

The \(\w+\) matches one or more word characters. The \(\S*\) matches zero or more characters that are not spaces. In the resulting JSL list, the field names (person, id, friend, favorite) and their corresponding values (Fred, 77, '', tea) are separate strings.

If the first argument to Regex Match() is a variable and a third argument specifies the replacement value, the matched text is replaced in the variable.

#### Comparing Regex and Regex Match

Regex() and Regex Match() match a pattern in a given string but return different results. To transforms your string into another string, use Regex(). To identify the substrings that match specific parts of the pattern, use Regex Match().

This example shows the efficiency of Regex Match() compared to Regex(). The source is a list of six strings. The goal is to extract portions of those six strings into the subject, verb, and object columns of a data table.

#### Figure 6.4 Final Data Table

<table>
<thead>
<tr>
<th></th>
<th>subject</th>
<th>verb</th>
<th>object</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>cat</td>
<td>ate</td>
<td>chicken</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
<td>chased</td>
<td>cat</td>
</tr>
<tr>
<td>3</td>
<td>ralph</td>
<td>like</td>
<td>mary</td>
</tr>
<tr>
<td>4</td>
<td>girl</td>
<td>pets</td>
<td>dog</td>
</tr>
<tr>
<td>5</td>
<td>cat</td>
<td>chased</td>
<td>dog</td>
</tr>
</tbody>
</table>
source = {"the cat ate the chicken", "the dog chased the cat", "did ralph like mary", "the girl pets the dog", "these words are strange", "the cat was chased by the dog"};

dt = New Table( "English 101", // create the data table
    New Column( "subject", character ),
    New Column( "verb", character ),
    New Column( "object", character )
);
// iterate through the strings in the list
For( i = 1, i <= N Items( source ), i++,

    // assign the result of each match to matchList
    matchList = Regex Match(
        source[i],
        /* scan each string, match zero or more characters
           and one item in each group */
        ".*?(cat|dog|ralph|girl).*?(ate|chased|like|pets).*?(chicken|cat|mary|dog)"
    );

    /* If matchList has zero items (string 5), don't add a row
       to the table. Put each matched string in separate
       data table cells. */
    If( N Items( matchList ) > 0,
        dt << Add Rows( 1 );
        dt:subject = matchList[2]; // match the first open parenthesis
        dt:verb = matchList[3]; // match the second open parenthesis
        dt:object = matchList[4]; // match the third open parenthesis
    );
);

Regex Match() returns {"the cat was chased by the dog", "cat", "chased", "dog"} in a single try with each answer in a separate string. Compare this example to a similar one using Regex(), which returns one answer at a time and builds the final string using backreferences.

For( i = 1, i <= N Items( source ), i++,
    s = Regex( source[i],
        ".*?(cat|dog|ralph|girl).*?(ate|chased|like|pets).*?(chicken|cat|mary|dog)"
    ', "\1" ); // match an item in the first group
    v = Regex( source[i],
        ".*?(cat|dog|ralph|girl).*?(ate|chased|like|pets).*?(chicken|cat|mary|dog)"
    ', "\2" ); // match an item in the second group
Backreferences are discussed in “Backreferences and Capturing Groups” on page 181.

Special Characters in Regular Expressions

Special characters are commonly used in regular expressions. The period is a special character that matches one instance of the specified character. It must be escaped with a backslash to be interpreted as a period. In the following expression, the period is replaced with an exclamation point.

```regex
Regex( "Bicycling makes traveling to work fun.", ".", "!", GLOBALREPLACE );
"Bicycling makes traveling to work fun!"
```

Table 6.9 describes the special characters and provides examples.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
</table>
| \ | Precedes a literal character.  
| <\a> interprets the forward slash literally in the end HTML anchor tag.  
| Precedes an escape sequence.  
| \n matches a newline character. |
| ^ | Matches the beginning of a string, not including the newline character.  
| ^apple matches “apple” at the beginning of a string. |
| $ | Matches the end of a string, not including the newline character.  
| apple$ matches “apple” at the end of a string. |
| . | Matches any single character including a newline character.  
| .apple matches any single character and then “apple”. |
| | Represents a logical OR to separate alternative values.  
| (apple|orange|banana) matches “apple”, “orange”, or “banana”. |
Escaped Characters in Regular Expressions

The backslash in a regular expression precedes a literal character. You also escape certain letters that represent common character classes, such as \w for a word character or \s for a space. The following example matches word characters (alphanumeric and underscores) and spaces.

```
Regex(
    "Are you there, Alice?, asked Jerry.", // source
    "(here|there).+(\w+).+(said|asked)(\s)(\w+)\." ); // regular expression
    "there, Alice?, asked Jerry."
)
```

<table>
<thead>
<tr>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>\w+</td>
<td>Matches zero or one instance.</td>
</tr>
<tr>
<td>\w{3}</td>
<td>apple matches one word.</td>
</tr>
<tr>
<td>\w{3,}</td>
<td>apple repeats at least 3 times.</td>
</tr>
<tr>
<td>\w{3,10}</td>
<td>apple repeats at most 10 times.</td>
</tr>
<tr>
<td>\w{3,}?</td>
<td>apple repeats at most 3 times.</td>
</tr>
</tbody>
</table>

\w matches “a” through “z” and numbers “0” through “9”.

\s matches a whitespace character or a digit.

[a-z0-9] matches “a” through “z” and numbers “0” through “9”.

\( ) Encloses a sub-expression.

(\w+) matches “Alice”.

\[ ] Encloses an expression that matches set of characters.

[\s] matches a whitespace character or a digit.

[a-z0-9] matches “a” through “z” and numbers “0” through “9”.

\{ \} Encloses an expression that represents repetition.

\w{3} repeats three times.

\w{3,} repeats at least three times as many times as possible.

\w{3, 10} repeats three times but no more than 10 times.

Append a question mark to indicate repeating as few times as possible. For example, \w{3,}? repeats at least three times as few times as possible.
Table 6.10 describes the escaped characters supported in JMP. \C, \G, \X, and \z are not supported.

**Table 6.10 Escaped Characters**

<table>
<thead>
<tr>
<th>Escape</th>

<td>word character [a-zA-Z0-9_]</td>
</tr>
<tr>
<td>\W</td>
<td>single character that is NOT a word character [^a-zA-Z0-9_]</td>
</tr>
</tbody>
</table>
Greedy and Reluctant Regular Expressions

The ?, *, and + operators are greedy by default. They match as many of the preceding character as possible. The ? operator makes them reluctant; ?? matches 0, then 1 if needed; +? matches 1 and then additional characters; *? matches 0 and then additional characters.

The following example starts at the letter n and compares it to the first \d (digits) in the pattern. No digit matches. Because the pattern does not begin with ^ (start of line), the matcher advances to u. The process repeats until the 3 matches the first \d and the 2 matches the second \d.

```c
Regex( "number=32.5", \d\d\ );
"32"
```

Change the pattern to use the greedy + (match one or more).

```c
Regex( "number=324.5", \d+\ );
"324"
```

The preceding example begins much the same, but as soon as the 3 is found and the \d matches, the + greedily matches the 2 and the 4.

Usually, the greedy behavior makes pattern matching faster because the string is consumed sooner. Sometimes a reluctant behavior is better. Adding the ? after the * or + changes them from greedy to reluctant.

```c
Regex( "number=324.5", \d+?\ );
"3"
```

Here, + requires at least one match of a digit character, but ? changes it from “as many as possible” to “as few as possible”. It stopped after the 3 because the pattern was satisfied.

Compare the following results.

Greedy:

```c
Regex( "number=324.5", \(\d+)(\d+)/", "first=\1 second=\2" );
"first=32 second=4"
```

Reluctant:

```c
Regex( "number=324.5", \(\d+?)(\d+)/", "first=\1 second=\2" );
"first=3 second=24"
```
In the greedy example above, the matcher greedily matched 3, 2, and 4 for the first \d+. The matcher then had to give back the 4 so that the second \d+ could match something. The reluctant example followed a different path to get a different answer. Initially, the second value was 2, but the pattern could not match the period to the 4, so the second \d+? reluctantly matched the 4 as well.

**Use the Reluctant Match for Speed**

The greedy and reluctant matches usually produce the same result but not always. See the previous section. One reason you might need the reluctant match is for speed. Suppose that you have a million-character string that begins “The quick fox…" and you want to find the word before “fox”. You might write the following expression and expect \1 to contain “quick”.

The (\.+?) fox

\1 might contain “quick” eventually, after the .+ grabs the million characters to the end of the string and then gives them up, one at a time, until “fox” is found. If there is more than one “fox”, it will be the last fox, not this one. To speed it up and make sure we get the first fox, add the ? operator.

The (\.+?) fox

The ? advances one character at a time to get past “quick” and find the first “fox”. This method is much faster than going too far.

Typically, the + or * operator is applied to a more restrictive expression such as \d* to match a run of digits, and greedy is faster than reluctant.

Aside from the multiple fox possibility, greedy and reluctant eventually get the same answer. Using the right operator speeds up the match. The right one might be greedy, or it might be reluctant. It depends on what is being matched.

The greedy .* finds the last fox after backing up.

```
Regex(
    "The quick fox saw another fox eating grapes",
    "The (\.*) fox",
    "\1"
);
"quick fox saw another"
```

The reluctant .*? stops on the first fox.

```
Regex(
    "The quick fox saw another fox eating grapes",
    "The (\.*?) fox",
    "\1"
);
"quick"
```
The greedy .* has to back up a lot. There is no second fox.

```javascript
Regex(
    "The quick fox saw another animal eating grapes",
    "The (.*) fox",
    "\1"
);  // quick
```

The greedy word character match is an even better choice for this problem.

```javascript
Regex(
    "The quick fox saw another fox eating grapes",
    "The (\w*) fox",
    "\1"
);  // quick
```

### Backreferences and Capturing Groups

A regular expression can consist of patterns grouped in parentheses, also known as capturing groups. In ([a-zA-Z])\s([0-9]), ([a-zA-Z]) is the first capturing group; ([0-9]) is the second capturing group.

Use a backreference to replace the pattern matched by a capturing group. In Perl, these groups are represented by the special variables $1, $2, $3, and so on. ($1 indicates text matched by the first parenthetical group.) In JMP, use a backslash followed by the group number (\1, \2, \3).

The following example includes a third argument that specifies the replacement text and backreferences.

```javascript
Regex(
    "   Are you there, Alice?, asked Jerry.", // source
    " (here|there).+ (\w+).+(said|asked) (\w+)\.", // regular expression
    "   I am \1, \4, replied \2." ); // optional format argument
    "   I am there, Jerry, replied Alice."

"   I am \1, " Creates the text “I am”, a space, and then the first matched pattern, “there”.
\4, " Creates the text “Jerry” with the fourth matched pattern (\w+).
replied \2." " Creates the text “replied” and a space. Matches “Alice.” with the second matched pattern (\w+).
Lookaround Assertions

Lookaround assertions check for a pattern but do not return that pattern in the results. Lookaheads look forward for a pattern. Lookbehinds look back for a pattern.

Negative Lookahead Example

Negative lookaheads check for the absence of a pattern before a specific pattern. ?! indicates a negative lookahead. The following expression matches a comma not followed by a number or space and replaces the pattern with a comma and space:

```regex
Regex( "one,two 1,234 cat,dog,duck fish, and chips, to go",
     ",(?![d|\s])", ", ", GLOBALREPLACE );
"one, two 1,234 cat, dog, duck fish, and chips, to go"
```

Positive Lookahead Example

Positive lookaheads check for the presence of a pattern before a specific pattern. ?= indicates a positive lookahead. The following expression has the same result as the preceding negative lookahead but matches a comma followed by any lowercase character:

```regex
Regex( "one,two 1,234 cat,dog,duck fish, and chips, to go",
     ",(?=[a-z])", ", ",GLOBALREPLACE );
"one, two 1,234 cat, dog, duck fish, and chips, to go"
```

Positive Lookbehind Example

In this example, the positive lookbehind regular expression matches the “ssn=” or “salary=” keywords without including the keyword in the matched text. The matched text is the string of characters that consists of zero or more dollar signs, digits, and hyphens.

```python
data = "name=bill salary=$5 ssn=123-45-6789 age=13,name=mary salary=$6
      ssn=987-65-4321 age=14";
redacted = Regex(data, "(?<=(ssn=)|(salary=))\[$\d-]*", "###", GLOBALREPLACE);
"name=bill salary=### ssn=### age=13,name=mary salary=### ssn=### age=14"
```

Here is another way to get the same result using a backreference substitution. ((ssn=)|(salary=)) is the capturing group. "\1" is the backreference to that group.

```python
data = "name=bill salary=$5 ssn=123-45-6789 age=13,name=mary salary=$6
      ssn=987-65-4321 age=14";
redacted = Regex(data, "((ssn=)|(salary=))\[$\d-]*", "\1###", GLOBALREPLACE);
"name=bill salary=### ssn=### age=13,name=mary salary=### ssn=### age=14"
```

Backreferences are discussed in “Backreferences and Capturing Groups” on page 181.
Pattern Matching

Pattern matching in JSL is a flexible method for searching and manipulating strings.

You define and use pattern variables just like any JMP variable:

```javascript
i = 3; // a numeric variable
a = "Ralph"; // a character variable
t = textbox("Madge"); // a display box variable
p = ( "this" | "that" ) + patSpan(" ")
    + ( "car" | "bus" ); // a pattern variable
```

When the above statement executes, `p` is assigned a pattern value. The pattern value can be used either to construct another pattern or to perform a pattern match. The `patSpan` function returns a pattern that matches a span of characters specified in the argument; `patSpan("0123456789")` matches runs of digits.

```javascript
p2 = "Take " + p + "."; // using p to build another pattern
If( Pat Match( "Take this bus.", p2 ), // performing a match
    Print( "matches" ),
    Print( "no match" )
);
```

Sometimes all you need to know is that the pattern matched the source text, as above. Other times, you might want to know what matched; for example, was it a bus or a car?

```javascript
p = ( "this" | "that") + Pat Span( " " ) + ("car" | "bus") >?
    vehicleType; // conditional assignment ONLY if pattern matches
If( Pat Match( "Take this bus.", p ),
    // do not use vehicleType in the ELSE because it is not set
    Show( vehicleType ),
    Print( "no match" )
);
```

You could pre-load `vehicleType` with a default value if you do not want to check the outcome of the match with an `if`. The `>?` conditional assignment operator has two arguments, the first being a pattern and the second a JSL variable. `>?` constructs a pattern that matches the pattern (first argument) and stores the result of the match in the JSL variable (second argument) after the pattern succeeds. Similarly, `>>` does not wait for the pattern to succeed. As soon (and as often) as the `>>` pattern matches, the assignment is performed.

```javascript
findDelimString = Pat Len( 3 ) >> beginDelim + Pat Arb() >?
    middlePart +Expr( beginDelim );
testString = "SomeoneSawTheQuickBrownFoxJumpOverTheLazyDog'sBack";
rc = Pat Match( testString, findDelimString, "<<<" || middlePart || ">>>" );
Show( rc, beginDelim, middlePart, testString );
```
The above example shows a third argument in the `patMatch` function: the replacement string. In this case, the replacement is formed from a concatenation (|| operator) of three strings. One of the three strings, `middlePart`, was extracted from the `testString` by `?>` because the replacement cannot occur unless the pattern match succeeds (`rc == 1`).

Look at the pattern assigned to `findDelimString`. It is a concatenation of 3 patterns. The first is a `>>` operator that matches 3 characters and assigns them to `beginDelim`. The second is a `?>` operator that matches an arbitrary number of characters and, when the entire match succeeds, assigns them to `middlePart`. The last is an unevaluated expression, consisting of whatever string is in `beginDelim` at the time the pattern is executing, not at the time the pattern is built. Just like `expr()`, the evaluation of its argument is postponed. That makes the pattern hunt for two identical three letter delimiters of the middle part.

Other pattern functions might be faster and represent the problem that you are trying to solve better than writing a lot of alternatives; for example, "a"|"b"|"c" is the same as `Pat Any("abc")`. The equivalent example for `Pat Not Any("abc")` is much harder. Similar to `Pat Span` (above), `Pat Break("0123456789")` matches up to, but not including, the first number.

Here is a pattern that matches numbers with decimals and exponents and signs. It also matches some degenerate cases with no digits; look at the pattern assigned to `digits`.

```plaintext
digits = Pat Span( "0123456789" ) | "";

number = (Pat Any( "+-" ) | ") >? signPart + (digits) >? wholePart + ("." +digits | ") >? fractionPart + (Pat Any( "eEdD" ) + (Pat Any( "+-" ) | ") + digits | "") >? exponentPart;

If( Pat Match( "-123.456e-78", number ), Show( signPart, wholePart, fractionPart, exponentPart ) );
```

### Parsing Strings in Fixed Fields

Sometimes data is in fixed fields. The `Pat Tab()`, `Pat R Tab()`, `Pat Len()`, `Pat Pos()`, and `Pat R Pos()` functions make it easy to split out the fields in a fixed field string. `Pat Tab()` and `Pat R Tab()` work from the left and right end of the string and take a number as their argument. They succeed by matching forward to the specified tab position. For example:

```plaintext
p = Pat Pos(10) + Pat Tab(15);
```

`Pat Pos(10)` matches the null string if it is in position 10. So at match time, the matcher works its way forward to position 10, then `Pat Tab(15)` matches text from the current position (10) forward to position 15. This pattern is equivalent to `Pat Pos(10)+patLen(5)`. Another example:

```plaintext
p = Pat Pos(0) + Pat R Tab(0);
```
This example matches the entire string, from 0 characters from the start to 0 characters from the end. the `Pat Rem()` function takes no argument and is shorthand for `Pat R Tab(0)`; it means the remainder of the string. Pattern matching can also be anchored to the beginning of the string like this:

```
Pat Match( "now is the time", Pat Len(15) + Pat R Pos(0), NULL, ANCHOR );
```

The above pattern uses `NULL` rather than a replacement value, and `ANCHOR` as an option. Both are uppercase, as shown. `NULL` means that no replacement is done. `ANCHOR` means that the match is anchored to the beginning of the string. The default value is `UNANCHORED`.

Patterns can be built up like this, but this is not recursive:

```
p = "a" | "b"; // matches one character
p = p + p; // two characters
p = p + p; // four characters
Pat Match( "babb", Pat Pos(0) + p + Pat R Pos(0) );
```

A recursive pattern refers to its current definition using `Expr()`:

```
p = "<" + Expr(p) + "*" + Expr(p) + ">" | "x";
Pat Match( "<<x*<x*x>>*x>", Pat Pos(0) + p + Pat R Pos(0) );
```

Remember, `expr()` is the procrastination function; when the pattern is assigned to the variable `p`, `expr()` delays evaluating its argument (`p`) until later. In the next statement, `patMatch` performs the pattern match operation, and each time it encounters `expr()`, it looks for the current value of the argument. In this example, the value does not change during the match. So, if `p` is defined in terms of itself, how can this possibly work?

`p` consists of two alternatives. The right hand choice is easy: a single letter `x`. The left side is harder: `<p*p>`. Each `p` could be a single letter `x`, since that is one of the choices `p` could match, or it could be `<p*p>`. The last few example have used `patPos(0) + ... + patRPos(0)` to make sure the pattern matches the entire source text. Sometimes this is what you want, and sometimes you would rather the pattern match a subtext. If you are experimenting with these examples by changing the source text, you probably want to match the entire string to easily tell what was matched. The result from `Pat Match` is 0 or 1.

This example uses “Left” recursion:

```
x =  Expr(x) + "a" | "b"; // + binds tighter than |
```

If the pattern is used in `FULLSCAN` mode, it eventually uses up all memory as it expands. By default, the `patMatch` function does not use `FULLSCAN`, and makes some assumptions that allow the recursion to stop and the match to succeed. The pattern matches either a “b”, or anything the pattern matches followed by an “a”.

```
rc = Pat Match( "baaaaa", x );
```
Patterns and Case

Unlike regular expressions, pattern matching is case insensitive. To force case sensitivity, you can add the named argument MATCHCASE to either `Pat Match()` or `Regex Match()`. For example:

```plaintext
string = "abcABC";

result = Regex Match( string, Pat Regex( "[aBc]+" ) );
Show( string, result );
  // *returns string = "abcABC"
result = {"abcABC"}*/

result = Regex Match( string, Pat Regex( "[cba]+" ), NULL, MATCHCASE );
Show( string, result );
  // * returns string = "abcABC"
result = {"abc"}*/
```

Troubleshooting Patterns

When a pattern isn’t working the way you expect, use `Log()` to send pieces of the match to the JMP log. The following example shows how to debug pattern matching and rewrite a script to account for the white space between words in the phrase “the quick brown fox”.

```plaintext
// greedy match for one or more characters except for white space
word = Pat Repeat( Pat Not Any( " " ) );

Pat Match(
  "the quick brown fox",
  word >> a +
  word >> b +
  word >> c +
  word >> d
);

Show( a, b, c, d );
  a = "qu";
  b = "i";
  c = "c";
  d = "k";

The output is probably not what you want, given the name of the pattern `word`. None of the words in the pattern were matched.

The `Show( a, b, c, d )` expression is a good first step. If it doesn’t tell you how JMP got that answer, try inserting `Log()`:

```plaintext
word = Pat Repeat( Pat Not Any( " " ) );
```
Pattern Matching

```
Pat Match(
    "the quick brown fox",
    (word >> a) >> Log("a") +
    (word >> b) >> Log("b") +
    (word >> c) >> Log("c") +
    (word >> d) >> Log("d")
);

Show( a, b, c, d );
0(a) the (the number 0 is the position of the match)
0(a) th (the “a” is an arbitrary identifier you supplied to the log)
2(b) e ...
4(a) quick
4(a) quic ...
```

With this extra information, you can now see into the workings of the match, how the word pattern does, in fact, match a word, at least initially. But then it backs up and tries a smaller amount of the word so that the next word pattern can match some non-whitespace characters. However, there’s no provision in this pattern to match the white space between words. And that’s exactly what it did (find four consecutive words of one or more non-whitespace characters). Maybe the following script is what you need:

```
word = Pat Repeat( Pat Not Any(" ") );
gap = Pat Repeat( Pat Any(" "), 1, 999, GREEDY );

Pat Match(
    "the quick brown fox",
    word >> a + gap +
    word >> b + gap +
    word >> c + gap +
    word >> d
);

Show( a, b, c, d );
a = "the";
b = "quick";
c = "brown";
d = "fox";
```
JSL provides these basic data structures that can hold a variety of data in a single variable:

- A list holds a number of other values, including nested lists and expressions.
- A matrix is a row-by-column table of numbers.
- An associative array maps keys to values, which can be almost any other type of data.

Lists

Lists are containers to store items, such as the following:

- numbers
- variables
- character strings
- expressions (for example, assignments or function calls)
- matrices
- nested lists

Create a list in one of the following ways:

- use the `List` function
- use `{}` curly braces

Examples

Use the `List()` function or curly braces to create a list that includes numbers and variables:

```plaintext
x = List(1, 2, b);
x = {1, 2, b};
```

A list can contain text strings, nested lists, and function calls:

```plaintext
{"Red", "Green", "Blue", {1, "true"}, sqrt( 2 )};
```

You can place a variable into a list and assign it a value at the same time:

```plaintext
x = {a = 1, b = 2};
```

Evaluate Lists

When you run a script that contains a list, a copy of the list is returned. The items inside the list are not evaluated.

```plaintext
b = 7;
x = {1, 2, b, Sqrt( 3 )};
Show( x );
x = {1, 2, b, Sqrt(3)};
```

To evaluate items in a list, use the `Eval List()` function.

```plaintext
b = 7;
x = {1, 2, b, Sqrt( 3 )};
c = Eval List( x );
{1, 2, 7, 1.73205080756888}
```
When using a list of variables that reference lists, you will need to use an `Eval()` function.

Consider the following example, where you have a variable called `fullMonth` that is a list of 12 items.

```plaintext
::fullMonth = {January, February, March, April, May, June, July, August, September, October, November, December};
::abbrevMonth = {Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec};
::dow = {Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday};
::levels = {Very Low, Low, Medium Low, Medium, Medium High, High, Very High};
::feel = {Strongly Disagree, Disagree, Neutral, Indifferent, Agree, Strongly Agree};
::rating = {Failing, Unacceptable, Very Poor, Poor, Bad, Acceptable, Average, Good, Better, Very Good, Excellent, Best};
::mlist = {::fullMonth, ::abbrevMonth, ::dow, ::levels, ::feel, ::rating};
N Items(::fullMonth); // returns 12 because fullMonth has 12 items.
N Items(::mlist[1]); /* returns this message: "N Items() argument must be a list" because ::mlist[1] is a variable (fullMonth) and fullMonth is a list. */
```

When you add the `Eval()` function:

```plaintext
N Items( Eval( ::mlist[1] ) );
12 /* returns 12 because ::mlist[1] holds ::fullMonth, and evaluating it returns ::fullMonth's list. */
```

In a loop, you need the `Eval()` function in the nested loop to evaluate the variable’s contents. For example:

```plaintext
For( g = 1, g <= N Items( ::mlist ), g++,
    For( i = 1, i <= N Items( ::mlist[g] ), i++,
        Show( ::mlist[g][i] )
    )
);
// returns the message "N Items() argument must be a list."
```

To fix the problem, add the `Eval()` function:

```plaintext
::mlist = {::fullMonth, ::abbrevMonth, ::dow, ::levels, ::feel, ::rating};
For( g = 1, g <= N Items( ::mlist ), g++,
    For( i = 1, i <= N Items( Eval( ::mlist[g] ) ), i++,
        Show( ::mlist[g][i] )
    )
);
```
Assignments with Lists

Create a list to assign values to variables.

Examples

\{a, b, c\} = \{1, 2, 3\};  // assign 1 to a, 2 to b, and 3 to c
\{a, b, c\}--;  // decrement a, b, and c
\{\{a\}, \{b, c\}\}++;  // increment a, b, and c by 1

mylist = \{1, log(2), e()^pi(), height[40]\};  // store the expressions

Perform Operations in Lists

In lists, you can perform operations.

\a = \{{{1, 2}, 3, \{4, 5\}\}};
\b = \{{{10, 20}, 30, \{40, 50\}\}};
\c = \a + \b;
\c = \{{{11, 22}, 33, \{44, 55\}\}}

Find the Number of Items in a List

To determine the number of items in a list, use the N Items() function.

\x = \{1, 2, y, Sqrt(3), \{a, b, 3\}\};
\N = N Items(\x);
Show(\n);
\n = 5;

Subscripts

Subscripts extract specified items from a list. Use a list as a subscript to return multiple items from a list.

Note: JSL starts counting from 1, so the first element in a list is [1], not [0] as in some other languages.

Examples

List \a contains four items.

\a = \{"bob", 4, \{1, 2, 3\}, \{x, y, z\}\};
Show(\a[1]);
\a[1] = "bob";
Show(\a[{1, 3}]);
You can also use subscripts to select or change items in a list:

```plaintext
a[{1, 3}] = {"bob", [1, 2, 3]};
a[2] = 5; // assign 5 to the second list item
```

When you have assignments or functions in a list, you can use a quoted name for the subscript to extract the value.

```plaintext
x={sqrt( 4 ), log( 3 )};
xx= {a = 1, b = 3, c = 5};
x["sqrt"];
 4
xx["b"];
 3
```

The name must be in quotation marks, or else JMP tries to evaluate it and use its value. The following example shows the values of the second item in the list, rather than the value of a in the list.

```plaintext
a = 2;
Show( xx[a] );
  xx[a] = b = 3;
```

**Notes:**

- Multiple left-side subscripts (for example, `a[i][j] = value` where `a` contains a list of things that are subscriptable) are allowed in the following circumstances:
  - Each level except the outermost level must be a list. So, in the example above, `a` must be a list but `a[i]` can be anything subscriptable.
  - Each subscript except the last must be a number. So, in the example above, `i` must be a number, but `j` could be a matrix or list of indices.

- Subscripting can be done to any level of nesting, such as the following:
  ```plaintext
  a[i][j][k][l][m][n] = 99;
  ```

**Note:** To get a value in the matrix of an expression column, use double subscripts, as in `:Discrim Data Matrix[row()][i]`.

```plaintext
a[1, 3] = {"bob", [1, 2, 3]};
a[2] = 5; // assign 5 to the second list item
```
Locate Items in a List

Use the `Loc()` function or the `Contains()` function to find values in a list:

```plaintext
Loc( list, value );
Contains( list, value );
```

`Loc()` and `Contains()` return the positions of the values. `Loc()` returns the results in a matrix, and `Contains()` returns the results as a number.

**Notes:**

- The `Loc` function returns each occurrence of a repeated value. `Contains()` returns only the first occurrence of a repeated value.
- If the value is not found, the `Loc` function returns an empty matrix and `Contains()` returns a zero.
- To assess whether an item is in a list, use `Loc()` and `Contains()` with `>0`. A returned value of zero means that the item is not in the list. A returned value of 1 means that the item is in the list at least once.

**Note:** For more information about matrix manipulation and a description of the equivalent `Loc()` command for matrices, see “Matrices” on page 202.

**Examples**

```plaintext
nameList = {"Katie", "Louise", "Jane", "Jane"};
numList = {2, 4, 6, 8, 8};
```

Search for the value "Katie" in the `nameList`:

```plaintext
Loc( nameList, "Katie" );
[1]
Contains( nameList, "Katie" );
1
```

Search for the value "Erin" in the `nameList`:

```plaintext
Loc( nameList, "Erin" );
[]
Contains( nameList, "Erin" );
0
```

Search for the number 8 in the `numList`:

```plaintext
Loc( numList, 8 );
[4, 5]
Contains( numList, 8 );
4
```

Find out if the number 5 exists in the `numList`:
List Operators and Functions

Table 7.1 describes the list operators and their syntax.

Table 7.1 List Operators

<table>
<thead>
<tr>
<th>Operator and Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>As List()</td>
<td>As List(matrix)</td>
<td>Returns the matrix as a list. A matrix with multiple columns is returned as a list of lists, one list per row.</td>
</tr>
<tr>
<td>=</td>
<td>Assign()</td>
<td>= value</td>
</tr>
<tr>
<td>+=</td>
<td>Add To()</td>
<td>+= value</td>
</tr>
<tr>
<td>-=</td>
<td>SubtractTo()</td>
<td>-= value</td>
</tr>
<tr>
<td>*=</td>
<td>MultiplyTo()</td>
<td>*= value</td>
</tr>
<tr>
<td>/=</td>
<td>DivideTo()</td>
<td>/= value</td>
</tr>
<tr>
<td>++</td>
<td>Post Increment()</td>
<td>++ value</td>
</tr>
<tr>
<td>--</td>
<td>Post Decrement()</td>
<td>-- value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>=</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- If you want to test equality of lists, use \(==\), not \(=\).
- JMP does not have pre-increment or pre-decrement operators. Instead, use the Add To() operator, which is \(+=\), or the Subtract To() operator, which is \(-=\).
Table 7.1 List Operators (Continued)

<table>
<thead>
<tr>
<th>Operator and Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eval List()</td>
<td>Eval List(list)</td>
<td>Returns a list of the evaluated expressions inside list. See “Evaluate Lists” on page 191.</td>
</tr>
<tr>
<td>Insert Into()</td>
<td>Insert Into(list, x, &lt;i&gt;)</td>
<td>Inserts a new item (x) into the list at the given position (i). If i is not given, the item is added to the end of the list. This function does change the original list.</td>
</tr>
<tr>
<td>Insert()</td>
<td>list = Insert(list, x, &lt;i&gt;)</td>
<td>Returns a copy of the list with a new item (x) inserted into the list at the given position (i). If i is not given, the item is added to the end of the list. This function does not change the original list.</td>
</tr>
<tr>
<td>Is List()</td>
<td>Is List(arg)</td>
<td>Returns true (1) if arg is a classical list (in other words, one that would result from the construction by List(items) or {items}) and returns false (0) otherwise. An empty list is still a list, so IsList({}) returns true. If miss=., then IsList(miss) returns false, not missing.</td>
</tr>
<tr>
<td>{ } List</td>
<td>List(a, b, c)</td>
<td>Constructs a list from a set of items. An item can be any expression, including other lists. Items must be separated by commas. Text should either be enclosed in double quotation marks (&quot; &quot;) or stored in a variable and called as that variable.</td>
</tr>
<tr>
<td>N Items</td>
<td>N Items(list)</td>
<td>Returns the number of elements in the list specified. Can be assigned to a variable.</td>
</tr>
</tbody>
</table>

<td>Substitute(list, pattExpr1, replExpr1, ...)</td>
<td>Returns a copy of a string, list, or expression, replacing instances of each pattern expression with the corresponding replacement expression. See “Substitute and Substitute Into” on page 171 in the “Types of Data” chapter.</td>
</tr>
<tr>
<td>Substitute Into()</td>
<td>Substitute Into(list, pattExpr1, replExpr1, ...)</td>
<td>Changes a string, list, or expression, replacing instances of each pattern expression with the corresponding replacement expression. <strong>Note:</strong> The list or expression must be a variable. See “Substitute and Substitute Into” on page 171 in the “Types of Data” chapter.</td>
</tr>
</tbody>
</table>

**Iterate through a List**

Iterate through a list to do something with each value or look for a particular value. The following script looks at each item in the list. If the item in the list is less than or equal to 10, it is replaced with its square.

```
x = {2, 12, 8, 5, 18, 25};
```
\[ n = N \text{ Items}(x); \]
\[
\text{For}(i = 1, i \leq n, i++,
    \text{If}(x[i] \leq 10,
        x[i] = x[i] ^ 2
    )
);
\]
\[
\text{Show}(x);
\]
\[
x = \{4, 12, 64, 25, 18, 25\};
\]

You can use \texttt{Loc()} to locate the items in the new list that are equal to 25:
\[
\text{Loc}(x, 25);
\]
\[
[4, 6] // The fourth and sixth items in the list are equal to 25.
\]

## Concatenate Lists

Join two or more lists into one list using \texttt{Concat()} or the \texttt{||} operator. The original lists are not changed.

The following example uses \texttt{Concat()} to join lists \texttt{a} and \texttt{b}:
\[
a = \{1, 2\};
b = \{7, 8, 9\};
\text{concat}(a, b);
\]
\[
\{1, 2, 7, 8, 9\}
\]

The following example joins the same lists using the \texttt{||} operator:
\[
\{1, 2\} || \{7, 8, 9\}
\]
\[
\{1, 2, 7, 8, 9\}
\]

Lists of different types can be concatenated (for example, lists that contain character strings and numbers).
\[
d = \{"apples", "bananas"\};
e = \{"oranges", "grapes"\};
f = \{1, 2, 3\};
\text{concat}(d, e, f);
\]
\[
\{"apples", "bananas", "oranges", "grapes", 1, 2, 3\}
\]

Join two or more lists and replace the first list with the combined list using \texttt{Concat to()} or the \texttt{||=} operator. The following example performs concatenation in place using \texttt{Concat to()}:
\[
d = \{"apples", "bananas"\};
e = \{"peaches", "pears"\};
\text{concat to}(d, e);
\text{Show}(d);
\]
\[
d = \{"apples", "bananas", "peaches", "pears"\}
\]

The following example joins the same lists using the \texttt{||=} operator:
\[
d = \{"apples", "bananas"\};
\]
e = {"peaches", "pears"};
d||=e;
Show( d );
d = {"apples", "bananas", "peaches", "pears"}

Insert a Nested List in an Existing List

To insert a nested list in an existing list, specify the placement of the list:

```
list2 = {{"a", "b"}, {"c", "d"}};
list2[3] = {"apple", "banana"}; // specify a list as the third item
Show( list2 );
list2 = {{"a", "b"}, {"c", "d"}, {"apple", "banana"}};
```

If you do not know the number of items in a list, use N Items(). In this example, an empty list is inserted at the end of the list.

```
list1 = {"a", "b"};
list1[N Items( list1 ) + 1] = {};
Show( list1 );
list1 = {"a", "b", {}};
```

Index into a List with Another List

Indexing into a list with another list is a powerful technique for making scripts fast and small. See “Indexing into a Matrix or List with Another Matrix or List” on page 213.

Send Messages to Lists

You can send a single message to a list instead of having to send individual messages. Suppose that you want to create a Bivariate report with a By variable. The script returns a list of the bivariate objects, one for each level of the By variable. Send a single Fit Line message to the list to fit a line to all of the Bivariate reports.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
/* return a list of bivariate objects:
{Bivariate[], Bivariate[], Bivariate[], Bivariate[], Bivariate[]}; */
biv = dt << Bivariate( X( dt:weight ), Y( dt:height ), By( dt:age ) );

biv << Fit Line; /* send the Fit Line message to each Bivariate object in the list */
```
Troubleshooting Messages Sent to a List

Any message that is sent to a list is sent to each object in the list. If the message saves a file, it’s performing the save for each object in the list to the same file. This means that only the last object is actually saved in a file.

Suppose that you have a list of three control charts and you send a message (such as Save Interactive HTML) to the list. The message is sent to each member of the list in turn. First, it saves an HTML page with the first control chart; then it saves a second HTML page with the same name that contains the second control chart; and then it saves a third HTML page with the same name that contains only the third control chart. You end up with a page that contains only the third control chart.

The solution is to send the message to a single container higher up the tree that contains all control charts. To do this, rewrite the following line of code:

```java
obj << Save Interactive HTML( "Control Charts.html" );
```

Top Parent treats the first object as the single container:

```java
tp = obj[1] << Top Parent();
tp << Save Interactive HTML( "Control Charts.html" );
```

--

Matrices

A matrix is a rectangular array of numbers that are arranged in rows and columns. Use matrices to store numbers and perform calculations on those numbers using matrix algebra.

Note the following for this section:

- Matrices are represented with an uppercase bold variable (for example, \( \mathbf{A} \)).
- A matrix with one row or one column is a vector (or more specifically, a row vector or a column vector respectively).
- For clarity, we represent matrices that are vectors with lowercase bold letters (such as \( \mathbf{x} \)).
- A scalar is a numeric value that is not in a matrix.

Construct Matrices

Note the following when creating matrices:

- Place matrix literals in square brackets. [...]  
- Matrix values can contain decimal points, can be positive or negative, and can be in scientific notation.
• Separate items across a column with blank spaces. You can use any number of blank spaces.
• Separate rows with a comma.

For constructing more advanced matrices, see “Special Matrices” on page 219.

Examples
Create matrix A with 3 rows and 2 columns:

\[
A = \begin{bmatrix} 1 & 2, & 3 & 4, & 5 & 6 \end{bmatrix}
\]

R is a row vector and C is a column vector:

\[
R = \begin{bmatrix} 10 & 12 & 14 \end{bmatrix};
C = \begin{bmatrix} 11, & 13, & 15 \end{bmatrix};
\]

B is a 1-by-1 matrix, or a matrix with one row and one column:

\[
B = \begin{bmatrix} 20 \end{bmatrix};
\]

E is an empty matrix:

\[
E = [];\]

The following examples show two ways of creating empty matrices:

\[
J(0, 4);
\]

\[
J(0, 4)
\]

\[
J(5, 0);
\]

\[
J(5, 0)
\]

Specifying the number of rows and columns in an empty matrix is optional. JMP creates the matrix as necessary. For example, the following script defines an empty matrix, iterates over each row in the data table, and returns the heights and weights in a matrix.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
data = [[](0,2);
For Each Row( data |/= Matrix( {{dt:height, dt:weight}} ) );
Show( data );
data = [59 95, 61 123, 55 74,...]
```

A script can return an empty matrix. In Big Class.jmp, the following expression looks for rows in which age equals 8, finds none, and returns an empty matrix:

```javascript
a = dt << Get Rows Where( age == 8 );
Show( a );
a = [[](0,1);```
Construct Matrices from Lists

If you want to convert lists into a matrix, use the `Matrix()` function. A single list is converted into a column vector. Two or more lists are converted into rows.

Create a column vector from a single list:

\[
A = \text{Matrix}( \{1, 2, 3\} ); \\
[1,2,3]
\]

Create a matrix from a list of lists. Each list is a row in the matrix.

\[
A = \text{Matrix}( \{\{1, 2, 3\}, \{4, 5, 6\}, \{7, 8, 9\}\} ); \\
[1 \ 2 \ 3, \ 
4 \ 5 \ 6, \ 
7 \ 8 \ 9]
\]

Construct Matrices from Expressions

To construct matrices from expressions, use `Matrix()`. Elements must be expressions that resolve to numbers.

\[
A = \text{Matrix}( \{4 \times 5, 8 \wedge 2, \text{Sqrt}(9)\} ); \\
[20, 64, 3]
\]

Subscripts

Use the subscript operator (\[ \]) to pick out elements or submatrices from matrices. The `Subscript()` function is usually written as a bracket notation after the matrix to be subscripted, with arguments for rows and columns.

Single Element

The expression \( A[i, j] \) extracts the element in row \( i \), column \( j \), returning a scalar number. The equivalent functional form is `Subscript(A,i,j)`.

\[
P = \left[ \begin{array}{cccc} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & \end{array} \right]; \\
P[2, 3]; // \text{ returns } 6 \\
\text{Subscript}(P, 2, 3); // \text{ returns } 6
\]

Assign the value that is in the third row and the first column in the matrix \( A \) (which is 5) to the variable \( \text{test} \).

\[
A = \left[ \begin{array}{cccc} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & \end{array} \right]; \\
\text{test} = A[3, 1]; \\
\text{Show}(\text{test}); \\
\text{test} = 5;
\]
Matrix or List Subscripts

To extract a sub-matrix, use matrix or list subscripts. The result is a matrix of the selected rows and columns. The following expressions select the second and third rows with the first and third columns.

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[[2 3],[1 3]]; // matrix subscripts
P[[2, 3],[1, 3]]; // list subscripts
\]

Both of these methods provide the following output:

\[
\begin{bmatrix} 4 & 6, \\
7 & 9 \end{bmatrix}
\]

Single Subscripts

A single subscript addresses matrices as if all the rows were connected end-to-end in a single row. This makes the double subscript \( A[i, j] \) the same as the single subscript \( A[(i-1)\times ncol(A)+j] \).

Examples

\[
Q = \begin{bmatrix} 2 & 4 & 6, & 8 & 10 & 12, & 14 & 16 & 18 \end{bmatrix};
Q[8]; // same as Q[3,2]
16
\]

The following examples all return the column vector \([10, 14, 18]\):

\[
Q = \begin{bmatrix} 2 & 4 & 6, & 8 & 10 & 12, & 14 & 16 & 18 \end{bmatrix};
Q[[5, 7, 9]];
Q[[5 \ 7 \ 9]];
ii = [5 \ 7 \ 9];
Q[ii];
ii = {5, 7, 9};
Q[ii];
Subscript( Q, ii );
\]

This script returns the values 1 through 9 from the matrix \( P \) in order:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
For( i = 1, i <= 3, i++,
    For( j = 1, j <= 3, j++,
        Show( P[i, j] )
    )
);
Delete Rows and Columns

Deleting rows and columns is accomplished by assigning an empty matrix to that row or column.

\[
A[k, 0] = []; // deletes the kth row
A[0, k] = []; // deletes the kth column
\]

Select Whole Rows or Columns

A subscript argument of zero selects all rows or columns.

\[
P = [1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9];
\]
Select column 2:

\[
P[0, 2];
[2, \ 5, \ 8]
\]
Select columns 3 and 2:

\[
P[0, [3, 2]];\]
\[
[3 \ 2, \ 6 \ 5, \ 9 \ 8]
\]
Select row 3:

\[
P[3, 0];\]
\[
[7 \ 8 \ 9]
\]
Select rows 2 and 3:

\[
P[[2, 3], 0];\]
\[
[4 \ 5 \ 6, \ 7 \ 8 \ 9]
\]
Select all columns and rows (the whole matrix):

\[
P[0, 0];\]
\[
[1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9]
\]

Assignment through Subscripts

You can change values in matrices using subscripts. The subscripts can be single indices, matrices or lists of indices, or the zero index representing all rows or columns. The number of selected rows and columns for the insertion must either match the dimension of the inserted argument, or the argument can be inserted repeatedly into the indexed positions.

Examples

Change the value in row 2, column 3 to 99:

\[
P = [1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9];
P[2, 3] = 99;
Show( P );\]
\[ P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 99, & 7 & 8 & 9 \end{bmatrix} \]

Change the values in four locations:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[\begin{bmatrix} 1 & 2 \end{bmatrix}, \begin{bmatrix} 2 & 3 \end{bmatrix}] = \begin{bmatrix} 66 & 77, & 88 & 99 \end{bmatrix};
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 1 & 66 & 77, & 4 & 88 & 99, & 7 & 8 & 9 \end{bmatrix}
\]

Change three values in one column:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[\begin{bmatrix} 0, & 2 \end{bmatrix}] = \begin{bmatrix} 11, & 22, & 33 \end{bmatrix};
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 1 & 11 & 3, & 4 & 22 & 6, & 7 & 33 & 9 \end{bmatrix}
\]

Change three values in one row:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[\begin{bmatrix} 3, & 0 \end{bmatrix}] = \begin{bmatrix} 100, & 102, & 104 \end{bmatrix};
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 100 & 102 & 104 \end{bmatrix}
\]

Change all the values in one row to the same value:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[\begin{bmatrix} 2, & 0 \end{bmatrix}] = 99;
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 1 & 2 & 3, & 99 & 99 & 99, & 7 & 8 & 9 \end{bmatrix}
\]

**Operator Assignment**

You can use operator assignments (such as + =) on matrices or subscripts of matrices. For example, the following statement adds 1 to the \( i \)-th j-th element of the matrix:

\[
P = \begin{bmatrix} 1 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
P[\begin{bmatrix} 1, & 1 \end{bmatrix}] += 1;
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 2 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
\]
\[
P[\begin{bmatrix} 1, & 1 \end{bmatrix}] += 1;
\]
\[
\text{Show( P );}
P = \begin{bmatrix} 3 & 2 & 3, & 4 & 5 & 6, & 7 & 8 & 9 \end{bmatrix};
\]

**Ranges of Rows or Columns**

If you are working with a range of subscripts, use the `Index()` function or `::` to create matrices of ranges.
T1 = 1 :: 3; // create the vector [1 2 3]
T2 = 4 :: 6; // create the vector [4 5 6]
T3 = 7 :: 9; // create the vector [7 8 9]
T = T1 |/ T2 |/ T3; // concatenate the vectors into a single matrix
T[1 :: 3, 2 :: 3]; // refer to rows 1 through 3, columns 2 and 3
[2 3, 5 6, 8 9]
T[Index( 1, 3 ), Index( 2, 3 )]; // equivalent Index function
[2 3, 5 6, 8 9]

Inquiry Functions

The NCol() and NRow() functions return the number of columns and rows in a matrix (or data table), respectively:

NCol( [1 2 3, 4 5 6] ); // returns 3 (for 3 columns)
NRow( [1 2 3, 4 5 6] ); // returns 2 (for 2 rows)

To determine whether a value is a matrix, use the Is Matrix() function, which returns a 1 if the argument evaluates to a matrix.

A = [20, 64, 3];
B = {20, 64, 3};
Is Matrix( A ); // returns 1 for yes
Is Matrix( B ); // returns 0 for no

Comparisons, Range Checks, and Logical Operators

JMP's comparison, range check, and logical operators work with matrices and produce matrices of elementwise Boolean results. You can compare conformable matrices.

A < B; // less than
A <= B; // less or equal
A > B; // greater than
A >= B; // greater or equal
A == B; // equal to
A != B; // not equal to
A < B < C; // continued comparison (range check)
A | B; // logical OR
A & B; // logical AND
( A & !B ) | ( !A & B ); // exclusive OR
!( A & B ) & ( A | B ); // exclusive OR

You can use the Any() or All() functions to summarize matrix comparison results. Any() returns a 1 if any element is nonzero. All() returns a 1 if all elements are nonzero.

[2 2] == [1 2]; // returns [0 1], therefore:
All( [2 2] == [1 2] ); // returns 0
Any( [2 2] == [1 2] ); // returns 1

Min() or Max() return the minimum or maximum element from the matrix or matrices given as arguments.

A = [1 2 3, 4 5 6, 7 8 9, 10 11 12];
B = [0 1 2, 2 1 0, 0 1 1, 2 0 0];
Min( A ); // returns 1
Max( A ); // returns 12
Min( A, B ); // returns 0

**Numeric Operations**

You can perform numeric operations (such as subtraction, addition, and multiplication) on matrices. Most statistical methods are expressed in compact matrix notation and can be implemented in JSL.

For example, the following expression uses matrix multiplication and inversion to illustrate least squares regression:

\[ b = (X'X)^{-1}X'y \]

Implement this equation through the following JSL expression:

\[ b = \text{Inv}(X^*X)*X^*y; \]

**Basic Arithmetic**

You can perform the following basic arithmetic on matrices:

- addition
- subtraction
- multiplication
- division (multiplying by the inverse)

**Note:** The standard multiply operator is a matrix multiplier, not an elementwise multiplier.

To perform matrix multiplication, use one of the following methods:

- * operator
- Multiply() function
- Matrix Mult() function

To perform matrix division, use one of the following methods:

- / operator
• Divide() function

Note the following about matrix multiplication and division:

• Remember that while multiplication or division of scalars is commutative \((ab = ba)\), multiplication or division of matrices is \textit{not} commutative.

• When one of the two elements is a scalar, elementwise multiplication or division is performed.

• To use elementwise multiplication, use `:*` or the `EMult()` function.

• To use elementwise division, use `:/`, or the equivalent `EDiv()` function.

\textbf{Examples}

\begin{verbatim}
A = [1 2 3, 4 5 6, 7 8 9, 10 11 12];
B = [0 1 2, 2 1 0, 0 1 1, 2 0 0];
C = [1 2 3 4, 4 3 2 1, 0 1 0 1];
D = [0 1 2, 2 1 0, 1 2 0];
\end{verbatim}

Matrix addition:

\begin{verbatim}
R = A + B;
[1 3 5,
 6 6 6,
 7 9 10,
12 11 12]
\end{verbatim}

Matrix subtraction:

\begin{verbatim}
R = A - B;
[1 1 1,
 2 4 6,
 7 7 8,
 8 11 12]
\end{verbatim}

Matrix multiplication (inner product of rows of \(A\) with columns of \(C\)):

\begin{verbatim}
R = A * C;
[9 11 7 9,
24 29 22 27,
39 47 37 45,
54 65 52 63]
\end{verbatim}

Matrix division (equivalent to \(A \times \text{Inverse}(D)\)):

\begin{verbatim}
R = A / D;
[1.5 0.5 0,
 3 2 0,
 4.5 3.5 0,
 6 5 0]
\end{verbatim}

Matrix elementwise multiplication:

\begin{verbatim}
R = A :* B;
\end{verbatim}
Matrix scalar multiplication:

\[
R = C \times 2;
\]

\[
\begin{bmatrix}
2 & 4 & 6 & 8 \\
8 & 6 & 4 & 2 \\
0 & 2 & 0 & 2
\end{bmatrix}
\]

Matrix scalar division:

\[
R = C \div 2;
\]

\[
\begin{bmatrix}
0.5 & 1 & 1.5 & 2 \\
2 & 1.5 & 1 & 0.5 \\
0 & 0.5 & 0 & 0.5
\end{bmatrix}
\]

Matrix elementwise division (division by zero results in missing values):

\[
R = A \div B;
\]

\[
\begin{bmatrix}
. & 2 & 1.5 & . \\
2 & 5 & . & . \\
. & 8 & 9 & . \\
5 & . & . & .
\end{bmatrix}
\]

**Numeric (Scalar) Functions on Matrices**

Numeric functions work elementwise on matrices. Most of the pure numeric functions can be applied to matrices, resulting in a matrix of results. You can mix conformable matrix and scalar arguments.

Examples of numeric functions include the following:

- Sqrt(), Root(), Log(), Exp(), ^ Power(), Log10()
- Abs(), Mod(), Floor(), Ceiling(), Round(), Modulo()
- Sine(), Cosine(), Tangent(), ArcSine(), and other trigonometry functions.
- Normal Distribution(), and other probability functions.

**Example**

\[
A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 \\
10 & 11 & 12
\end{bmatrix};
\]

\[
B = \text{Sqrt}( A ); // \text{elementwise square root}
\]

\[
\begin{bmatrix}
1.414213562373095 & 1.732050807568877, \\
2.2360677749979 & 2.449489742783178, \\
2.645751311064591 & 2.828427124746193, \\
3.16227766016838 & 3.3166247903554, \\
3.464101615137754
\end{bmatrix}
\]
Concatenation

The Concat() function combines two matrices side by side to form a larger matrix. The number of rows must agree. A double vertical bar (||) is the infix operator, equivalent for horizontal concatenation.

\[
\text{Identity}(2) || \text{J}(2, 3, 4); \\
[1 0 4 4 4, 0 1 4 4 4]
\]

\[
B = [1, 1]; \\
B || \text{Concat}(\text{Identity}(2), \text{J}(2, 3, 4)); \\
[1 1 0 4 4 4, 0 1 4 4 4]
\]

The VConcat() function stacks two matrices on top of each other to form a larger matrix. The number of columns must agree. A vertical-bar-slash (|/) is the infix operator, equivalent for vertical concatenation.

\[
\text{Identity}(2) |/ \text{J}(3, 2, 1); \\
// or \text{VConcat}(\text{Identity}(2), \text{J}(3, 2, 1)); \\
[1 0, 0 1, 1 1, 1 1, 1 1]
\]

Both Concat() and VConcat() support concatenating to empty matrices, scalars, and lists.

\[
a=[]; \\
a || [1]; // returns [1] \\
a || \{2\}; // returns [2] \\
a || [3, 4, 5]; // returns [3 4 5]
\]

There are two in place concatenation operators: ||= and |/=. They are equivalent to the Concat To() and V Concat To() functions, respectively.

- \(a ||= b\) is equivalent to \(a = a || b\)
- \(a |/= b\) is equivalent to \(a = a |/ b\)

Transpose

The Transpose() function transposes the rows and columns of a matrix. A back-quote (`) is the postfix operator, equivalent to Transpose(). In matrix notation, Transpose() is expressed as the common prime or superscript-T notation (\(A'\) or \(A^T\)).

\[
A = [1 2 3, 4 5 6, 7 8 9, 10 11 12]; \\
A' \\
[1 4 7 10, \\
2 5 8 11, \\
3 6 9 12] \\
\text{Transpose}(\text{[1 2, 3 4]}); \\
[1 3, 2 4]
\]
Indexing into a Matrix or List with Another Matrix or List

Indexing into a matrix (or a list) with another matrix (or list) is a powerful technique for making scripts fast and small. JMP 13 and later handles one edge case differently.

Consider the following example of using a matrix as an index into a data column.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
tall rows = Loc( :height << Get Values() >= 67 ); // [25, 27, 30, 37, 39, 40]
:height[tall rows]; // [68, 69, 67, 68, 68, 70]
N Rows( :height[tall rows] ); // 6
```

The second line is the key. :height << Get Values() returns the values of the height column as a matrix. The comparison >= 67 returns a matrix of 0s and 1s corresponding to where the expression is false (0) or true (1). The Loc() function returns the locations of the 1s within the previous matrix.

In this case, you get [25, 27, 30, 37, 39, 40] as the row numbers where the height column is greater than or equal to 67. That’s pretty handy by itself, but the real power comes from being able to use that matrix as the index into a column or other matrix as in the third and fourth lines.

The alternative to this technique is to write a For() loop to iterate through every row explicitly. JMP still loops through the rows in either case, but the looping is much faster if done internally rather than in JSL. And the JSL is more compact without the explicit loop.

You can do the same thing with a matrix variable instead of a data column reference:

```plaintext
m = :height << Get Values();
tall rows = Loc( m >= 67 ); // [25, 27, 30, 37, 39, 40]
m[tall rows]; // [68, 69, 67, 68, 68, 70]
N Rows( m[tall rows] ); // 6
```

Consider the same examples with a different height cutoff (70 instead of 67):

```plaintext
tall rows = Loc( :height << Get Values() >= 70 ); // [40]
:height[tall rows]; // [70]
N Rows( :height[tall rows] ); // 1
```

```plaintext
m = :height << Get Values();
tall rows = Loc( m >= 70 ); // [40]
m[tall rows]; // [70]
N Rows( m[tall rows] ); /* error in JMP 12 and prior versions */
```

Notice that m[tall rows] returned 70 instead of [70]. In many cases, a 1x1 matrix and a number are treated the same way, but not always. The N Rows() function is one example where it makes a difference. The indexing is too aggressively simplifying the 1x1 matrix into a number.
One work-around is to call `Is Matrix()` before using `N Rows()`. An alternative is to concatenate an empty matrix to the result, which creates a matrix whether the source is a number or a matrix:

```plaintext
m = m | [ ]
```

In JMP 13 and later, the 1x1 matrix is maintained so that the result of the index operation is a matrix whenever the index itself is a matrix. The same principle applies to list indexing. Data table column indexing has always followed this principle.

## Matrices and Data Tables

You can move information between a matrix and a JMP data table. You can use matrix algebra to perform calculations on numbers that are stored in JMP data tables, and you can save the results back to JMP data tables.

### Move Data into a Matrix from a Data Table

These sections describe how to move data from a data table into a matrix.

#### Move All Numeric Values

The `Get As Matrix()` function generates a matrix containing all of the numeric values in a data table or column:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
A = dt << Get As Matrix;
[12 59 95,
 12 61 123,
 12 55 74, ...]
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = Column( "Height" );
A = col << Get As Matrix;
[59, 61, 55, 66, 52, ...]
```

#### Move All Numeric Values and Character Columns

The `Get All Columns As Matrix()` function returns the values from all columns of the data table in a matrix, including character columns. Character columns are numbered according to the alphanumeric order, starting at 1.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
A = dt << Get All Columns As Matrix;
[21 12 1 59 95,
 28 12 1 61 123, ...]
```
Move Only Certain Columns

To get certain columns of a data table, use column list arguments (names or characters).

\[
dt = \text{Open}( "\$SAMPLE\_DATA/Big Class.jmp" );
x = dt << \text{Get As Matrix}( \{"height", "weight"\} );
\]
or

\[
x = dt << \text{Get As Matrix}( \{\text{height}, \text{weight}\} );
\]

\[\begin{bmatrix}
59 & 95,
61 & 123,
55 & 74,
\ldots
\end{bmatrix}\]

Currently Selected Rows

To get a matrix of the currently selected row numbers in the data table:

\[
dt << \text{Get Selected Rows};
\]

\textbf{Note:} If no rows are selected, the output is an empty matrix.

Find Rows Where

To see a matrix of row numbers where the expression is true:

\[
dt << \text{Get Rows Where( expression )};
\]

For example, the following script returns the row numbers where the sex is male (M):

\[
dt = \text{Open}( "\$SAMPLE\_DATA/Big Class.jmp" );
A = dt << \text{Get Rows Where( Sex == "M" )};
\]

\[\begin{bmatrix}
6, 7, 8, 12, 13, 14, \ldots
\end{bmatrix}\]

Move Data into a Data Table from a Matrix

This section describes how to move data from a matrix into a data table.

Move a Column Vector

The \texttt{Set Values()} function copies values from a column vector into an existing data table column:

\[
col << \text{Set Values( x );}
\]

\texttt{col} is a reference to the data table column, and \texttt{x} is a column vector.

For example, the following script creates a new column called test and copies the values of vector \texttt{x} into the test column:

\[
dt = \text{Open}( "\$SAMPLE\_DATA/Big Class.jmp" );
dt << \text{New Column( "test" )};
col = \text{Column( "test" )};
x = 1::40;
\]
col << Set Values( x );

**Move All Matrix Values**

The Set Matrix() function copies values from a matrix into an existing data table, making new rows and new columns as needed to store the values of the matrix. The new columns are named Col1, Col2, and so on.

```
dt = New Table( "B" );
dt << Set Matrix([1 2 3 4 5, 6 7 8 9 10]);
```

This script creates a new data table called B containing two rows and five columns.

To create a new data table from a matrix argument, use the As Table(matrix) command. The columns are named Col1, Col2, and so on. For example, the following script creates a new data table containing the values of A:

```
A = [1 2 3, 4 5 6, 7 8 9, 10 11 12];
dt = As Table( A );
```

### Matrices and Reports

You can extract matrices of values from reports. First, you need to locate the items that you want to extract. This information is in the tree structure of the report.

Run the following script to create a table of parameter estimates in a Bivariate report:

```
  dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( X( height ), Y( weight ), Fit Line );
```

Now, open the tree structure to identify which item contains the parameter estimates:

- Right-click a gray disclosure icon and select **Edit > Show Tree Structure**.

  The parameter estimates are contained in NumberColBox(13). Continue with the script:

```
colBox = Report( biv )[Number Col Box( 13 )];
beta = colBox << Get As Matrix;
  [ -127.145248610915, 3.711354893859555 ]
```

**Notes:**

- When a variable contains a reference to a table box, Get As Matrix() creates a matrix A that contains the values from all numeric columns in the table:
  
  ```
  A = tableBox << Get As Matrix;
  ```

- When a variable contains a reference to a numeric column in a report table, Get As Matrix() creates a matrix A as a column vector of values from that column:
  
  ```
  A = colBox << Get As Matrix;
  ```
 Loc Functions

The Loc(), Loc Nonmissing(), Loc Min(), Loc Max(), and Loc Sorted() functions all return matrices that show positions of certain values in a matrix.

Loc

The Loc() function creates a matrix of positions that locate where A is true (nonzero and nonmissing).

\[
A = \begin{bmatrix} 0 & 1 & . & 3 & 4 & 0 \\ B = \begin{bmatrix} 2 & 0 & 0 & 2 & 5 & 6 \\
\end{bmatrix}
\]

The following example returns the indices for the values of A that are nonmissing and nonzero.

\[
I = \text{Loc}(A);
\]

\[
[2, 4, 5]
\]

The following example returns the indices for the values of A that are less than the corresponding values of B. Note that the two matrices must have the same number of rows and columns.

\[
I = \text{Loc}(A < B);
\]

\[
[1, 5, 6]
\]

The following script replaces all values less than 4 in A with 0.

\[
A = \begin{bmatrix} 0 & 1 & 0 & 3 & 4 & 0 \\ A[\text{Loc}(A < 4)] = 0;
\]

\[
\text{Show}(A);
\]

\[
A = \begin{bmatrix} 0 & 0 & 0 & 0 & 4 & 0 \\
\]

The following script returns an empty matrix:

\[
\text{Loc}(\begin{bmatrix} 2 & 3 & 4 & 5 & 6 \end{bmatrix} > 7);
\]

\[
[](0, 1)
\]

Loc Nonmissing

The Loc Nonmissing() function returns a vector of row numbers in a matrix that do not contain any missing values. For example,

\[
A = \begin{bmatrix} 1 & 2 & 3 & . & 6 & 7 & 8 & ., & 8 & 7 & 6 \\
\]

\[
\text{Loc Nonmissing}(A);
\]

\[
[1, 4]
\]
Loc Min and Loc Max

The \texttt{Loc Min()} and \texttt{Loc Max()} functions return the position of the first occurrence of the minimum and maximum elements of a matrix. Elements of a matrix are numbered consecutively, starting in the first row, first column, and proceeding left to right.

\begin{verbatim}
A = [1 2 2, 2 4 4, 1 1 1];
B = [6, 12, 9];
Show( Loc Max( A ) );
Show( Loc Min(B) );
Loc Max(A) = 5;
Loc Min(B) = 1;
\end{verbatim}

Loc Sorted

The \texttt{Loc Sorted()} function is mainly used to identify the interval that a number lies within. The function returns the position of the highest value in \texttt{A} that is less than or equal to the value in \texttt{B}. The resulting vector contains an item for each element in \texttt{B}.

\begin{verbatim}
A = [10 20 30 40];
B = [35];
Loc Sorted(A, B );
[3]
A = [10 20 40];
B = [35 5 45 20];
Loc Sorted(A, B );
[2, 1, 3, 2]
\end{verbatim}

Here's an example that defines a list of strings. \texttt{Loc Sorted()} identifies the string at the seventh interval and puts it in a list.

\begin{verbatim}
{"No Fat", "Some Fat", "Low Fat", "Normal Fat", "Medium Fat", "High Fat"}
[Loc Sorted( [0, 1, 5, 10, 20, 25], 7)]
{"Low Fat"}
\end{verbatim}

To convert the returned value to a string, include the subscript [1] at the end of the expression:

\begin{verbatim}
{"No Fat", "Some Fat", "Low Fat", "Normal Fat", "Medium Fat", "High Fat"}
[Loc Sorted( [0, 1, 5, 10, 20, 25], 7)][1]
"Low Fat"
\end{verbatim}

Notes:

- \texttt{A} must be sorted in ascending order.
- The returned values are always 1 or greater. If the element in \texttt{B} is smaller than all of the elements in \texttt{A}, then the function returns a value of 1. If the element in \texttt{B} is greater than all of the elements in \texttt{A}, then the function returns \texttt{n}, where \texttt{n} is the number of elements in \texttt{A}.
Ranking and Sorting

The Rank() function returns the positions of the numbers in a vector or list, as if the numbers were sorted from lowest to highest.

\[
E = [1 \ -2 \ 3 \ -4 \ 0 \ 5 \ 1 \ 8 \ -7];
\]
\[
R = \text{Rank}(E);
\]
\[
[9, 4, 2, 5, 7, 1, 3, 6, 8]
\]

If \(E\) were sorted from lowest to highest, the first number would be \(-7\). The position of \(-7\) in \(E\) is 9.

The original matrix \(E\) can then be sorted using the matrix \(R\) as subscripts to \(E\).

\[
\text{sortedE} = E[R];
\]
\[
[{-7, -4, -2, 0, 1, 1, 3, 5, 8}]
\]

The Ranking Tie() function returns ranks for the values in a vector or list, with ranks for ties averaged. Similarly, Ranking() returns ranks for the values in a vector or list, but the ties are ranked arbitrarily.

\[
E = [1 \ -2 \ 3 \ -4 \ 0 \ 5 \ 1 \ 8 \ -7];
\]
\[
\text{Ranking Tie}(E);
\]
\[
[5.5, 3, 7, 2, 4, 8, 5.5, 9, 1]
\]
\[
E = [1 \ -2 \ 3 \ -4 \ 0 \ 5 \ 1 \ 8 \ -7];
\]
\[
\text{Ranking}(E);
\]
\[
[5, 3, 7, 2, 4, 8, 6, 9, 1]
\]

The Sort Ascending() and Sort Descending() functions sort vectors.

\[
E = [1 \ -2 \ 3 \ -4 \ 0 \ 5 \ 1 \ 8 \ -7];
\]
\[
\text{Sort Ascending}(E);
\]
\[
[{-7 -4 -2 0 1 1 3 5 8}]
\]
\[
E = [1 \ -2 \ 3 \ -4 \ 0 \ 5 \ 1 \ 8 \ -7];
\]
\[
\text{Sort Descending}(E);
\]
\[
[8 5 3 1 1 0 -2 -4 -7]
\]

If the argument is not a vector or list, an error message is generated.

Special Matrices

Construct an Identity Matrix

The Identity() function constructs an identity matrix of the dimension that you specify. An identity matrix is a square matrix of zeros except for a diagonal of ones. The only argument specifies the dimension.

\[
\text{Identity}(3);
\]
Construct a Matrix with Specific Values

The \texttt{J()} function constructs a matrix with the number of rows and columns that you specify as the first two arguments, whose elements are all the third argument, for example:

\[
\texttt{J( 3, 4, 5 );}
\]
\[
\begin{bmatrix}
5 & 5 & 5 & 5 \\
5 & 5 & 5 & 5 \\
5 & 5 & 5 & 5 \\
\end{bmatrix}
\]
\[
\texttt{J( 3, 4, \text{Random Normal}() ); // your results will differ}
\]
\[
\begin{bmatrix}
0.407709113182904 & 1.67359154091978 & 1.00412665221308 & 0.240885679837327 \\
-0.557848036549455 & -0.620833861982722 & 0.877166783247633 & 1.50413740148892 \\
-2.09920574748608 & -0.154797501010655 & 0.0463943433032137 & 0.064041826393316
\end{bmatrix}
\]

Create a Diagonal Matrix

The \texttt{Diag()} function creates a diagonal matrix from a square matrix (having an equal number of rows and columns) or a vector. A diagonal matrix is a square matrix whose nondiagonal elements are zero.

\[
\texttt{D = [1 -1 1];}
\]
\[
\texttt{Diag( D );}
\]
\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & -1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]
\[
\texttt{Diag([1, 2, 3, 4]);}
\]
\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 \\
0 & 0 & 3 & 0 \\
0 & 0 & 0 & 4
\end{bmatrix}
\]

\[
\texttt{A = [1 2,3 4];}
\]
\[
\texttt{f = [5];}
\]
\[
\texttt{D = Diag( A, f );}
\]
\[
\begin{bmatrix}
1 & 2 & 0 \\
3 & 4 & 0 \\
0 & 0 & 5
\end{bmatrix}
\]

In the third example, at first glance, not all of the nondiagonal elements are zero. Using matrix notation, the matrix can be expressed as follows:

\[
[\mathbf{A} \mathbf{0},
\mathbf{0}^\top \mathbf{f}]
\]

Where \(\mathbf{A}\) and \(\mathbf{f}\) are the matrices from the example, and \(\mathbf{0}\) is a column vector of zeros.
Create a Column Vector from Diagonal Elements

The `VecDiag()` function creates a column vector from the diagonal elements of a matrix.

\[
v = \text{Vec Diag}(\begin{bmatrix}1 & 0 & 0 & 1, & 5 & 3 & 7 & 1, & 9 & 9 & 8 & 8, & 1 & 5 & 4 & 3 \end{bmatrix}) \begin{bmatrix}1, & 3, & 8, & 3\end{bmatrix}
\]

Calculate Diagonal Quadratic Forms

The `Vec Quadratic()` function calculates the hats in regression that go into the standard errors of prediction or the Mahalanobis or T2 statistics for outlier distances. `Vec Quadratic(Sym, X)` is equivalent to calculating `Vec Diag(X*Sym*X')`. The first argument is a symmetric matrix, usually an inverse covariance matrix. The second argument is a rectangular matrix with the same number of columns as the symmetric matrix argument.

Return the Sum of Diagonal Elements

The `Trace()` function returns the sum of the diagonal elements for a square matrix.

\[
D = \begin{bmatrix}0 & 1 & 2, & 2 & 1 & 0, & 1 & 2 & 0 \end{bmatrix};
\text{Trace}(D); // \text{returns 1}
\]

Generate a Row Vector of Integers

The `Index()` function generates a row vector of integers from the first argument to the last argument. A double colon `::` is the equivalent infix operator.

\[
6::10;
\begin{bmatrix}6 & 7 & 8 & 9 & 10\end{bmatrix}
\text{Index}(1, 5);
\begin{bmatrix}1 & 2 & 3 & 4 & 5\end{bmatrix}
\]

The optional `increment` argument changes the default increment of +1.

\[
\text{Index}(0.1, 0.4, 0.1);
\begin{bmatrix}0.1, & 0.2, & 0.3, & 0.4\end{bmatrix}
\]

The increment can also be negative.

\[
\text{Index}(6, 0, -2);
\begin{bmatrix}6, & 4, & 2, & 0\end{bmatrix}
\]

The default value of the increment is 1, or -1 if the first argument is higher than the second.
Reshape a Matrix

The `Shape()` function reshapes an existing matrix across rows to be the specified dimensions. The following example changes the 3x4 matrix `a` into a 12x1 matrix:

```plaintext
a = [1 1 1, 2 2 2, 3 3 3, 4 4 4];
Shape( a, 12, 1 );
[1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4]
```

Summarize Columns of a Matrix

There are several functions that return a row vector based on summary values for each column in a matrix.

```plaintext
mymatrix = [11 22, 33 44, 55 66];
V Max( mymatrix ); // returns the maximum of each column
[55 66]
V Min( mymatrix ); // returns the minimum of each column
[11 22]
V Mean( mymatrix ); // returns the mean of each column
[33 44]
V Median( mymatrix ); // returns the median of each column
[33 44]
V Quantile( mymatrix, 0.75 ); // returns the 0.75 quantile of each column
[55 66]
V Sum( mymatrix ); // returns the sum of each column
[99 132]
V Std( mymatrix ); // returns the standard deviations of each column
[22 22]
```

Create Design Matrices

The `Design()` function creates a matrix of design columns for a vector or list. There is one column for each unique value in the vector or list. The design columns have the elements 0 and 1. For example, `x` below has values 1, 2, and 3, then the design matrix has a column for 1s, a column for 2s, and a column for 3s. Each row of the matrix has a 1 in the column representing that row’s value. So, the first row (1) has a 1 in the 1s column (the first column) and 0s elsewhere; the second row (2) has a 1 in the 2’s column and 0s elsewhere; and so on.

```plaintext
x = [1, 2, 3, 2, 1];
Design( x );
[1 0 0,
0 1 0,
0 0 1,
0 1 0,
1 0 0]
```
A variation is the Design Nom() or Design F() function, which removes the last column and subtracts it from the others. Therefore, the elements of Design Nom() or Design F() matrices are 0, 1, and -1. And the Design Nom() or Design F() matrix has one less column than the vector or list has unique values. This function makes full-rank versions of design matrices for effects.

\[
x = [1, 2, 3, 2, 1];
\]
\[
\text{Design Nom}(x);
\]
\[
[1 0, 0 1, -1 -1, 0 1, 1 0]
\]

Design Nom() is further demonstrated in the “ANOVA Example” on page 235.

To facilitate ordinal factor coding, use the Design Ord() function. This function produces a full-rank coding with one less column than the number of unique values in the vector or list. The row for the lowest value in the vector or list is all zeros. Each succeeding value adds an additional 1 to the row of the design matrix.

\[
x = [1, 2, 3, 4, 5, 6];
\]
\[
\text{Design Ord}(x);
\]
\[
[0 0 0 0 0, 1 0 0 0 0, 1 1 0 0 0, 1 1 1 0 0, 1 1 1 1 0, 1 1 1 1 1]
\]

Design(), Design Nom(), and Design Ord() support a second argument that specifies the levels to be looked up and their order. This feature allows design matrices to be created one row at a time.

- Design( values, levels ) creates a design matrix of indicator columns.
- DesignNom( values, levels ) creates a full-rank design matrix of indicator columns.

Notes:
- The values argument can be a single element or a matrix or list of elements.
- The levels argument can be a list or matrix of levels to be looked up.
- The result has the same number of rows as there are elements in the values argument.
- The result always has the same number of columns as there are items in the levels argument. In the case of Design Nom() and Design Ord(), there is one less column than the number of items in the levels argument.
- If a value is not found, the whole row is zero.

Examples

\[
\text{Design}(20, [10 20 30]);
\]
\[
[0 1 0]
\]
\[
\text{Design}(30, [10 20 30]);
\]
Find the Direct Product

The Direct Product() function finds the direct product (or Kronecker product) of two square matrices. The direct product of a $m \times m$ matrix and a $n \times n$ matrix is the $mn \times mn$ matrix whose elements are the products of numbers, one from $A$ and one from $B$.

$$G = \begin{bmatrix} 1 & 2 \\ 3 & 5 \end{bmatrix}$$
$$H = \begin{bmatrix} 2 & 3 \\ 5 & 7 \end{bmatrix}$$

Direct Product( G, H );

$$\begin{bmatrix} 2 & 3 & 4 & 6 \\ 5 & 7 & 10 & 14 \\ 6 & 9 & 10 & 15 \\ 15 & 21 & 25 & 35 \end{bmatrix}$$

The H Direct Product() function finds the row-by-row direct product of two matrices with the same number of rows.

H Direct Product( G, H );

$$\begin{bmatrix} 2 & 3 & 4 & 6, \\ 15 & 21 & 25 & 35 \end{bmatrix}$$

HDirect Product() is useful for constructing the design matrix columns for interactions.

$XA = \text{Design Nom}( A );$
$XB = \text{Design Nom}( B );$
$XAB = HDirect Product( XA, XB );$
$X = J( NRow( A ), 1 ) || XA || XB || XAB;$

Inverse Matrices and Linear Systems

JMP has the following functions for computing inverse matrices: Inverse(), GInverse(), and Sweep(). The Solve() function is used for solving linear systems of equations.
**Inverse or Inv**

The `Inverse()` function returns the matrix inverse for the square, nonsingular matrix argument. `Inverse()` can be abbreviated `Inv`. For a matrix \( A \), the matrix product of \( A \) and \( \text{Inverse}(A) \) (often denoted \( A(A^{-1}) \)) returns the identity matrix.

\[
A = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}; \\
A\text{Inv} = \text{Inv}(\ A); \\
A^*A \text{ Inv}; \\
\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}
\]

\[
A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}; \\
A\text{Inv} = \text{Inverse}(\ A); \\
A^*A\text{Inv}; \\
\begin{bmatrix} 1 & 1.110223025e-16 \\ 0 & 1 \end{bmatrix}
\]

**Note:** There can be small discrepancies in the results due to floating point limitations, as illustrated in the second example.

**GInverse**

The (Moore-Penrose) generalized inverse of a matrix \( A \) is any matrix \( G \) that satisfies the following conditions:

\[
AGA = A \\
GAG = G \\
(AG)^\prime = AG \\
(GA)^\prime = GA
\]

The `GInverse()` function accepts any matrix, including non-square ones, and uses singular-value decomposition to calculate the Moore-Penrose generalized inverse. The generalized inverse can be useful when inverting a matrix that is not full rank. Consider the following system of equations:

\[
x + 2y + 2z = 6 \\
2x + 4y + 4z = 12 \\
x + y + z = 1
\]

Find the solution to this system using the following script:

\[
A = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 4 & 4 \\ 1 & 1 & 1 \end{bmatrix}; \\
B = \begin{bmatrix} 6 \\ 12 \\ 1 \end{bmatrix}; \\
\text{Show}( \ GInverse(\ A ) * B ); \\
GInverse(A) * B = \begin{bmatrix} -4 \\ 2.5 \\ 2.5 \end{bmatrix};
\]
Solve

The `Solve()` function solves a system of linear equations. `Solve()` finds the vector \( x \) so that \( x = A^{-1}b \) where \( A \) equals a square, nonsingular matrix and \( b \) is a vector. The matrix \( A \) and the vector \( b \) must have the same number of rows. `Solve(A,b)` is the same as `Inverse(A)*b`.

\[
A = \begin{bmatrix}
1 & -4 & 2 \\
3 & 3 & 2 \\
0 & 4 & -1
\end{bmatrix};
b = \begin{bmatrix}
1 \\
2 \\
1
\end{bmatrix};
x = \text{Solve}( A, b );
\]
\[
\begin{bmatrix}
-16.999999999999999 \\
4.999999999999999 \\
18.999999999999999
\end{bmatrix}
\]
\[
A*x;
\begin{bmatrix}
1 \\
2 \\
0.9999999999999997
\end{bmatrix}
\]

**Note:** There can be small discrepancies in the results due to floating point limitations, as illustrated in the example.

Sweep

The `Sweep()` function inverts parts (or pivots) of a square matrix. If you sequence through all of the pivots, you are left with the matrix inverse. Normally the matrix must be positive definite (or negative definite) so that the diagonal pivots never go to zero. `Sweep()` does not check whether the matrix is positive definite. If the matrix is not positive definite, then it still works, as long as no zero pivot diagonals are encountered. If zero (or near-zero) diagonal pivots are encountered on a full sweep, then the result is a g2 generalized inverse if the zero pivot row and column are zeroed.

About the Sweep Function

Suppose matrix \( E \) consists of smaller matrix partitions, \( A, B, C, \) and \( D \):

\[
E = \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}
\]

The syntax for `Sweep()` appears as follows:

\[
\text{Sweep}( E, [...] );
\]

`[...]` indicates partition \( A \).

This produces the matrix result equivalent to the following:

\[
\begin{bmatrix}
A^{-1} & A^{-1}B \\
-C A^{-1} & D - C A^{-1}B
\end{bmatrix}
\]

**Notes:**

- The submatrix in the \( A \) position becomes the inverse.
• The submatrix in the \( B \) position becomes the solution to \( Ax = B \).
• The submatrix in the \( C \) position becomes the solution to \( xA = C \).

**Use of the Sweep Function**

\( \text{Sweep()} \) is sequential and reversible:

• \( A = \text{Sweep}(A, \{i,j\}) \) is the same as \( A = \text{Sweep}(\text{Sweep}(A, i), j) \). It is sequential.
• \( A = \text{Sweep}(\text{Sweep}(A, i), i) \) restores \( A \) to its original values. It is reversible.

If you have a cross-product matrix partitioned as follows:

\[
C = \begin{bmatrix}
X'X & X'y \\
y'X & y'y
\end{bmatrix}
\]

Then after sweeping through the indices of \( X'X \), the result appears as follows:

\[
\begin{bmatrix}
(X'X)^{-1} & (X'X)^{-1}X'y \\
yX(X'X)^{-1} & y'y - y'X(X'X)^{-1}X'y
\end{bmatrix}
\]

The partitions are recognizable to statisticians as follows:

• the least squares estimates for the model \( Y = Xb + e \) in the upper right
• the sum of squared errors in the lower right
• a matrix proportional to the covariance of the estimates in the upper left

The \( \text{Sweep} \) function is useful in computing the partial solutions needed for stepwise regression.

The \textit{index} argument is a vector that lists the rows (or equivalently the columns) on which you want to sweep the matrix. For example, if \( E \) is a 4x4 matrix, to sweep on all four rows to get \( E^{-1} \) requires these commands:

\[
E = \begin{bmatrix}
5 & 4 & 1 & 1, \\
4 & 5 & 1 & 1, \\
1 & 1 & 4 & 2, \\
1 & 1 & 2 & 4
\end{bmatrix};
\]

\[
\text{Sweep}(E, [1, 2, 3, 4]);
\]

\[
\begin{bmatrix}
0.56 & -0.44 & -0.02 & -0.02, \\
-0.44 & 0.56 & -0.02 & -0.02, \\
-0.02 & -0.02 & 0.34 & -0.16, \\
-0.02 & -0.02 & -0.16 & 0.34
\end{bmatrix}
\]

\[
\text{Inverse}(E); // notice that these results are the same
\]

\[
\begin{bmatrix}
0.56 & -0.44 & -0.02 & -0.02, \\
-0.44 & 0.56 & -0.02 & -0.02, \\
-0.02 & -0.02 & 0.34 & -0.16, \\
-0.02 & -0.02 & -0.16 & 0.34
\end{bmatrix}
\]

Sweep() is further demonstrated in the “ANOVA Example” on page 235.

**Determinant**

The Det() function returns the determinant of a square matrix. The determinant of a 2 × 2 matrix is the difference of the diagonal products, as demonstrated below. Determinants for \( n \times n \) matrices are defined recursively as a weighted sum of determinants for \((n - 1) \times (n - 1)\) matrices. For a matrix to have an inverse, the determinant must be nonzero.

\[
\begin{vmatrix} 1 & 2 \\ 3 & 5 \end{vmatrix} = (1 \cdot 5) - (3 \cdot 2) = -1
\]

\[
F = \begin{bmatrix} 1 & 2 \\ 3 & 5 \end{bmatrix};
\]

\[
\text{Det}(F); 
\]

\[-1\]

**Decompositions and Normalizations**

This section contains functions that calculate eigenvalues and eigenvectors and functions that decompose matrices.

**Eigenvalues**

The Eigen() function performs eigenvalue decomposition of a symmetric matrix. Eigenvalue decompositions are used in many statistical techniques, most notably in principal components and canonical correlation, where the transformation associated with the largest eigenvalues are transformations that maximize variances.

Eigen() returns a list of matrices. The first matrix in the returned list is a column vector of eigenvalues; the second matrix contains eigenvectors as the columns.

\[
A = \begin{bmatrix} 5 & 4 & 1 & 1, 4 & 5 & 1 & 1, 1 & 1 & 4 & 2, 1 & 1 & 2 \end{bmatrix};
\]

\[
\text{Eigen}(A); 
\]

\[
\{[[10, 5, 2, 1], 0.632455532033676 - 0.316227766016838 - 0.77555756156289e-16 - 0.707106781186547, 0.632455532033676 - 0.316227766016837 - 1.66533453693773e-16 0.707106781186547, 0.316227766016837 - 0.632455532033676 - 0.707106781186548, 0.316227766016837 - 0.632455532033676 - 0.707106781186547 0, 0.316227766016837 - 0.632455532033676 - 0.707106781186547 0]]\}
\]

Since the function returns a list of matrices, you might want to assign it to a list of two global variables. That way, the column vector of eigenvalues is assigned to one variable, and the matrix of eigenvectors is assigned to another variable:
{evals, evecs} = Eigen( A );

For some $n \times n$ matrix $A$, eigenvalue decomposition finds all $\lambda$ (lambda) and vectors $x$, so that the equation $Ax = \lambda x$ has a nonzero solution $x$. The $\lambda$’s are called eigenvalues, and the corresponding $x$ vectors are called eigenvectors. This is equivalent to solving $(A - \lambda I)x = 0$. You can reconstruct $A$ from eigenvalues and eigenvectors by a statement like the following:

```
newA = evecs * Diag( evals ) * evecs';
[[5.00000000000001 4 1 1,
  4 5 1 1,
  1 1 4 2,
  1 1 2 4]]
```

Note the following about eigenvalues and eigenvectors:

- The eigenvector matrices are orthonormal, such that the inverse is the transpose: $E'E = EE' = I$.
- Eigenvectors are uniquely determined only if the eigenvalues are unique.
- Zero eigenvalues correspond to singular matrices.
- Inverses can be obtained by inverting the eigenvalues and reconstituting with the eigenvectors. Moore-Penrose generalized inverses can be formed by inverting the nonzero eigenvalues and reconstituting. (See “GInverse” on page 225.)

**Note:** You must decide whether a very small eigenvalue is effectively zero.

- The eigenvalue decomposition enables you to view any square-matrix multiplication as the following:
  - a rotation (multiplication by an orthonormal matrix)
  - a scaling (multiplication by a diagonal matrix)
  - a reverse rotation (multiplication by the orthonormal inverse, which is the transpose),
  or in notation:
  $$A \ast x = E' \ast \text{Diag}(M) \ast E \ast x;$$
  $E$ rotates, $\text{Diag}(M)$ scales, and $E'$ reverse-rotates.

**Cholesky Decomposition**

The Cholesky() function performs Cholesky decomposition. A positive semi-definite matrix $A$ is re-expressed as the product of a nonsingular, lower-triangular matrix $L$ and its transpose: $L^*L' = A$.

```
E = [ 5 4 1 1, 4 5 1 1, 1 1 4 2, 1 1 2 4];
L = Cholesky( E );
[[2.23606797749979 0 0 0,
  1.78885438199832 1.341640786499874 0 0,
  0.447213595499958 0.149071198499986 1.9436506316151 0,
  0.447213595499958 0.149071198499986 0.914659120760047 1.71498585142509]]
```
To verify the results, enter the following:

```
L*L';
[5 4 1 1,
 4 5 1 1,
 1 1 4 2,
 1 1 2 4]
```

### About Cholesky Decomposition

Cholesky() is useful for reconstituting expressions into a more manageable form. For example, eigenvalues are available only for symmetric matrices in JMP, so the eigenvalues of the product $AB$ could not be obtained directly. (Although $A$ and $B$ can be symmetric, the product is not symmetric.) However, you can usually rephrase the problem in terms of eigenvalues of $L'BL$ where $L$ is the Cholesky root of $A$, which has the same eigenvalues.

Another use of Cholesky() is in reordering matrices within Trace() expressions. Expressions such as $\text{Trace}(A*B*A')$ might involve huge operations counts if $A$ has many rows. However, if $B$ is small and can be factored into $LL'$ by Cholesky, then it can be reformulated to $\text{Trace}(A*L*L'^*A')$. The resulting matrix is equal to $\text{Trace}(L'A'*AL)$. This expression involves a much smaller number of operations, because it consists of only the sum of squares of the $AL$ elements.

Use the function Chol Update() to update a Cholesky decomposition. If $L$ is the Cholesky root of a $n \times n$ matrix $A$, then after using cholUpdate($L$, $C$, $V$), $L$ will be replaced with the Cholesky root of $A+V*C*V'$. $C$ is an $m \times m$ symmetric matrix and $V$ is an $n \times m$ matrix.

### Examples

Manually update the Cholesky decomposition, as follows:

```plaintext
exS = [16 1 0 11 -1 12, 1 11 -1 1 -1 1, 0 -1 12 -1 1 0, 11 1 -1 11 -1 9, -1 -1 1 -1 9 -1, 12 1 0 9 -1 12];
exAchol = Cholesky( exS ); // conducts the Cholesky decomposition
```
```
// add two column vectors to the design matrix
exV = [1 1, 0 0, 0 1, 0 0, 0 0, 0 1];
```
```
/* The first column vector is added to one of the rows in the design matrix. The second column vector is subtracted from one of the rows in the design matrix. */
exC = [1 0, 0 -1];
exAnew = exS + exV * exC * exV';
```
```
// update the Cholesky decomposition manually
exAcholnew = Cholesky( exAnew );
```
Instead of manual updating, use Chol Update() to update the Cholesky decomposition, as follows:

```plaintext
// update the Cholesky decomposition more efficiently
exAcholnew_test = Chol Update( exAchol, exV, exC );
Show( exAcholnew_test );
exAcholnew_test =
[ 4 0 0 0 0 0,
 0.25 3.30718913883074 0 0 0 0, ...]
```

```plaintext
// results are the same as the manual process
Show( exAcholnew );
exAcholnew =
[ 4 0 0 0 0 0,
 0.25 3.30718913883074 0 0 0 0, ...]
```

**Singular Value Decomposition**

The SVD() function finds the singular value decomposition of a matrix. That is, for a matrix \( A \), SVD() returns a list of three matrices \( U, M, \) and \( V \), so that \( U \cdot \text{diag}(M) \cdot V^\prime = A \).

**Notes:**

- When \( A \) is taller than it is wide, \( M \) is more compact, without extra zero diagonals.
- Singular value decomposition re-expresses \( A \) in the form \( USV^\prime \), where:
  - \( U \) and \( V \) are matrices that contain orthogonal column vectors (perpendicular, statistically independent vectors)
  - \( S \) is a \( n \times n \) diagonal matrix containing the nonnegative square roots of the eigenvalues of \( A^\prime A \), the singular values of \( A \).
- Singular value decomposition is the basis of correspondence analysis.

**Example**

```plaintext
A = [1 2 1 0, 2 3 0 1, 1 0 1 5, 0 1 5 1];
{U, M, V} = SVD( A );
newA = U * Diag( M ) * V';
[1 2 0.999999999999997 -2.99456640040496e-15,
 2 3 -1.17505831453979e-15 1,
 0.999999999999997 -2.16851276518826e-15 0.999999999999999 5,
 2.22586706011274e-15 1 5 0.999999999999997]
```

**Orthonormalization**

The Ortho() function orthogonalizes the columns and then divides the vectors by their magnitudes to normalize them. This function uses the Gram-Schmidt method. The column vectors of orthogonal matrices are unit-length and are mutually perpendicular (their dot products are zero).
B = Ortho( [1 -1, 1 0, 0 1] );
[0.408248290463863 -0.707106781186548, 0.408248290463863 0.707106781186548,
-0.816496580927726 3.14018491736755e-16]

To verify that these vectors are orthogonal, multiply B by its transpose, which should yield the
identity matrix.

C = B' * B;
[1 -3.119061760824e-16, -3.119061760824e-16 1]

By default, vectors are normalized, meaning that they are divided by their magnitudes, which
scales them to have length 1. Include the option Scaled(0) to turn scaling off:

Ortho( [1 -1, 1 0, 0 1], Scaled( 0 ) );
[0.408248290463863 -0.353553390593274, 0.408248290463863 0.353553390593274,
-0.816496580927726 1.57009245868377e-16]

To create vectors whose elements sum to zero, include the Centered(1) option. This option is
useful when constructing a matrix of contrasts.

result = Ortho( [1 -1, 1 0, 0 1], Centered( 1 ) );
[0.408248290463863 -0.707106781186548, 0.408248290463863 0.707106781186548,
-0.816496580927726 3.14018491736755e-16]

To verify that the elements of each column sum to zero, premultiply by a vector of ones to sum
the columns.

J(1, 3) * result;
[1.11022302462516e-16 2.02996189274239e-16]

Orthogonal Polynomials

The Ortho Poly() function returns orthogonal polynomials for a vector of indices. The
polynomial order is specified as a function argument. Orthogonal polynomials can be useful
for fitting polynomial models where some regression coefficients might be highly correlated.

Ortho Poly( [1 2 3], 2 );
[-0.707106781186548 0.408248290463862, 0 -0.816496580927726, 0.707106781186548
0.408248290463864]

The polynomial order must be less than the dimension of the vector. Use the Scaled(1)
option to produce vectors of unit length, as described in “Orthonormalization” on page 231.

QR Decomposition

QR() factorization is useful for numerically stable matrix work. QR() returns a list of two
matrices. Here is an example:

{Q, R} = QR( [11 22, 33 44] );

Q and R hold the results. For a m × n matrix, QR() creates an orthogonal m × m matrix Q and an
upper triangular m × n matrix R, so that X = Q*R.
Update Inverse Matrices

To add or drop one or more rows in an inverse of an $M^\prime M$ matrix, use the Inv Update($S$, $X$, $w$) function. Updating inverse matrices is helpful in drop-1 influence diagnostics and also in candidate design evaluation.

Notes:

- The first argument, $S$, is the matrix to be updated.
- The second argument, $X$, is the matrix of rows to be added or dropped.
- The third argument, $w$, is either 1 to add or -1 to delete the row or rows.
- Multiple rows can be added or deleted.

Using the Inv Update($S$, $X$, $w$) function is equivalent to calculating the following:

$$S - w \times S \times X^\prime \times \text{Inv}( I + w \times X \times S \times X^\prime ) \times X \times S$$

Where $I$ is an identity matrix and $\text{Inv}(A)$ is an inverse matrix of $A$.

Build Your Own Matrix Functions

You can store your own operations in macros. See “Macros” on page 265 in the “Programming Methods” chapter. Similarly, you can create custom matrix functions. For example, you can make your own matrix operation called Mag() to find the magnitude of a vector:

```javascript
mag = Function( {x},
    Sqrt( x^\prime \times x )
);
```

Similarly, you could create a function called Normalize to divide a vector by its magnitude:

```javascript
normalize = Function( {x},
    x / Sqrt( x^\prime \times x )
);
```

Statistical Examples

This section contains statistical examples of using matrices.

Regression Example

Suppose that you want to implement your own regression calculation, rather than use the facilities built into JMP. Because of the compact matrix notation, it might require only a few lines of code:

```javascript
Y = [98, 112.5, 84, 102.5, 102.5, 50.5, 90, 77, 112, 150, 128, 133, 85, 112];
```
X = [65.3, 69, 56.5, 62.8, 63.5, 51.3, 64.3, 56.3, 66.5, 72, 64.8, 67, 57.5, 66.5];
X = J( N Row( X ), 1 ) || X; // put in an intercept column of 1s
beta = Inv( X` * X ) * X` * Y; // the least square estimates
resid = Y - X * beta; // the residuals, Y - predicted
sse = resid` * resid; // sum of squared errors
Show( beta, sse );

This could be expanded into a script that gets its data from a data table, calculates additional results, and shows the results in a report window:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );

// get data into matrices
x = (Column( "Age" ) << Get Values ) || (Column( "Height" ) << Get Values);
x = J(N Row( x ), 1, 1) || x;
y = Column( "Weight" ) << Get Values;

// regression calculations
xpxi = Inv( x` * x );
beta = xpxi * x` * y; // parameter estimates
resid = y - x * beta; // residuals
sse = resid` * resid; // sum of squared errors
dfe = N Row( x ) - N Col( x ); // degrees of freedom
mse = sse / dfe; // mean square error, error variance estimate

// additional calculations on estimates
stdb = Sqrt( Vec Diag( xpxi ) * mse ); // standard errors of estimates
alpha = .05;
qt = Students t Quantile( 1 - alpha / 2, dfe );
betau95 = beta + qt * stdb; // upper 95% confidence limits
betal95 = beta - qt * stdb; // lower 95% confidence limits
tratio = beta :/ stdb; // Student's T ratios
probt = ( 1 - TDistribution( Abs( tratio ), dfe ) ) * 2; // p-values

// present results
New Window( "Big Class Regression",
    Table Box(
        String Col Box( "Term","Intercept", "Age", "Height" ) ),
        Number Col Box( "Estimate", beta ),
        Number Col Box( "Std Error", stdb ),
        Number Col Box( "TRatio", tratio ),
        Number Col Box( "Prob>|t|", probt ),
        Number Col Box( "Lower95%", betal95 ),
        Number Col Box( "Upper95%", betau95 ) ) );
ANOVA Example

You can implement your own one-way ANOVA. This example presents a problem involving a three-level factor indicating Low, Medium, and High doses and a response measurement. Therefore, this example solves the general linear model, as follows:

\[ Y = a + bX + e \]

Where:

- \( Y \) is a vector of responses
- \( a \) is the intercept term
- \( b \) is a vector of coefficients
- \( X \) is a design matrix for the factor
- \( e \) is an error term

```python
factor = [1, 2, 3, 1, 2, 3, 1, 2, 3];
y = [1, 2, 3, 4, 3, 2, 5, 4, 3];
```

First, build a design matrix for the factor:

```python
Design Nom( factor );
```

\[
\begin{bmatrix}
1 & 0 & 0 & 1 & 0 & 1 & -1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 & 1 & -1
\end{bmatrix}
\]

Next, add a column of 1s to the design matrix for the intercept term. You can do this by concatenating \( J \) and \( \text{Design Nom()} \):

```python
x = J( 9, 1, 1) || Design Nom( factor );
```

\[
\begin{bmatrix}
1 & 1 & 0,
1 & 0 & 1,
1 & -1 & -1,
1 & 0 & 1,
1 & -1 & -1,
1 & 1 & 0,
1 & 0 & 1,
1 & -1 & -1
\end{bmatrix}
\]

Now, to solve the normal equation, you need to construct a matrix \( M \) with partitions:

\[
\begin{bmatrix}
X'X & X'y \\
y'X & y'y
\end{bmatrix}
\]

You can construct matrix \( M \) in one step by concatenating the pieces:

```python
M = ( x` * x || x` * y )
```

\[
\begin{bmatrix}
9 & 0 & 0 & 27, \\
0 & 6 & 3 & 2, \\
0 & 3 & 6 & 1,
\end{bmatrix}
\]
Now, sweep $M$ over all the columns in $X'X$ for the full fit model, and over the first column only for the intercept-only model:

```
FullFit = Sweep( M, [1, 2, 3] ); // full fit model
InterceptOnly = Sweep( M, [1] ); // model with intercept only
```

Recall that some of the standard ANOVA results are calculated by comparing the results of these two models. This example focuses on the full fit model, which produces this swept matrix:

```
\[
\begin{bmatrix}
0.111111111111111 & 0 & 0 & 3, \\
0 & 0.222222222222222 & -0.111111111111111 & 0.333333333333333, \\
0 & -0.111111111111111 & 0.222222222222222 & 0, \\
-3 & -0.333333333333333 & 0 & 11.33333333333333
\end{bmatrix}
\]
```

Examine the model coefficients from the upper right partition of the matrix. The lower left partition is the same, except that the signs are reversed: $3, 0.333, 0$. The results can be interpreted as follows:

- The coefficient for the intercept term is $3$.
- The coefficient for the first level of the factor is $0.333$.
- The coefficient for the second level is $0$.
- Because of the use of `Design Nom()`, the coefficient for the third level is the difference, $-0.333$.
- The lower right partition of the matrix holds the sum of squares, $11.333$.

You could modify this into a generalized ANOVA script by replacing some of the explicit values in the script with arguments. These results match those from the Fit Model platform.
Figure 7.1 ANOVA Report Within Fit Model

Here is how to construct the report in Figure 7.1:

1. Build a data table (described in the “Data Tables” chapter on page 321):
   
   ```julia
   dt = New Table( "Data" );
   dt << New Column( "y", Set Values( [1, 2, 3, 4, 3, 2, 5, 4, 3] ) );
   dt << New Column( "factor", "Nominal", Values( [1, 2, 3, 1, 2, 3, 1, 2, 3] ) );
   ```

2. Run a model (described in “Launch the Analysis and Save the Script to a Window” on page 472 in the “Scripting Platforms” chapter):
   
   ```julia
   obj = Fit Model(    
     Y( :y ),
     Effects( :factor ),
     Personality( "Standard Least Squares" ),
     Run(       
       y << {Plot Actual by Predicted( 0 ), Plot Residual by Predicted( 0 ),
             Plot Effect Leverage( 0 )}
     )
   );
   ```

3. Use JSL techniques for navigating displays (described in “Display Box Object References” on page 524 in the “Display Trees” chapter):
   
   ```julia
   ranova = obj << Report;
   ranova[Outline Box( 6 )] << Close( 0 );
   ranova[Outline Box( 7 )] << Close( 1 );
   ranova[Outline Box( 9 )] << Close( 1 );
   ranova[Outline Box( 5 ), Number Col Box( 2 )] << Select;
   ranova[Outline Box( 6 ), Number Col Box( 1 )] << Select;
   ```
The result is shown in Figure 7.1.

### Associative Arrays

An associative array maps unique keys to values that can be non-unique. An associative array is also called a dictionary, a map, a hash map, or a hash table.

Note the following about keys:

- Keys are placed in quotes.
- The value associated with a key can be a number, date, matrix, list, and so on.
- A key cannot be a floating point number. Only integers are supported.
- You can use matrices as both keys and values, or lists as both keys and values, but you cannot mix the two. In other words, you cannot use a matrix as a key and a list as a value, or the other way around.
- Though associative arrays are not usually ordered, in JMP, keys are returned in alphanumeric order for the purpose of iteration and serialization.

For very large lists, using an associative array is more efficient and faster.

### Create Associative Arrays

To create an empty associative array, use the `Associative Array()` function or `[]`.  

```julia
   cary = Associative Array();
cary = [=> ];
   Associative array( 0 elements ) assigned.
```

Keys and values can be any JSL objects. Items can be added and changed with subscripting:

```julia
   cary = Associative Array();
cary["state"] = "NC";
cary["population"] = 116234;
cary["weather"] = "cloudy";
cary["population"] += 10;
cary["weather"] = "sunny";
cary["high schools"] = {"Cary", "Green Hope", "Panther Creek"};
```
Default Values

A default value determines the value of a key that does not exist in an associative array. If you try to access a key that does not exist in an associative array, an error results. If you define a default value for your associative array, accessing a key that does not exist results in the following:

- adds the key to the associative array
- assigns the default value to the new key
- returns the new key’s (default) value instead of an error

If you construct an associative array from a list of strings without assigning values to the keys, then the keys are assigned values of 1. The default value for the associative array is set to 0.

To set the default value:

```csharp
cary = Associative Array();
cary << Set Default Value( "Cary, NC" );
```

To determine whether there is a default value set for an associative array, use the <<Get Default Value message.

```csharp
cary << Get Default Value;
"Cary, NC"
```

If there is no default value, Empty() is returned.

Besides the Set Default Value message, a default value can be set in the literal constructor using =>value without a key.

```csharp
counts = ["a" => 10, 
"b" => 3, 
=> 0]; // default value of 0
counts["c"] += 1;
Show( counts );
```

In the first line, the default value is set to 0. In the second line, the key "c" does not exist in counts. In the output, the key "c" is created with the default value of 0 and then incremented by 1.

**Note:** If a key’s value is the default value, then the key is dropped because any key will return the default value.

### Associative Array Constructors

Create an empty associative array:

```csharp
map = [=>];
map = Associative Array();
```
Create an empty associative array with a default value:

```javascript
map = [=>0];
map = Associative Array( 0 );
```

Create an associative array with specific values:

```javascript
map = ["yes" => 0, "no" => 1];
```

Create an associative array with specific values with a default value:

```javascript
map = ["yes" => 0, "no" => 1, => 2];
```

Create an associative array with specific values that contains an associative array:

```javascript
map = ["yes" => 0, "no" => 1, "alt" => ["a" => "1", "b" => "2"]];
```

Create an associative array from a list that contains two lists of a key-value pair:

```javascript
map = Associative Array( {{"yes", 0},{"no", 1}} );
```

Create an associative array from a list that contains two lists of a key-value pair with a default value:

```javascript
map = Associative Array( {{"yes", 0},{"no", 1}}, 2 );
```

Create an associative array from a list of keys and a list of values:

```javascript
map = Associative Array( {"yes", "no"}, {0, 1} );
```

Create an associative array from a list of keys and a list of values with a default value:

```javascript
map = Associative Array( {"yes", "no"}, {0, 1}, 2 );
```

Create an associative array from two column references. The first column contains the keys and the second contains the values.

```javascript
map = Associative Array( :name, :height );
```

Create an associative array from two column references with a default value:

```javascript
map = Associative Array(:name, :height, .);
```

Create an associative array from a single list of keys or a single column reference of keys with a default value of 0:

```javascript
set = Associative Array( {"yes", "no"} );
set = Associative Array( :name );
```
Work with Associative Arrays

Find the Number of Keys

To determine the number of keys that an associative array contains, use the N\ Items() function.

```javascript
  cary = Associative Array();
  cary["state"] = "NC";
  cary["population"] = 116234;
  cary["weather"] = "cloudy";
  cary["population"] += 10;
  cary["weather"] = "sunny";
  cary["high schools"] = {"Cary", "Green Hope", "Panther Creek"};
  N\ Items( cary );
  4
```

Add and Delete Keys and Values

To add or delete key-value pairs from an associative array, use the following functions:

- Insert()
- Insert Into()
- Remove()
- Remove From()

Notes:

- Insert() and Remove() return a named copy of the given associative array with the key-value pair added or removed.
- Insert Into() and Remove From() add or remove the key-value pairs directly from the given associative array.
- Insert() and Insert Into() take three arguments: the associative array, a key, and a value.
- Remove() and Remove From() take two arguments: the associative array and a key.
- If you insert a key with no value provided, the key is assigned a value of 1.

Examples

The following examples illustrate Insert() and Insert Into():

```javascript
  cary = Associative Array();
  cary["state"] = "NC";
  cary["population"] = 116234;
  cary["weather"] = "cloudy";
  cary["population"] += 10;
```
cary["weather"] = "sunny";
cary["high schools"] = \{"Cary", "Green Hope", "Panther Creek"\};
newcary = Insert( cary, "time zone", "Eastern" );
Show( cary, newcary );

cary = Associative Array();
cary["state"] = "NC";
cary["population"] = 116234;
cary["weather"] = "cloudy";
cary["population"] += 10;
cary["weather"] = "sunny";
cary["high schools"] = \{"Cary", "Green Hope", "Panther Creek"\};

Note that cary \textless\texttt{Insert} is a message sent to an associative array that does the same thing as the function Insert Into(). For example, these two statements are equivalent:

cary \textless\texttt{Insert( "county", "Wake" )};
Insert Into( cary, "county", "Wake" );

The following examples illustrate Remove() and Remove From():

cary = Associative Array();
cary["state"] = "NC";
cary["population"] = 116234;
cary["weather"] = "cloudy";
cary["population"] += 10;
cary["weather"] = "sunny";
cary["high schools"] = \{"Cary", "Green Hope", "Panther Creek"\};
newcary = Remove( cary, "high schools" );

Remove From( cary, "weather" );

Show( cary );
Show( cary, newcary );

newcary = ["population" => 116244, "state" => "NC", "weather" => "sunny"];
Note that `aa << Remove` is a message sent to an associative array that does the same thing as the function `Remove From()`. For example, these two statements are equivalent:

```plaintext
cary << Remove("weather");
Remove From(cary, "weather");
```

## Find Keys or Values in an Associative Array

To determine whether a certain key is contained within an associative array, use the `Contains()` function.

```plaintext
cary = Associative Array();
cary["state"] = "NC";
cary["population"] = 116234;
cary["weather"] = "cloudy";
cary["population"] += 10;
cary["weather"] = "sunny";
cary["high schools"] = {"Cary", "Green Hope", "Panther Creek"};
Contains(cary, "high schools");
1
Contains(cary, "lakes");
0
```

To obtain a list of all keys contained in an associative array, use the `<< Get Keys` message.

```plaintext
cary << Get Keys;
{"high schools", "population", "state", "weather"}
```

To obtain a list of all values contained in an associative array, use the `<<Get Values` message.

```plaintext
cary << Get Values;
{"Cary", "Green Hope", "Panther Creek"}, 116244, "NC", "sunny"}
```

If you want to see only the values for certain keys, you can specify them as arguments. The keys must be given as a list.

```plaintext
cary << Get Values({"state", "population"});
{"NC", 116244}
```

To see a value for a single key, use the `<<Get Value` message. Specify only one key and do not place it in a list.

```plaintext
cary << Get Value("weather");
"sunny"
```

To obtain a list of all key-value pairs in an associative array, use the `<<Get Contents` message.

```plaintext
cary << Get Contents;
{"high schools", {"Cary", "Green Hope", "Panther Creek"}},
{"population", 116244},
{"state", "NC"},
{"weather", "sunny"}
```
**Note:** Using the `<<Get Contents` message, the returned list does not include the default value. Keys are listed alphabetically.

### Iterate through an Associative Array

To iterate through an associative array, use the `<<First` and `<<Next` messages. `<<First` returns the first key in the associative array. `<<Next(key)` returns the key that follows the `key` that is given as the argument.

The following example removes all key-value pairs from the associative array `cary`, leaving an empty associative array:

```plaintext
currentkey = cary << First;
total = N Items( cary );
For( i = 1, i <= total, i++,
    nextkey = cary << Next( currentkey );
    Remove From( cary, currentkey );
    currentkey = nextkey;
);
Show( cary );
cary = [=>];
```

### Applications for Associative Arrays

You can use associative arrays to quickly and efficiently perform other tasks.

#### Get the Unique Values from a Data Table Column

**Note:** The strategy described here is not useful for columns with floating point numbers. Use `Summarize` instead. See “Store Summary Statistics in Global Variables” on page 364 in the “Data Tables” chapter.

A key can exist only once in an associative array, so putting a column’s values into one automatically results in the unique values. For example, the `Big Class.jmp` sample data table contains 40 rows. To see how many unique values are in the column `height`, run this script:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
unique heights = Associative Array( dt:height );
nitems( unique heights );
17
```

There are only 17 unique values for `height`. You can use those unique values by getting the keys:

```plaintext
unique heights << Get Keys;
{51, 52, 55, 56, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70}
```
**Note:** This is possible because you can use any JMP data type as keys in an associative array, not only strings.

Using an associative array to discover unique values in a column is efficient and fast. The following script takes some time to create a data table with 100,000 rows. Finding the 39 unique values takes very little time.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
nms = dt:name << Get Values;
dtbig = New Table( "Really Big Class",
    New Column( "name",
        Character,
        Set Values( nms[J( 100000, 1, Random Integer( N Items( nms ) ) )] )
    ));
Wait( 0 );
t1 = Tick Seconds();
Write("
\!N# names from Really Big Class = ",
    N Items( Associative Array( dtbig:name ) ),
    ", elapsed time=",
    Tick Seconds() - t1);

# names from Really Big Class = 39, elapsed time=0.116666666639503
```

**Sort a Column’s Values in Lexicographic Order**

Because keys are ordered lexicographically, putting the values into an associative array also sorts them. For example, the `<<Get Keys` message returns the keys (unique values of the names column) in ascending order:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
unique names = Associative Array( dt:name );
unique names << Get Keys;
```

**Compare Columns in Two Different Data Tables**

Using associative arrays, determining which values in one column are not in another column (or determining which values are in both columns) is fast. For example, given two data tables with information about countries, which countries are in both data tables?

Place the columns of each data table that contain country names into associative arrays:
dt1 = Open( "SAMPLE_DATA/BirthDeathYear.jmp" );
dt2 = Open( "SAMPLE_DATA/World Demographics.jmp" );
aa1 = Associative Array( dt1:Country );
aa2 = Associative Array( dt2:Territory );

Use N Items() to see how many countries appear in each data table:

N Items(aa1);
 23
N Items(aa2);
 239

Use the <<Intersect message to find the common values:

aa1 = Associative Array( dt1:Country );
aa1 << Intersect( aa2 );

Look at the results:

Show(N Items(aa1), aa1 << Get Keys);
  N Items(aa1) = 21;

This example uses a set operation called intersection. For more examples of using set operations with associative arrays to compare values, see “Associative Arrays in Set Operations” on page 249.

**Associative Arrays in Graph Theory**

You can use associative arrays for graph theory data structures, such as the following directed graph example:

```markdown
g = Associative Array();
g[1] = Associative Array({1, 2, 4});
g[2] = Associative Array({1, 3});
g[3] = Associative Array({4, 5});
g[4] = Associative Array({4, 5});
g[5] = Associative Array({1, 2});
```

This is a two-level associative array. The associative array g contains five associative arrays (1, 2, 3, 4, and 5). In the containing array g, both the keys (1-5) and the values (the arrays that define the map) are important. In the inner associative arrays, the values do not matter. Only the keys are important.

The associative array represents the graph shown in Figure 7.2:

- node 1 is incident on nodes 1, 2, and 4
- node 2 is incident on nodes 1 and 3
• node 3 is incident on nodes 4 and 5
• node 4 is incident on nodes 4 and 5
• node 5 is incident on nodes 1 and 2

Figure 7.2 Example of a Directed Graph

The following depth-first search function can be used to traverse this graph, or any other directed graph represented as an associative array:

```plaintext
defs = Function( {ref, node, visited},
    {chnode, tmp},
    Write( "\NNode: ", node, ", ", ref[node] << Get Keys );
    visited[node] = 1;
    tmp = ref[node];
    chnode = tmp << first;
    While( !Is Missing( chnode ),
        If( !visited[chnode],
            visited = Recurse( ref, chnode, visited )
        );
        chnode = tmp << Next( chnode );
    );
    visited;
);
```

Notes:
• The first argument is the associative array that contains the map structure.
• The second argument is the node that you want to use as the starting point.
• The third argument is a vector that the function uses to keep track of nodes visited.

To see how the preceding example works, add the following expression to the end of the script:

```plaintext
defs( g, 2, J( N Items( g << Get Keys ), 1, 0 ) );
```
Here is the output:

Node 2: \{1, 3\}
Node 1: \{1, 2, 4\}
Node 4: \{4, 5\}
Node 5: \{1, 2\}
Node 3: \{4, 5\}

\[[1, 1, 1, 1, 1]\]

The first five output lines show that starting from node 2, you can reach all the other nodes in the order in which they are listed. Each node also lists the nodes it is incident on (the keys). The value for each key is 1. The final line is a matrix that shows that you can reach each node from 2. If there were nodes that could not be reached from node 2, their values in the matrix would be 0.

Here is how to read the traversal of the nodes:
1. Start at node 2 and go to node 1.
2. From node 1, go to node 4.
3. From node 4, go to node 5.
4. From node 5, go back to node 2, and then to node 3.

Map Script

Here is the script that produced the map shown in Figure 7.2.

```plaintext
New Window( "Directed Graph",
  Graph Box(
    Frame Size( 300, 300 ),
    X Scale( -1.5, 1.5 ),
    Y Scale( -1.5, 1.5 ),
    Local( {n = N Items( g ), k = 2 * Pi() / n, r, i, pt, from, to,
      edge, v, d},
      Fill Color( "green" );
      Pen Size( 3 );
      r = 1 / (n + 2);
      For( i = 1, i <= n, i++,
        pt = Eval List( {Cos( k * i ), Sin( k * i )} );
        edges = g[i];
        For( edge = edges << First, !Is Empty( edge ),
          edge = edges << Next( edge ),
          to = Eval List( {Cos( k * edge ), Sin( k * edge )} );
          If( i == edge,
            Circle( Eval List( 1.2 * pt ), 0.9 * r ), // else
            v = pt - to;
            d = Sqrt( Sum( v * v ) );
            {from, to} = Eval List(
              {pt * (d - r) / d + to * r / d, pt * r / d + to *
```

Scripting Guide  
Data Structures  
Associative Arrays

You can also use associative arrays to perform set operations. The following examples show how to take a union of two sets, a difference of two sets, and an intersection of two sets.

First, create three sets and view them in the log:

```plaintext
set_y = Associative Array( \{"chair", "person", "relay", "snake", "tripod"\} );
set_z = Associative Array( \{"person", "snake"\} );
set_w = Associative Array( \{"apple", "orange"\} );
```

```
// write the sets to the log
Write(
  "\!NExample:\!N\tset_y = ",
  set_y << Get Keys,
  "\!N\tset_z = ",
  set_z << Get Keys,
  "\!N\tset_w = ",
  set_w << Get Keys);

Example:
  set_y = \{"chair", "person", "relay", "snake", "tripod"\}
  set_z = \{"person", "snake"\}
  set_w = \{"apple", "orange"\}
```

**Union Operation**

To find the union of two sets, insert one set into the other:

```plaintext
set_z << Insert( set_w );
Write( "\!N\tUnion operation (set_w, set_z):\!N\tset_z = ", set_z << Get Keys);
```

```plaintext
set_z = \{"apple", "orange", "person", "snake"\}
```
Difference Operation

To find the difference of two sets, remove one set from the other:

```plaintext
set_y << Remove( set_z );
Write( "\!N\!NDifference operation (set_z from set_y):\!N\!tset_y = ", set_y
  << Get Keys );
Difference operation (set_z from set_y):
  set_y = {"chair", "relay", "tripod"}
```

Intersect Operation

To find the intersection of two sets, use the `aa << Intersect` message.

```plaintext
set_w << Intersect( set_z );
Write( "\!N\!NIntersect operation (set_w, set_z):\!N\!tset_w = ", set_w << Get
  Keys );
Intersect operation (set_w, set_z):
  set_w = {"apple", "orange"}
```

Example of Using Set Operations

Given a list of names, which of them are not contained in Big Class.jmp? You can find the
answer by taking the difference of the two sets of names.

1. Get the list of names and open the data table:
   ```plaintext
   names list = {"ROBERT", "JEFF", "CHRIS", "HARRY"};
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
   ```

2. Put the list of names into an associative array:
   ```plaintext
   names = Associative Array( names list );
   ```

3. Perform a difference operation by removing the column values from your list:
   ```plaintext
   names << Remove( Associative Array( dt:name ) );
   ```

4. Look at the result:
   ```plaintext
   Write( "\!NWhich of \{ROBERT, JEFF, CHRIS, HARRY\}, is not in Big Class = ",
     names << Get Keys );
   Which of \{ROBERT, JEFF, CHRIS, HARRY\}, is not in Big Class = {"HARRY", "JEFF"}
   ```
This chapter includes advanced techniques, such as throwing and catching exceptions, encrypting scripts, and using complex expressions.

Lists and Expressions

Expressions

This section delves into JSL expressions and introduces several JSL functions that can be used to manipulate JSL expressions. These functions provide JSL programmers with a rich, powerful, meta programming toolkit. One of the benefits of such a toolkit is that it provides JSL programmers with a powerful macro system capability that is similar in functionality to macro systems available in other modern programming languages.

In order to understand JSL expressions, it is useful to keep in mind that everything that happens in JSL is a result of a function call. Function calls come in three varieties:

**prefix** The function name comes before its arguments (for example, Foo( m, n )). Most function calls in JSL are of this form.

**infix** The function name is between its arguments (for example, m + n). This form is common for mathematical operators.

**special** Functions like [ ] (the subscript operator) fall into this category. Since there are only a handful of special functions, they are not discussed further in this section.

Although function calls come in three forms, all function calls can be written in prefix form. It turns out that JMP actually uses the prefix form internally and so, in general, it is very useful to think of JSL expressions in this way.

To illustrate this idea, begin by examining the syntactic structure of JSL expressions a bit more closely. All JSL expressions must conform to a very simple syntactic structure. Each expression consists of a head expression and a sequence of zero or more argument expressions. Consider the following JSL expressions, written first in infix form and then in prefix form, to see how this syntactic structure applies:

\[
\begin{align*}
x &= 100.1 \\
m &\& n \\
1 &\leq z &\leq 20
\end{align*}
\]

Using the prefix form, these expressions are written equivalently:

\[
\begin{align*}
Assign( x, 100.1 ) \\
And( m, n ) \\
Less or Equal( 1, z, 20 )
\end{align*}
\]
The head of the first example is Assign and its arguments are \( x \) and 100.1. For the second example, the head is And and its arguments are \( m \) and \( n \), whereas for the third example, the head is Less or Equal and its arguments are 1, \( z \), and 20. For these examples, the “\( = \)”, “\&”, and “\( \leq \)” operators are just human friendly ways of representing Assign, And, and Less or Equal.

Examine a few additional simple examples.

\[
\begin{align*}
\text{Assign}(100.1, x) \\
\text{And}( ) \\
\text{Less or Equal}(z)
\end{align*}
\]

These examples also conform to the required syntactic structure, but they differ from the previous examples in that they all produce an error message when they are evaluated. This point leads to an important distinction that you should make when thinking about JSL expressions. That is, you should separate the idea of the syntactic structure of a JSL expression from what happens when the expression is evaluated.

Consider the following examples that present both the human friendly form and the prefix form in each case:

\[
\begin{align*}
\text{x = 100.1 + Log(z) // human friendly form} \\
\text{Assign(x, Add(100.1, Log(z))) // prefix form}
\end{align*}
\]

This example illustrates that the arguments of a head expression can also be expressions.

\[
\begin{align*}
\text{// human friendly form} \\
\text{x = 0.8;} \\
\text{x ||= Random Uniform(0.2, 0.6);}
\end{align*}
\]

\[
\begin{align*}
\text{// prefix form} \\
\text{Glue(} \\
\text{Assign(x, 0.8),} \\
\text{Concat To(x, Random Uniform(0.2, 0.6))})
\end{align*}
\]

This example illustrates two important points:

1. The “\( ; \)” symbol is another instance of a human friendly operator. In this case, it is for the Glue function.
2. There is no distinction between what are typically referred to as a JSL script and a JSL expression.
The remainder of this section covers how to assign an expression to a variable and then how to manipulate, or execute, that expression when needed. For information about how JMP resolves names when evaluating JSL expressions, see the section “Rules for Name Resolution” on page 111 in the “JSL Building Blocks” chapter.

**Quoting and Unquoting Expressions**

The operators to control when expressions are evaluated are `Expr` and `Eval`, which you should think of as the procrastination and eager operators. `Expr` just copies its argument as an expression, rather than evaluating it. `Eval` does the opposite: it evaluates its argument, and then takes that result and evaluates it again.

`Expr` and `Eval` can be thought of as quoting and unquoting operators, telling JMP when you mean the expression itself, and when you mean the result of evaluating the expression.

The following examples all assume these two assignments:

```
x = 1; y = 20;
```

If you assign the expression `x+y` to `a`, quoting it as an expression with `Expr`, then whenever `a` is evaluated, it evaluates the expression using the current values of `x` and `y` and returns the result. (Exceptions are the utilities `Show`, `Write`, and `Print`, which do not evaluate expressions for pure name arguments.)

```
x = 1; y = 20;
a = Expr(x + y);
a;
```

```
21
```

If you want the expression that is stored in the name, rather than the result of evaluating the expression, use the `NameExpr` function. See “Retrieve a Stored Expression Rather than its Result” on page 257.

```
x = 1; y = 20;
Show( NameExpr(a) );
NameExpr(a) = x + y
```

If you assign an extra level of expression-quoting, then when `a` is evaluated, it unpacks one layer and the result is the expression `x+y`.

```
x = 1; y = 20;
a = Expr( Expr( x + y ) );
Show( a );
a = Expr(x + y)
```

If you want the value of the expression, then use `Eval` to unpack all layers:

```
x = 1; y = 20;
Show( Eval(a) );
Eval(a) = 21
```
You can do this to any level, for example:

```javascript
x = 1; y = 20;
a = Expr( Expr( Expr( Expr( x + y ) ) ) );
b = a;
  Expr( Expr( x + y ) )
c = Eval( a );
  Expr( x + y )
d = Eval( Eval( a ) );
  x+y
e = Eval( Eval( Eval( a ) ) );
  21
```

For more information about expression handling, see Morgan (2010).

### Quote an expression as a string

The JSL `Quote()` function returns the contents of an expression as a quoted string. Comments and white space in the string are preserved.

The following expression is an example:

```javascript
x = JSL Quote( /* Begin quote. */
    For (i = 1, i <= 5, i++,
        // Print the value of i.
        Print( i );
    );
    // End expression.
); Show( x );
```

In the output, the contents of the JSL `Quote()` function are enclosed in quotes.

```javascript
x = " /* Begin quote. */
    For (i = 1, i <= 5, i++,
        // Print the value of i.
        Print(i);
    );
    // End expression.
";
```

### Quoting Expressions

A common use of the `Expr()` function is to store an expression in a JSL variable. This could be considered as a macro. Consider the following script:

```javascript
dist = Expr( Distribution( Column( height ) ) );
```

To execute the above expression, just use the following:

```javascript
dist;
```
You can use expressions in a loop to execute it:

For( i = 0, i < 3, i = i + 1, dist );

This loop results in three Distribution platform reports for height.

Use Eval() to evaluate an expression explicitly:

Eval( dist );

Note, however, that in column formulas, Eval() only works if it is outermost in the formula. So, for example,

Formula( Log( Eval( Column Name( i ) ) ) );

would generate an error. Instead, use:

Formula( Eval( Substitute( Expr( Log( xxx ) ), Expr( xxx ), Column Name( i ) ) ) );

As another example,

Formula( Eval( Column Name( i ) ) + 10 );

generates an error, since Eval() is actually under the Add function. Instead, use:

Formula( Eval( Substitute( Expr( xxx+10 ), Expr( xxx ), column name(i) ) ) )

Retrieve a Stored Expression Rather than its Result

What if you wanted the symbolic value of a variable (such as the expression Distribution(Column(height)) stored in dist above), rather than the evaluation of it (the actual launched platform)? The Name Expr function does this. Name Expr retrieves its argument as an expression without evaluating it.

Expr returns its argument exactly, whereas Name Expr looks up the expression stored in its argument. Name Expr “unpacks” just one layer to get the expression, but does not keep unpacking to get the result.

For example, you would need to use this if you had an expression stored in a name and you wanted to edit the expression:

\[ \text{popVar} = \text{Expr} \left( \text{Summation} \left( i = 1, N \text{Row}(), (y[i] - \text{Col Mean}( y ))^2 / N \text{Row}() \right) \right); \]

\[ \text{Summation} \left( i = 1, N \text{Row}(), (y[i] - \text{Col Mean}( y ))^2 / N \text{Row}() \right) \]

\[ \text{unbiasedPopVar} = \text{Substitute} \left( \text{Name Expr} \left( \text{popVar} \right), \text{Expr} \left( \text{Wild}() / N \text{Row}() \right), \text{Expr} \left( (y[i] - \text{Col Mean}( y ))^2 / (N \text{Row}() - 1) \right) \right); \]

\[ \text{Summation} \left( i = 1, N \text{Row}(), (y[i] - \text{Col Mean}( y ))^2 / (N \text{Row}() - 1) \right) \]

Compare x, Expr(x), NameExpr(x), and Eval(x) after submitting this script:

\[ a = 1; b = 2; c = 3; \]
\[ x = \text{Expr}( a + b + c ); \]
JSL also supports functions to access and traverse expressions, all of them either a name or a literal expression as an argument. In the following, expressionArg is either a single name or a compound expression to be taken literally.

\[
\text{NArg}(\text{expressionArg})
\]

finds the number of arguments in expressionArg.

The expressionArg can be a name holding an expression, an expression evaluated to an expression, or a literal expression quoted by Expr().

\[
\text{NArg}(\text{name})
\]

obtains the expression held in name (it is not evaluated) and returns the number of arguments.

\[
\text{NArg}(\text{expression})
\]

evaluates expression and returns the number of arguments.

\[
\text{NArg}(\text{Expr(}\text{expression})\text{)}
\]

returns the number of arguments to literal expression.

For example, if \(a\text{Expr} = \{a+b,c,d,e+f+g\}\):

- \(\text{NArg}(a\text{Expr})\) results in 4.
- \(\text{NArg}(\text{Arg}(a\text{Expr},4))\) results in 3.
- \(\text{NArg}(\text{Expr(}\{1,2,3,4\}\text{)})\) results in 4.

\[
\text{Head}(\text{expressionArg})
\]

returns the head of the expression without any arguments. If the expression is an infix, prefix, or postfix special character operator, then it is returned as the functional equivalent.

The expressionArg can be a name holding an expression, an expression evaluated to an expression, or a literal expression quoted by Expr().
For example, if \texttt{aExpr = expr(a+b)};

- \texttt{r = Head(aExpr)} results in \texttt{Add()}.  
- \texttt{r = Head(Expr(sqrt(r))}) results in \texttt{Sqrt()}.  
- \texttt{r = Head({1,2,3})} results in \texttt{\{}.

\texttt{Arg(expressionArg, indexArg)} extracts the specified argument of the symbolic expression, resulting in an expression.

For example, \texttt{Arg(expressionArg, i)} extracts the \textit{i}th argument of \textit{expressionArg}.

The \textit{expressionArg} can be a name holding an expression, an expression evaluated to an expression, or a literal expression quoted by \texttt{Expr()}.

- \texttt{Arg(name, i)} obtains the expression held in \textit{name} (it is not evaluated) and finds the \textit{i}th argument.
- \texttt{Arg(expression, i)} evaluates \textit{expression} and finds the \textit{i}th argument.
- \texttt{Arg(Expr(expression), i)} finds the \textit{i}th argument of \textit{expression}.

As another example, if \texttt{aExpr = Expr(12+13*sqrt(14-15))};

- \texttt{Arg(aExpr, 1)} yields 12.
- \texttt{Arg(aExpr, 2)} yields \texttt{13*sqrt(14-15)}.
- \texttt{Arg(Expr(12+13*sqrt(14-15)), 2)} yields \texttt{13*sqrt(14-15)}.

To extract an argument of an argument inside an expression, you can nest \texttt{Arg} commands:

- \texttt{Arg(Arg(aExpr, 2), 1)} yields the first argument within the second argument of \texttt{aExpr}, or 13.
- \texttt{Arg(Arg(aExpr, 2), 2)} yields \texttt{Sqrt(14-15)}.
- \texttt{Arg(Arg(Arg(aExpr, 2), 2), 1)} yields 14-15.
- \texttt{Arg(Arg(Arg(aExpr, 2), 2), 3)} yields \texttt{Empty()}

Here is a description of how the last example line unwraps itself:

1. The inner \texttt{Arg} statement is evaluated.
   \begin{verbatim}
   Arg(aExpr,2)
   13 * Sqrt( 14 - 15 )
   \end{verbatim}
2. Then the next one is evaluated.
   \begin{verbatim}
   Arg(Arg(aExpr,2),2)
   // this is equivalent to Arg(Expr(13 * Sqrt( 14 - 15 ) ), 2)
   Sqrt( 14 - 15 )
   \end{verbatim}
3. Finally, the outer \texttt{Arg} is evaluated.
   \begin{verbatim}
   Arg(Arg(Arg(aExpr,2),2),3)
   // this is equivalent to Arg(Expr(Sqrt( 14 - 15 ) ), 3)
   \end{verbatim}
Empty()

There is only one element to the Sqrt expression, so a request for the third argument yields Empty(). To access the two arguments inside the Sqrt expression, try this:

\[
\text{Arg(Arg(Arg(aExpr,2),2),1),2);}
\]

HeadName(\text{expressionArg}) returns the name of the head of the expression as a string. If the expression is an infix, prefix, postfix, or other special character operator, then it is returned as the functional equivalent.

The \text{expressionArg} can be a name holding an expression, an expression evaluated to an expression, or a literal expression quoted by Expr().

For example, if \text{aExpr = expr(a+b)};

- \text{r = HeadName (aExpr)} results in "Add".
- \text{r = HeadName (Expr(sqrt(r)) results in "Sqrt".}
- \text{r = HeadName ([1,2,3]) results in "List".}

In previous versions of JMP, other versions of Arg, Narg, Head, and HeadName were implemented, called ArgExpr, NArgExpr, HeadExpr, and HeadNameExpr, respectively. These did the same thing, but did not evaluate their argument. These forms are now deprecated and will not be documented in future versions.

Making Substitutions

Eval Insert is for the situation where you want to make substitutions, by evaluating expressions inside a character string.

With Eval Insert, you specify characters that delimit the start and end of an expression, and everything in between is evaluated and expanded.

There are two functions, one to return the result, the other to do it in-place.

\[
\text{resultString = EvalInsert( string with embedded expressions, startDelimiter, endDelimiter )}
\]

\[
\text{EvalInsertInto( string l-value with embedded expressions, startDelimiter, endDelimiter )}
\]

The delimiter is optional. The default start delimiter is "^". The default end delimiter is the start delimiter.

\[
\text{xstring = "def";}
\text{r = Eval Insert( "abc^xstring^ghi" ); // returns "abcdefghi";}
\]

\[
\text{r = "abc^xstring^ghi"; // in-place evaluation}
\text{Eval Insert Into( r ); // r now has "abcdefghi";}
\]
// with specified delimiter
r = Eval Insert( "abc%xstring%ghi","%" );  // returns "abcdefghi";

// with different start and end delimiters
r = Eval Insert( "abc[xstring]ghi","[","]" );  // returns "abcdefghi";

When a numeric value contains locale-specific formatting, include the <<Use Locale(1) option. The following example substitutes a comma for the decimal point based on the computer's locale setting.

    Eval Insert( "^1.2^", <<Use Locale( 1 ) );
    1,2

Evaluate expressions inside lists

Eval List evaluates expressions inside a list and returns a list with the results:

    x = { 1 + 2, 3 + 4 };
    y = Eval List( x );  // returns y is {3,7}

Eval List is useful for loading the list of user choices returned by Column Dialog or New Window with the Modal argument.

Evaluate expressions inside expressions

Eval Expr() evaluates only the inner expressions and returns an expression that contains the results of the evaluation. By comparison, Eval evaluates the inner expressions, takes the results, and then evaluates it again.

Suppose that a data table contains a column named X3. Here is an example of using Eval Expr() to evaluate the inner expression first:

    x = Expr( Distribution( Column( Expr("X"|| Char( i ) ) ) ) );
    i = 3;
    y = Eval Expr( x );  // returns Distribution( Column( "X3" ) )

To evaluate further, you need to either call the result in a subsequent step, or else put Eval() around the Eval Expr(). The following examples create a Distribution report.

    // two-step method
    x = Expr( Distribution( Column( Expr("X" || Char( i ) ) ) ) );
    i = 3;
    y = Eval Expr( x );
    y;

    // one-step method
    x = Expr( Distribution( Column( Expr("X" || Char( i ) ) ) ) );
    i = 3;
    Eval( Eval Expr( x ) );
See Table 8.3 on page 263 to learn what would happen if you tried to use Eval directly on \( x \) without first doing Eval Expr.

### Parsing Strings into Expressions, and Vice Versa

Parsing is the syntactic scanning of character strings into language expressions. Suppose that you have read in a valid JSL expression into a character string, and now want to evaluate it. The Parse function returns the expression. To evaluate it, use the Eval function.

\[
x = \text{Parse}( \text{"a=1"} ) ;  \quad // \ x \ \text{now has the expression} \ a=1
\]
\[
\text{Eval}( \text{Parse}( \text{"a=1"} ) ) ;  \quad // \ a \ \text{now has the value} \ 1
\]

To go in the reverse, use the Char function, which converts an expression into a character string. Usually the argument to a Char function is an Expr function (or a NameExpr of a variable), since Char evaluates its argument before deparsing it.

\[
y = \text{Char}( \text{Expr}( \ a = 1 \ ) ) ;  \quad // \ \text{results in} \ y \ \text{having the character value} \ "a=1"
\]
\[
z = \text{Char}( \ 42 \ ) ;  \quad // \ \text{returns} \ "42"
\]

The Char function allows arguments for field width and decimal places if the argument is a number. The default is 18 for width and 99 for decimal (Best format).

\[
\text{Char}( \ 42, 5, 2 \ ) ;  \quad // \ \text{returns the character value} \ "42.00"
\]

To preserve locale-specific formatting in the numeric value, include the <<Use Locale(1) option as shown in the following example:

\[
\text{Char}( \ 42, 5, 2, \text{<<Use Locale(1)} ) ;  \quad // \ \text{returns the character value} \ "42,00" \ \text{in the French locale}
\]

The reverse of Char is not quite as simple. To convert a character string into an expression, you use Parse, but to convert a character string into a number value, you use Num.

\[
\text{Parse}( \ y ) ;  \\
\text{Num}( \ z ) ;
\]

### Table 8.2 Functions to Store or Evaluate Expressions

<table>
<thead>
<tr>
<th>Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Char</td>
<td>\text{Char(Expr(expression))} \text{Char(name)}</td>
<td>Converts an \textit{expression} into a character string. The expression must be quoted with \textit{Expr}; otherwise its evaluation is converted to a string.</td>
</tr>
<tr>
<td></td>
<td>\quad \text{string = char(number, width, decimal)}</td>
<td>Converts a \textit{number} into its character representation. \textit{Width} and \textit{decimal} are optional arguments to specify formatting; the default is 18 for width and 99 for decimal.</td>
</tr>
</tbody>
</table>
Table 8.2 Functions to Store or Evaluate Expressions (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>

<td></td>
<td>unevaluated expression stored in the name rather than the unevaluated name x.</td>
</tr>
<tr>
<td>Num</td>
<td>Num(&quot;string&quot;)</td>
<td>Converts a character string into a number.</td>
</tr>
<tr>
<td>Parse</td>
<td>Parse(&quot;string&quot;)</td>
<td>Converts a character string into a JSL expression.</td>
</tr>
</tbody>
</table>

Summary

Table 8.3 compares various ways that you can use the evaluation-control functions with x. Assume that a data table contains a column named X3, and x and i have been assigned:

\[
x = \text{Expr( Distribution(Column( Expr("X"||Char( i ) ) ) ) )};
i = 3;
\]

Table 8.3 Functions for Controlling Evaluation

<tbody>
<tr>
<td>x; // or Eval(x);</td>
<td>Eval(x) and simply calling x are equivalent.</td>
</tr>
<tr>
<td>Not Found in access or evaluation of 'distribution', Bad Argument( {&quot;X&quot;</td>
<td></td>
</tr>
<tr>
<td>Expr(x); x</td>
<td>Returns the expression x (packs an additional layer).</td>
</tr>
</tbody>
</table>
**Table 8.3 Functions for Controlling Evaluation (Continued)**

<table>
<thead>
<tr>
<th>Commands and results</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name Expr(x);</td>
<td>Returns the expression stored in $x$ exactly as is: Distribution(Column(Expr(&quot;X&quot;</td>
</tr>
<tr>
<td>Distribution(Column(Expr(&quot;X&quot;</td>
<td></td>
</tr>
<tr>
<td>y=Eval Expr(x);</td>
<td>Evaluates the inner expression but leaves the outer expression unevaluated, so that $y$ is Distribution(Column(&quot;X3&quot;).)</td>
</tr>
<tr>
<td>Distribution(Column(&quot;X3&quot;))</td>
<td></td>
</tr>
<tr>
<td>y; //or Eval(Eval Expr(x));    Distribution[]</td>
<td>Eval(eval expr(x)) and simply calling y are equivalent. Evaluates Distribution(Column(&quot;X3&quot;)) to launch the platform.</td>
</tr>
<tr>
<td>z = Char(nameexpr(x)); &quot;Distribution(Column(Expr (!&quot;X!&quot;</td>
<td></td>
</tr>
<tr>
<td>Parse(z); Distribution(Column(Expr(&quot;X&quot;</td>
<td></td>
</tr>
<tr>
<td>a = Parse(Char( NameExpr(x))); Eval(EvalExpr(a)); Distribution[]</td>
<td>Evaluation control taken to its logical extreme. Note that you must break this into at least two steps as shown. Combining it into one giant step produces different results because the Eval Expr layer causes the Parse layer to be copied literally, not executed.</td>
</tr>
<tr>
<td>Eval( EvalExpr( Parse( Char( NameExpr(x))))); Distribution(Column(Expr(&quot;X&quot;</td>
<td></td>
</tr>
</tbody>
</table>
Macros

Stored expressions can serve as a macro feature. You can store a generalized action as an expression in a JSL variable, and then call that variable wherever you need that action to be performed. This example has four macros as the arguments to If:

\[
\text{lastStdzdThickness} = \text{expr}( \\
    (\text{thickness}[\text{nrow()}] - \text{col mean(thickness)}) / \text{col std dev(thickness)}); \\
\text{continue} = \text{expr}(\ldots<\text{script to read in more data}>\ldots); \\
\text{log} = \text{expr}(\text{print(\"In control at \"||\text{char( long date(today())})\\")}); \\
\text{break} = \text{expr}(\ldots<\text{script to shut down process}>\ldots); \text{limitvalue} = 1; \\
\]

\[
\text{if(lastStdzdThickness < limitvalue, log, continue, break);}
\]

Storing the expression with Expr delays its evaluation until the variable is evaluated. Any variables, data points, or expressions included in that expression are evaluated on the fly when the expression is evaluated. See “Expressions” on page 253, for detailed rules for storing expressions and later evaluating them.

Manipulating Lists

The following functions manipulate lists. They can also be used to manipulate expressions, as shown in the next section, “Manipulating Expressions” on page 268. A summary of commands with explanations is in Table 8.4 on page 270.

Most of the functions have two variants, one that produces a new value, and one that works in-place directly on its arguments. Here are some examples:

```
// In-place example
A = {2, 3, 4, 2, 1, 2, 1};
A = Remove( A, 3 ); // delete the third item in the list A, storing result in A
Remove From( A, 3 ); // delete the third item in the list A, in place
Show( A ); // A = {2, 3, 2, 1, 2, 1};

// New value example
B = {2, 3, 4, 2, 1, 2, 1};
onetwo = Insert( {1}, 2 ); // {1, 2}
Insert Into( B, {1, 2}, 4 ); // put 1, 2 before the current 4th item
Show( B ); // B = {2, 3, 4, 1, 2, 2, 1, 2, 1};
```

**Note:** If the position is omitted in the Insert Into command, items are placed at the end of the list.

```
a = Shift( {1,2,3,4}, 1 ); // store the list {2,3,4,1} in a
Shift Into( a, -1 );
Show( a ); // a = {1, 2, 3, 4};
```
b = Reverse( a ); // b is now {4,3,2,1}
Reverse Into( a ); // a is now {4,3,2,1}
Show( a ); // a = {4, 3, 2, 1};

s = Sort List( {1,4,2,5, -7.2, Pi(), -11, cat, apple, cake} );
Show( s ); // s = {-11, -7.2, 1, 2, 4, 5, apple, cake, cat, Pi()};

c = {5, pie, 2, Pi(), -2};
Sort List Into( c );
Show( c ); // c = {-2, 2, 5, Pi(), pie};

In-place functions

In-place functions are those that operate on lists or expressions directly. They have From or Into in their names (for example, Remove From and Insert Into). They do not return a result; you have to show the list to see the result. The first argument for an in-place function must be an L-value. An L-value is an entity such as a variable whose value can be set.

myList = {a, b, c, d};
Insert Into( myList, 2, 3 );
Show( myList );
myList = {a, b, 2, c, d}

These examples show how to use Insert Into and Remove From with nested lists:

a = {{1, 2, 3}, {"A", "B", "C"}};
Show( a );
a = {{1, 2, 3}, {"A", "B", "C"}}

Insert Into( a[1], 99, 1 );
Show( a );
a = {{99, 1, 2, 3}, {"A", "B", "C"}}

Remove From( a[1], 1 );
Show( a );
a = {{1, 2, 3}, {"A", "B", "C"}}

Not in-place functions

For the not-in-place functions, you must either state the list directly or else quote a name that evaluates to a list. Such functions do not have From or Into in their names. They return manipulated lists or expressions without changing the original list or expression given in the first argument.

myNewList = Insert( {a, b, c, d}, 2, 3 );
{a, b, 2, c, d}

oldList = {a, b, c, d};
newList = Insert( oldList, 2, 3 );
Substituting

Substitute() and Substitute Into() merit further discussion. Both functions find all matches to a pattern in a list (or expression) and replace them with another expression. Each pattern must be a name. The arguments are evaluated before they are applied, so most of the time you must quote them with an Expr() function.

\[
\text{Substitute( \{a,b,c\}, Expr( a ), 23); // returns \{23,b,c\}}
\]

\[
\text{Substitute( Expr( Sine( x ) ), Expr( x ), Expr( y ) ); // returns Sine(y)}
\]

To delay evaluating an argument, use NameExpr instead of Expr:

\[
a = \{\text{quick}, \text{brown}, \text{fox}, \text{jumped}, \text{over}, \text{lazy}, \text{dogs}\};
b = \text{Substitute( a, Expr( dogs ), Expr( cat ) )};
canine = Expr( dogs );
equine = Expr( horse );
c = \text{Substitute( a, NameExpr( canine ), NameExpr( equine ) )};
\]

Show( a, b, c );

\[
a = \{\text{quick}, \text{brown}, \text{fox}, \text{jumped}, \text{over}, \text{lazy}, \text{dogs}\}
b = \{\text{quick}, \text{brown}, \text{fox}, \text{jumped}, \text{over}, \text{lazy}, \text{cat}\}
c = \{\text{quick}, \text{brown}, \text{fox}, \text{jumped}, \text{over}, \text{lazy}, \text{horse}\}
\]

Substitute Into does the same work, in place:

\[
\text{Substitute Into( a, Expr( dogs ), Expr( horse ) );}
\]

You can list multiple pattern and replacement arguments to do more than one replacement in a single step:

\[
d = \text{Substitute( a,}
         \text{ NameExpr( quick ), NameExpr( fast ),}
         \text{ NameExpr( brown ), NameExpr( black ),}
         \text{ NameExpr( fox ), NameExpr( wolf )};
\]

\[
\{\text{fast, black, wolf, jumped, over, lazy, dogs}\}
\]

Note that substitutions are done repeatedly over multiple instances of the expression pattern. For example:

\[
\text{Substitute( Expr( a + a ), Expr( a ), Expr( aaa ) );}
\]

results in:

\[
\text{aaa + aaa}
\]
Manipulating Expressions

The functions for manipulating lists can also operate on most expressions. Be sure to quote the expression with `Expr()`. For example:

```plaintext
Remove( Expr( A + B + C + D ), 2 ); // results in the expression A + C + D
b = Substitute( Expr( Log( 2 ) ^ 2 / 2 ), 2, 3 ); /* returns the expression
Log( 3 ) ^ 3 / 3*/
```

As with lists, remember that the first argument for in-place functions must be an L-value. An L-value is an entity such as a variable whose value can be set. In-place functions are those that operate on lists or expressions directly. They have `From` or `Into` in their names (for example, `Remove From` and `Insert Into`). They do not return a result; you have to show the expression to see the result.

```plaintext
coefficients = Expr( a * x ^ 2 + b * x + c );
Insert Into( polynomial, Expr( d * x ^ 3 ), 1 );
Show( polynomial );

polynomial = d * x ^ 3 + a * x ^ 2 + b * x + c
```

For the not-in-place functions, you must either state the expression directly or else quote a name that evaluates to an expression using `NameExpr`. Such functions do not have `From` or `Into` in their names. They return manipulated lists or expressions without changing the original list or expression given in the first argument.

```plaintext
cubic = Insert( Expr( a * x ^ 2 + b * x + c ), Expr( d * x ^ 3 ), 1 );
d * x ^ 3 + a * x ^ 2 + b * x + c
```

```plaintext
quadratic = Expr( a * x ^ 2 + b * x + c );
cubic = Insert( Name Expr( quadratic ), Expr( d * x ^ 3 ), 1 );
d * x ^ 3 + a * x ^ 2 + b * x + c
```

Substituting

Substituting is extremely powerful; please review the earlier discussion “Substituting” on page 267. Here are a few notes regarding substituting for expressions.

```plaintext
Substitute(pattern, name, replacement) substitutes for names in expressions

NameExpr() looks through the name but copies instead of evaluates:

```plaintext
a = Expr(
    Distribution( Column( x ), Normal Quantile Plot )
);
show( Name Expr( a ) );

Name Expr(a) = Distribution(Column(x), Normal Quantile Plot);
```

Substitute() evaluates all its arguments, so they must be quoted correctly:

```plaintext
b = Substitute( Name Expr( a ), Expr( x ), Expr( :weight ) );
```
Show( Name Expr( b ) );
    Name Expr(b) = Distribution(Column(:weight), Normal Quantile Plot);

SubstituteInto() needs an L-value, so the first argument is not quoted:

Substitute Into( a, Expr( x ), Expr( :weight ) );
Show( Name Expr( a ) );
    Name Expr(a) = Distribution(Column(:weight), Normal Quantile Plot);

Substitute() is useful for changing parts of expressions, such as in the following example that tests the Is functions:

    data = {1, {1, 2, 3}, [1 2 3], "abc", x, x( y )};
    ops = {is number, is list, is matrix, is string, is name, is expr};
    m = J( N Items( data ), N Items( ops ), 0 );
    test = Expr(
        m[r, c] = _op( data[r] )
    );
    For( r = 1, r <= N Items( data ), r++,
        For( c = 1, c <= N Items( ops ), c++,
            Eval( Substitute( Name Expr( test ), Expr( _op ), ops[c] ) )
        )
    );
Show( m );
    m =
        [1 0 0 0 0 0,
         0 1 0 0 0 1,
         0 0 1 0 0 0,
         0 0 0 1 0 0,
         0 0 0 0 1 1,
         0 0 0 0 0 1];

You can use SubstituteInto() to have JMP solve quadratic equations. The following example solves $4x^2 - 9 = 0$:

    /* FIND THE ROOTS FOR THE EQUATION: 
        a*x^2 + b*x + c = 0
    The quadratic formula is $x=\frac{(-b + - \sqrt{b^2 - 4ac})}{2a}$.
    Use a list to store both the + and - results of the +- operation */
    x = {Expr(
        (-b + Sqrt( b ^ 2 - 4 * a * c )) / (2 * a)
    ), Expr(
        (-b - Sqrt( b ^ 2 - 4 * a * c )) / (2 * a)
    )};
    Substitute Into( x, Expr( a ), 4, Expr( b ), 0, Expr( c ), -9 );

    // plug in the coefficients
    Show( x ); // see the result of substitution
    Show( Eval Expr( x ) ); // see the solution
    x = {Expr(((0) + Sqrt(0 ^ 2 - 4 * 4 * -9)) / (2 * 4)), Expr(((0) - Sqrt(0
        ^ 2 - 4 * 4 * -9)) / (2 * 4))};
The functions for manipulating lists and expressions are discussed in the previous section, “Manipulating Lists” on page 265, and summarized in Table 8.4.

### Table 8.4 Functions for Manipulating Lists or Expressions

Advanced Scoping and Namespaces

Scripts that are used in production environments need to use more advanced scoping techniques to avoid collisions between scripts. JMP provides three progressively more advanced techniques:

- The Names Default To Here() function. If you have simple scripting needs, this single command might be sufficient. See “Names Default To Here” on page 272.
- Scopes that are pre-defined by JMP. See “Scoped Names” on page 276.
- Namespaces that you can create for your scripts. See “Namespaces” on page 280.

Names Default To Here

If you write production scripts, you need to insulate the script from the current user environment. Otherwise, the variables that you use might interact with variables used by the user and by other scripts. The way to do this is to keep your names in a local environment, which you can do by setting an execution mode with the statement:

```
Names Default To Here( 1 );
```

Unqualified names in a script with the Names Default To Here mode turned on are private to that script. However, the names persist as long as the script persists, or as long as objects created by or holding the script are still active. It is recommend that all production scripts start with Names Default To Here(1) unless there is a specific reason not to do so. When the script uses an unqualified name in this mode, that name is resolved in the local namespace.

To refer to global variables, scope the name specifically as a global variable (for example, ::global_name). To refer to columns in a data table, scope with name specifically as a data table column (for example, :column_name).

**Note:** Names Default To Here( 1 ) defines a mode for a particular script. It is not a global function. One script can have this mode turned on, while another script can have it turned off. The default setting is off.

---

Table 8.4 Functions for Manipulating Lists or Expressions (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Substitute Into</td>
<td>Substitute Into(list</td>
<td>expr, Expr(pattern), Expr(replacement), ...)</td>
</tr>
</tbody>
</table>
In JMP 8 and earlier, the only method to the insulate scripts was to use lengthy names that were less likely to collide with names in other scripts. Using `Names Default To Here(1)` makes this technique unnecessary.

If you have simple scripting needs, `Names Default To Here(1)` might be sufficient.

**Local()**

`Local()` creates local scopes only in specific contexts within a script and cannot enclose a longer script with interacting functions, while `Names Default To Here(1)` creates a local scope for an entire script. In `Local()`, you list the variables that are local to the local block. Anything not explicitly listed is not local to that block.

**Local Here()**

`Local Here()` provides a namespace block with `Names Default to Here(1)`. Use `Local Here()` to prevent name collisions when multiple scripts are executed from the same root namespace (for example, when a script executes two button scripts that have the same variables or an included script is run from the main script).

`Local()` does not always work due to the lifetime of the local block, but `Local Here()` is persistent across the call.

Here’s an example that runs an included script from a main script. The scripts define x and y variables as different values. Variables in the included script are in the Local Here namespace.

**Main.jsl:**

```javascript
Names Default To Here( 1 );

x = 5;
y = 0;

Print( "Main, Before: x=" || Char( x ) || ", y=" || Char( y ) );
Include( "Inc1.jsl" );
Print( "Main, After: x=" || Char( x ) || ", y=" || Char( y ) );
```

**Inc1.jsl:**

```javascript
Names Default To Here( 1 );

Local Here( // variables are local to this script
  x = 100;
y = 100;

Print( "Inc1: x=" || Char( x ) || ", y=" || Char( y ) );
);
Print( "Inc1 outside: x=" || Char( x ) || ", y=" || Char( y ) );
```
Programming Methods

Chapter 8
Advanced Scoping and Namespaces

Return:

"Main, Before: x=5, y=0" // defined in Main.jsl, before running Inc1.jsl
"Inc1: x=100, y=100" // defined in Inc1.jsl
"Inc1 outside: x=5, y=0" // from Inc1.jsl, referring to Main.jsl
"Main, After: x=5, y=0" // from Main.jsl, after running Inc1.jsl

Notice that the x and y variables in inc1.jsl don’t change because they’re in the Local Here namespace.

Handling Unqualified Named Variable References

The Names Default To Here() function determines how unqualified named variable references are resolved. Explicitly scoping a variable using here:var_name always works, whether Names Default To Here() is on or off. See “Scoped Names” on page 276 for more information about here and other scopes.

Enabling the Names Default To Here mode associates a scope called Here with an executing script. The Here scope contains all of the unqualified named variables that are created when they are the target of an assignment (as an L-value). In JMP 8 and earlier, these variables normally would have been placed in the Global scope. Using a Here scope keeps variables in multiple executing scripts separate from each other, avoiding name collisions and simplifying the scripting and management of variable name collisions. You can still share information using the Global scope.

Names Default To Here and Global Variables

Run this example script one line at a time to see how the Names Default To Here() function changes the resolution of variable names.

Example Script

```javascript
a = 1;
Names Default To Here( 1 );
a = 5;
Show( global:a, a, here:a );
   global:a = 1;
a = 5;
   here:a = 5;
```

1. Run the first line to create a global variable named a that holds the value 1.
2. Run the second line to turn on the Names Default To Here mode.
3. Run the third line to create a new variable named a in the local space that holds the value 5. This line does not change the value assigned to the global variable a.
4. Run the fourth line to see how scoped and unscoped variables are resolved.
The unqualified $a$ is resolved to here:$a$. If Names Default To Here() were not on, $a$ would be resolved to the global variable named $a$.

Note that if you use ::$a$ instead of global:$a$ in the Show() function, your output is a little different:

```javascript
Show(::$a$, $a$, here:$a$);
$a$ = 1;
$a$ = 5;
here:$a$ = 5;
```

**Example of Using the Names Default To Here() Function**

You have two scripts with the following definitions, and Names Default To Here() is turned off (the default condition) in both scripts.

**Note:** Both scripts must be in separate script windows for this example.

```javascript
a = 1; // script 1
Show( $a$ );

a = 3; // script 2
Show( $a$ );
```

1. Run Script 1. Here is the result:
   
   $a$ = 1

2. Run Script 2. Here is the result:
   
   $a$ = 3

3. Run only the show($a$); line in Script 1. Here is the result:
   
   $a$ = 3

The log shows $a$ = 3 because variable $a$ is global, and was last modified by Script 2. This is the default behavior in JMP 9 and later, and it is the only possible behavior in JMP 8 and earlier.

4. Now turn on Names Default To Here() in both scripts.
   
   Names Default To Here(1);

   **Note:** Names Default To Here() is local to a particular script. It is not a global setting.

5. Run Script 1. Here is the result:
   
   $a$ = 1

6. Run Script 2. Here is the result:
   
   $a$ = 3

7. Run only the Show( $a$ ); line in Script 1. Here is the result:
   
   $a$ = 1
The log shows \( a = 1 \), because a copy of variable \( a \) is maintained for each script.

**Note:** Problems using this function are generally due to the mixing of unqualified and qualified references to global variables. Always explicitly scoping a name prevents accessing an unintended variable.

### Scoped Names

Specify where a name is to be resolved by using a scope in the form `scope:name` where `scope` indicates how to resolve the name. For example, `here:name` indicates that the name should be resolved locally. Using the *Names Default To Here* mode, `here:name` is equivalent to `name`. The scope instructs how to look up the name.

The syntax is to use the colon scope operator:

```
scope:name
```

There are several types of scopes:

- Scope can be a resolution rule. For example, `here:x` means that \( x \) should be resolved to a name that is local to the script. `Global:x` means that \( x \) should be resolved to a global name.
- Scope can be a namespace reference variable. For example, `ref:a` means that \( a \) should be resolved within the namespace that `ref` refers to.
- Scope can be a data table reference to look up names as column names. For example, `dt:height` means that `height` should be resolved as a column in the data table that `dt` references.
- Scope can be the name of a namespace that you created. For example, `myNamespace:b` where `myNamespace` is a namespace that you created. "myNamespace":b is equivalent. See “Namespaces” on page 280.

**Note:** If you create a function, make sure you scope it to avoid conflicts with built-in functions.

### Examples of Scoping Column Formulas

The following examples demonstrate how to scope columns that contain formulas. In both scripts, \( x \) is a global variable, local variable, and column name.

In the first script, the column name \( x \) is unscoped. the formula in the second column multiplies the value in column \( x \) by 100. In this case, The result is a column with the values 100, 200, and 300.

```
::x = 5;
```
New Table( "Test",
    New Column( "x", Values( [1, 2, 3] ) ),
    New Column( "y", Formula( 100 * x ) ),
);  

In the following script, the formula in column y assigns 500 to x and then adds 50 to x. Each cell in the column contains the value 550.

::x = 5;
New Table( "Test",
    New Column( "x", Values( [1, 2, 3] ) ),
    New Column( "y", Formula( Local{ x = 500 }, x + 50 ) ),
);  

Predefined Scopes

JMP provides predefined that cannot be removed or replaced. Each of these scopes has specific roles, depending on its associated object.

Table 8.5 Predefined Scopes

<table>
<thead>
<tr>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global</td>
<td>Global names are shared throughout the JMP environment.</td>
</tr>
<tr>
<td>Here</td>
<td>Scope of the executing script.</td>
</tr>
<tr>
<td>Builtin</td>
<td>JMP built-in functions. For example, Builtin:Sqrt(). These names are shared throughout the JMP environment. If you over-ride a JSL function with a custom function, you can still access the built-in JSL function by using this scope.</td>
</tr>
<tr>
<td>Local</td>
<td>Nearest local scope. Can be nested within the user-defined functions, Local and Parameter.</td>
</tr>
<tr>
<td>Local Here</td>
<td>Provides a namespace block inside Names Default to Here(1). Use Local Here() to prevent name collisions when multiple scripts are executed from the same root namespace (for example, when a script executes two button scripts that have the same variables). The argument can be any valid JSL expression. Local( {Default Local}, ) does not always work due to the lifetime of the local block, but Local Here() is persistent across the call.</td>
</tr>
<tr>
<td>Window</td>
<td>Scope of the containing user-defined window. (Rare.)</td>
</tr>
<tr>
<td>Platform</td>
<td>Scope of the current platform. (Rare.)</td>
</tr>
</tbody>
</table>
Table 8.5 Predefined Scopes *(Continued)*

<table>
<thead>
<tr>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Box</td>
<td>Scope of the containing context box. A context box is nested within a user-defined window. (Rare.)</td>
</tr>
</tbody>
</table>

**Example of Using the Window Scope**

This example uses the `Window` scope to pass information during execution. Explicitly scoping the variables `x` and `y` to this window ensures that JMP does not try to scope `x` and `y` in other contexts, such as a data table. The variables `x` and `y` are created and used solely inside the `Window` environment. The `Window` scope is similar to using `Local()`, but more useful because `Local()` is limited in the places that it can be used.

```julia
New Window( "Example",
    window:gx = 20;
    window:gy = 50;
    Graph Box(
        Frame Size( 200, 200 ),
        Handle(
            window:gx,
            window:gy,
            Function( {x, y},
                window:gx = x;
                window:gy = y;
            )
        );
        Circle( {0, 0}, Sqrt( window:gx * window:gx + window:gy * window:gy ) );
    );
);
```

**Figure 8.1** Example of Current Window Namespace
Example of Using the Here Scope

This example uses the Here scope to pass information between windows that are created by the same script. Scoping a variable using Here: is not dependent on turning Names Default To Here() on. The Here: scope is always available.

This script produces two windows and uses two different scopes.

The Launcher window asks the user for two values. Those two values are passed to the Output window, which uses them to graph a function. The Launcher window scopes aBox and bBox to the window: essentially, those two variables (pointers to Number Edit Boxes) exist only in the Launcher window and are not available to the Output window. The values from those two boxes are then copied into variables that are scoped to Here, and so are available to both windows that are produced by this script.

```plaintext
launchWin = New Window( "Launcher",
    <<Modal,
    V List Box(
        Lineup Box( N Col( 2 ), Spacing( 10 ),
            Text Box( "a" ),
            window:aBox = Number Edit Box( 50 ),
            Text Box( "b" ),
            window:bBox = Number Edit Box( 20 ),
        ),
        Lineup Box( N Col( 2 ), Spacing( 20 ),
            Button Box( "OK",
                // copy values before window goes away
                here:a = window:aBox << Get;
                here:b = window:bBox << Get;
            ),
            Button Box( "Cancel", Throw( 1 )
        ),
    ),
);

New Window( "Output",
    Graph Box( Y Function( here:a + here:b * Sin( x / 30 ), x )
);```
Namespaces

A namespace is a collection of unique names and corresponding values. You can store references to namespaces in variables. Namespace names are global, because JMP has only one namespace map. Namespace references are variables like any other variable that references an object, so they must be unique within their scope or namespace. The members of a namespace are referenced with the : scoping operator, such as my_namespace:x to refer to the object that is named x within the namespace called my_namespace. See “User-Defined Namespace Functions” on page 280 for more information about creating and managing your own namespaces. Namespaces are especially useful for avoiding name collisions between different scripts.

User-Defined Namespace Functions

Create your own namespaces to hold related sets of variables and function definitions. There are several functions that you can use to manage namespaces.

New Namespace

nsref = New Namespace( <"nsname">, <{ name = expr, ... }> );

Creates a new namespace called nsname (a string expression) and returns a reference to the namespace. All arguments are optional.

Nsname is the name of the namespace in the internal global list of namespace names. Nsname can be used as the prefix in a scoped variable. The function returns a reference to the namespace, and can also be used as the prefix in a scoped variable reference. If nsname is absent, the namespace is anonymous and is given a unique name created by JMP. Show Namespace() shows all namespaces and their names, whether assigned or anonymous.
**Important:** If you already have a namespace named `nsname`, it is replaced. This behavior means that while you are developing your script, you can make your changes and re-run the script without having to clear or delete your namespace. To avoid unintentional replacement, you can either use anonymous namespaces, or test to see whether a particular namespace already exists:

```javascript
If( !Namespace Exists( "nsname" ), New Namespace( "nsname" ) );
```

A list of named expressions is optional. The names are JMP variables that exist only within the namespace.

**Note:** The named expressions must be a comma-separated list. Separating the expressions with semi-colons causes the list to be ignored.

These namespaces must be uniquely named to prevent collisions in situations where multiple user-defined namespaces are being used. Using anonymous namespace names prevents collisions.

### Namespace

```javascript
nsref = Namespace( "nsname" | nsref);
```

Returns a namespace reference. The argument might be either of the following:

- a quoted string that contains a namespace
- a reference to a namespace

**Note:** `Namespace()` returns a reference to a namespace that already exists. It does not create a new namespace.

### Is Namespace

```javascript
b = Is Namespace( nsref );
```

Returns 1 (true) if `nsref` is a namespace or 0 (false) otherwise.

### As Scoped

```javascript
b = As Scoped( "nsname", var_name);
nsname:var_name;
```

`As Scoped()` is the function form of a scoped reference. The function returns a reference to the specified variable in the specified scope.
Namespace Exists

    b = Namespace Exists( "nsname" );

Returns 1 (true) if *nsname* exists in the list of global namespaces, or 0 (false) otherwise.

Show Namespaces

    Show Namespaces();

Shows the contents of all namespaces contained in the list of global namespaces. Namespaces are not visible unless a reference is made to one, using either the *New Namespace* or *Namespace* functions.

Namespace Messages

In addition to the namespace management functions, a namespace also supports a set of messages to access and manipulate its contents.

Note that these messages, as with all message, must be sent to a scriptable object. A namespace name is not a defined scriptable object and cannot be used in a Send operation. However, you can use the name of a namespace in variable references. For example, *nsname::var* is equivalent to *nsref::var*.

See the *JSL Syntax Reference* for descriptions of the messages that are supported by user-defined namespace references.

Using Namespace References

The following are all equivalent references to a variable that is named *b* in the namespace that is named *nsname* that has a reference *nsref*:

    nsref::b
    nsname::b
    "nsname":b
    nsref["b"]
    nsref<<Get Value("b") // used as an r-value

Namespaces and Included Scripts

An included script runs in the namespace of the parent script. If the included script has its own namespace definitions, you need to do one of the following:

- manage the namespace names to avoid name collisions
- use anonymous names created by the *New Namespace* function

In either case, you still need to manage variable references to namespaces.
There is also an option for the Include function (New Context) that creates a namespace that the included script runs in. This namespace is anonymous and it is independent from the parent script’s namespace. For example:

```
Include("file.jsl", <<New Context);
```

This anonymous namespace can be referenced using Here.

If both the parent and included scripts use the global namespace, add Names Default To Here to the New Context option to avoid name collisions. For example:

```
Include("file.jsl", <<New Context, <<Names Default To Here);
```

See “Includes” on page 294 for more information about the Include function.

### Examples of User-Defined Namespaces

#### Creating and Using a Basic Namespace with Expressions

This example shows creating an anonymous namespace and using functions and variables within it.

```
new_emp = New Namespace(
    {name_string = "Hello, *NAME*!",
     print_greeting = Function( {a},
         Print( Substitute( new_emp:name_string, "*NAME*", Char( a ) ) )
     )
);
```

Note that you must use the fully qualified name for variables defined within the namespace.

```
new_emp:print_greeting( 6 );
"Hello, 6!"
```

#### Complex Number Operations

This example creates a namespace that contains functions to support using two-element lists to represent complex numbers, and then locks the namespace.

```
If( !Namespace Exists( "complex" ),
    New Namespace(
        "complex"
    );
    complex:makec = Function( {a, b},
        Eval List( {a, b} )
    );
    complex:addc = Function( {a, b}, a + b );
    complex:subtractc = Function( {a, b}, a - b );
    complex:multiplyc = Function( {a, b},
```
);

complex:dividec = Function( {a, b},
    d = b[1] ^ 2 + b[2] ^ 2;
    Eval List(
    );
);

complex:charc = Function( {a},
    Char( a[1] ) || "+" || Char( a[2] ) || "i"
);
);

Namespace( "complex" ) << Lock;

Here are examples using functions that are within the above user-defined namespace.

c1 = complex:makec( 3, 4 );
c2 = complex:makec( 5, 6 );
cadd = complex:addc( c1, c2 ); // returns {8, 10}
csum = complex:subtractc( c1, c2 ); // returns {-2, -2}
cmul = complex:multiplyc( c1, c2 ); // returns {-9, 38}
cdiv = complex:dividec( c1, c2 ); // returns {14.6065573770492, 19.7049180327869}
Show( complex:charc( c1 ) ); // returns complex:char(c1) = "3+4i";
cml = complex:makec( [1, 2, 3], [4, 5, 6] ); // returns {[1, 2, 3], [4, 5, 6]}

Referencing Namespaces and Scopes

There are a number of factors in resolving a named variable reference. Table 8.6 describes the named variable references that are resolved for specific situations.

Notes:

• In JMP 9 and later, a, :a, and ::a have the same meaning with the Names Default To Here mode turned off.

• If the current point of execution is in a user-defined function, or a Local or Parameter JSL function body, then the Local namespace is used for creation when Default Local is specified. However, the reference rule is unchanged.
Table 8.6 Namespace References

Resolving Named Variable References

When variables are referenced within a JMP script, JMP resolves the storage location of the variable using a specific set of rules. If the variable is referenced by a qualified name, then the resolution is based on the specific qualification specification. If the variable is referenced by an unqualified name, the situation is a bit more complex. JMP looks through a hierarchy of scopes representing the point of execution with the executing script. This section describes the rules that are used to resolve named variable references.

By default, variable name resolution in JMP 9 and later worked the same way as in JMP 8 and earlier, allowing your current JSL scripts to be executed unchanged. For JMP 9 and later, the difference between qualified and unqualified variable named references is important to understand.
Qualified Named References

A qualified named reference uses the : and :: operators to provide specific information about where a referenced variable resides, or where it is created. Examples of qualified named references include the following:

```
:var
::globalvar
datatable:var
nsref:var
"nsname":var
```

Unqualified Named References

An unqualified named reference provides no explicit information to completely identify where a variable resides or where it is created. No scoping operator (: or ::) is specified in the reference. To change the behavior of JMP when resolving unqualified named variable references, use the Names Default To Here(1) function. For more information about variable name resolution, see the “Rules for Name Resolution” on page 111 in the “JSL Building Blocks” chapter.

Rules for Resolving Variable References

JMP applies rules in sequence to resolve variable references. See “Rules for Resolving Names” on page 112 in the “JSL Building Blocks” chapter.

Best Practices for Advanced Scripting

Minimize Polluting the Global Namespace and Prevent Scripts from Interacting

Always start your script with this line:

```
Names Default To Here(1);
```

Share Variables Across Scripts

Use named namespaces. Namespace names are placed in the global scope.

Use Anonymous Namespaces

Using namespace references to anonymous namespaces avoids possible conflicts with other namespaces.
Advanced Programming Concepts

This section covers some more advanced programming techniques that can be useful for developing scripts.

- "Throw and Catch Exceptions"
- "Functions"
- "Recursion"
- "Includes"
- "Load and Save Text Files"
- "Run External Programs"
- "Classes"

Throw and Catch Exceptions

A script can stop itself by executing the \texttt{Throw()} function. If you want to escape from part of a script when it is in an error condition, you can enclose it in a \texttt{Try()} expression.

If you include a character-valued expression as a \texttt{Throw()} argument, one of the following occurs:

- Throwing stores the string in a global variable named \texttt{exception_msg}. This is illustrated in the first example below.
- Throwing stores the string in a local variable named \texttt{exception_msg} if you define \texttt{exception_msg} in the Here namespace using \texttt{Names Default to Here(1)}.

\texttt{Try()} takes two expression arguments. It starts by evaluating the first expression, and if or when the first expression throws an exception by evaluating \texttt{Throw}, it does the following:

1. Immediately stops evaluating that first expression.
2. Returns nothing
3. Evaluates the second expression.

Examples

You can use \texttt{Try()} and \texttt{Throw()} to catch an exception that JMP itself throws.

\begin{verbatim}
Try( Throw( "Hello." ), Show( exception_msg ) );
exception_msg = "Hello.";
\end{verbatim}

The following example prints a message to the log when the \texttt{Try()} expression cannot be executed:

\begin{verbatim}
Try(
\end{verbatim}
dt = Open( "Mydata.jmp" ); // a file that cannot be opened
Summarize( a = by( age ), c = count, meanHt = Mean( Height ) );
Show( a, c, meanHt );
Print( "This script does not work without the data set." );
Throw();
);

If the Throw() string begins with “!” and is inside a Try() expression, throwing creates an error message about where the exception was caught.

Try(
    Throw( "!This message has an exclamation point." );
    Write( "\!Nexception_msg: ", exception_msg );
    Print( "Hello from the catch block (WITH exclamation)." );
);
Print( "This AFTER message will NOT print due to error." );

When writing the Try() error handler code, consider wrapping the exception variable exception_msg in a Char() function. If your script calls Concat() without wrapping it in a Char() call, you might get an error depending on what was actually returned in this variable. Though some commands return a string in exception_msg, other commands (such as Open()) return a list or another data structure. This would cause an error in the error handler if it were passed directly as an argument to Concat().

Try(
    Open( "no file" ),
    If( Is Empty( exception_msg ),
        // use Write to print "no error" if exception_msg is empty
        Write( "\!Nexception_msg (0): no error" ),
        // use Print to print the exception message
        Print( "\!Nexception_msg (1): ", exception_msg );
        /* or first make sure that exception message is a string
         * and then use Concat to build the message that is passed to Print(). */
        Print( "\!Nexception_msg (2): " || Char( exception_msg ) );
    )
);

exception_msg (1): "
{"Cannot open table"(1, 2, "Open", Open /*###*/("no file"))}
"
exception_msg (2): {\"Cannot open table\"(1, 2, \"Open\", Open /*###*/(\"no file\"))}
"

You can also use Try() and Throw() to escape from deep inside For loops.

a = [1 2 3, 4 5 ., 7 8 9];
b = a;
nr = N Row( a );
nc = N Col( a );
// a[2, 3] = 2; // uncomment this line to see the "Missing b" outcome

Try(
   sum = 0;
   For( i = 1, i <= nr, i++,
      For( j = 1, j <= nc, j++,
         za = a[i, j];
         If( Is Missing( za ),
            Throw( "Missing a" )
         );
         zb = b[j, i];
         If( Is Missing( zb ),
            Throw( "Missing b" )
         );
         sum += za * zb;
      )
   );
   ,
   Show( i, j, exception_msg );
   Throw();
);

i = 2;
j = 3;
exception_msg = "Missing a";

You do not have to use Try() to make use of Throw(). In this example, Throw() is not caught by Try() but still stops a script that cannot proceed:

   dt = New Table(); // to get an empty data table
   If( N Row( dt ) == 0,
      Throw( "!Empty Data Table" )
   );

Functions

JSL also has a function called Function to extend the macro concept with a local context arguments. Suppose that you want to create a function that takes the square root but tolerates negative arguments, returning zero rather than errors. You first specify the local arguments in a list with braces {} and then state the expression directly. You do not need to enclose the expression in Expr because Function stores it as an expression implicitly.

   myRoot = Function( {x},
      If( x > 0, Sqrt( x ), 0 )
   );
   a = myRoot( 4 ); // returns 2
   b = myRoot( -1 ); // returns 0
Functions are stored in variables, the same as values. This means that you cannot have both a root function and a root value. It also means that you can redefine a function anytime except when you are inside the function itself.

When a function is called, its arguments are evaluated and given to the local variables specified in the list forming the first argument. Then the body of the function, the second argument, is evaluated.

The values of the arguments are for the temporary use of the function. When the function is exited, the values are discarded. The only value returned is the return value. If you want to return several values, then return a list instead of a single value.

In defined functions, the stored function is not accessible directly, even by the `Name Expr` command. If you need to access the function expression in your script, you have to create the function within an `expr()` clause. For example,

```plaintext
makeFunction = Expr(
    myRoot = Function( {x},
        If( x > 0, Sqrt( x ), 0 )
    );
    d = Substitute( Name Expr( MakeFunction ), Expr( x ), Expr( y ) );
    Show( d );
    makeFunction;
)
```

**Optional Arguments**

You can create optional arguments. For example:

- `f1 = Function( {x, y, z}); // all arguments are required`
- `f2 = Function( {x = 2, y=4}); // x is required, y and z are optional`

**Notes:**

- To make an argument optional, give it a default value in the function's definition (x=1 rather than just x).
- Optional arguments always must follow a required argument. For example, this is not allowed:
  ```plaintext
  Function( {x = 1, y}, ... )
  ```
  It will work when defined, but you will always have to pass in a value for x and y, because the default value will never be used.
- When you call the function, you cannot skip optional arguments. In this example, you have to supply a value for y to supply a value for z when you call the function:
  ```plaintext
  ex = Function( {x, y = 2, z = 3},
      Return( x + y + z )
  );
  ex( 1, 4 ); // passes in 1 for x and 4 for y; z will be 3. returns 8.
  ```
Local Symbols

You can declare variables as local to a function so that they do not affect the global symbol space. This is particularly useful for recursive functions, which need to keep separate the values of the local variables at each level of function call evaluation.

As shown above, a function definition looks like this:

```
functionName=Function({arg1, ...}, body);
```

You can also have the function definition default all the unscoped names to be local.

```
functionName=Function({arg1, ...}, {Default Local}, body);
```

For the purposes of creation, the use of Default Local localizes all the names that meet the following qualifications:

- Are not scoped as globals (for example, ::name)
- Are not scoped as data table column names (for example, :name)
- Occur without parentheses after them (for example, are not of the form name(...))

For example, the following function sums three numbers.

```
add3 = Function( {a, b, c},
    {temp},
    temp = a + b;
    temp + c;
);
X = add3( 1, 5, 9 );
15
```

The following function does the same thing, automatically finding locals.

```
add3 = Function( {a, b, c},
    {Default Local},
    temp = a + b;
    temp + c;
);
X = add3( 1, 5, 9 );
15
```

In both cases, the variable temp is not a global, or, if it is already a global, remains untouched by evaluating the functions.

Using Default Local in user-defined functions can cause some confusion because it is context-sensitive. That is, the same function may behave differently in different contexts (depending on whether same-named outer variables are in scope) because the reference rules for unqualified names are unchanged when using Default Local. To make a function less context-sensitive, enumerate each and every variable that you want to be local. This reduces the confusion and the potential incorrect use of outer scope variable values.
Recursion

The `Recurse()` function makes a recursive call of the defining function. For example, you can make a function to calculate factorials. A factorial is the product of a number, the number minus 1, the number minus 2, and so on, down to 1.

```javascript
myfactorial = Function( {a},
    If( a == 1,
        1,
        a * Recurse( a - 1 )
    )
);
myfactorial( 5 );
120
```

You can define recursive calculations without using `Recurse()`. For example, you could replace `Recurse()` by `myfactorial`, and the script would still work. However, `Recurse()` offers these advantages:

- It avoids name conflicts when a local variable has the same name as the function.
- You can recurse even if the function itself has not been named (for example, assigned to a global variable, such as `myfactorial` above).

Includes

The `Include()` function opens a script file, parses the script in it, and executes the JSL in the specified file.

```javascript
Include( "pathname" );
```

For example,

```javascript
Include( "$SAMPLE_SCRIPTS/myStartupScript.jsl" );
```

There is an option to obtain the parsed expression from the file, rather than evaluating the file.

```javascript
Include( "pathname", <<Parse Only );
```

Another named option creates a namespace that the included script runs in. This namespace is an anonymous namespace and it is independent from the parent script’s namespace.

```javascript
Include( "file.jsl", <<New Context );
```

See “Advanced Scoping and Namespaces” on page 272 for information about using namespaces with your scripts.

Note the following about included files:

- JMP files aside from JSL cannot be used.
• Other recognized file types, such as image files, SAS data sets, and Microsoft Excel files cannot be used.
• Unrecognized file types are treated as a JSL file.
• Files with the .txt extension are treated as a JSL file. A text file that contains data can be included, however an error will appear since this is not valid JSL.

Load and Save Text Files

The `Load Text File()` and `Save Text File()` commands allow manipulation of text files from JSL. Note that the paths in the following code are strings.

```javascript
text = Load Text File( "path" );
Save Text File( "path", text );
```

You can load a text file from a Web site:

```javascript
Load Text File( "URL", <blob> );
```

The URL is a quoted string that contains the URL for the text file. The text file is returned as a string. If you add the optional named argument `blob`, a blob is returned instead.

Run External Programs

`Run Program()` enables you to control a program that uses standard input and standard output. Line-mode programs read commands from stdin and write answers to stdout. `cmd.exe`, the Windows command prompt, is one example. You can also use it to launch GUI programs, such as Windows Notepad.

```javascript
Run Program(
  Executable( "cmd.exe" ),
  Options( {"/c", "TaskList\n"} ),
  Read Function( "text" ) // returns all text
);
```

The preceding script writes the Windows task list and details to the log.

**Figure 8.3 Log Output**

```
<table>
<thead>
<tr>
<th>Image</th>
<th>Name</th>
<th>PID</th>
<th>Session</th>
<th>Session#</th>
<th>Mem Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Idle Process</td>
<td></td>
<td>0</td>
<td>Services</td>
<td>0</td>
<td>24 K</td>
</tr>
<tr>
<td>System</td>
<td></td>
<td>4</td>
<td>Services</td>
<td>0</td>
<td>64,340 K</td>
</tr>
<tr>
<td>smss.exe</td>
<td></td>
<td>516</td>
<td>Services</td>
<td>0</td>
<td>1,568 K</td>
</tr>
</tbody>
</table>
```

You can also print the task list directly without using `cmd.exe` and then import the task list into a data table.
blob = Run Program(
    Executable( "tasklist.exe" ),
    Read Function( "blob" )
);

Open(
    blob,
    Columns(
        Column( "Image Name", Character, "Nominal" ),
        Column( 
            "PID",
            Numeric,
            "Continuous",
            Format( "Best", 10 )
        ),
        Column( "Session Name", Character, "Nominal" ),
        Column( 
            "Session#",
            Numeric,
            "Continuous",
            Format( "Best", 10 )
        ),
        Column( "Mem Usage", Character, "Nominal" ),
        Omitted Column( . )
    ),
    Import Settings(
        Fixed Column Widths( 26, 9, 17, 12, 12, 63 ),
        Labels( 1 ),
        Column Names Start( 2 ),
        Data Starts( 4 )
    )
);

Figure 8.4 Imported Data from Run Program()

---

See the JSL Syntax Reference.

**Note:** If you use Run Program() to launch a GUI program, JMP is inoperable until you close the program.
Classes

Classes enable you to create objects based on templates. You can use JSL to create a definition of a class. A class definition is a template, which contains definitions for member variables, methods, and functions. After you have defined a class in JSL, you can instantiate an object that has all of the characteristics defined in the class definition.

Use the JSL function `Define Class()` to create a JSL class definition. Use the JSL function `New Object()` to instantiate an instance of a JSL class.

The JSL function `Define Class()` has a number of arguments that define the contents of the class:

```
Define Class("class name",
   <Base Class("base class name", "base class name", ... )>,
   <Show( All( Boolean ) ) | Show( Members( Boolean ) ),
      <Methods( Boolean )>,
      <Functions( Boolean )> ),
   <Assignment Statements>);
```

Where:

- "class name" is the name of the class being defined.
- "base class name" is one or more class names that make the set of base classes that are used as the foundation of the class being created.
- `Show` defines the value that appears when a class object is written out using the Show(), Print(), or Write() functions. Options include:
  - `All( Boolean )` shows all members, methods, and functions defined in a class object instance. The default value for `All` is true. If you specify the `All` option, that setting overrides any other arguments in the `Show` option.
  - `Members( Boolean )` shows all member variables contained in a class object instance.
  - `Methods( Boolean )` shows all methods contained in a class object instance.
  - `Functions( Boolean )` shows all functions contained in a class object instance.

**Note:** You can specify either the `All` option or any number of the Members, Methods, and Functions options, but you cannot specify both options at the same time.

**Note:** If a class contains a `_show_` method, that method overrides the `Show` option.

- Assignment Statements are zero or more of the following assignment statements, separated by semicolons:
  - `Member = JSL Expression`
  - `Method Name = Method({<argument, ...>}, body )`
- Function Name = Function( {<argument, ...}, {<local variable, ...>},
                    body )

Note: The Assignment Statements can alternatively be specified as a list of JSL expressions.

There are three specialized methods that you can use in a class definition:

_init_  Initializes the object at the time it is instantiated. This is considered the constructor for the class. You can have only one constructor per class.

_show_  Defines the output of the Show(), Print(), and Write() JSL functions when an instance of the class is used as the argument.

_to string_  Defines the output of the Char() JSL function when an instance of the class is used as the argument.

Notes:

- All methods, member variables, and functions are public.
- Functions defined within a class cannot access method variables or methods within the class.

Example of Defining a Class

The following example defines a simple class for a pet, containing the following information: name, breed, and color.

In this example, you define the constructor to require all information to create a new Pet object. Also, you define a set of accesser methods to obtain each of the attributes of a Pet object.

```javascript
Define Class( "Pet",
    name = ""; breed = ""; color = "";
    _init_ = Method( { name, breed, color },
       this:name = name;
       this:color = color;
       this:breed = breed;
    );
    _show_ = Method( {},
       Return( name || " is a " || color || " " || breed || "." )
    );
    Get Pet Name = Method( {}, Return( name ) )
);`
Instantiating a Class

To instantiate an instance of a JSL class object, use `New Object()` JSL function with any of the following functions and arguments:

```javascript
New Object("Class Name"( constructor arguments ));
New Object(Class Name(constructor arguments ));
New Object(Class Reference(constructor arguments ));
New Object("Class Name", { constructor arguments });
New Object(Class Name, { constructor arguments });
New Object(Class Reference, { constructor arguments });
```

Examples of Instantiating and Using a Class

The following example shows how to instantiate a class to create and access JSL class objects.

```javascript
class = "Pet";
xa = New Object(Pet("Oliver", "Schnauzer", "Black" ));
xb = New Object(class, {"Flynn", "Cockapoo", "Brown" });
xc = New Object(class("Mandi", "King Charles Cavalier", "Ruby" ));
xd = New Object("Pet"("Charlie", "Asian", "White" ));
xd1 = New Object(xd("Fred", "Siamese", "Silver" ));
xd2 = New Object(xd, {"Sam", "German Shepard", "Black and White" });

Show(xa );
Show(xb);
Show(xc);
Show(xd);
Show(xd1);
Show(xd2);
xd2 = xd; // returns a second reference to xd
xdclone = xd << Clone; // copy xd to a new instance, named xdclone
xd2:name = "Jerry";
Show(xd:Get Pet Name(), xd2:Get Pet Name(), xdclone:Get Pet Name());
```

This example creates multiple instances of the Pet class. The output of the `Show()` JSL function is determined by the `_show_` method that is defined in the Pet class definition. This example also illustrates the difference between creating a second JSL reference to a class instance and cloning a class instance. When using the `Clone` message, you are creating a new class instance that is independent of the original. However, the new instance starts out as a copy of the original.
File and Directory Operations

Pick Directory() and Pick File() enable the user to select a file or directory when the script is run. To get a list of files in a directory, use Files In Directory().

- “Select a Directory or File”
- “Get a List of Filenames”
- “Connect to a Network Directory”

Select a Directory or File

You can prompt the user to select a directory using the Pick Directory() function. The command displays a platform-specific window in which the user selects a folder. On Windows, the optional prompt string appears at the top of the Browse window (Windows) or below “Open” on the Finder window (macOS). You can also specify the path for an initial directory that appears, and specify whether files should appear in the Pick Directory window.

Pick Directory ( "Select a directory." );

To let the user select a file, use the Pick File() function:

Pick File(
   "prompt message", "initial directory", {filter list},
   first filter, save flag, "default file",
   multiple)

The "prompt message" is used as the window title. The "initial directory" defines which folder initially appears. If a directory is defined as an empty string, the default directory is used.

You can also define the {filter list} used for the Open() window, forcing it to show only certain file types. This list must use the following syntax:

{"Label1|suffix1;suffix2;suffix3", "Label2|suffix4;suffix5"}

Each quoted string adds an entry to the File name list in the Open() window. Label defines the text that is displayed for each menu option. The following list of suffixes defines the file types that are displayed if its corresponding label is selected. Note the use of "*" to list all files in the window.

Pick File(
   "Select JMP File", // prompt message
   "$SAMPLE_DATA", // initial directory
   {"JMP Files|jmp;jsl;jrn", "All Files|*"}, // file filter list
   1, // initially selected item
   0, // doesn't prompt the user to save the file
"Analgesics.jmp" // file that is selected by default
);

**Tip:** All arguments are optional, however, they are also positional. This means that you can leave out arguments only at the end of the script. Use empty strings for the arguments that you want to omit from the beginning of the script.

The script below does not set the default directory or the default file:

```javascript
Pick File(
    "Select JMP File",
    "", // no default directory
    {"JMP Files|jmp;jsl;jrn", "All Files|*"},
    1,
    0,
    "" // no default file
);
```

The `<first filter>` argument sets the default selection where `n` is the index for the list item. In the script above, the `<first filter>` is the first item in the list: "JMP Files|jmp;jsl;jrn".

If `<Save Flag>` is false, the `Multiple` argument can be added to allow the user to select multiple files using the one window:

```javascript
Pick File(
    "Select JMP File",
    "", // no default directory
    {"JMP Files|jmp;jsl;jrn", "All Files|*"},
    1,
    0,
    "", // no default file
    multiple // save flag is 0, allows multiple file selection
);
```

Get a List of Filenames

To obtain a list of filenames in a specific directory, use the `Files In Directory` command.

```javascript
Files In Directory( path, <recursive( 0 | 1 )> );
```

Both filenames and subdirectory names are returned as shown in the following example:

```javascript
Files In Directory( "$SAMPLE_DATA" );
    { "2D Gaussian Process Example.jmp", "Abrasion.jmp", ... "Design Experiment", "Detergent.jmp", ... }
```

Notice that the files within the `Design Experiment` subdirectory are not included. And only files in the root `$SAMPLE_DATA` directory are listed.
To return a list of all file names, add the optional recursive(Boolean) argument to Files In Directory:

```
Files In Directory( "$SAMPLE_DATA", recursive( 1 ) );
{
  "2D Gaussian Process Example.jmp", "Abrasion.jmp", ...
  "Design Experiment/2x3x4 Factorial.jmp", "Design Experiment/Algorithm Data.jmp",
... }
```

To get the full pathnames, recurse the directories and concatenate the file paths and file names. The following example loops through each file in the $SAMPLE_DATA directory and subdirectories. The file path is concatenated to each file name.

```
names = Files In Directory( "$SAMPLE_DATA", recursive( 1 ) );
For( i = 1, i <= N Items( names ), i++,
  names[i] = Convert File Path( "$SAMPLE_DATA" ) || names[i]
);
names;
{
  "/C:/Program Files/SAS/JMP/16/Samples/Data/2D Gaussian Process Example.jmp",
  "/C:/Program Files/SAS/JMP/16/Samples/Data/Abrasion.jmp",
... }
```

The Files in Directory command accepts native and POSIX paths, as well as paths using path variables. See “Path Variables” on page 145 in the “Types of Data” chapter for more information about working with paths.

### Connect to a Network Directory

On Windows, you can connect to a network directory without connecting to the shared drive first.

```
Files in Directory( "\\myserver.company.com/source/Users/Smith" );
```

On macOS, you have to mount the volume first and then connect to the directory using a combination of JSL and AppleScript. Note that you can also modify this script to work on Windows. On macOS only, the user is prompted for a password.

```
mount = Function( {server},
  {Default Local},
  If( Host is( "Mac" ),
    /* Use osascript to mount the volume.
    The user will be prompted for credentials. */
    Run Program(
      Executable( "/usr/bin/osascript" ),
      Options( {"-e", Eval Insert( "mount volume \!"smb://^server^\!" )} ),
      Read Function( "text" )
    );
    server = Concat Items( Remove( Words( server, "/" ), 1 ), "/" );
  );
```
Eval Insert( "/Volumes/^server^" );

// Windows can use UNC to auto-mount the server.
Eval Insert( "\\\\^server^" )
);

users = Mount( "myserver.company.com/Users" );
Files In Directory( Eval Insert( "^users^/Smith" ) );

Scripting By Groups

By group arguments are supported for these functions: ColMean(), ColStdDev(), ColNumber(), ColNMissing(), ColMinimum(), ColMaximum().

Any number of By arguments can be specified, and you can use expressions for the By arguments. By arguments must be used in a column formula, or in the context of ForEachRow(). The first argument can also be a general numeric expression.

Here is an example:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Mean of height by sex", Numeric, Formula( Col Mean( :height, :sex ) ) );

dt << New Column( "Minimum of height by sex and age", Numeric,
   Formula( Col Minimum( :height, :sex, :age ) )
);

dt << Distribution( Continuous Distribution( Column( :height ) ), By( :sex )
);

dt << Tabulate(
   Show Control Panel( 0 ),
   Add Table(
      Column Table(
         Analysis Columns( :height ),
         Statistics( Mean, N, Std Dev, Min, Max, N Missing )
      ),
      Row Table( Grouping Columns( :age, :sex )
      )
   )
);
```
Encrypt and Decrypt Scripts

To add a basic level of protection to scripts, you can encrypt it so only someone who knows the password can view it; you can also require a password to run it. This is useful in situations when you want to implement controlled sharing of a script.

To encrypt a script:

1. Open the script that you want to encrypt.
2. Select **Edit > Encrypt Script**.
3. Enter a decrypt password so that the user needs a password to view the script.
4. (Optional) Enter a run password to require the user to enter a password before running the encrypted script.

   **Note:** The passwords must consist of single-byte characters; using a text Input Method Editor (IME) does not work.

5. Click **OK**.
6. If you entered only a decrypt password, click **Yes** to confirm that you do not want to assign a run password.

   The encrypted script opens in a new window. For example:

   ```
   //e6.0.2
   S@FTQ;VGMUTF?J<;LS;B<=IRLXCu=BV;@NS<TW;LR<ZFOP=JJ<s>NNDA<T<v><DZA>SU@MG;LR<ZFO
   P=JJ<s>NNDA<T<v><DZA>SU@MG;LR<ZFOP=JJ<s>NNDA<T<v><DZA>SU@MG;LR<ZFOP=JJ<s>NNDA
   @T<hNIZ;W DN?RMJ;FR>KYAXTEPPF?;XFJJOP=RQGBIAGXOYNNZ>PLIF>SW>L>ACL<KGP;=QTC
   EG??U<PUXLV?TRBO?J=QGW<TCFJ@BNHwLVORNNQYPIKL<IM><@G?LJ>=;RBODH@PTKK@S
   IUE;IJO<UTRMTGSYRSVGOR<XX<F=IWQYE=LvZFP;AUHA?YJLL;EIT?ZJZC;*
   
   7. Save the encrypted script.

To encrypt a column formula in a script:

Column formulas created by an encrypted script are visible by default. If you want a formula to be encrypted, follow these steps:

1. Paste just the formula into a new script window.
2. Encrypt the script by clicking **Edit > Encrypt Script**.
3. Provide a password only.
4. Copy the encrypted script.
5. Paste the encrypted script in a new script as a string argument for JSL `Encrypted()` as shown below.
```
dt = Open( "$SAMPLE_DATA\Big Class.jmp" );

dt << New Column( "Encrypted",
    Numeric,
    Continuous,
    Format( "Best", 12 ),
    Formula(
        JSL_Encrypted(
            "//-e6.0.2
            0,
            136,4112eJwFwYkRhCAMAMB+roUQcITwDcoP4fovxN3Ri0B+MFqvqXB8Z0hZdFC+dgqc1Jo0dwr1Z
            bFjgyPlZRuRZhp3990bhphxQXP8
            GPtft0MN6Rwz8pDnjmK1K0qq1bEG+H0xvyBb
            ,0,"
        )
    )
);
```

To decrypt a JSL script:

1. Open the encrypted script in JMP.
2. Select **Edit > Decrypt Script**.
3. Enter the decrypt password and click **OK**.
   
The decrypted script opens in a new window.

To run an encrypted JSL script:

**Note:** You must know which data table the script runs on before running an encrypted script. If you do not know the name of the data table, you must decrypt the script before running it.

1. Open the encrypted script in JMP.
2. Select **Edit > Run Script**.
3. Enter the run password and click **OK**.
   
The script runs:
   - If the script references a data table, you are prompted to open the data table, and then the script runs.
   - If the script requires an empty data table, you must create the table and then run the encrypted script.

Note that entering the run password runs the script, but does not show the script: you must supply the decrypt password to actually view the script.
Encryption and Global Variables

Encryption alone does not hide global variables and their values. A `Show Globals()` command displays them normally. If you want to hide global variables in an encrypted script, you can give them special names.

Any global variable whose name begins with two underscore characters (__) is hidden, and `Show Globals()` displays neither its name nor its value. For example:

```plaintext
myvar = 2;
__myvar = 5;
Show Symbols();
// Globals
myvar = 2;
// 2 Global (1 Hidden)
```

This strategy works whether your script is encrypted or not.

Encrypting Scripts in Data Tables

You can also encrypt a script that is saved to a data table using the JSL `Encrypted()` or `Include( Char to Blob() )` functions.

- `JSL Encrypted()` is more straightforward, because it involves one function. You can include comments inside the encrypted script.
- `Include( Char to Blob() )` lets you include comments, but not inside the script.

**Note:** Column formulas in encrypted scripts are not encrypted. To encrypt them, include them in the `JSL Encrypted()` function.

Follow these steps to encrypt a data table script:

1. Place the script in a script window.  
   You cannot directly encrypt a script that is already saved to a data table.
2. In the script window, select **Edit > Encrypt**.
3. Enter a decrypt password.
4. (Optional) Enter a run password to require the user to enter a password before running the script.
5. If you entered only a decrypt password, click **Yes** to confirm that you do not want to assign a run password.  
   The encrypted script opens in a new script window.
6. Copy the entire encrypted script.
7. Create a new data table script or open an existing script.
8. In the script portion of the window, type one of the following functions:

\[
\text{JSL Encrypted( "" );}
\]
\[
\text{Include( Char to Blob( "" ) );}
\]

9. Paste the encrypted script inside the quotation marks in the function.
10. Click OK.

**Figure 8.5** Example of an Encrypted Data Table Script

```jscript
JSL Encrypted{

}"/*-60.0.2
WEB0S&CG7\?C\K\E=0:G\B<\RL\;CU=8U;8N3<\W\:L\<2FOP=JJS>;XND\&8<\V\<DZA
>S\XG;L\<2FOP=JJS>;XND\&8<\V\<DZA
>S\XG;L\<2FOP=JJS>;XND\&8<\V\<DZA
>

Figure 8.5 Example of an Encrypted Data Table Script

Working with Expressions in an Encrypted Script

An encrypted script might not run the same as the unencrypted script if the script attempts to convert parts of itself from expressions back to character strings. This is necessary to keep the script encrypted. You can avoid this problem by using the expression manipulation functions such as \texttt{Arg()}, \texttt{Head()}, \texttt{Substitute()}, and so on. You can also use \texttt{Parse()} to make expressions from character strings that are part of the encrypted script.

For example, here is a script that modifies an expression the wrong way for encryption:

```jscript
ex = Expr(
    aaa = 20;
    Show( aaa );
);
// Wrong, don't do this.
temp = (Parse( Substitute( Char( Name Expr( ex ) ), "aaa", "bbb" ) ));
temp;
```

The script fails when encrypted because \texttt{Char()} is unable to break the encryption of the expression stored in \texttt{ex}. A second example follows:

```jscript
ex = Expr(
    aaa = 20;
    Show( aaa );
);
// Best choice if it works for you.
temp = Substitute( Name Expr( ex ), Expr( aaa ), Expr( bbb ) );
temp;
```
A third example, though not optimal, follows:

```javascript
ch = "aaa = 20; Show(aaa);"
/* Leaves the ch variable holding unencrypted text
   and Temp holds an unencrypted expression.*/
temp = Parse( Substitute( ch, "aaa", "bbb" ) );
temp;
```

You might prefer the third choice over the second choice because it looks easier to understand; be aware that you might want to clear variables like `ch` and `Temp` when you are done with them. You probably encrypted the script to keep other folks from reading it, and they will definitely be able to see the content of variables when you are done.

---

### Additional Numeric Functions

JSL also offers several categories of operations that do not make much sense in the context of the formula editor: matrix operations and numeric derivatives of functions. Algebraic derivatives are also available.

The basic arithmetic operators can also be used with matrix arguments for matrix-wise addition, subtraction, and so on. Matrices also have a few special operators for elementwise multiplication and division, concatenation, and indexing. See “Matrices” on page 202 in the “Data Structures” chapter.

---

### Derivatives

JSL has three internal functions (not all available in the calculator) for taking derivatives.

`Derivative()` takes the first derivative of an expression with respect to names you specify in the second argument. A single name might be entered as this second argument; or multiple values can be specified in a list, in other words, surrounded by braces.

**Note:** `Derivative()` is also available as an editing command inside the formula editor (calculator), located on the drop-down list in the top center of the formula editor (above the keypad). To use it, highlight a single variable in the expression (to designate which variable the derivative should be taken with respect to), then select the Derivative command from the menu. The whole formula is replaced by its derivative with respect to the highlighted name.

In scripts, the easiest way to use the function is with a single name. In this example, the mathematical notation is shown first followed by the JSL equivalent.

For \( f(x) = x^3 \), the first derivative is \( f'(x) \) or \( \frac{d}{dx} x^3 = 3x^2 \).

```javascript
result = Derivative( x ^ 3, x );
```
Show( result );
result = 3 * x ^ 2

If you want an efficient expression to take the derivative with respect to several variables, then the variables are specified in a list. The result is a list containing a threaded version of the original expression, followed by expressions for the derivatives. The expression is threaded by inserting assignments to temporary variables of expressions that are needed in several places for the derivatives.

Here is an example involving an expression involving three variables. Listing all three variables returns the first derivatives with respect to each. The result is a list with the original expression and then the derivatives in the order requested. However, note here that JMP creates a temporary variable T#1 for storing the subexpression \( x^2 \), and then uses that subexpression subsequently to save calculations.

result2 = Derivative( 3 * y * x ^ 2 + z ^ 3, {x, y, z} );
Show( result2 );
result2 = {3 * y * (T#1 = x ^ 2) + z ^ 3, 6 * x * y, 3 * T#1, 3 * z ^ 2}

To take second derivatives, specify the variable as a third argument. Both the second and third arguments must be lists. JMP returns a list with the original expression, the first derivative(s), and then the second derivative(s) in the order requested.

second = Derivative( 3 * y * x ^ 2, {x}, {x} );
Show( second );
second = {3 * y * x ^ 2, 6 * x * y, 6 * y}

second = Derivative( 3 * y * x ^ 2, {y}, {y} );
Show( second );
second = {3 * y * (T#1 = x ^ 2), 3 * T#1, 0}

second = Derivative( 3 * y * x ^ 2, {y}, {x} );
Show( second );
second = {3 * y * (T#2 = x ^ 2), 3 * T#2, 6 * x}

**Num Deriv()** takes the first numeric derivative of a function with respect to the value of the first argument by calculating the function at that value and at that value plus a small delta \( \Delta \) and dividing the difference by the delta. **Num Deriv2()** computes the second numeric derivative in a similar fashion. These are used internally for nonlinear modeling but are not frequently useful in JSL. Note that these functions do not differentiate using a variable, but only with respect to arguments to a function. In order to differentiate with respect to \( x \), you have to make \( x \) one of the immediate arguments, not a symbol buried deep into the expression.

Suppose to differentiate \( y = 3x^2 \) at the value of \( x = 3 \). The incorrect way would be to submit the following script:

```julia
x = 3;
n = Num Deriv( 3 * x ^ 2 );
```
The correct way is to make $x$ an argument in the function.

\[
x = 3;
\]
\[
f = \text{Function}( \{x\}, 3 \times x^2 );
\]
\[
n = \text{Num Deriv}( f(x), 1 );
\]
\[
18.000029999854
\]

Consider both the mathematical notation and the JSL equivalent for another example:

For $f(x) = x^2$, it calculates $\frac{d}{dx} x^2 = \frac{(x + \Delta)^2 - x^2}{\Delta}$. At $x_0 = 3$, $\frac{d}{dx} x^2 = 6.00001$.

\[
x = 3;
\]
\[
y = \text{Num Deriv}( x^2 ); // or equivalently: y = \text{Num Deriv}( 3^2 );
\]
\[
6.0000099999513
\]

And here are a few more examples:

\[
x = \text{Num Deriv}( \text{Sqrt}(7) ); // returns 0.188982168980445
\]
\[
y = \text{Num Deriv}( \text{Normal Distribution}(1) ); // returns 0.241969514669371
\]
\[
z = \text{Num Deriv2}( \text{Normal Distribution}(1) ); // returns -0.241969777547979
\]

### Table 8.7 Derivative functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Derivative</td>
<td>Derivative($expr$, {name, ...})</td>
<td>Returns the derivative of the $expr$ with respect to $name$. Note that the second argument can be specified in a list with braces {} or simply as a variable if there is only one. Give two lists of names to take second derivatives.</td>
</tr>
<tr>
<td>NumDeriv</td>
<td>NumDeriv($expr$)</td>
<td>Returns the first numeric derivative of the $expr$ with respect to the first argument in the expression.</td>
</tr>
<tr>
<td>NumDeriv2</td>
<td>NumDeriv2($expr$)</td>
<td>Returns the second numeric derivative of the $expr$ with respect to the first argument in the expression.</td>
</tr>
</tbody>
</table>

### Algebraic Manipulations

JSL provides a way of algebraically unwinding an expression (essentially, solving for a variable). It is accomplished through the Invert Expr() function.

\[
\text{Invert Expr}(\text{expression}, \text{name}, y)
\]

where

- $\text{expression}$ is the expression to be inverted, or the name of a global containing the expression
- $\text{name}$ is the name inside expression to unwind the expression around
• y is what the expression was originally equal to.

For example,

\[ \text{Invert Expr}( \text{Sqrt}( \log(x) ), x, y ); \]

is wound around the name x (which should appear in the expression only once), and results in

\[ \text{Exp}(y^2) \]

It is performed exactly as you would when doing the algebra by hand.

\[ y = \text{Sqrt}(\log(x)); \]
\[ y^2 = \log(x); \]
\[ \text{Exp}(y^2) = x; \]

\text{Invert Expr} supports most basic operations that are invertible, and makes assumptions as necessary, such as assuming you are interested only in the positive roots, and that the trigonometric functions are in invertible areas so that the inverse functions are legal.

\( F, \) Beta, Chi-square, \( t, \) Gamma, and Weibull distributions are supported for the first arguments in their Distribution and Quantile functions. If it encounters an expression that it cannot convert, \text{Invert Expr}() returns \text{Empty}().

\text{JSL provides a Simplify Expr command that takes a messy, complex formula and tries to simplify it using various algebraic rules. To use it, submit}

\[ \text{result} = \text{Simplify Expr(expr(expression))}; \]

or

\[ \text{result} = \text{Simplify Expr(nameExpr(global))}; \]

For example,

\[ \text{Simplify Expr}( \text{Expr}(2 * 3 * a + b * (a + 3 - c) - a * b )); \]

results in

\[ 6a + 3b + -1b*c \]

\text{Simplify Expr()} also unwinds nested \text{If} expressions. For example:

\[ r = \text{Simplify Expr}( \text{Expr}( \text{If}( \text{cond1, result1, If( cond2, result2, If( cond3, result3, resultElse ) ) ) ) ) ); \]

results in

\[ \text{If}(\text{cond1, result1, cond2, result2, cond3, result3, resultElse}); \]
Maximize and Minimize

The Maximize() and Minimize() functions find the factor values that optimize an expression. The expression is assumed to be a continuous function of the factor values.

Here is the form of the call:

```
result = Maximize(objectiveExpression, {list of factor names}, <<option(value))
result = Minimize(objectiveExpression, {list of factor names}, <<option(value))
```

`objectiveExpression` is the expression whose value is to be optimized, and can either be the expression itself, or the name of a global containing a stored expression.

`{list of factor names}` is an expression yielding a list of names involved in `objectiveExpression`.

The name can be followed by limits that bound the permitted values, for example `name(lowerBound, upperBound)`.

If you want to limit the values on one side, make the other side a missing value, for example:

```
{beta} // unconstrained
{beta (0,1)} // constrained between 0 and 1
{beta (.1)} // upper limit of 1
{beta (0,.)} or {beta (0)} // lower limit of 0
```

Factor values can be either numbers or matrices.

Options available, shown with their default value, include:

```
<< Tolerance(.00000001) // convergence criterion
<< Max Iter(250) // maximum number of iterations
<< Limits() //
```

Initial values are assumed to be already supplied the factor values before calling the function.

These functions are not expected to find global optima for functions that have multiple local optima; they are useful only for taking an initial value and moving it to either a local or global optimum.

The return value is currently the value of the objective function, if the optimization was successful, or `Empty()` if not.
Least Squares Example

The following example uses Minimize to find the least squares estimates of this exponential model, with data taken from the Nonlinear Example/US Population.jmp sample data table.

```math
xx = [1790, 1800, 1810, 1820, 1830, 1840, 1850, 1860, 1870, 1880, 1890, 1900,
     50.155, 62.947, 75.994, 91.972, 105.71, 122.775, 131.669, 151.325, 179.323,
     203.211, 226.5, 248.7];
b0 = 3.9;
b1 = .022;
sseExpr = Expr(
    Sum( (yy - (b0 * Exp( b1 * (xx - 1790) ))) ^ 2 )
);
sse = Minimize( sseExpr, {b0, b1}, <<Tolerance( .00001 ) );
Show( b0, b1, sse );
```

```
b0 = 13.9991388055261;
b1 = 0.0147104409355048;
sse = 1862.14141218875;
```

Identifying Differences Between Strings, Lines, or Sequences

The Shortest Edit Script() function compares two strings, lines, or sequences and returns a list of changes or a matrix that describes the changes. You might use Shortest Edit Script() to identify differences between two columns, lists, or matrices. The function describes a (not the) shortest list of instructions to convert sequence A into sequence B. There might be more than one shortest script.

Example of Sequences

```math
t1 = New Table( "t1",
    New Column( "Column 1",
        Numeric,
        Continuous,
        Format( "Best", 12 ),
        Set Values( [1, 2, 3, 4, 5, 6, 1, 2, 3, 4, 5, 6, 7] )
    );

t2 = New Table( "t2",
    New Column( "Column 1",
        Numeric,
```
Continuous,

Format( "Best", 12 ),
Set Values( [2, 3, 4, 5, 2, 3, 4, 5, 2, 3, 4, 5, 6] )

EditScript = Shortest Edit Script( // compares column 1 in each table sequences(
  N Rows( t1 ),
  N Rows( t2 ),
  Function( {a, b}, // subscripts the columns	n1:column 1[a] == t2:column 1[b] // in data tables t1 and t2
  )
)
);

[-1 1 . 1, // delete 1 item at position 1 in string a
  0 2 1 4, // keep 4 items at position 2 in string a, position 1 in string b
  1 6 . 2, // delete 2 items at position 6 in string a
  1 . 5 4, // add 4 items at position 5 in string b
  0 8 9 5, // keep 5 items at position 8 in string a, position 9 in string b
  -1 13 . 1] // delete 1 item at position 13 in string a

Here are the columns in the matrix:

- Column 1: delete the items (-1), keep the common items (0), or add the items (1)
- Column 2: the position in string a
- Column 3: the position in string b
- Column 4: the number of items the instruction uses

A missing value indicates that the position isn’t used in the comparison.

Example of Separators

The following example considers “@” and “$” to be separators.

aa = "this is$a test of@shortest$edit script lines$with several words";
bb = "this is a$test of$shortest$edit script lines with several@words";

// @ and $ separators
Shortest Edit Script( lines( aa, bb, separators( "$" ) ) );

See the JSL Syntax Reference.
Scheduling Actions

A Schedule() function lets you set up a script to be executed some number of seconds later.

```
Schedule( 15, Print( "hello" ) );
```

Figure 8.6 JMP Scheduler

A Scheduler window shows the time until the next event and has buttons for restarting (Go) or stopping (Stop) the schedule. Its pop-up menu has a command Show Schedule, which echoes the current schedule to the log. For example, if you checked the schedule several times during the “hello” example, you would see something like this:

```
Scheduled at 11.55000000000018 :Print("hello")
Scheduled at 4.716666666666697 :Print("hello")
Scheduled at 3.083333333333485 :Print("hello")
```

The script might also be a name referring to a stored expression. For example, try submitting this script, which calls itself:

```
quickieScript = Expr(  
    Show( "Hi there" );  
    Schedule( 15, quickieScript );  
);
quickieScript;
```

This script should show the string “Hi there” in a log window after 15 seconds, and reschedule itself for another 15 seconds, continuing until the Stop button is clicked.

More typically, in a production setting you might want to set up a schedule like this:

```
FifteenMinuteCheck = Expr(  
    Show( "Checking data" );  
    Open( "my file", options... );  
    distribution( Column( column1 ), capability( spec limits ) );  
    Schedule( 15 * 60, FifteenMinuteCheck );  
);
FifteenMinuteCheck;
```

Schedule() initiates an event queue, but once it has the event queued, JMP proceeds with the next statement in the script. For example, the following has results that might surprise you:

```
Schedule( 3, Print( "one" ) );
```
If you want the script to wait until the scheduled events are finished before proceeding, one solution would be to use `Wait( )` with a suitable pause. Another is to embed the subsequent actions into the schedule queue. `Schedule()` accepts a series of arguments to queue many events in sequence. Each event is a separate call to the schedule. Each event time is an absolute time relative to “now” (or the instant that Go is clicked). Therefore, the following sequence finishes in five seconds, not in twelve:

```javascript
Schedule( 3, Print( "hello" ) );
Schedule( 4, Print( "world" ) );
Schedule( 5, Print( "--bye" ) );
```

To cancel all events in a schedule queue, use `Clear Schedule`.

```javascript
scheduler[1] << Clear Schedule( );
```

Note: It is not possible to create multiple threads using `Schedule`.

### Table 8.8 Schedule commands

<table>
<thead>
<tr>
<th>Message</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schedule</td>
<td><code>sc=Schedule(n, script)</code></td>
<td>Queues an event to run the <code>script</code> after <code>n</code> seconds.</td>
</tr>
<tr>
<td>Clear Schedule</td>
<td><code>sc&lt;&lt;Clear Schedule()</code></td>
<td>Cancels all events in a schedule queue.</td>
</tr>
</tbody>
</table>

### Functions that Communicate with Users

`Show()`, `Print()`, and `Write()` put messages in the log window. `Speak()`, `Caption()`, `Beep()`, and `StatusMsg()` provide ways to say something to a viewer. `Mail()` can send an e-mail alert to a process operator.

The JMP scripting language has methods for constructing dialog boxes to ask for data column choices and other types of information. See “Modal Windows” on page 609 in the “Display Trees” chapter.

Tip: To preserve locale-specific numeric formatting in `Show()`, `Print()`, or `Write()` output, include `<<Use Locale(1)`.  

```javascript
Print( "two" );
"two"
"one"
```
Writing to the Log

Show

Show() displays the items that you specify in the log. Notice that when you show variables, the resulting message is the variable name, an equal sign, and its current value.

```javascript
X = 1;
A = "Hello, World"
Show( X, A, "foo" );
x = 1
a = "Hello, World"
"foo"
```

Print

Print() sends the message that you specify to the log. Print() is the same as Show() except that it prints only the value of each variable without the variable name and an equal sign.

```javascript
X = 1;
A = "Hello, World"
Print( X, A, "foo" );
1
"Hello, World"
"foo"
```

Write

Write() sends the message that you specify to the log. Write() is the same as Print() except that it suppresses the quotation marks around the text string, and it does not start on a new line unless you include a return character yourself with the \!N escape sequence.

```javascript
myText = "Here is a message."
Write( "Here is a message." );
Here is a message.

Write( myText || " Do not forget to buy milk." ); // use || to concatenate
Write( "\!NAnd bread." ); // use \!N for return
Here is a message. Do not forget to buy milk.
And bread.
```

The sequence \!N inserts the line breaking characters that are appropriate for the host environment. For an explanation of the three line breaking escape sequences, see “Double Quotes” on page 99 in the “JSL Building Blocks” chapter.
Send Information to the User

Beep

Beep() causes the user’s computer to make an alert sound.

Speak

Speak() reads text aloud. On macOS, Speak() has one Boolean option, Wait(), to specify whether JMP should wait for speaking to finish before proceeding with the next step. The default is not to wait, and you need to issue Wait(1) each time. For example, here is a script certain to drive anybody crazy. With Wait(1), you probably want to interrupt execution before too long. If you change it to Wait(0), the iterations proceed faster than the speaking possibly can and the result sounds strange. On Windows, you can use a Wait(n) command to accomplish the same effect.

```
For( i = 99, i > 0, i--, 
    Speak( 
        Wait( 1 ), 
        Char( i ) || " bottles of beer on the wall, " || Char( i ) || " bottles of beer; " ||
        "If one of those bottles should happen to fall, " || Char( i - 1 ) || " bottles of beer on the wall. "
    );
```

A more practical example has JMP announce the time every sixty seconds:

```
script = Expr( 
    tod = Mod( Today(), In Days( 1 ) ); 
    hr = Floor( tod / In Hours( 1 ) ); 
    min = Floor( Mod( tod, In Hours( 1 ) ) / 60 ); 
    timeText = "time, " || Char( hr ) || " " || Char( min ); 
    text = Long Date( Today() ) || ", " || timeText; 
    Speak( text ); 
    Show( text ); 
    Schedule( 60, script );    // seconds before next script
);
```

You might use a similar technique to have JMP alert an operator that a process has gone out of control.
Caption

Caption() brings up a small window with a message to the viewer. Captions are a way to annotate demonstrations without adding superfluous objects to results windows. The first argument is an optional \( \{h,v\} \) screen location given in pixels from the upper left; the second argument is the text for the window. If the location argument is omitted, windows appear in the upper left corner.

You can include pauses in the playback by including the named argument Delayed and a time in seconds. Such a setting causes that caption and all subsequent caption windows to be delayed by that number of seconds, until a different Delayed setting is issued in a Caption statement. Use Delayed(0) to stop delaying altogether.

Specify the font type, font size, text color, or background color with the following arguments:

\[
\begin{align*}
\text{Font( font );} \\
\text{FontSize( size );} \\
\text{TextColor("color");} \\
\text{BackColor("color");}
\end{align*}
\]

The Spoken option causes captions to be read aloud by the operating system’s speech system (if available). Spoken takes a Boolean argument, and the current setting (on or off) remains in effect until switched by another Caption statement that includes a Spoken setting.

This script turns speaking on and leaves it on until the last caption. In the first caption, the font type, color, and background color is specified. Run the script and notice that the font and color settings apply only to the first caption.

\[
\begin{align*}
\text{Caption(} \\
\quad \{10, 30\}, \\
\quad \text{"A Tour of the JMP Analyses"}, \\
\quad \text{Font( "Arial Black" ),} \\
\quad \text{FontSize( 16 ),} \\
\quad \text{TextColor( "blue" ),} \\
\quad \text{BackColor("yellow")}, \\
\quad \text{Spoken( 1 ),} \\
\quad \text{Delayed( 5 )} \\
\text{);} \\
\text{Caption( "Open a data table." );} \\
\text{bigClass = Open( "$SAMPLE_DATA/Big Class.jmp" );} \\
\text{Caption( "A data table consists of rows and columns of data." );} \\
\text{Caption( "The rows are numbered and the columns are named." );} \\
\text{Caption( \{250, 50\}, "The data itself is in the grid on the right" );} \\
\text{Caption(} \\
\quad \{5, 30\}, \\
\quad \text{Spoken( 0 ),} \\
\quad \text{"A panel along the left side shows columns and other attributes."} \\
\text{);} \\
\end{align*}
\]
Each new Caption hides the previous one. In other words, there is only one caption window available at a time. To close a caption without displaying a new one, use the named argument Remove.

```
Caption( remove );
```

### StatusMsg

This command sends a message to the status bar.

```
StatusMsg( "string" );
```

### Mail

Mail() sends an e-mail message to a user. For example, a process control manager might include a test alert script in a control chart to trigger an e-mail warning to her pager:

```
Mail(
    "JaneDoe@company.com",
    "out of control",
    "Process 12A out of control at " || Format( Today(), "d/m/y h:m:s" )
);
```

Mail() can also send an attachment with the e-mail. An optional fourth argument specifies the attachment. The attachment is transferred in binary format after its existence on the disk is verified. For example, to attach the Big Class.jmp data table, submit

```
Mail(
    "JohnDoe@company.com",
    "Interesting Data Set",
    "Have a look at this class data.",
    "$SAMPLE_DATA\Big Class.jmp"
);
```

**Note:** On macOS, Mail() works on Mountain Lion and later operating systems. On Mountain Lion, you must enter the e-mail address and subject in the e-mail due to operating system limitations. Click the **Send message** button to send the e-mail.
Before you can work with a data table or with objects in a data table, you must first open the data table and assign a reference to it. In the Scripting Guide, $dt$ represents a reference to a data table object.

To manipulate an object in JSL, you send a message to the reference that represents the object, asking the object to perform one of its tasks. Messages are commands that can be understood only in context by a particular type of object. For example, messages for data table objects include Save, New Column, Sort, and so on. Most of these messages would not make sense for another object, such as a platform object.

In this chapter, you can learn the following:

- How to assign a reference to a data table
- How to send messages to the reference, resulting in specific actions
- About the different types of messages that data table objects can understand

Most of this chapter focuses on the different types of messages that you can send to data table objects, such as data tables, columns, rows, and values.

**Tip:** This chapter contains most, but not all of the JSL commands that you can use with data tables. For an exhaustive list, see the JMP Scripting Index. Select Help > Scripting Index. Select *Objects* from the menu, and then select *Data Table*.

Get Started with Data Tables

Tip: Keep the log window open to see the output of each script that you run. Select View > Log to open the Log window. See “Work with the Log” on page 70 in the “Scripting Tools” chapter.

The typical way to work with values in a data table is to follow these steps:

1. Set up the data table whose values you want to access as the current data table. Or, if you already have a data table reference, you can simply use that reference.
2. Specify the row or rows whose values you want to access and specify the column name that contains the values that you want to access.

The following example opens the Big Class.jmp sample data table (making it the current data table), and then specifies row 2 in the weight column. A value of 123 is returned in the log, which is the weight for Louise in row 2.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt:weight[2];
123
```

If the data table that you want to work with is already open, proceed using one of the following examples:

```
dt = Data Table( "My Table" ); // the open table named My Table
dt = Current Data Table(); // the table in the active window
dt = Data Table( 3 ); // the third open table
```

Once you have an open data table with a reference, you can send it messages using either the << operator or the Send function. The following example illustrates both methods:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Save();
Send( dt, Save() );
```

Note the following about messages:

- You can send messages to any data table object (a data table, column, row, and so on).
- Messages sent to data table objects always have the same pattern:
  ```
  Reference << Message( Arguments );
  ```
- Usually, creating a reference and sending many messages to the reference is the easiest approach. However, you can also use the direct route instead of using a reference if you have only one message to send. The following example saves the current data table:
  ```
  Current Data Table() << Save();
  ```
• You can stack up a series of messages in one statement. Commands are evaluated from left to right, and each returns a reference to the affected object. The following example creates a new data table called My Table, adds two columns to it, and prompts you to save it:

```julia
dt = New Table( "My Table" );
dt << New Column( "Column 1" ) << New Column( "Column 2" ) << Save( "" );
```

In this example, each message returns a reference to the data table (dt).

• If you specify too few arguments for a message, JMP presents a window to get the necessary information from you. JMP often presents windows when your script is incomplete, a behavior that you can use to your advantage when writing scripts that need to query users for their choices.

• Some messages come in pairs; one to “set” or assign each attribute, and one to “get” or query the current setting of each attribute.

**Why are Some Commands Sent to Objects and Others Used Directly?**

New Table and Open are commands to create objects that do not exist yet. Once created, you send them messages requesting changes. To close such objects, you must close the objects’ container, because the objects cannot delete themselves.

The following example creates a table and assigns the data table reference to the dt variable. New Column messages are sent to the data table reference. To delete one of those columns, the Delete Columns message is sent to the data table reference, not to the column itself.

```julia
dt = New Table( "Airline Data" );
dt << New Column( "Date" );
dt << New Column( "Airline" );
dt << Delete Columns( "Date" );
```

**How Can I See All of the Messages that Can be Sent to a Data Table Object?**

To see all of the messages that can be sent to a data table object, see the Scripting Index:

1. Select Help > Scripting Index.
2. Select All Categories from the list.
3. Select Data Table in the list.

You can also use the Show Properties() command. This is a good approach if you want to print or copy the list of messages. The Show Properties() command lists the messages that you can send to a data table in the Log window. Show Properties() is a command that takes any scriptable object (such as a data table or column) as its argument. To show properties for a data table:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Show Properties( dt );
```

The resulting message list is hierarchical.
[Subtable] refers to a set of JMP menu commands. For example, the Tables subtable represents the JMP Tables menu, and the indented messages in this subtable correspond to commands in the Tables menu. Many messages include a short description.

Messages labeled as [Action] all result in some action being taken. Some messages are available for [Scripting Only]. Some messages take a Boolean argument, labeled as [Boolean].

The platforms in the Analyze and Graph menus appear in the properties list because you can send a platform name as a message to a data table. This launches the platform for the data table through the usual launch window. For more information about writing platform-specific scripts, see the “Scripting Platforms” chapter on page 469.

```julia
dt << Distribution( Y( height ) );
```

**Note:** In addition to data tables, Show Properties also works with platforms and display boxes.

The JMP Scripting Index provides more information about these properties. You can also run and modify sample scripts from the Scripting Index. Select Help > Scripting Index and search for the property in the Objects list.
Basic Data Table Scripting

Before you can work with data table objects, you must open or create a data table, and assign a reference to the data table.

- “Open a Data Table”
- “Create a New Data Table”
- “Import Data”
- “Set the Current Data Table”
- “Name a Data Table”
- “Save a Data Table”
- “Hide a Data Table”
- “Print a Data Table”
- “Resize a Data Table”
- “Close a Data Table”
- “Set and Get a Data Table”
- “Perform Actions on All Open Data Tables”
- “Create Journals”
- “Create Excel Workbooks”
- “Prevent Changes to a Data Table”

Open a Data Table

Use the `Open()` function to open a data table.

- To simply open a data table without returning a reference to it:
  ```javascript
  Open( "$SAMPLE_DATA/Big Class.jmp" ); // open the data table
  ```
- To open a data table and retain a reference to it:
  ```javascript
  dt = Open( "$SAMPLE_DATA/Big Class.jmp" ); // open and store a reference
  ```

The path to the data table can be a quoted literal path (absolute or relative) or an unquoted expression that yields a pathname. Relative paths are interpreted relative to the location of the .jsl file (for a saved script). For unsaved scripts, the path is relative to your primary partition (Windows) or your `<username>/Documents` folder (macOS).

```javascript
Open( "../My Data/Repairs.jmp" ); // relative path on Windows and macOS
Open( "::My Data:Repairs.jmp" ); // relative path on macOS
Open( "C:/My Data/Repairs.jmp" ); // absolute path
```
JMP provides shortcuts (*path variables*) to directories or files. Instead of entering the entire path to the directory or file, you include a path variable in the `Open()` expression. For example, JMP sample scripts typically use the `$SAMPLE_DATA` path variable to open files in the Samples/Data folder. For more information about path variables, see “Path Variables” on page 145 in the “Types of Data” chapter.

If you do not want to specify the entire path every time you open a data table, define a filepath string and concatenate the path with the filename:

```plaintext
myPath = "C:/My Data/Store25/Maintenance/Expenses/";
Open( myPath || "Repairs.jmp" );
```

Upon opening a data table, JMP stores the data table in memory. This means that if a script attempts to open a data table that is already open, the opened version appears. JMP does not read the version that is saved on your computer.

### Test for an Open Data Table

In a script that depends on an opened data table, you can test to see whether the table is open using `Is Empty()` or `Is Scriptable()`. In the following example, the script performs a Bivariate analysis on Big Class.jmp and then closes the data table. Before proceeding to the Oneway analysis later in the script, `Is Scriptable()` tests for the open data table. If 1 (true) is returned, the table opens, and the script continues.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
obj = dt << Bivariate( Y( :height ), X( :age ), Fit Line );
Close( dt );
If( Not( Is Scriptable( dt ) ),
   dt = Open( "$SAMPLE_DATA/Big Class.jmp" ),
);
obj = dt << Oneway( Y( :height ), X( :age ), Means( 1 ), Mean Diamonds( 1 ) );
```

You might want to see if the data table is open and then close it to discard any changes before running another script on the data table. To test for and close Big Class.jmp, run the following script:

```plaintext
Try( Close( Data Table( "Big Class" ) ) );
```

### Prompt Users to Open a Data Table

You can use an `If()` expression to prompt a user to open a data table, if no open data table is found. And if they do not select a table, the script should end. The following script shows an example:

```plaintext
dt = Current Data Table();
If( Is Empty( dt ),
   Try( dt = Open(), Throw( "No data table found" ) )
);
The user is prompted to open a data table. If the user clicks Cancel instead of opening a data table, an error appears in the log.

**Show Only Specific Columns**

To open a data table and show only a specific set of columns, identify those columns in the `Open()` expression. This is particularly helpful with a large data table in which only a few columns are necessary.

The following example opens `Big Class.jmp` and includes only the `age`, `height`, and `weight` columns.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp", Select Columns( "age", "height", "weight" ) );
```

You can also specify the columns to leave out of the open data table:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp", Ignore Columns( "name", "sex" ) );
```

**Create a New Data Table**

You can start a new data table, or start a new data table and store its reference in a global variable. In either case, specify the table name as an argument.

```julia
New Table( "My Table" );
```

or

```julia
dt = New Table( "My Table" );
```

The following sections describe the optional arguments for the `New Table()` function.

**Private, Invisible, and Visible**

The optional `visibility` argument specifies whether the new data table is shown. `visibility( "invisible" )` hides the data table from view; it appears only in the JMP Home Window and the Window menu. `visibility( "private" )` avoids opening the data table. `visibility( "visible" )` shows the data table. "visible" is the default value.

```julia
New Table( "My Table", visibility( "private" ) );
```

A private data table enables you to avoid exposing the table to general use. Sometimes a script creates a private data table to store private data generated by a process. It is not for saving memory.

When you do not need a view of the data, or when you do not need to interact with the data, use an invisible data table.
Notes:

- The advantages of using private data tables is based on the size of the data in the table. If the data table has only five columns and 20 rows, the savings for a private data table is substantial. However, for a table with 100 columns and 1,000,000 rows, the overhead of the actual window is small in comparison to the actual data.
- Private tables are not counted when `N Table()` returns the number of open data tables.
- Private tables cannot be made current with `Current Data Table()`.

Actions

An optional argument that can define the new table. For example, the following script creates a new data table named `Little Class`. It adds three rows and two named columns as well as entering values for each cell in the table:

```r
dt = New Table( "Little Class",
    Add Rows( 3 ),
    New Column( "name",
        Character,
        "Nominal",
        Set Values( {"KATIE", "LOUISE", "JANE"} )
    ),
    New Column( "height",
        "Continuous",
        Set Values( [59, 61, 55] )
    )
);
```

Import Data

Upon importing, JMP converts file types such as text files and Microsoft Excel files to the data table format. On Windows, JMP relies on filename extensions to identify the type of file and how to interpret its contents. Here are some examples of filename extensions identified by JMP:

```r
Open( "$SAMPLE_IMPORT_DATA/Bigclass.xlsx" ); // Microsoft Excel file
Open( "$SAMPLE_IMPORT_DATA/Bigclass.txt" ); // text file
Open( "$SAMPLE_IMPORT_DATA/Carpoll.xpt" ); // SAS transport file
```

On macOS, JMP relies on the macOS Type and Creator codes (if present) and secondarily on three-letter filename extensions. Be sure to add the file extension before importing the file on macOS.

- Type and Creator codes are invisible data that enable the Finder to display a file with the correct icon corresponding to the application that created it.
• Files with generic icons should have the filename extensions (as with files created on other operating system).

    Open("$SAMPLE_IMPORT_DATA/Bigclass.txt", text);

Additional supported formats include .csv, .jsl, .dat, .tsv, and .jrn.

For more detailed information about import options, see the JSL Syntax Reference.

### Import Multiple Files

When you save a script from the Multiple File Import (MFI) window into a script window, you get a compact form of the script that includes all of the parameters, default or otherwise, as messages. You could pare down the script as follows:

    mfi = Multiple File Import(
        <<Set Folder("$SAMPLE_IMPORT_DATA"),
        <<Set Name Filter("UN*.csv"), // import files with this name
        <<Set Name Enable(1),
        <<Set Add File Name Column(1) // display the file names in a column
    )
    <<Import Data();

Note the slight distinction between the following expressions:

    mfi = Multiple File Import();
    mfi holds the Multiple File Import object.

    dtlist = Multiple File Import(...) << Import Data;
    dtlist holds the list of files produced by sending the Import Data message to the MFI object. The MFI object is gone because it was not stored in a variable or window. You can keep the MFI object by sending Create Window to it or storing the object in a variable, such as mfi, and by sending messages such as Import Data to that variable. Sending Import Data to an MFI object always returns a list, which could affect tasks such as creating reports.

Create Window can be useful for debugging. The window is visible and the MFI object is available. Run the following lines one at a time to see the results:

    mfi = Multiple File Import();
    mfi <<Create Window;
    mfi <<Set Folder("$DESKTOP");

Here's an example of using a callback function to get a list of imported files after the user clicks Import on the Multiple File Import window.

    Delete Directory("$TEMP/test");
    Create Directory("$TEMP/test");
    Save Text File("$TEMP/test/argylesocks1.txt", "a1\n1"); // make some
    Save Text File("$TEMP/test/argylesocks2.txt", "a2\n1"); // data
global::importedFiles={};

mfi = Multiple File Import( // make an MFI object
   <<Set Folder( "$TEMP/test/" ),
   <<Set Name Filter( "argylesocks?.txt;" ),
   <<Set Name Enable( 1 ),
   <<Set Add File Name Column( 1 ),
   <<Set Import Callback(
      Function( {this, files}, // the callback function
         global::importedFiles = files;
      /* optional: omit Close Window to keep the Multiple File Import window open so
       that the user can modify the settings. */
      win << Close Window;
   )
   )
);

win = mfi << Create Window; // open the window
While(
   Try(
      win << Parent;
      1;
      ,
      0
   ),
   Wait( 1 )
);
// wait for the dialog to close
Show( global::importedFiles ); // proceed

Notes:

• See Using JMP for more information about MFI.

• See “Import Images from a Directory” on page 350 for more information about using MFI to import images from a web page into a data table.

Import a PDF File

In a PDF file, data is laid out in tables. JMP auto-detects these tables to determine where the rows and columns begin and end.

You write scripts that specify the dimensions of each table on each page, the number of column headers, whether the tables should be concatenated or individual, and more.

Note: A PDF file consists of tables that contain data. In the PDF preview of the PDF Import Wizard, the tables are outlined and selected on each page.
The following options are available for importing a PDF file:

```
Open( "PDF file path" ),
  Tables(
    Table( "data table name",
      Add Rows( Header Rows( number ),
        (Rect( left, right, top, bottom ),
          Page( number ), Row Borders(), Column Borders()) )
      | Tables( Combine( All | Matching Headers | None),
          Minimum Rows( number ), Minimum Columns(#))
    | PDF wizard );
```

**Concatenate Tables Into One Data Table**

This section shows how to import and concatenate the tables into one data table. The script that you create appears in a Source variable in the final data table, so you can run it again anytime. For this example, Figure 9.1 shows the sample import data file called *Food Distribution.pdf*, which contains one table per page.

**Figure 9.1 Initial PDF File**

![Table Image]

```
Open( "$SAMPLE_IMPORT_DATA/Food Distribution.pdf",
  PDF Tables(
    Table( // import tables into one table
      Table Name( "Food Distribution" ), // data table name
      Add Rows( // rows on page 1
        Header Rows( 7 ), // number of header rows
        Page( 1 ),
        Rect( 0.6922, 0.7155, 7.2842, 10.1124 ) // size of the table
      ), // rows and specifications on page 2
      Add Rows( Page( 2 ), Rect( 0.6922, 0.7156, 7.2842, 10.0708 )
    )
  )
);
Tip: Import a PDF file in the PDF Import Wizard and copy the script from the Source variable into a standalone script. This is a quick way to get the settings and avoid having to guess at the Rect settings.

Save as Individual Data Tables

The following syntax shows how to save tables in a PDF file into individual data tables. Each resulting data table contains a Source script like the one below.

```
Open("PDF file path",
    PDF Tables(
        Table(
            TableName("data table name"),
            AddRows(Page(number), Rect(left, right, top, bottom))
        )
    )
);
```

Concatenate Data Based on Column Headers

The following example shows how to concatenate data when column names on each page match.

Figure 9.2 Data with Matching Column Headers on each Page

```
pdfTable = Open("$SAMPLE_IMPORT_DATA/Iris.pdf",
    PDFAllTables(Combine(MatchingHeaders))
);
```
Import PDF Pages that Contain Multiple Tables

A PDF file might contain data divided into multiple columns on each page. Figure 9.4 shows the sample import data PDF file called *Groundhog Day Predictions.pdf*, which contains multiple tables per page.

Figure 9.4 Multiple Columns on a Page

The following script imports all columns into a single data table.

```python
Open("$SAMPLE_IMPORT_DATA/Groundhog Day Predictions.pdf",
PDF Tables(
    Table(
        Table Name( "Groundhog Day Predictions" ),
        // specifications for page 1
        Add Rows( Page( 1 ), Rect( 0.9726, 1.4325, 3.0351, 9.9974 ) ),
        Add Rows( Page( 1 ), Rect( 3.3063, 1.4325, 5.3688, 9.9608 ) ),
```

Chapter 9

Data Tables

Scripting Guide

Basic Data Table Scripting

Add Rows( Page( 1 ), Rect( 5.6399, 1.4325, 7.7025, 8.7925 ) ),
// specifications for page 2
Add Rows( Page( 2 ), Rect( 0.9726, 1.4325, 3.0351, 9.9441 ) ),
Add Rows( Page( 2 ), Rect( 3.3063, 1.4325, 5.3688, 9.9274 ) ),
Add Rows( Page( 2 ), Rect( 5.6399, 1.4325, 7.7025, 8.8225 ) ),
// specifications for page 3
Add Rows( Page( 3 ), Rect( 0.9726, 1.4325, 3.0351, 7.6404 ) ),
Add Rows( Page( 3 ), Rect( 3.3063, 1.4325, 5.3688, 7.1254 ) ),
Add Rows( Page( 3 ), Rect( 5.6399, 1.4325, 7.7025, 7.4721 ) )

)
);

Figure 9.5 Final Data Table

Export Data to a Text String

You can export data from a PDF file into a text string. You might want to do this to extract a pattern from the data.

Here is a basic example that imports all text from the Iris.pdf sample import data.

Open( "$SAMPLE_IMPORT_DATA/Iris.pdf", PDF text );

The following script finds the word “Figure” followed by a space, a digit, a period, and another digit and then prints the data to the log.

```javascript
txt = Open( "$JMP_HOME/Documentation/JMP Documentation Library.pdf", PDFText() );
figures = {};
For( page = 1, page < N Items( txt ), page++,
    // search for the string
    next = Regex Match( txt[page], "Figure[s+]\d+\.\d+", "" );
    While( N Items( next ) > 0,
```

figures = Insert(figures, next);
// extract the string
next = Regex Match(txt[page], "Figure\s+\d+\./\d+", "" );
);
Print(figures);

 figured = Insert(figures, next);
// extract the string
next = Regex Match(txt[page], "Figure\s+\d+\./\d+", "" );
);
Print(figures);

Import Data from a Text File

The Import Settings in the Text Data Files preferences determine how text files are imported. For example, column names begin on line one and data begin on line two by default. To use different settings, specify the import settings as `Open()` options in your script.

The default Import Settings and your custom import settings are saved in the data table Source script, so you can reimport the data using the same settings. However, the default Import Settings are optional in the script.

The following `Open()` options are available:

/* Charset options: "Best Guess", "utf-8", "utf-16", "us-ascii",
 "windows-1252", "x-max-roman", "x-mac-japanese", "shift-jis", "euc-jp",
 "utf-16be", "gb2312" */
Charset("option")

Number of Columns(Number)

/* colType is Character|Numeric
 colWidth is an integer specifying the width of the column */
Columns(colName=colType(colWidth),... )

Treat Empty Columns as Numeric(Boolean)
Scan Whole File(Boolean)
End Of Field(Tab|Space|Comma|Semicolon|Other|None)
EOF Other("char")
End Of Line(CRLF|CR|LF|Semicolon|Other)
EOL Other("Char")
Strip Quotes|Strip Enclosing Quotes(Boolean)
Labels | Table Contains Column Headers(Boolean)
Year Rule | Two digit year rule ("Decade Start")
Column Names Start | Column Names are on line(Number)
Data Starts | Data Starts on Line(Number)
Lines to Read(Number)
Use Apostrophe as Quotation Mark
CompressNumericColumns(Boolean)
CompressCharacterColumns(Boolean)
CompressAllowListCheck(Boolean)
The following script opens a text file of comma-delimited text, which includes no column names. The script defines the column names and the column widths.

```
Open(
  "$SAMPLE_IMPORT_DATA/EOF_comma.txt",
  End of Field( comma ),
  Labels( 0 ),
  Columns(
    name = Character( 12 ),
    age = Numeric( 5 ),
    sex = Character( 5 ),
    height = Numeric( 3 ),
    weight = Numeric( 3 )
  )
);
```

Here is an example of opening a text file in which the field separator is a space and the text file does not contain column headings:

```
Open(
  "$SAMPLE_IMPORT_DATA/EOF_space.txt",
  Labels( 0 ),
  End of Field( Space )
);
```

In the preceding example of a text file with space field separators, JMP can select the best file format so that you do not have to specify the labels or separator:

```
Open(
  "$SAMPLE_IMPORT_DATA/EOF_space.txt",
  Import Settings( Guess File Format() )
);
```

To set the import options interactively, include the `Text Wizard` argument. A preview of the text file opens in the text import window.

```
Open( "$SAMPLE_IMPORT_DATA/EOF_space.txt", "Text Wizard" );
```

The following sections describe each argument in more detail. For more information about import options, see the *JSL Syntax Reference*.

**Number of Columns**

Specifies the total number of columns in the source file. This option is important if data is not clearly delimited.

**Columns**

Identifies column names, column types, and column widths with a `Columns` argument as shown in the preceding examples.
If you specify settings for a column other than the first column in the file, you must also specify settings for all the columns that precede it. Suppose that you want to open a text file that has four columns (name, sex, and age, and ID, in that order). age is a numeric column, and the width should be 5. You must also set the name and sex column types and widths, and list them in the same order:

```plaintext
Columns(
    name = Character( 15 ),
    sex = Character( 5 ),
    age = Numeric( 5 )
);
```

You are not required to provide settings for any columns that follow the one that you want to set (in this example, ID).

After the data is imported, you use the modeling type for a column. See “Set or Get Data and Modeling Types” on page 416.

**Note:** Most of the following arguments are defined in the JMP preferences. To override the preference, include the corresponding argument described below in your import scripts.

### Treat Empty Columns as Numeric

Imports columns of missing data as numeric rather than character data. A period, Unicode dot, NaN, or a blank string are possible missing value indicators. This is a Boolean value. The default value is false.

### Scan Whole File

Specifies how long JMP scans the file to determine data types for the columns. This is a Boolean value. The default value is true; the entire file is scanned until the data type is determined. To import large files, consider setting the value to false, which scans the file for five seconds.

### Strip Quotes | Strip Enclosing Quotes

Specifies whether to include or remove the double quotation marks (" ) that surround string values. This is a Boolean value. The default value is true.

For example, suppose that the field delimiter is a space:

- *John Doe* is interpreted as two separate strings (*John* and *Doe*).
- "*John Doe*" is interpreted as a single string. Most programs (including JMP) read a quotation mark and ignore other field delimiters until the second quotation occurs.
- If you include Strip Quotes(1), "*John Doe*" is interpreted as *John Doe* (one string without quotation marks).
Note that many word processors have a “smart quotation marks” feature that automatically converts double quotation marks (""") into left and right curled quotation marks ("""). Smart quotation marks are interpreted literally as characters when the text file is imported, even when JMP strips double quotation marks.

**End of Line(CR | LF | CRLF | Semicolon | Other)**

Specifies the character or characters that separate rows:
- CR for carriage returns (typical for text files created on macOS up to version 9)
- LF for linefeeds (typical for UNIX and Mac OS X text files)
- CRLF for both a carriage return followed by a linefeed (typical for Windows text files).

All three characters are line delimiters by default.

Use the Other option to use an additional character for the row separator, which you must specify in the EOLOther argument. JMP interprets either this character or the default character as a row separator.

**End of Field(Tab | Space | Spaces | Comma | Semicolon | Other | None)**

Specifies the character or characters used to separate fields.

**Notes:**
- The default field delimiter is Tab.
- Use the Other option to use a different character for the field separator, which you must specify in the E0FOther argument.
- The Space option uses a single space as a delimiter.
- The Spaces option uses two or more spaces.

**E0FOther, E0LOther**

Specifies the character or characters used to separate fields or rows. For example, E0LOther("*"") indicates that an asterisk separates rows in the text file.

**Labels | Table Contains Column Headers**

Indicates whether the first line of the text file contains column names. This is a Boolean value. The default value is true.

**Year Rule | Two Digit Year Rule**

Specifies how to import two-digit year values. If the earliest date is 1979, specify "1970". If the earliest date is 2001, specify "20xx".
Column Names Start | Column Names Are on Line

Specifies the starting line for column names. The following example specifies that the column names in the text file start on line three.

```julia
Open(
    "$SAMPLE_IMPORT_DATA/Animals_line3.txt",
    Columns(
        Column( "species", Character, "Nominal" ),
        Column( "subject", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "miles", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "season", Character, "Nominal" )
    ),
    Column Names Start( 3 )
);
```

Data Starts | Data Starts on Line

Specifies the starting line for data.

The following example specifies that the data in the text file start on line five.

```julia
Open(
    "$SAMPLE_IMPORT_DATA/Bigclass_L.txt",
    Columns(
        Column( "name", Character, "Nominal" ),
        Column( "age", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "sex", Character, "Nominal" ),
        Column( "height", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "weight", Numeric, "Continuous", Format( "Best", 10 ) )
    ),
    Data Starts( 5 )
);
```

Lines to Read

Specifies the number of lines to include in the data table. JMP starts counting after column names are read.

The following example includes only the first 10 lines in the data table.

```julia
Open(
    "$SAMPLE_IMPORT_DATA/Bigclass_L.txt",
    Columns(
        Column( "name", Character, "Nominal" ),
        Column( "age", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "sex", Character, "Nominal" ),
        Column( "height", Numeric, "Continuous", Format( "Best", 10 ) ),
        Column( "weight", Numeric, "Continuous", Format( "Best", 10 ) )
    )
);
```
Use Apostrophe as Quotation Mark

For data that are enclosed in apostrophes, this option treats apostrophes as quotation marks and omits them. For example, '2010' is imported as 2. This is a Boolean value. The default value is false.

This option is not recommended unless your data comes from a nonstandard source that places apostrophes around data fields rather than quotation marks.

Set Text Import Preferences

If you want to set preferences for importing text, it can be helpful to first see a list of all preferences. To do so, use the `Show Preferences (All)` function.

Then, copy and paste only the section you want into a Preferences function. For example, to specify import settings, write the following expression:

```plaintext
Preferences(
    Import Settings(
        End Of Field( Tab, Spaces, Comma )
    )
);
```

Import Data from a Microsoft Excel File

When you open a Microsoft Excel workbook in JMP, the file is converted to a data table. JMP supports `.xls`, `.xlsm`, and `.xlsx` formats. See Using JMP for more information about Microsoft Excel support.

Excel Preferences

In the JMP preferences, settings in the Third Party Data group can help determine how worksheets are imported:

**Excel Open Method**  Specifies how a Microsoft Excel file should be opened by default, when using a non-specific open statement.

**Use Excel Wizard**  Opens the Excel Import Wizard to import the file. This is the default setting.

**Open All Sheets**  Opens all worksheets in the Microsoft Excel file.

**Select Individual Worksheets**  Prompts users to select one or more worksheets when they open the file.
Use Excel Labels as Headings  Determines whether text in the first row of the worksheet is converted to column headings in the data table.

By default, JMP takes the best guess. If names have been defined for all cells in the first row, the text in those cells is converted to column heading. Otherwise, columns are named Column 1, Column 2, and so on.

To override a preference, include the corresponding argument described later in this section.

Note: See “Create Excel Workbooks” on page 361 for information about exporting data tables to an Excel workbook.

Open() Function

Using the Open() function without additional arguments to open an Excel file has different behaviors depending on the context:

- If the Open() function is a direct part of the script, the Excel files open into data tables using your Excel preferences. The following example opens both worksheets into data tables without using the wizard:

  Path = Convert File Path( "SAMPLE_IMPORT_DATA/Team Results.xlsx", absolute );
  dt = Open( Path );

  Note: To use the Excel Wizard, you must specify the Excel Wizard option in the argument as in Open( "SAMPLE_IMPORT_DATA/Team Results.xlsx","Excel Wizard" );.

- However, if the Open() function is part of a script that is run from clicking a button, the Preview window opens and requires the user to interact with it. Run the following example and click the button to see the Excel Import Wizard:

  Path = Convert File Path( "SAMPLE_IMPORT_DATA/Team Results.xlsx", absolute );
  New Window( "button", Button Box( "Open", dt = Open( Path ) ) );

- To prevent the button script from opening the Preview window and importing the Excel file directly, provide additional arguments to the Open() function. Run the example and click the button. Both worksheets are opened into data tables without using the Excel Import Wizard.

  Path = Convert File Path( "SAMPLE_IMPORT_DATA/Team Results.xlsx", absolute );
  New Window( "button", Button Box( "Open", dt = Open( Path, Use for all sheets(1) ) ) );

Alternatively, you can set the Excel Open Method preference to open all sheets:

  Preference( Excel Open Method( "Open All Sheets" ) );
  Path = Convert File Path( "SAMPLE_IMPORT_DATA/Team Results.xlsx", absolute );
  New Window( "button", Button Box( "Open", dt = Open( Path ) ) );
Open a Workbook in the Excel Import Wizard

The Excel Import Wizard shows a preview of the data and lets you modify the settings before importing the data. Specify "Excel Wizard" as the argument.

```
dt = Open( "$SAMPLE_IMPORT_DATA/Team Results.xlsx", Excel Wizard );
```

Customize Import Settings

Customize settings such as the number of rows in the column headers.

```
Open( 
"$SAMPLE_IMPORT_DATA/Team Results.xlsx",
Worksheets( "Grouped Team Results" ),
Use for all sheets( 1 ),
Concatenate Worksheets( 0 ),
Create Concatenation Column( 0 ),
Worksheet Settings( 
  1,
  Has Column Headers( 1 ),
  Number of Rows in Headers( 1 ),
  // customization based on Team Results structure
  Headers Start on Row( 3 )
);
```

When you click a custom button to open a workbook, the Excel Open Method preference applies. To force the worksheet to open directly, specify the Excel Open Method in your script:

```
Preference( Excel Open Method( "Open All Sheets" ) );
```

Import Specific Worksheets

Suppose that you want to import data from specific worksheets in your workbook. Specify those worksheets using the Worksheets argument. In the following example, the worksheet named small is imported into JMP.

```
Open( "C:\My Data\cars.xlsx", Worksheets( "small" ) );
```

Or specify the number of the worksheet, the third worksheet in the following example:

```
Open( "C:\My Data\cars.xlsx", Worksheets( "3" ) );
```

Import multiple or all worksheets by including the worksheet names in a list:

```
Open( "C:\My Data\cars.xlsx", Worksheets( {"small", "medium", "large"} ) );
```
Import XML and JSON Files

The XML Import Wizard imports two types of nested text data: XML and JSON files. Both kinds of files contain structured text that can be nested to represent hierarchical relationships. This wizard helps you pick out the elements of the hierarchy that hold values and elements that determine rows to build a data table.

A useful way to imagine a nested text file: the document is a book of short stories. Some of the short stories might have chapters, others only have paragraphs. Chapters have paragraphs. Paragraphs have sentences. Here’s an example of the full tree for such a book. This content is also available in the JMP Samples/Import Data directory as Book.xml.

```
<book>
  <story name="car poll">
    <wheels>4</wheels>
    <para><name>chev</name></para>
    <para><name>ford</name></para>
    <para><name>volk</name></para>
  </story>
  <story name="big class">
    <para><name>ralph</name><height>6</height></para>
    <para><name>billy</name><height>5</height></para>
  </story>
  <story name="cheese" location="NC">
    <chapter name="american">
      <para>1</para>
    </chapter>
    <chapter name="swiss">
      <para>1</para>
    </chapter>
  </story>
</book>
```

This XML document (the book) contains three short stories; each short story is a data table, all different. This particular XML file uses paragraphs to represent rows in a table in all of the tables. That is not required, nor are any of the names special. If you wanted to import the cheese table, which is slightly more complicated than the other two, you’d probably want a variety column, containing “american” or “swiss” for each row. You would also want price and quantity columns. And you might want a column that doesn’t have a clearly defined name for the 1, 2, 3, 1, 2 values of <para>. You’d expect five rows. Finally, you might want a table variable or a column for the location NC value.

The following example shows how to import the preceding data into a data table.

```python
Open(Book.xml)
```
"$SAMPLE_IMPORT_DATA/Book.xml",
XML Settings(
   Row( "/book/story/chapter/para" ),
   // create a row for each value in <para>
   Col(
      "/book/story/@location",
      // create a column for the location attribute
      Column Name( "location" ),
      // rename the column
      Fill( "Use Forever" ),
      // fill an empty cell with the preceding value
      Type( "Character" ), // data type
      Format( "best" ) // column format
   ),
   Col(
      "/book/story/chapter/@name",
      Column Name( "variety" ),
      Fill( "Use Once" ),
      Type( "Character" ),
      Format( "best" )
   ),
   Col(
      "/book/story/chapter/para",
      Column Name( "interesting" ),
      Fill( "Use Once" ),
      Type( "Numeric" ),
      Format( "best" )
   ),
   Col(
      "/book/story/chapter/para/price",
      Column Name( "price" ),
      Fill( "Use Once" ),
      Type( "Character" ),
      Format( "best" )
   ),
   Col(
      "/book/story/chapter/para/quantity",
      Column Name( "quantity" ),
      Fill( "Use Once" ),
      Type( "Character" ),
      Format( "best" )
   ),
),
XML Wizard( 0 ) /* omit or change to 1 to preview the data in the XML Import Wizard */
Import from and Export to Google Sheets

A Google Sheet is a spreadsheet (which consists of sheets, like tabs) that is saved in your Google account. This enables you to continue to edit the spreadsheet and to share it with others.

To write a script to import data from a Google spreadsheet, log in to your Google account and get the URL for the spreadsheet. Also notice how the data is structured. For example, you must know which row the data begin on if there are column headers.

Give Google access to JMP when running the script for the first time.

To import data from a Google spreadsheet

```
dt = Google Sheet Import(
    Email( "yourgoogleaccount@gmail.com" ),  // modify the email address
    Spreadsheet(
        "https://docs.google.com/spreadsheets/d/1J01M4ScGsAHb-bCUa0i57SVWvQjXciQIVNOwVTrXDSe/edit#gid=2303744702" ),
    Sheets( "May","June" ),  // specify the sheet name(s)
    Sheet Settings(  // specify the structure of the data
        Has Column Headers( 1 ),
        Headers Start on Row( 1 ),
        Data Starts on Row( 2 ),
        Cell Range( "" ),
        Import Cell Colors( 1 ),
        Suppress Empty Columns( 1 )
    )
);
```

**Note:** See *Using JMP* for more information about security, country restrictions, and more.

To export a JMP data table to a Google spreadsheet

Export a JMP data table to a new spreadsheet in Google Sheets by following this example:

```
email = "yourgoogleaccount@gmail.com";  // modify the Google account
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Google Sheet Export(
    dt,
    Email( email ),
    New Spreadsheet( "JSL Example" ),  // specify the name of the spreadsheet
    Sheet Name( "Example 1" )  // specify the sheet name
);
```

"1" is returned in the log when the export is successful.
Export a JMP data table to an existing spreadsheet in Google Sheets by following this example. You’ll need the URL of the existing spreadsheet.

```javascript
id = "https://docs.google.com/spreadsheets/d/1J01M4ScGsAHb-bCUa0i575WvQjXciQIVN0wVTrXD5e/edit#gid=2303744702"; // modify the URL
email = "yourgoogleaccount@gmail.com"; // modify the Google account
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Google Sheet Export(
dt,
    Email( email ),
    Spreadsheet( id ),
    Sheet Name( "Example 1" )
);

"1" is returned in the log when the export is successful.
```

**Note:** See *Using JMP* for more information about security, country restrictions, and more.

### Import SAS Data Sets

Open a SAS file as a data table without connecting to a SAS server.

```javascript
sasxpt = Open( "$SAMPLE_IMPORT_DATA/carpoll.xpt" );
```

To convert the labels to column headings, include the `Use Labels for Var Names` argument.

```javascript
sasdbf = Open( "$SAMPLE_IMPORT_DATA/Bigclass.sas7bdat", Use Labels for Var Names( 1 ) );
```

.xpt and .stx file formats are also supported.

On Windows, you can also open SAS data sets from a SAS server. See “Connect to a SAS Metadata Server” on page 789 in the “Extending JMP” chapter.

### Import Web Pages and Remote Files

You can import data from websites or from other computers. The data might be a JMP data table, a table defined in a web page, or another file type that JMP supports.

#### Open or Import Data from a Website

In the `Open()` command, specify the quoted URL to open a file from a website. You can open JMP data tables or other supported file types this way.

```javascript
Open( "http://company1.com/Repairs.jmp" );
Open( "http://company1.com/My Data.txt", text); // specify text on macOS
```
Import a Web Page

A web page can include data in tabular format. Import the table as a JMP data table:

```julia
Open( "http://company1.com", HTML Table( n ) );
```

*n* identifies which table you want to import. For example, to import the fourth table on the page, specify `HTML Table(4)`. If you omit the value, only the first table on the page is imported.

JMP attempts to preserve the table header defined in a `<th>` HTML tag. The table header is converted to column headings in the data table. If the `<th>` tag is wrong or missing, use `ColumnNames(n)` to specify the *n*th row. By default, `DataStarts(n)` will be the next row, or you can specify the `DataStarts` row.

Import Images from a Web Page

You can import images on the web into a data table, using the Expression data type. The following example creates a new data table and adds two images to it.

```julia
dt = New Table( "test", New Column( "Image", Expression ) );
dt << Add Rows( 1 );
dt:Image = New Image( Open( "https://www.jmp.com/support/help/en/16.0/jmp/images/iris_first.gif" ) );
dt << Add Rows( 1 );
dt:Image = New Image( Open( "https://www.jmp.com/support/help/en/16.0/jmp/images/trimeth.png" ) );
```

Import Images from a Directory

You can use `Multiple File Import()` and an Event Handler script to create a data table of thumbnail images that link to a directory of full-size pictures. This example sets the cell height so that it fits the height of the tallest thumbnail.

**Note:** Typically, the `Multiple File Import` option is for importing multiple text files. However, this example shows how to use the option to import images.

```julia
path = "$SAMPLE_IMAGES/"; // images are in this directory
{dtx} = Multiple File Import( <<Set Folder( path ), <<Set Name Filter( "*.jpg; " ), <<Set Name Enable( 1 ), /* enable the ability to filter by name, in this example, files with the .jpg extension */ <<Set Add File Name Column( 1 ), // must be included but can be hidden <<Set Add File Size Column( 1 ) // for Show Sizes at end
```
) << Import Data;

/* FileName is the column that contains the image file name. The column is required for the image links to work, but you don’t need to see it. */
dtx:FileName << Hide;
maxheight = 0;

For Each Row( // recreate each image to minimize size of data table
    x = Eval( dtx:Picture );
    x << Scale( .1 ); // scale the image by 10%
    m = x << Get Pixels; // compress the image by recreating it
    dtx:Picture = New Image( m );
    maxheight = Max( maxheight, (dtx:Picture[] << Get Size)[2] );
    // width x height is returned, [2] gets the height
);

Eval( /* insert the value in the path variable into the Click handler. The path variable won’t be available later, but the path value is needed to concatenate with the file name column’s value to build a link to the image on the computer. */
    Eval Expr(
        dtx:picture << Set Property( 
            "Event Handler",
            Event Handler( // Event Handler column property
                Click( JSL Quote( Function( {thisTable, thisColumn, iRow}, // insert links to images
                    Open( Expr( path )||Char( thisTable:FileName[ iRow ] ) ); ); ); ) ),
                Tip( JSL Quote( Function( {thisTable, thisColumn, iRow}, "Open " || Char( thisTable:FileName[ iRow ] ) || " in your viewer."; ); ); ) ),
            // color of the link -- blue
            Color( JSL Quote( Function( {thisTable, thisColumn, iRow}, 5; );); )
        )
    )
);

// add two pixels to the maximum height
dtx << Set Cell Height( maxheight + 2 );

/* save the file to show that the data table is much smaller than the original file */
dtx << Save( "$TEMP/Sample Images.jmp" );
Show( File Size( "$TEMP/Sample Images.jmp" ), Col Sum( dtx:FileSize ) );
Import a File from a Shared Computer

JMP can import files stored on a shared computer, such as another computer or a network drive. The following example shows how to open a file from Windows:

```plaintext
Open( "\Data\Repairs.jmp" ); // UNC name
Open( "z:/Data/Repairs.jmp" ); // mapped letter drive
Open( "Repairs.jmp" ); // relative path in which the script is in the same directory as the file that you are importing
```

macOS doesn’t have a concept like UNC naming or drive letters. Instead, you need to mount the volume through the user interface. It is possible to do it from a script, but you would need to have connected interactively at least once and stored the password in your keychain.

Here is an example that connects to a remote volume from either macOS or Windows:

```plaintext
mount = Function( {server},
  {Default Local},
  If( Host is( Mac ),
    Run Program( 
      Executable( "/usr/bin/osascript" ),
      // replace ^server^ with your server name throughout the script
      Options( {"-e", Eval Insert( "mount volume \!smb://^server^!\"" )} ),
      Read Function( "text" )
    );
    server = Concat Items( Remove( Words( server, "/" ), 1 ), "/" );
    Eval Insert( "/Volumes/^server^" );
    Eval Insert( "!/\!/\!/^server^" )
  )
);

users = mount( "data.company.com/Users" );
Files In Directory( Eval Insert( "^users^/Smith" ) );
```

Import JSON Data

JSON (JavaScript Object Notation) is a data interchange format that is based on JavaScript. It shares many of the same principles as languages based on C and is easy to read and write. Because of these characteristics, JSON is highly portable and can be imported into JMP.
JSON consists of name-value pairs in an associative array. For example, here is JSON code that shows name-value pairs:

```
[ { "key1": "a", "key2": "b"}, {"key1": "c", "key2": "d" }, {"key2": "f", "key1": "e", "key3": "g"} ];
```

Each list is imported as a column in the data table. “key1” is the name of the first column. The first value in the column is “a”. The second value is “c”, and the third value is “e”.

Use **JSON To Data Table()** to convert the JSON into a data table.

```javascript
js = "[ { "key1": "a", "key2": "b"}, {"key1": "c", "key2": "d" }, {"key2": "f", "key1": "e", "key3": "g"} ]

d = JSON To Data Table( js ); // convert JSON to a data table
```

You can also use **JSON To List()** to convert a string containing JSON into a list.

```javascript
list = JSON To List( ...
```
Data Tables
Chapter 9
Basic Data Table Scripting
Scripting Guide

```
"[ { "name":"KATIE", "age": 12, "sex": "F", "height": 59, "weight": 95 }, 
{ "name":"LOUISE", "age": 12, "sex": "F", "height": 61, "weight": 123 }, 
{ "name":"JANE", "age": 12, "sex": "F", "height": 55, "weight": 74 } ]
```

};
Show( list );
list = {{{"name", "KATIE"}, {"age", 12}, {"sex", "F"}, {"height", 59}, 
{"weight", 95}}, ...}};

Exporting JSL to JSON

As JSON Expr() converts an associative array to a JSON string. You can then export the data into a JSON document.

```
list_of_associative_arrays = {["key1" => "a", "key2" => "b"], ["key1" => "c", 
"key2" => "d"], ["key2" => "f", "key1" => "e", "key3" => "g"]};
xj = As JSON Expr( list_of_associative_arrays );
"[{{"key1":"a!"","key2":"b!"}...]{{"key1":"a!"","key2":"b!"}"
```

Note: To import the data table as invisible, include the argument Invisible(1) in JSON To
Data Table() and omit New Data View.

Import HDF5 Files

Hierarchical Data Format, Version 5 (HDF5) is a portable file format for storing data. An HDF5 file consists of groups and datasets. When you import the file, JMP opens a group to present the names of the inner datasets.

JMP handles only tables with numeric (integer, float, double) and string types, and compound files with three or fewer dimensions that contain only simple types.

You can import up to 1,000,000 columns and an unbounded number of rows.

Here is the syntax:

```
Open( "filename.h5", {"list_of", "dataset_names"});
```

Errors are written to the log when invalid data set names are passed.

Import ESRI Shapefiles

An ESRI shapefile is a geospatial vector data format used to create maps. JMP imports shapefiles as data tables. A .shp shapefile consists of coordinates for each shape. A .dbf shapefile includes values that refer to regions. To create maps in JMP, you modify the structure of the data and save the files with specific suffixes.
The following example imports a .shp file and saves it with the -XY suffix.

```plaintext
dt = Open( "SAMPLE_IMPORT_DATA/Parishes.shp"),
:X << Format( "Longitude DDD", 14, 4 );
:Y << Format( "Latitude DDD", 14, 4 );
dt << Save( "c:/Parishes-XY.jmp" );
```

Save the .dbf file with the -Name suffix.

```plaintext
dt = Open( "SAMPLE_IMPORT_DATA/Parishes.dbf" );
dt << Save( "c:/Parishes-Name.jmp" );
```

Restructuring the data requires several steps, including adding a Map Role column property to names in the -Name.jmp file. See Essential Graphing.

**Import a Database**

`Open Database()` opens a database using Open Database Connectivity (ODBC) and extracts data into a JMP data table. See the “Database Access” on page 783 in the “Extending JMP” chapter.

JMP also converts DataBase Files (.dbf) files to data table format.

```plaintext
sasdbf = Open( "SAMPLE_IMPORT_DATA/Bigclass.dbf",
    Use Labels for Var Names( 1 )
);
```

**Set the Current Data Table**

**Tip:** Be careful about assuming that the data table that you want is the current data table, even if you set it to be earlier in your script, because interim actions could change that.

A data table becomes the current data table in the following instances:

- When you open it like this:
  ```plaintext
dt1 = Open( "SAMPLE_DATA/Big Class.jmp" );
  ```
- When you create a new table like this:
  ```plaintext
dt2 = New Table( "Cities" );
  ```

To switch to another open data table, specify the name of the data table in `Current Data Table()`:

```plaintext
dt1 = Open( "SAMPLE_DATA/Big Class.jmp" );
dt2 = New Table( "Cities" );
Current Data Table( dt1 ); // make Big Class.jmp the current data table
```
Current Data Table() can also take a scriptable object reference as an argument. The following expression would make the data table in use by the second Bivariate object the current data table:

```
Current Data Table( Bivariate[2] );
```

For more information about using references to analysis platform objects, see “Send Messages to a Platform” on page 475 in the “Scripting Platforms” chapter.

### Name a Data Table

Assign a name to a data table by sending it the Set Name message. The argument is a filename in quotation marks, or something that evaluates to a filename.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Set Name( "New Big Class.jmp" );
```

```
s = "New Big Class"

dt << Set Name( s );
```

To retrieve the name, send a Get Name message to the data table:

```
dt << Get Name();

"New Big Class"
```

### Save a Data Table

To save a data table, send a Save message to the data table. Here are some examples:

```
dt << Save(); // save using the current name
dt << Save( "Newest Big Class.jmp" ) // save as a new file
dt << Save( "c:/My Data/New Big Class.jmp" ); // save as a new file
dt << Save( "My Table", JMP( 5 ) ); // save as JMP 5 table
dt << Save(""") // prompt to select the directory and save in the desired format
```

```
dt << Save( "Big Class.xlsx" ); // save as a Microsoft Excel file
Create Excel Workbook( "c:/MyData/data.xlsx", {"Abrasion", "Big Class"}, 
{"Abrasive", "Class"} ); // save several data table as a workbook
```

**Note:** If you specify the filename with no path and have not set the default directory, the file is saved on your primary partition (Windows) or in your <username>/Documents folder (macOS). For more information about setting the default directory, see “Relative Paths” on page 149 in the “Types of Data” chapter.

On Windows, saving with a .txt extension exports according to the Text Export preferences. On macOS, add Text as a second argument to the Save function:
dt << Save( "New Big Class.txt", Text );

If you plan to set the name of a data table and later send the Save message, you can just specify the name in a Save message.

dt << Set Name( "New Big Class.jmp" );
dt << Save();

works the same as

dt << Save( "New Big Class.jmp" );

Including Save and the pathname is also an alternative to using Save As along with the pathname.

Revert to a Saved Data Table

To return to the most recently saved data table, send a Revert message to the data table.

dt << Revert();

Hide a Data Table

There are two ways to hide a data table if the user does not need to see the table: by opening it as invisible or private.

Invisible Data Tables

An invisible data table is hidden from view but linked to analyses that you run on it. Open a data table as an invisible file:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp", "invisible" );
```

Here is an example of creating an invisible table, called Abc, that has ten rows. One column is named X.

```
dt = New Table( "Abc", "invisible", New Column( "X" ), Add Rows( 10 ) );
```

To find out if an open data table is invisible, pass the Boolean Has Data View message to the data table object. The following expression returns 0 (false) if the data table is invisible:

```
dt << Has Data View();
```

After you are finished with an invisible data table, do not forget to close it with the Close() function. Otherwise, the data table remains in memory until you quit JMP.

Showing an Invisible Data Table

The Show Window() function shows an invisible data table.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp", "invisible" );
```
dt << Show Window( 1 );

The user has the option of opening the table from the JMP interface. On Windows, an invisible data table appears in the Window List on the Home Window and the **Window > Unhide** menu. On macOS, the data table appears in the JMP Home window and the **Window > Hidden** menu.

**Private Data Tables**

Completely hide the data table from view by including the **private** argument:

```
   dt = Open( "$SAMPLE_DATA/Big Class.jmp", "private" );
```

A private data table enables you to avoid exposing the table to general use. Sometimes a script creates a private data table to store private data generated by a process. It is not for saving memory.

**Print a Data Table**

Print a data table by sending it a **Print Window** message. JMP uses your computer's default printer settings.

```
   dt << Print Window();
```

This message also applies to other display boxes.

**Resize a Data Table**

```
   dt << Optimize Display forces the data table to remeasure all of its columns and zoom to the best-sized window.
   dt << Optimize Display;
```

**Close a Data Table**

To close a data table, use a **Close** command with the data table’s reference as the argument. Data tables with unsaved changes are saved automatically, including any linked tables. Reports and graphs generated from the data tables are also closed.

To save and close the data table:

```
   dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
   Close( dt );
```

To close the data table without saving changes:

```
   Close( dt, No Save );
```
To save a copy with a new name and then close the original version:

```plaintext
Close( dt, Save("c:/My File.jmp" ) );
```

You can also close all data tables at once and either save or discard changes:

```plaintext
Close All( Data Tables );
Close All( Data Tables, No Save );
```

To close all private or invisible data tables, specify the appropriate argument:

```plaintext
Close All( Data Tables, private );
Close All( Data Tables, invisible );
```

**Tip:** Close All() also works with journals. Specify “Journals” in the argument.

---

**Set and Get a Data Table**

To specify the data table in a display box, for example, in New Data Box(), use Set Data Table() and Get Data Table() to set and return a data table.

The following example uses the Big Class.jmp and Cities.jmp sample data tables. The sample data tables are opened invisibly. In a new window, a new data box is created containing Big Class.jmp. After waiting 1 second, the data box contents change to display cities.jmp.

```plaintext
dtC = Open( "$SAMPLE_DATA/Cities.jmp", "invisible" );
dtA = Open( "$SAMPLE_DATA/Big Class.jmp", "invisible" );
nw = New Window( "My Table", H List Box( dtBox = dtA << New Data Box() ) );
Wait( 1.0 );
dtBox << Set Data Table( Data Table( "Cities.jmp" ) );
```

**Perform Actions on All Open Data Tables**

If you want to perform an action on all of the data tables that are currently open (except private tables), use N Table() to get a list of references to each one:

```plaintext
dt1 = Open( "$SAMPLE_DATA/Cities.jmp" );
dt2 = Open( "$SAMPLE_DATA/Big Class.jmp" );
openDTs = List();
For( i = 1, i <= N Table(), i++,
    Insert Into( openDTs, Data Table( i ) );
);
```

openDTs now is a list of references to all open data tables. You can send messages to any one by using openDTs(n). You can use a for loop to send messages to all of the open data tables. This loop adds a new column named My Column to each open data table.

```plaintext
For( i = 1, i <= N Items( openDTs ), i++,
    ```
openDTs[i] << New Column( "My Column" );
);

If you just want a list of table names and not references, use the Get Name message:

For( i = 1, i <= N Table(), i++,
    Insert Into( openDTs, Data Table( i ) << Get Name());
);

You can then use the list of table names to put the names of all of the open data tables in a list box (window) so that the user can choose and perform tables operations. Or, you can write the names out to a file.

Create Journals

Journals consist of JMP graphs and reports, graphics, text, and links to items such as web pages and files. They make it easy to reuse content in presentations and import into other documents.

Note: Layout is deprecated and will be removed in a future release. Use Journal instead.

Here is the basic syntax for journals:

dt << Journal;

You can also create a new journal window and immediately add to it within the New Window() command. The following examples create an empty untitled journal:

New Window( << Journal);

The following examples create an empty journal named “Sales“:

New Window( "Sales", << Journal);

Here is an example of creating a journal named “Test Buttons” that contains two buttons.

New Window( "Test Buttons", << Journal,
    Button Box( "Test One", New Window( "Hi there1", << Modal ) ),
    Button Box( "Test Two", New Window( "Hi there2", << Modal ) ) );

Capturing Journals

There is an optional argument in the journal and journal window commands. This argument captures (or freezes) the current display. That is, it converts the display tree with just a picture.

Here are the four options for arguments:

- Makes a bitmap “snapshot” of the display when it is sent to the journal, rather than sending a clone of the more editable display box structure to the journal. By freezing the display into a bitmap, references to variables from scripts in graphs are less problematic.
Current Journal

Current Journal() returns a reference to the display box at the top of the current journal display window. If no journal is open, one is created. There are no arguments.

You can add to the journal using the Append command. The following example adds a text box to the bottom of the current journal:

    Current Journal() << Append( Text Box( "Hello World" ) );

You can also find items in an existing journal by enclosing the search specification in square brackets. Suppose that the current journal includes the string “Parameter Estimates”. The following script appends a text box to the bottom of that journal:

    Current Journal()["Parameter Estimates"] << Append( Text Box( "Asterisks show items significant at 0.05" ) );

Create Excel Workbooks

You can save open data tables in a new or existing Excel workbook by using the Create Excel Workbook() function. The first example adds all open data tables without changing the worksheet names:

    dt1 = Open( "$SAMPLE_DATA/Big Class Families.jmp" );
    dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
    Create Excel Workbook( "c:/MyWorkbook1.xlsx" );

The following example creates MyWorkbook2.xlsx by combining the open Big Class Families.jmp and San Francisco Crime.jmp sample data tables.

    dt1 = Open( "$SAMPLE_DATA/Big Class Families.jmp" );
    dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
    // specify the data tables
    tableList = {"Big Class Families", "San Francisco Crime"};
// specify the worksheets (optional)
sheetList = {'Families', 'Crime'};
Create Excel Workbook( "c:/MyWorkbook2.xlsx", tableList, sheetList );

Use data table references to create the workbook.

d1 = Open( "$SAMPLE_DATA/Big Class Families.jmp" );
d2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
Create Excel Workbook(
"c:/MyWorkbook3.xlsx",
{d1, d2}, // data table references
{"Families", "Crime"}
);

Create Excel Workbook() also accepts a mix of data table references and data table names in the list. For example, {d1, d2} above can also be expressed as {d1, "San Francisco Crime"}.

Notes:
• The saved file is an .xlsx file; the .xls format is not supported.
• The JMP data tables must conform to the maximum Excel limit of 1 million rows and 16,535 columns, or the data will be truncated in Excel.
• Data table references or data table names must always be in a list, even if the list has only one item.

Prevent Changes to a Data Table

To prevent editing cells in the data table, use Set Edit Lock with the Modify Cells argument.

d = Open( "$SAMPLE_DATA/Big Class.jmp" );
d << Set Edit Lock( "Modify Cells" );

To prevent adding or deleting columns and rows:

d << Set Edit Lock( "Add Columns", "Delete Columns" );
d << Set Edit Lock( "Add Rows", "Delete Rows" );

To get a list of data table operations that are locked, use Get Edit Lock:

d << Get Edit Lock();
{"Modify Cells", "Add Rows", "Delete Rows", "Add Columns", "Delete Columns"}

To allow a specific data table operation again, use Clear Edit Lock:

d << Clear Edit Lock( "Modify Cells" );

You can lock all three data table components (cells, columns, and rows) at once by using Lock Data Table.
Advanced Data Table Scripting

This section covers more advanced actions that you can perform on a data table.

- "Select Columns in a Data Table"
- "Store Summary Statistics in Global Variables"
- "Create a Table of Summary Statistics"
- "Subset a Data Table"
- "Add a Data Filter"
- "Sort a Data Table"
- "Stack Values in a Data Table"
- "Split Values in a Stacked Data Table"
- "Transpose a Data Table"
- "Vertically Concatenate Data Tables"
- "Horizontally Concatenate Data Tables"
- "Virtually Join Data Tables"
- "Replace Data in Data Tables"
- "Create a Table Using Tabulate"
- "Copy Data Tables"
- "Find Missing Data Patterns"
- "Compare Data Tables"
- "Create a Summary Table"
- "Subscribe to a Data Table"
- "Move Data Between Matrices and Data Tables"
- "Add Hyperlinks to Text Columns"

Select Columns in a Data Table

To select one or more columns, send the Select Columns message to the data table.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
clist = {:Height, :Weight};
dt << Select Columns( clist );
```

To select all columns, send the Select Columns message with the All argument to the data table.

```julia
dt << Lock Data Table( 1 );
```
Store Summary Statistics in Global Variables

The `Summarize` command collects summary statistics for a data table and stores them in global variables. The `Summarize` command is different from the `Summary` command, which also calculates summary statistics, but presents them in a new data table.

The first argument is an optional data table reference. Include it if more than one data table might be open.

```plaintext
dt1 = Open( "\$SAMPLE_DATA/Big Class.jmp" );
dt2 = Open( "\$SAMPLE_DATA/Animals.jmp" );
Summarize( dt1,
   exg = By( :sex ),
   exm = Mean( :height )
);
Show( exg );
Show( exm );
```

Named arguments include the following: `Count`, `Sum`, `Mean`, `Min`, `Max`, `StdDev`, `First`, `Corr`, and `Quantile`. These statistics can be calculated only for numeric columns. Each argument takes a data column argument.

Notes:

- If a `name=By(groupvar)` statement is included, then a list of subgroup statistics is assigned to each `name`.
- `Count` does not require a column argument, but it is often useful to specify a column to count the number of nonmissing values.
- `Quantile` also takes a second argument for specifying which quantile, such as 0.1 for the 10th percentile.
- When you summarize data that contain row states, the summary statistics are not calculated. An error appears in the log instead.

Note: Excluded rows are excluded from `Summarize` calculations. If all data are excluded, `Summarize` returns lists of missing values. If all data have been deleted (there are no rows), `Summarize` returns empty lists.

The following example uses the Big Class sample data table:

```plaintext
dt = Open( "\$SAMPLE_DATA/Big Class.jmp" );
Summarize( a = By( :age ),
   c = Count,
```
sumHt = Sum(:height),
meanHt = Mean(:height),
minHt = Min(:height),
maxHt = Max(:height),
sdHt = Std Dev(:height),
q10Ht = Quantile(:height, .10)
);
Show(a, c, sumHt, meanHt, minHt, maxHt, sdHt, q10Ht);

Because the script included a By group, the results are a list and six matrices:

\[
\begin{align*}
a &= \{"12", "13", "14", "15", "16", "17"\} \\
c &= [8, 7, 12, 7, 3, 3] \\
sumHt &= [465, 422, 770, 452, 193, 200] \\
meanHt &= [58.125, 60.28571428571428, 64.16666666666667, 64.57142857142857, 64.33333333333333, 66.66666666666667] \\
minHt &= [51, 56, 61, 62, 60, 62] \\
maxHt &= [66, 65, 69, 67, 68, 70] \\
sdHt &= [5.083235752381126, 3.039423504234876, 2.367712103711172, 1.988059594776032, 4.041451884327343, 4.163331998932229] \\
q10Ht &= [51, 56, 61.3, 62, 60, 62]
\end{align*}
\]

You can format the results using Table Box.

\[
\begin{align*}
\text{New Window("Summary Results")}, \\
\text{Table Box(} \\
\quad \text{String Col Box("Age", a)}, \\
\quad \text{Number Col Box("Count", c)}, \\
\quad \text{Number Col Box("Sum", sumHt)}, \\
\quad \text{Number Col Box("Mean", meanHt)}, \\
\quad \text{Number Col Box("Min", minHt)}, \\
\quad \text{Number Col Box("Max", maxHt)}, \\
\quad \text{Number Col Box("SD", sdHt)}, \\
\quad \text{Number Col Box("Q10", q10Ht)} \\
\text{)} \\
\end{align*}
\]

You can add totals to the window:

\[
dt = \text{Open("$SAMPLE_DATA/Big Class.jmp")}; \\
\text{Summarize(}
\]

---

</table>
a = By( :age ),
c = Count,
sumHt = Sum( :height ),
meanHt = Mean( :height ),
minHt = Min( :height ),
maxHt = Max( :height ),
sdHt = Std Dev( :height ),
q10Ht = Quantile( :height, .10 )
);

Summarize(
  tc = Count,
tsumHt = Sum( :height ),
tmeanHt = Mean( :height ),
tminHt = Min( :height ),
tmaxHt = Max( :height ),
tsdHt = Std Dev( :height ),
tq10Ht = Quantile( :height, .10 )
);

Insert Into( a, "Total" );
c = c |/ tc;
sumHt = sumHt |/ tsumHt;
meanHt = meanHt |/ tmeanHt;
minHt = minHt |/ tminHt;
maxHt = maxHt |/ tmaxHt;
sdHt = sdHt |/ tsdHt;
q10Ht = q10Ht |/ tq10Ht;

New Window( "Summary Results",
  Table Box(
    String Col Box( "Age", a ),
    Number Col Box( "Count", c ),
    Number Col Box( "Sum", sumHt ),
    Number Col Box( "Mean", meanHt ),
    Number Col Box( "Min", minHt ),
    Number Col Box( "Max", maxHt ),
    Number Col Box( "SD", sdHt ),
    Number Col Box( "Q10", q10Ht )
  )
);
If you do not specify a By group, the result in each name is a single value:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Summarize(
    // a = By( :age ),
    c = Count,
    sumHt = Sum( :height ),
    meanHt = Mean( :height ),
    minHt = Min( :height ),
    maxHt = Max( :height ),
    sdHt = Std Dev( :height ),
    q10Ht = Quantile( :height, .10 )
);
Show( c, sumHt, meanHt, minHt, maxHt, sdHt, q10Ht );
c = 40;
sumHt = 2502;
meanHt = 62.55;
minHt = 51;
maxHt = 70;
sdHt = 4.24233849397192;
q10Ht = 56.2;
```

Summarize supports multiple By groups. For example, in Big Class.jmp, proceed as follows:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Summarize( g = By( :age, :sex ), c = Count() );
Show( g, c );
c = [5,3,3,4,5,7,2,5,2,1,1,2]
```

If you specify a By group, the results are always matrices. Otherwise, the results are scalars.

### Create a Table of Summary Statistics

The `Summary` command creates a new table of summary statistics according to the grouping columns that you specify. Do not confuse `Summary` with `Summarize`, which collects summary statistics for a data table and stores them in global variables. See “Store Summary Statistics in Global Variables” on page 364.

```javascript
summDt = dt << Summary(
    Age  Count  Sum  Mean  Min  Max  SD  Q10
12    8     465  68.126 51   66   5.08324  51
13    7     422  60.267 56   65   3.03842  56
14    12    770  64.167 61   69   2.38771  61.3
15    7     452  64.514 62   67   1.98806  62
16    3     193  64.333 60   68   4.08145  60
17    3     200  66.667 62   70   4.13333  62
Total 40    2502 62.55 51   70   4.24234  56.2
```
Group( groupingColumns ),
Subgroup( subGroupColumn ),
Statistic( columns ),// where statistic is Mean, Min, Max, Std Dev, and so on.
Output Table Name( newName ) );

The following example creates a new table with columns for the mean of height and weight by age, and the maximum height and minimum weight by age:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
summDt = dt << Summary(
    Group( :age ),
    Mean( :height, :weight ), Max( :height ), Min( :weight ),
    Output Table Name( "Height-Weight Chart" ) );

Tip: Output Table Name can take a quoted string or a variable that is a string.

By default, a summary table is linked to the original data table. If you want to produce a summary that is not linked to the original data table, add this option to your Summary message:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
summDt = dt << Summary( Group( :age ), Mean( :height ),
    Link to Original Data Table( 0 )
 );

You can choose to add marginal statistics for grouping variables to the output columns of your data table. JMP also adds a row to the end of the data table that summarizes each level of the grouping variables. To add marginal statistics, add this option to your Summary message:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
summDt = dt << Summary( Group( :age ), Mean( :height ),
    Include marginal statistics
 );

You can specify the format of the statistics column name using statistics column name format(). Table 9.2 shows the option and examples:

Table 9.2 Statistics Column Name Format Options and Examples

<table>
<thead>
<tr>
<th>Option</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>stat (column)</td>
<td>Mean (Profits ($M))</td>
</tr>
<tr>
<td>column</td>
<td>Profits ($M)</td>
</tr>
<tr>
<td>stat of column</td>
<td>Mean of Profits ($M)</td>
</tr>
<tr>
<td>column stat</td>
<td>Profits ($M) Mean</td>
</tr>
</tbody>
</table>
For example, add an option like this to your Summary message:

```plaintext
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
summDt = dt << Summary( Group( :age ), Mean( :height ),
    statistics column name format( "stat of column" )
);
```

The height column is named Mean of height.

**Subset a Data Table**

Subset() creates a new data table from rows that you specify. If you specify no rows, Subset uses the selected rows. If no rows are selected or specified, it uses all rows. If no columns are selected or specified, it uses all columns. And if Subset has no arguments, the Subset window appears.

```plaintext
dt << Subset(("Private"|("Invisible")), <Selected Columns>, <Columns(column list>), <Selected Rows>, <Rows([number, number, ...])>, <By(column list>), <Sampling Rate(fraction)>, <Sample Size(integer)>, <Stratify(column list)>, <Link to Original Data Table(Boolean)>, <Copy Formula(Boolean)>, <Suppress Formula Evaluation(Boolean)>, <Keep by Column>);
```

**Note:** For more arguments, see the Scripting Index in the Help menu.

For example, using Big Class.jmp, to select the columns for all rows in which the age is 12:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( Selected( Row State() ) = (:age == 12) );
subdt = dt << Subset( Output Table Name( "Subset" ) );
```

To select three columns and all rows, run this script:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
subDt1 = dt << Subset( Columns( :name, :age, :height ),
    Output Table Name( "Big Class 2" )
);
```

To select specified rows of two columns and link the two data tables, run this script:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
subDt2 = dt << Subset( Columns( :name, :weight ),
    Rows( [2, 4, 6, 8] ),
    Linked
);
```

To select the columns for all rows in which the age is 12, run this script:
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age == 12 );
dt << Subset( ( Selected Rows ), Output Table Name( "Subset" ) );

To verify that rows were selected and then conditionally proceed to subset the current data table or open another data table, run this script:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age == 12 );

/* If the condition selected no rows, open Fitness.jmp.
   Else, generate the desired subset table of Big Class.jmp. */
If( N Rows( dt << Get Selected Rows ) == 0,

newdt = Open( "$SAMPLE_DATA/Fitness.jmp" ),
   newdt = dt << Subset( All Columns( 1 ), Selected Rows( 1 ) ));

Add a Data Filter

The Data Filter provides a variety of ways to identify subsets of data. Using Data Filter commands and options, you can select complex subsets of data, hide these subsets in plots, or exclude them from analyses.

Here is the basic syntax:

   dt << Data Filter(<Columns>, <Mode(...)>, <Add Filter(...)>, <Show Columns()>,
   <Selector>, <Animation>, <Animate>, <Clear>, <Delete All>, <Delete>,
   <Filter Columns>, <Filter Column>, <Filter Group>, <Add Filter>, <Add>,
   <Match>, <Mode>, <Display>, <Where>, <Make Subset>, <Display>, <Show
Histograms and Bars>)

You can send an empty Data Filter message to a data table, and the initial Data Filter window appears, showing the Add Filter Columns panel that lists all the variables in the data table.

Mode takes three arguments, all of which are optional: Select(Boolean), Show(Boolean), Include(Boolean). These arguments turn on or off the corresponding options. The default value for Select is true (1). The default value for Show and Include is false (0).

Add Filter() adds rows and builds the WHERE clauses that describe a subset of the data table. Here is the basic syntax:

   Add Filter( Columns( col, ... ), Where( ... ), ... )

To add columns to the data filter, list the columns names separated by commas. Note that this is not a list data structure.

You can define one or more WHERE clauses to specify the filtered columns:
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Mode( Show( 1 ) ),
    Add Filter(
        Columns( :age, :sex, :height ),
        Where( :age == {13, 14, 15} ),
        Where( :sex == "M" ),
        Where( :height >= 52 & :height <= 65 )
    )
);

This script selects 13, 14, and 15-year-old males with a height greater than or equal to 52 and less than or equal to 65. In this filtered data, you can instead select the excluded ages by adding the Invert Selection message to the preceding script.

df << ( Filter Column( :age ) << Invert Selection );

In this example, ages other than 13, 14, and 15 in the filtered data are selected.

You can also use Add Filter() to select matching strings from columns with the Multiple Response property or Multiple Response modeling type.

dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
df = dt << Data Filter(
    Location( {437, 194} ),
    Add Filter(
        Columns( :Brush Delimited ),
        Match None( Where( :Brush Delimited == {"Before Sleep", "Wake"} ) ),
        Display( :Brush Delimited, Size( 121, 70 ), Check Box Display )
    )
);

This script selects rows with values in the Brush Delimited column that do not match either of the specified values ("Before Sleep", "Wake"). Other available scripting options include Match Any, Match All, Match Exactly, and Match Only. See Using JMP for more information about the Multiple Response property and the Multiple Response modeling type.

You can also send messages to an existing Data Filter object:

Clear(), Display( ... ), Animate(), Mode(), ...

Clear takes no arguments and clears the data filter.

To prevent the data filter from appearing when the script is run, set Show Window to 0:

obj = ( dt << Data Filter( Show Window( 0 ) ) );
To specify which values to exclude, use the != operator. The following example excludes ages 16 and 17 from the filtered values.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Add Filter( Columns( :age, :sex ) ),
    Match( Columns( :age, :sex ),
        Where( :sex = "M" ), Where( :age != {16, 17} )
    )
);
```

To omit the Data Filter outline and red triangle menu, specify No Outline Box.

```julia
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
obj = dt << Data Filter(
    Add Filter( Columns( :Region, :POP ), Where( :Region == {"C", "N"} ) ),
    Mode( Select( 0 ), Show( 0 ), Include( 1 ) ),
    No Outline Box( 1 )
);
```

### Add a Local Data Filter

A local data filter enables you to filter data in an individual report window without affecting other reports. When the local data filter is added to the platform, the reference to the data filter is returned. This provides an easy way to get access to the filter.

```julia
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
biv = dt << Bivariate(
    Y( :x ),
    X( :y ),
    Automatic Recalc( 1 ),
    Fit Line( {Line Color( {213, 72, 87} )} )
);

dfObj = biv << Local Data Filter(
    // include Show Histograms and Bars( 0 ) to hide them in the filter.
    Location( {566, 47} ),
    Mode( Select( 0 ), Include( 1 ) )
);

dfObj << Add Filter(
    Columns( :Region, :POP ),
    Where( :Region == {"C", "N"} )
);
```
Track Data Filter Changes

Make Filter Change Handler enables you to track changes to the data filter.

```
dt = Open( "SAMPLE_DATA/Cities.jmp" );
dist = Distribution(
  Automatic Recalc( 1 ),
  Continuous Distribution( Column( :POP ) )
);
filter = dist << Local Data Filter(Add Filter( columns( :Region ) ));
f = Function( {a}, Print( a ) );
rs = filter << Make Filter Change Handler( f );
```

Define the Context of a Data Filter

A data filter lets you interactively select complex subsets of data, hide the subsets in plots, or exclude them from analyses. Your selections affect all analyses of the data table.

Another option is to filter data from specific platforms or display boxes. Create a local data filter inside the Data Filter Context Box() function. This defines the context as the current platform or display box rather than the data table.

The following example creates a local data filter for a Graph Box. See Figure 9.9 for the output.

```
New Window( "Marker Seg Example",
  Data Filter Context Box(
    V List Box(
      dt << Data Filter( Local ),
      g = Graph Box(
        Frame Size( 300, 240 ),
        X Scale( Min( xx ) - 5, Max( xx ) + 5 ),
        Y Scale( Min( yy ) - 5, Max( yy ) + 5 ),
        Marker Seg( xx, yy, Row States( dt, rows ) )
      )
    )
  )
);
```

Tip: The preceding script is part of a larger script that first builds the arrays required for a marker seg. To experiment with this script, open the Local Data Filter for Custom Graph.jsl sample script.
A context box can also contain several graphs with one local filter. The filtering then applies to both graphs. The following script creates two bubble plots and one data filter in one context box. See Figure 9.10 for the output.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Window( "Shared Local Filter",
   Data Filter Context Box(
      H List Box(
         dt << Data Filter( Local ),
         Platform(
            dt,
            Bubble Plot( X( :weight ), Y( :height ), Sizes( :age ) )
         ),
         Platform(
            dt,
            Bubble Plot( X( :weight ), Y( :age ), Sizes( :height ) )
         )
      )
   )
)
```

Figure 9.9  Local Data Filter and Graph

![Local Data Filter and Graph](image)
Data filters can be hierarchical. One script might generate a data filter and a local data filter. The outer data filter for the data table determines which data is available for the local data filter. To illustrate this point, the following script produces both types of data filters as shown in Figure 9.11.

**Tip:** The following script is part of a larger script that first builds the arrays required for a marker seg. See the Local Data Filter for Custom Graph.jsl sample script for code that builds those arrays.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
...
New Window( "Marker Seg Example",
   Data Filter Context Box(
      V List Box(
         dt << Data Filter( Local ),
         g = Graph Box(
            Frame Size( 300, 240 ),
            X Scale( Min( xx ) - 5, Max( xx ) + 5 ),
            Y Scale( Min( yy ) - 5, Max( yy ) + 5 ),
            Marker Seg( xx, yy, Row States( dt, rows ) )
         )
      )
   )
);
```
Heights greater than or equal to 55 and less than or equal to 65 are initially filtered. Then the user can work with the local data filter to filter columns on the graph.

**Figure 9.11** Data Filter Hierarchy

---

**Sort a Data Table**

`Sort()` rearranges the rows of a table according to the values of one or more columns, either replacing the current table or creating a new table with the results. Specify ascending or descending sort for each `By` column.

```
dt << Sort({"<Private>"|"<Invisible>", <Replace Table>, By(columns),
Order(Descending | Ascending), <Output Table Name(name)>}
```

The following example creates a new data table based on `Big Class.jmp` that sorts the data in descending order by age and by name:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
sortedDt = dt << Sort(
By( :age, :name ),
Order( Descending, Ascending ),
```

You can also use an associative array to sort values in a column. The associative array gives you a quick look at unique values in a column. See “Sort a Column’s Values in Lexicographic Order” on page 245 in the “Data Structures” chapter.

### Stack Values in a Data Table

Stack() combines values from several columns into one column.

```julia
dt << Stack(
    Columns( columns ), // the columns to stack together
    Source Label Column( "name" ), // to identify source columns
    Stacked Data Column( "name" ), // name for the new stacked column
    Number of Series( n ), // stacks selected columns into two or more columns
    Contiguous, // specifies that the series consists of adjacent columns
    Keep ( columns ), // the columns to keep in the data table
    Drop ( columns ), // the columns to drop in the data table
    Output Table ( "name" ), // the name for the new data table
    Columns( columns ) ), // specify which columns to include in the stacked table
    Copy Formula( Boolean ), // copy the formula into the stacked column
    Drop All Other Columns( Boolean ), // omit the non-stacked columns from the new table
    Keep( col1, ... ) // the non-stacked columns to keep
    Drop( col1, ... ) // the non-stacked columns to omit
    Suppress Formula Evaluation( Boolean ) // do not evaluate the formula
)
```

For example, the following script stacks the weight and height columns in Big Class.jmp:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
StackedDt = dt << Stack(
    Columns( :weight, :height ),
    Source Label Column( "ID" ),
    Stacked Data Column( "Y" ),
    "Non-stacked columns"n )( Keep( :age, :sex ) ),
    Output Table( "Stacked Table" )
);
```

The Columns(columns) argument can take a list of columns, or an expression that evaluates to a list.

You can also stack multiple sets of columns into multiple columns.

```julia
dt = Open( "$SAMPLE_DATA/Blood Pressure.jmp" );
dt << Stack(
```
Columns(
  :BP 8M,
  :BP 12M,
  :BP 6M,
  :BP 8W,
  :BP 12W,
  :BP 6W,
  :BP 8F,
  :BP 12F,
  :BP 6F
),
Stacked Data Column( "BP" ),
Source Label Column( "Day" ),
Number of Series( 3 ), // number of sets in each series
Contiguous, /* If you want to stack vertically. Otherwise, omit the argument. */
);

**Split Values in a Stacked Data Table**

`Split()` breaks a stacked column into several columns.

```
dt << Split(  
  Split( columns ),
  // the column to split (required)

  Split by( column ),
  // the column to split by (required)

  Group(column),
  // split data within groups

  <Private>|<Invisible>,
  // resulting table is private or invisible

  Remaining Columns( Keep All | Drop All | Select( columns ) ),
  /* specify what to do with the remaining columns in the resulting table (Keep All by default) */

  <Copy formula( 0|1 )>,
  /* include column formulas from the source table in the resulting table (default is 1, true) */

  <Suppress formula evaluation( 0|1 )>,
  // stop any copied formulas from being evaluated (default is 1, true)
```

Sort by Column Property,
/* Sort the order of the output columns by the sort column property that is
defined for the Split by column. */

Output Table( "name" ));
// generate the output to the table name specified

The following example reverses the previous example for Stack(), returning essentially the
original table, except that the height and weight columns now appear in alphabetic order:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Stack(
   Columns( :weight, :height ),
   Source Label Column( "ID" ),
   Stacked Data Column( "Y" ),
   "Non-stacked columns"n( Keep( :age, :sex ) ),
   Output Table( "Stacked Table" )
);
dt2 = Data Table( "Stacked Table" );
dt2 << Split(
   /* Split adds the column or columns that you want to split into several
      new columns. */
   Split( Y ),
   /* Split By adds the column whose values you want to use as the new column
      names, and as the basis for splitting the column. */
   Split By( ID ),
   Output Table( "Split" )
);

When multiple rows are mapped to the same row, only one value is kept.

dtabc = New Table( "abc",
   New Column( "Column 1", Character, Set Values( {"a", "a", "b", "b", "c"} ) ),
   New Column( "Column 2", Character, Set Values( {"x", "y", "x", "y", ""} ) ),
   New Column( "Column 3", Set Values( [1, 2, 3, 4, 5] )
);
   /* Split adds Column 3. You want to split the values (1, 2, 3..) into several
      new cols.
   Split By adds Column 2. You want to use the values (x, y) as the new column
      names. */
   dtabc << Split( Split By( :Column 2 ), Split( :Column 3 )

**Transpose a Data Table**

Transpose creates a new data table by flipping a data table on its side, interchanging rows for
columns and columns for rows. If you specify no rows, Transpose() uses the selected rows. If
no rows are selected, it uses all rows.
The following example transposes the height and weight columns in the Big Class.jmp sample data table:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
tranDt = dt << Transpose( Columns( :height, :weight ),
                         Output Table Name( "Transposed Columns" ) ) ;
```

**Note:** The simple transpose command `dt << Transpose` brings up the Transpose window. If you do not want the window to appear, invoke the transpose as `dt << Transpose(no option)`.  

### Vertically Concatenate Data Tables

Concatenate, also known as a vertical join, combines rows of several data tables top to bottom.

```plaintext
dt << Concatenate( DataTableReferences,...,Keep Formulas,
                   Output Table Name( "name" ) ) ;
```

For example, if you have subsetted tables for males and females, you can put them back together using Concatenate:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :sex == "M" );
m = dt << Subset( Output Table Name( "M" ) ) ;
dt << Invert Row Selection;
f = dt << Subset( Output Table Name( "F" ) ) ;
both = m << Concatenate( f, Output Table Name( "Both" ) ) ;
```

Or, instead of creating a new table containing all the concatenated data, you can append all the data to the current data table:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :sex == "M" );
```
Horizontally Concatenate Data Tables

Join, also known as horizontal join or concatenate, combines data tables side to side.

```
dt << Join( // message to the first table
    With( dataTable ), // the secondary data table
    Select( columns ), /* select columns from the main table
        to add to the output table */
    Select With( columns ), /* select columns from the secondary table to
        add to the output table */
    // join type; alternatives are
    Cartesian join, By Row Number, By matching columns(col1=col2, ...)
    Merge Same Name Columns, // merge columns with the same name
    Copy Formula( 0 ), // on by default; 0 turns it off
    Suppress Formula Evaluation( 0 ), // on by default; 0 turns it off
    Match Flag( 1 ), /* add the Match Flag column from the joined data table
        when you are matching by column */
    Update, /* replace the data in the main table with the corresponding data
        from the secondary table */
    // options for each table:
    Drop Multiples( Boolean, Boolean ), // include all rows from the data table
    Include Non Matches( Boolean, Boolean ), // include non-matching rows
    Preserve Main Table Order(), // maintain the order of the original data
    Output Table Name( "name" )); // the resulting table
```

To try this, first break Big Class.jmp into two parts:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
part1 = dt << Subset( 
    Columns( :name, :age, :height ),
    Output Table Name( "Big Class 1" )
);
part2 = dt << Subset( 
    Columns( :name, :sex, :weight ),
    Output Table Name( "Big Class 2" )
);
```

To make it a realistic experiment, rearrange the rows in part 2:

```
sortedPart2 = part2 << Sort( By( :name ), Output Table Name( "Sorted_Big Class" ) );
```
Now you have a data set in two separate chunks, and the rows are not in the same order, but you can join them together by matching on the column that the two chunks have in common.

```julia
part1 << Join(
    With( sortedPart2 ),
    By Matching Columns( :name == :name ),
    Preserve Main Table Order();
    Output Table Name( "Joined Parts" );
);
```

The resulting table has two copies of the name variable, one from each part, and you can inspect these to see how `Join` worked. Notice that you now have four Robert rows, because each part had two Robert rows (there were two Roberts in the original table) and `Join` formed all possible combinations.

**Tip:** To maintain the order of the original data table in the joined table (instead of sorting by the matching columns), include `Preserve Main Table Order()`.

See the [JSL Syntax Reference](#) for more information about the `Join` arguments.

### Virtually Join Data Tables

Virtual Join links a main data table to one or more auxiliary data tables. The feature enables the main data table to access data from the auxiliary data tables without physically joining the tables. See [*Using JMP*](#).

The following example shows how to virtually join data tables and create distributions from the joined data:

```julia
dt1 = Open( "$SAMPLE_DATA/Pizza Profiles.jmp" );
dt1:ID << Set Property( "Link ID", 1 ); // add Link ID and turn it on

dt2 = Open( "$SAMPLE_DATA/Pizza Responses.jmp" );

// add Link Reference to the Choice1, Choice2, and Choice columns
dt2:Choice1 << Set Property( "Link Reference", Reference Table( "$SAMPLE_DATA/Pizza Profiles.jmp" ) );
dt2:Choice2 << Set Property( "Link Reference", Reference Table( "$SAMPLE_DATA/Pizza Profiles.jmp" ) );
dt2:Choice << Set Property( "Link Reference", Reference Table( "$SAMPLE_DATA/Pizza Profiles.jmp" ) );

obj = dt2 << Distribution( // create a distribution of Crust[Choice1]
    Weight( :Subject ),
    Nominal Distribution( 
```
For another example of virtual join, search the Help > Scripting Index for “virtual join”.

### Specifying Linked Column Names

The Columns panel in a data table shows you the names of the linked columns. For example, open the Movie Inventory.jmp and Movie Rentals.jmp sample data tables to see the linked columns shown in Figure 9.12.

The column name of the source column is followed by the name of the referencing column in brackets. For example, Figure 9.12 shows the Name source column followed by the referencing column [Item Number] in brackets.

**Figure 9.12** Linked Columns in Movie Rentals.jmp

You change the name of the virtually linked column name with **Set Title**. For example, the following script changes the name of the virtually linked column Rating[Item Number] to Movie Rating in the Distribution report.

```julia
dt1 = Open( "$SAMPLE_DATA/Movie Inventory.jmp" );
dt2 = Open( "$SAMPLE_DATA/Movie Rentals.jmp" );
dt2 << Distribution(
    Nominal Distribution(
        Column(
            Referenced Column( // specify the joined column name
                "Rating[Item Number]",
                Reference( Column( :Item Number ), Reference( Column( :Rating ) ) )
            )
        ),
        Nominal Distribution( Column( :Choice1 ) )
    )
);
```
Note that running the script automatically opens the referenced table (the one with the Link ID property), just like running any other platform script, before the referenced table is opened.

You can also specify that the referenced column name be used in linked columns. This option lets you define a shorter column name (for example, Rating instead of Rating[Item Number]). Include the Use Linked Column Name option:

```julia
Column( dt2, "Item Number" ) << Set Property( "Link Reference",
   {Reference Table( "Movie Inventory.jmp" ), Options( "Use Linked Column Name" ( 1 ) )}
);
```

### Merging Referenced Data into One Data Table

To share the data from virtually joined data tables with another user, you might want to merge the data so that the data tables are permanently joined. This option is helpful because you provide one data table, not the main and auxiliary data tables.

When you merge referenced data, the data are replicated from the auxiliary data table to the main data table. When you save the main data table, the actual data are also saved.

The following example shows how to merge two referenced columns:

```julia
dt1 = Open( "$SAMPLE_DATA/Pizza Profiles.jmp" );
dt2 = Open( "$SAMPLE_DATA/Pizza Responses.jmp" );
dt1:ID << Set Property( "Link ID", 1 );
```
dt2:Choice << Set Property( "Link Reference", Reference Table( dt1 ) );
dt2:Choice1 << Set Property( "Link Reference", Reference Table( dt1 ) );
dt2:Choice2 << Set Property( "Link Reference", Reference Table( dt1 ) );

// select the columns to merge
dt2 << Select Columns( :Choice1, :Choice2 );

dt2 << Merge Referenced Data();
/* linked data from the referenced columns are now embedded in
Pizza Responses.jmp */

Note: If you don’t select the columns to merge, all columns are merged.

Replace Data in Data Tables

Note: Merge Update() is an alias for Update().

Update() replaces data in one table with data from a second table.

dt << Update( // message to first table
    With( dataTable ), // the other data table
    By Row Number, /* default join type; alternative is
    By Matching Columns( col1 == col2 ) */
    Ignore Missing, // optional, does not replace values with missing values
);

To try this, make a subset of Big Class.jmp:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
NewHt = dt << Subset( Columns( :name, :height), Output Table Name( "hts" ) );

Next, add 0-6 inches to each student’s height:

diff = Random Uniform( 0, 6 );
For Each Row( NewHt, :height = :height + diff );

Finally, update the heights of students in Big Class.jmp with the new heights from the subset table:

dt << Update(
    With( NewHt ),
    By Matching Columns( :name == :name),
);
Controlling the Columns Added to an Updated Table

Your updated table might contain more columns than your original table. You can select which columns are included in your updated table using the option `Add Column from Update Table()`.

To add no additional columns:

```julia
Data Table( "table" ) << Update(
   With( Data Table( "update data" ) ),
   Match Columns( :ID = :ID ),
   Add Columns from Update Table( None )
);
```

To add some columns:

```julia
Data Table( "table" ) << Update(
   With( Data Table( "update data" ) ),
   Match Columns( :ID = :ID ),
   Add Columns from Update Table( :col1, :col2, :col3 )
);
```

Create a Table Using Tabulate

Tabulate constructs tables of descriptive statistics. The tables are built from grouping columns, analysis columns, and statistics keywords. The following example creates a table containing the standard deviation and mean for the height and weight of male and female students:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Tabulate( // message to data table
   Add Table( // start a new table
      Column Table( Grouping Columns( :sex ) ), // group using the column sex
      Row Table( // add rows to the table

         // use the height and weight columns for the analysis
         Analysis Columns( :height, :weight ),

         // show the standard deviation and mean
         Statistics( Std Dev, Mean )
   )
);
```

You can apply a transformation to a column in the Tabulate table and set the format of the column at the same time. Use the `Transform Column()` function inside `Analysis Column()`. For example, the following script applies the Log transformation to `height` and sets the column format for the Mean and % of Total columns.
Chapter 9  
Data Tables  
Scripting Guide  
Advanced Data Table Scripting

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Tabulate(  
    Set Format(  
        Mean(  
            :height( 10, 1 ),  
            Analysis Column(  
                Transform Column(  
                    "Log[height]",  
                    Formula( Log( :height ) )  
                ),  
                Format( 10, "Best" )  
            ),  
            "% of Total"n(:height( 12, 2 )),  
            Analysis Column(  
                Transform Column(  
                    "Log[height]",  
                    Formula( Log( :height ) )  
                ),  
                Format( 12, 2 )  
            )  
        ),  
        Add Table(  
            Column Table(  
                Analysis Columns(  
                    :height,  
                    Transform Column(  
                        "Log[height]",  
                        Formula( Log( :height ) )  
                    )  
                ),  
                Statistics( Mean, "% of Total"n )  
            ),  
            Row Table( Grouping Columns( :sex ) )  
        )  
    )  
);  
```

**Note:** You can also change the width of columns and perform additional operations within Tabulate. See the JMP Scripting Index in the Help menu.

**Copy Data Tables**

The most efficient way to copy a data table is with the Subset() function. The following example subsets all rows and columns into New Table.jmp.
sourceDT = Open( "$SAMPLE_DATA/Big Class.jmp" );
destDT = sourceDT << Subset( Columns(), Rows(), Output Table Name( "New Table.jmp" ) );

You can also use Copy File().

      Copy File( "$SAMPLE_DATA/Big Class.jmp", "c:/MyData/New Table.jmp" );

Copy File() is equivalent to copying the file on your computer. However, you have to consider whether the destination data table with the specified name already exists. And the source file has to be saved. If the source file is not saved, or the destination file already exists, the copy fails. It’s safer to use the Subset() method shown above.

**Find Missing Data Patterns**

If your data table contains a lot of missing data in different columns, you might want to see whether there is a pattern in the distribution of the missing data relative to the different columns.

    dt << Missing Data Pattern( // message to data table
     Columns( :miss ), // find missing data in this column
     Output Table( "Missing Data Pattern" ) // name the output table
    );

**Compare Data Tables**

JMP can compare two open data tables and report the differences between data, scripts, table variables, column names, column properties, and column attributes. To compare data tables using JSL:

    obj = dt << Compare Data Tables(
     Compare With( Data Table ( "Data Table Name" ) );
    )

For example, to compare the data tables Students1.jmp and Students2.jmp, proceed as follows:

    dt = Open( "$SAMPLE_DATA/Students1.jmp" );
    dt2 = Open( "$SAMPLE_DATA/Students2.jmp" );
    obj = dt << Compare Data Tables( Compare With( Data Table( "Students2" ) ) );

To view the difference summary matrix for the comparison results, use this function:

    mtx = ( obj << Get Difference Summary Matrix );

The resulting matrix appears in the log window:

```
[-1 1 2 2,  
-1 2 4 3,  
-1 1 7 4,  
1 3 8 4,  
1 1 10 9,
```
In the comparison summary matrix in the example, the first column represents the action performed on a column: -1 for a Delete, 0 for a Replace, and 1 for an Add. The second column represents the number of rows affected by the action. The third and fourth columns represent the row numbers affected in the two data tables in their respective order (Students1.jmp, Students2.jmp).

**Create a Summary Table**

A Summary table includes summary statistics for a data table, such as the mean, median, standard deviation, minimum value, and maximum value. By default, the summary table is linked to its source table. When you select rows in the summary table, the corresponding rows are highlighted in its source table.

```
dt << Summary( <private>, <invisible>, <Group( column )>, <Weight( column )>,
               <Freq( column )>, <N>, <Mean( column )>, <Std Dev( column )>, <Min( column )>,
               <Max( column )>...)
```

Include columns for any statistic listed in the Summary launch window.

The following example creates a summary table from the Fitness.jmp sample data table. The N Rows column, which specifies the number of rows for each level, is included in the Summary table by default. This script creates a column of the mean for Runtime by Sex.

```
dt = Open( "$SAMPLE_DATA/Fitness.jmp" );
dt << Summary(  
               Group( :Sex ),
               Mean( :Runtime ),
          );
```

You can override the preselected Freq or Weight columns in the data table by specifying the Freq or Weight columns in the script. To omit the preselected Freq or Weight, use the keyword "none".

```
dt = Open( "$SAMPLE_DATA/Fitness.jmp" );
dt << Summary(  
               Group( :Sex ),
               Mean( :Runtime ),
               Weight( "none" )
          );
```
To unlink the Summary table, include `Link to Original Data Table( 0 )` in the script.

```julia
dt = Open( "SAMPLE_DATA/Fitness.jmp" );
dt << Summary(
    Group( :Sex ),
    Mean( :Runtime ),
    Link to Original Data Table( 0 )
);
```

**Subscribe to a Data Table**

If you want to receive a message when a data table changes, use the `Subscribe` message. For example, you might want a message sent to the log when columns are added or deleted.

Here is the basic syntax:

```julia
dt << Subscribe( keyname(<client>), On Delete Columns|On Add Columns|On Add Rows|On Delete Rows|On Rename Column|On Close|On Save|On Rename(function) );
```

The first argument is a name for the subscription (or “client”), so that it can also be removed.

**Note:** The subscription is to the data table. The subscriber subscribes to the broadcast from the data table; it does not subscribe to a program or to script.

The application can also subscribe as a client to the data table (for example, most built-in platforms such as Distribution). If a data table has clients when the data table is closed, the user is warned that there are applications open that might need the data table.

Each subscription remains in effect until you unsubscribe:

```julia
dt << Unsubscribe("keyname", On Delete Columns | On Add Columns | On Add Rows | On Delete Rows | On Close | On Col Rename | All);
```

The following example sends messages to the log when a row is added or deleted:

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
delRowsFn = Function( {a, b, rows},
    dtname = ( a << Get Name());
    Print( dtname );
    Print( b );
    Print Matrix( rows );
);
addRowsFn = Function( {a, b, insert},
    dtname = ( a << Get Name() );
    Print( dtname );
    Print( b );
    Print( insert );
);
dt << Subscribe( "Test Delete", onDeleteRows( delRowsFn, 3 ) );
dt << Subscribe( "Test Add", onAddRows( addRowsFn, 3 ) );

Subscribe to Data Table List() subscribes to a list of data tables to be notified when a new data table has been added, closed, or renamed. The following example shows how to subscribe and unsubscribe:

f2 = Function( {x}, Show( x ) );
Show( Subscribe to Data Table List( "My Data", OnClose( f2 ) ) );
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Wait( 2 );
Close( dt );
Show( Unsubscribe to Data Table List( "My Data" ) );

Empty Application Names

If Subscribe is called with an empty application name, JMP generates a unique name that is returned to the caller. In the following example, appname2 is subscribed to the data table as a client.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
appname1 = dt << Subscribe( "", On Close( Print( "Closing Data Table" ) ) );
appname2 = dt << Subscribe( ""( "client" ),
  On Close(
    Function( {dtab},
      dtname = ( dtab << Get Name() );
      Print( dtname );
    )
  )
);  
dt << Unsubscribe( appname1, On Close );
dt << Run Script( "Distribution" )

Move Data Between Matrices and Data Tables

For information about moving information between a matrix and a data table, see "Matrices and Data Tables" on page 214 in the “Data Structures” chapter.
Add Hyperlinks to Text Columns

You can define a text column as a column of hyperlinks using the Event Handler column property. For example, you can create a column of geographical data as hyperlinks to a Google map, or you might want to include links to a Wikipedia web pages.

**Note:** To learn more about the Event Handler column property, add the column property to a column that contains a hyperlink and study the property in the JMP interface. Tips about the property are provided. To see the script that creates the property, select the data table red triangle menu; select **Copy Script (No Data)**; and copy the script to an empty script.

Use the Event Handler column property to build hyperlinks based on one or more columns in your data table. This example shows how the hyperlinks in the SAS Offices.jmp sample data table were created.

1. Select **Help > Sample Data Library** and open SAS Offices.jmp.
2. Right-click the City column and select **Column Info**.
   Notice that the Event Handler column property has been added.
3. The script on the Click tab inserts the code for the URL.
   ```
   Function( {thisTable, thisColumn, iRow},
     Web(
       "https://www.google.com/maps/@||Char(thisTable:latitude[irow])||","||Char(thisTable:longitude[irow])||",12z" );
   
   - thisTable is the data table object.
   - thisColumn is the column object.
   - iRow is the index of the row in thisColumn.
   - Web opens the URL in the default browser.
   - The @ sign in "https://www.google.com/maps/@" is specific to the Google API for maps. Google expects coordinates to follow it.
   - ||Char(thisTable:latitude[irow]) concatenates the latitude defined in the Latitude column.
   - ||"||Char(thisTable:longitude[irow])|| concatenates the longitude defined in the Longitude column.
   - The Google API uses ",12z" to specify a zoom factor.
   ```
4. The script on the Tip tab defines the tooltip that appears when you hover over the hyperlink. The tip accurately describes what happens after the link is clicked. Consider using this function to set the tooltip to the URL the Click script uses or a description of the platform.
   ```
   Function( {thisTable, thisColumn, iRow},
   ```
"Open " ||
"https://www.google.com/maps/@"||char(thisTable:latitude[irow])||","||char
(thisTable:longitude[irow])||"12z" || " in your browser.";);  
– Returns the tool tip string.

• The script on the Color tab defines the color of the hyperlink (in this example, blue).
  Function( {thisTable, thisColumn, iRow}, 5; );
  See “JMP Colors” on page 454 for a diagram of JMP colors.

You might also want to embed links to other files in a data table column. The following
example shows how to use Event Handler scripts and set the values to the audio and video
locations on your computer.

New Table( "Wildlife",
  New Column( "Column 1", Character, "Nominal",
    Set Property( "Event Handler",
      Event Handler(  
        Click( JSL Quote(Function( {thisTable, thisColumn, iRow}, Open(  
          Char(
            thisTable:thisColumn[ iRow ] ) ); ); ) ),
        Tip( JSL Quote(Function( {thisTable, thisColumn, iRow}, "Open " ||
          Char(
            thisTable:thisColumn[ iRow ] ) || " in a media player."; ); ) ),
        Color( JSL Quote(Function( {thisTable, thisColumn, iRow}, 5; ); ) )
      )
    ),
    Set Selected,
    Set Values( {  
      "C:\Users\Public\Videos\Sample Videos\Wildlife.wmv",
      "C:\Users\Public\Music\Sample Music\Kalimba.mp3"
    } )
  )
)

The SAS Country Office and Photo columns in SAS Offices.jmp also contain examples of Event
Handler scripts.
Columns

This section covers actions that you can perform on columns in a data table, such as creating, grouping, setting and getting attributes and properties, and so on.

- “Send Messages to Data Column Objects”
- “Create Columns”
- “Create a New Column by Text Matching”
- “Add Several Columns at Once”
- “Group Columns”
- “Use Set Selected to Select Columns”
- “Rearrange and Move Columns”
- “Recode Columns”
- “Add a Column Switcher”
- “Compress Selected Columns”
- “Create Custom Functions, Transforms, and Formats”
- “Custom Transform Example”
- “Delete Columns”
- “Get Column Names”
- “Column Attributes”
- “Column Properties”

Note: JMP can display math symbols and Greek letters (controlled in Preferences in the Font category). This means that if you save a column (such as T square limits), the column name could either be “T Square Limits” (no special characters) or “T^2 Limits” (with special characters). Any reference using the column name must match the name exactly, or it fails.

Send Messages to Data Column Objects

Just as you send data table messages to a data table reference, you can send column messages to a reference to a data column object. The Column function returns a data column reference. Its argument is either a name in quotation marks, something that evaluates to a name in quotation marks, or a number.

```plaintext
Column("age");       // a reference to the age column
col = Column(2);     // assign a reference to the second column
```
**Note:** You can also use the syntax "Profits ($M)" to evaluate to a name that contains special characters.

The *Scripting Guide* uses `col` to represent data column references. To see the messages that you can send to data column objects, see the Scripting Index (Help > Scripting Index > Objects > Data Tables > Column Scripting). Alternatively, you can use the `Show Properties()` command:

```
Show Properties( col);
```

**Note:** With column references, you must include a subscript to refer to the individual data values. Without a subscript, the reference is to the column object as a whole.

Once you have stored a data column reference in a global variable, to modify columns, you send messages to the data column reference.

Sending messages to columns is comparable to sending messages to data tables. Either state the object, a double-angle operator `<<`, and then the message with its arguments in parentheses, or use the `Send()` function with the object and then the message. In some cases the messages themselves need no arguments, so the trailing parentheses are optional.

```
col << message( arg, arg2, ... );
Send( col, message(arg, arg2, ... ) );
```

As with data tables and other types of objects, you can stack or list messages:

```
col << message << message2 << ... 
col << {message, message2, ...};
```

**Tip:** To delete a column, you must send the message to a data table reference, because objects cannot delete themselves, only their containers can delete them.

**Access Cell Values through Column References**

Always use a subscript on a column reference to access the values in the cells of columns. Without a subscript, the reference is to the column object as a whole.

```
x = col[irow]  // specific row 
x = col[]      // current row 
col[irow] = 2; // as an l-value for assignment 
dt << Select Where( col[] < 14 );  // in a WHERE clause
```

**Access Cell Values that have Value Labels**

If the column whose values you want to access has a Value Label property, you might want to access the value label (formatted value) instead of the actual data value. To do this, use the formatted option. Consider the following example:
dt = Open( "$SAMPLE_DATA\Big Class.jmp" );
dt << Run Script( "Set Age Value Labels" );
x = Column( dt, "age", formatted )[1];
  Show( x );
y = Column( dt, "age" )[1];
  Show( y );

The log shows the formatted value for x, which is Twelve, and the actual data value for y, which is 12.

Create Columns

To add a new column to a data table, send a New Column message to a data table reference or use the New Column() function. The first argument, the column’s name, is required. Either enclose the name in quotation marks or specify an expression evaluating to the name.

dt = New Table( "MyData1.jmp" );
dt << New Column( "wafer" );

or

dt = New Table( "MyData2.jmp" );
a = "wafer";
dt << New Column( a );

or

dt = New Table( "MyData3.jmp" );
col = New Column( "X", Formula( Random Uniform() ) );

If the table already includes a column by the same name, a sequential numeric value is appended to the new column name (wafer, wafer 2, wafer 3, and so on).

You can specify the following properties when creating a new column:

• Data type (numeric, character, row state, or expression)
• Modeling type (continuous, nominal, ordinal, multiple response, unstructured text, or vector)
• Column width (only for numeric columns)
• Numeric format

Unless otherwise specified, columns are numeric, continuous, and 12 characters wide.

The following example creates a new column whose data type is numeric, modeling type is continuous, width is set to 5, and numeric format is set to Best:

dt << New Column( "wafer", Numeric, "Continuous", Format( "Best", 5 ) );
The following example creates a character column and automatically assigns the nominal modeling type.

```julia
dt << New Column( "Last Name", Character );
```

You can also add formulas and other script messages appropriate to the column.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Ratio", Numeric, "Continuous", Formula( :height/:weight ) );
dt << New Column( "myMarkers", Row State, Set Formula( Marker State( age - 12 ) ) );
```

You can also create new columns that have the same properties as an existing column.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Like Name", Like( :name ) );
```

If you plan to work with specific columns later (for example, grouping or changing data types), create a column reference:

```julia
myCol = dt << New Column( "Birth Date" );
```

### Fill a Column with Data

To fill the column with data, use `Values` or its equivalent, `Set Values`. Include the value for each cell in a list.

The following example adds a new column called `Last Name` to a new data table. Three values are added: Smith, Jones, and Anderson.

```julia
dt = New Table( "My Data" );
dt << New Column( "Last Name", Character, Values( {"Smith", "Jones", "Anderson"} ) );
```

The column can also be filled with numeric values. The following example adds a new column called `Row Number` to a new data table. The function `N Row` returns the number of rows in the table, and numeric values populate all of the rows in the column, beginning with 1.

```julia
dt = New Table( "My Data" );
dt << New Column( "Last Name", Character, Values( {"Smith", "Jones", "Anderson"} ) );
dt << New Column( "Row Number", Numeric, Values( 1 :: N Row() ), Format( "Best", 5 ) );
```

To add a column of random numbers, insert a formula along with the random function.
Another option is to add a constant numeric value to each cell. In the following example, the number 5 is added to each cell.

```
dt << New Column( "Number" );
:Number << Set Each Value( 5 );
```

New Column() can also be used as a built-in function, in other words, without the << (Send) command applied to the data table reference. When used in this way, the column is added to the current data table.

```
dt << New Column( "Address" ); // command is sent to the data table reference
New Column( "Address" ); // column is added to the current data table
```

### Create a New Column by Text Matching

The New Column by Text Matching option enables you to use regular expressions (which identify patterns in text) to match text in a column and then create a new column from the matched text. This feature is an alternative to using the Text Explorer platform to write regular expressions and then save the results to a column.

The following example shows how to select cat, cats, dog, and dogs in a column and put the values in new columns.

```
dt = Open( "$SAMPLE_DATA/Pet Survey.jmp" );
dt << New Column by Text Matching(  
  Column( :Survey Response ),  
  Set Regex(  
    Custom(  
      Title( "Cat" ),  
      /* finds "cat", optionally followed by "s",  
      with either a space or period afterward. */  
      Regex( "(cat(?:s?))(\s\.)" ),  
      Result( "\[\1\]" ), // results in the value matched by (cat...)  
    ),  
    Output Column Name( "Instances of Cats" )  
  );
  dt << New Column by Text Matching(  
    Column( :Survey Response ),  
    Set Regex(  
      Custom(  
        Title( "Dog" ),  
        Regex( "(dog(?:s?))(\s\.)" ),  
        Result( "\[\1\]" ),  
      ),  
    ),
  );
```
For more information about using regular expressions in JSL, see “Regular Expressions” on page 172. To learn more about regular expressions, visit Regular-Expressions.info.

Add Several Columns at Once

The Add Multiple Columns message creates several columns at once. Arguments include the column name prefix, the number of columns, where to insert them (Before First, After Last, or After(col)), and the data type (Numeric, Row State, or Character(width)). An additional argument, field width, is optional for a numeric column.

```julia
// add two row state columns named "beginning <n>" before the first column
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Multiple Columns( "beginning", 2, Before First, Row State );

// add three numeric columns named "middle <n>" after the height column
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Multiple Columns( "middle", 3, After( :height ), Numeric );

// add four character columns named "end <n>" after the last column
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Multiple Columns( "end", 4, After Last, Character( 4 ) );
```

The column name is a prefix. If multiple columns with the same name are added, a sequential number is appended to each column name (beginning 1, beginning 2, and so on).

Group Columns

You can group columns by sending the data table the Group Columns message, which takes a list of columns to group as an argument. For example, the following code opens the Big Class.jmp sample data table and groups the age and sex columns.

```julia
dt = Open( "$SAMPLE_DATA\Big Class.jmp" );
dt << Group Columns( {:age, :sex} );
"age etc."
```

You can also send a column name followed by the number of columns to include in the group. The group includes the first column named and the \( n-1 \) columns that follow it. This line is equivalent to the line above, which groups age and sex:

```julia
dt << Group Columns( :age, 2 );
```
The group name is based on the first column specified in the argument. So in the preceding example, the group is automatically named age etc. To customize the name, include the group name as the first argument.

```julia
dt << Group Columns( "My group", :age, 2 );
```

To ungroup grouped columns, use the Ungroup Columns message, which takes a list of columns in a group as an argument. For example, the following line ungroups the two columns grouped in the previous example.

```julia
dt << Ungroup Columns( {:age, :sex} );
```

Note the following about grouping and ungrouping columns:

- Both messages take a single list as an argument. The list must be enclosed in braces.
- You cannot create more than one group in a single message (for example, by giving the Group Columns message two lists of columns). Instead, you must send the data table two separate Group Columns messages.
- The Ungroup Columns message takes a list of columns to ungroup, not the name of a group of columns. You can remove a partial list of columns from a group. For example, this line creates a group of four columns:

```julia
dt << Group Columns( {:age, :sex, :height, :weight} );
```

And this line removes two of the columns, while leaving the other two in the group:

```julia
dt << Ungroup Columns( {:age, :sex} );
```

Notice that the column group’s name does not change automatically. You have to change the name.

### Get Column Groups or Names

To get column groups or names, use Get Column Group or Get Column Groups Names. The first part of this example creates two sets of grouped columns as shown in the previous section. Get Column Group() returns the column names in the specific group. Get Column Groups Names returns the names of the column groups.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Group Columns( {:age, :sex} );
"age etc."
dt << Group Columns( {:weight, :height} );
"height etc."
dt << Get Column Group( "age etc." );
{:age, :sex}
dt << Get Column Groups Names();
{"age etc.", "height etc."}
```
Select a Column Group

To select or deselect a column group, use the following messages:

\[
\begin{align*}
dt &\ll Select\ Column\ Group(\ "name"\ ); \quad // \text{select the columns in the group} \\
dt &\ll Deselect\ Column\ Group(\ "name"\ ); \quad // \text{deselect the columns in the group}
\end{align*}
\]

The following example groups columns X and Y and groups columns Ozone through Lead, and then selects those groups in the data table:

\[
\begin{align*}
dt = Open(\ "$SAMPLE_DATA/Cities.jmp"\ ); \\
dt &\ll Group\ Columns(\ "xy",\ {:X,\ :Y}\ ); \\
dt &\ll Group\ Columns(\ \\
\ "pollutants", \\
\ :Ozone:::Lead \\
\ ); \\
dt &\ll Select\ Column\ Group(\ "xy",\ "pollutants"\ );
\end{align*}
\]

Rename a Column Group

To rename a column group, use the following message:

\[
\begin{align*}
dt &\ll Rename\ Column\ Group(\ "name",\ "toname"\ );
\end{align*}
\]

The following example renames the column group from xy to coordinates:

\[
\begin{align*}
dt = Open(\ "$SAMPLE_DATA/Cities.jmp"\ ); \\
dt &\ll Group\ Columns(\ "xy",\ {:X,\ :Y}\ ); \\
dt &\ll Group\ Columns(\ \\
\ "pollutants", \\
\ :Ozone:::Lead \\
\ ); \\
Wait(3); \\
dt &\ll Rename\ Column\ Group(\ "xy",\ "coordinates"\ );
\end{align*}
\]

Move a Column Group

To move a column group, use the following message:

\[
\begin{align*}
dt &\ll Move\ Column\ Group\ (\ To\ First\ |\ To\ Last\ |\ After(\ column)\ |\ After(\ group)\ );
\end{align*}
\]

The following example moves the columns in the pollutants group to the end:

\[
\begin{align*}
dt = Open(\ "$SAMPLE_DATA/Cities.jmp"\ ); \\
dt &\ll Group\ Columns(\ "xy",\ {:X,\ :Y}\ ); \\
dt &\ll Group\ Columns(\ \\
\ "pollutants", \\
\ :Ozone:::Lead \\
\ ); \\
dt &\ll Move\ Column\ Group(\ To\ Last,\ "pollutants"\ );
\end{align*}
\]
Use Set Selected to Select Columns

Send the Set Selected message to select a column.

```julia
col << Set Selected( 1 );
```

To select all columns with a specific string in the name, run the following script:

```julia
dt = Open( "$SAMPLE_DATA/Semiconductor Capability.jmp" );
coList = dt << Get Column Names( String );
For( i = 1, i <= N Cols( dt ), i++,
   If( Contains( coList[i], "NPN" ), /* select only columns with NPN in the name */
      Column( coList[i] ) << Set Selected( 1 )
   )
);
```

If you want to select many columns, consider sending the Select Columns message to the data table. See the Scripting Guide.

Get Selected Columns

To get a list of currently selected columns, use the Get Selected Columns message.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
:age << Set Selected( 1 );
:sex << Set Selected( 1 );
dt << Get Selected Columns();
{:age, :sex}
```

Return the list of selected columns as a string using the string argument:

```julia
dt << Get Selected Columns( string );
{"age", "sex", "height"}
```

Once you know what columns are selected, you can then write a script that acts upon these columns. Or your script can iteratively select columns and act upon them one at a time.

To actually select the columns before getting the columns, send the Set Selected message to a column. See “Column Attributes” on page 414.

Go To Column

To select and move to a specific column, use the Go To message.

```julia
dt << Go To( column name | column number );
```

For data tables with many columns, you can use this message to scroll the data table all the way to the left, so that the first column comes into view and is selected:
Invert Column Selections

To select any column that is currently deselected and deselect any column that is currently selected, use the Invert Column Selection message.

```
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Go To( 1 );
Invert Column Selection;
```

If a list of columns is provided, the columns that are not in the list are selected.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
a = {:height, :weight};
b = dt << Invert Column Selection( a );
```

Rearrange and Move Columns

These messages enable you to rearrange columns in a data table:

```
dt << Reorder By Name;           // alphanumeric order
dt << Reverse Order;             // reverse current order
dt << Reorder By Data Type;      // row state, character, and then numeric
dt << Reorder By Modeling Type;  // continuous, ordinal, nominal
dt << Original Order;            // saved order
```

These commands move the currently selected column or columns to the indicated destination point.

```
dt << Move Selected Column( to first );
dt << Move Selected Column( to last );
dt << Move Selected Column( after( "name" ) );
```

Note that Move Selected Column is an alias for Move Selected Columns.

You can also move columns without first selecting them in the data table by using the following syntax.

```
dt << Move Selected Columns( {"name"}, to first );
dt << Move Selected Columns( {"name"}, to last );
dt << Move Selected Columns( {"name"}, after( "name" ) );
```

You may use a list to specify the column names.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
list = {"name", "sex"};
```
Recode Columns

Use Recode Column to change all of the values in a column at once. Specify the original column, or reference column, a list of transformations, and a target column. The function applies the transformations to the reference column, updating the target column. If the Update Properties argument is turned on, the following column properties are updated when a column is recoded: Value Labels, Value Scores, Value Order, Value Colors, Supercategories, Coding, and Missing Value Codes.

```
obj << Recode Column(<column reference>, {<transform>, ...}, <Update Properties(0|1)>, Target Column(<column reference> | <column name>))
```

For example, in Consumer Preferences.jmp, change the coding of the Gender column to 0|1 instead of 1|2, but keep the value labels the same.

```
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
col = New Column( :Gender );
dt << Recode Column(
    :Gender,
    {if(
        _rcNow == 1, 0,
        1,
    )},
    Update Properties( 1 ),
    Target Column( col )
);
```

You can also make the transformations to the original column. Recode the age column to age groups in Big Class.jmp.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Recode Column(
    :age,
    {if(
        _rcNow >= 17, "Older",
        _rcNow >= 15, "Middle",
        "Younger"
    )},
    Target Column( :age )
);
```
Add a Column Switcher

Use JSL to add a Column Switcher panel to a report window. The Column Switcher lets you quickly analyze different variables without having to re-create your analysis.

```
// add a Column Switcher to the report
obj << Column Switcher(<default_col>(<col1>, <col2>, ...);

// remove the Column Switcher from a report
obj << Remove Column Switcher();
```

For example, add the Column Switcher to a Contingency report for the Car Poll.jmp data:

```
dt = Open( "$SAMPLE_DATA/Car Poll.jmp" );
obj = dt << Contingency(
    Y( :size ),
    X( :marital status )
);
ColumnSwitcherObject = obj << Column Switcher(
    :marital status,
    {:sex, :country, :marital status}
);
// number of pixels for the switcher width
ColumnSwitcherObject << Set Size( 200 );
// number of columns to display in the switcher
ColumnSwitcherObject << Set NLines( 6 );
```

You can also share a Column Switcher between two platform reports:

```
dt = Open( "$SAMPLE_DATA/Nicardipine.jmp" );
New Window( "Column Switcher Example",
    H List Box(
        sexCS = dt << Column Switcher( :Sex, {:Sex, :Causality, :Race} ),
        nDist = Distribution( Nominal Distribution( Column( :Sex ) ) ),
        bar = Graph Builder(
            Show Control Panel( 0 ),
            Variables( X( :Sex ), Y( :Age ) ),
            Elements( Box Plot( X, Y, Legend( 5 ) ) )
        ),
    )
);

sexCS << Link Platform( nDist );
sexCS << Link Platform( bar );
```

**Note:** If you are publishing reports that share a Column Switcher to JMP Public or JMP Live, add them to a dashboard instead of using JSL. See Using JMP.
For more information about the Column Switcher, see *Using JMP*.

## Compress Selected Columns

To minimize the size of a large data table, use the `Compress Selected Columns` message. Each column is compressed into the most compact form.

```julia
dt << Compress Selected Columns( {column name, column name} );
```

For example, compress the `age`, `sex`, `height`, and `weight` columns in *Big Class.jmp*:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Compress Selected Columns(
    {:age, :sex, :height, :weight}
);
```

For more information about this feature, see *Using JMP*.

## Create Custom Functions, Transforms, and Formats

You can create user-defined custom functions and then use them in the Formula Editor’s function list, in JSL scripting, as custom formats, and as custom transforms. Note that these custom functions can only be used in the context of the current JMP session. Restarting JMP removes previously defined custom functions. They must be defined and added for each session. An easy way to do this is to define your functions in an add-in or a startup script that runs each time you start JMP.

To define a custom function, use `New Custom Function()`. After a function is defined, you can add or activate it in the current running instance of JMP using `Add Custom Functions()`. Similarly, you can remove or deactivate a function using `Remove Custom Functions()`.

`New Custom Function()` requires three parameters: namespace, functionName, functionDefinition. Additional messages may be passed to define the following:

- Formula Editor values: Formula category, Result type, Parameters
- Custom transform values: Transform category
- Custom format values: Custom format category
- Scripting Index values: Description, Prototype, Scripting Index category, Examples

**Tip:** If you receive a data table that uses a custom transform, function, or format, you’ll see "###" in the column. The data table author must give you a script to add that custom item to your computer. Run the script and then reopen the data table.
Custom Function Example

Let’s create a completely specified function (including Scripting Index information and hint text). We will define the function first, then activate it.

```javascript
funcDef = Function( {x, y = 10}, x + y );
description = "This function adds 2 values. If only 1 argument is specified, the 2nd argument defaults to 10.";

// examples can be multiple statements inside expr()
ex2 = Expr(
   dt = Open( "SAMPLE_DATA/Big Class.jmp" );
   myNameSpace:Add Ten( :age[4], 20 );
);
parmHint1 = "x value";
parmHint2 = "<y=10>";

/* create function using variables
the commands can also be accepted as arguments in New Custom Function */
newAdd = New Custom Function( "myNamespace", "Add Ten", funcDef );
newAdd << Description( description );
newAdd << Prototype( "myNameSpace:Add Ten(x,<y=10>)" );
newAdd << Example( "myNameSpace:Add Ten(4)" );

// expr() Examples need to be passed inside NameExpr()
newAdd << Example( Name Expr( ex2 ) );
newAdd << Parameter( "Number", parmHint1 );
newAdd << Parameter( "Number", parmHint2 );
newAdd << Formula Category( "Number Stuff" );

// add myNamespace:Add Ten function to system
Add Custom Functions( newAdd );
```

Running the above example will write “Deploying function: myNamespace:Add Ten” in the JMP log. Search for this function in the Scripting Index to see the results of using the Description, Prototype, and Example messages.
The `Formula Category` message results in a new category in the Formula Editor’s list of formula categories. Custom functions are shown with an underline in the Formula Editor. Also see the hint text from the `Parameter` messages.

**Delete a Custom Function Example**

To delete a custom function, use `Remove Custom Functions( {"name"} )`.

```javascript
Remove Custom Functions( {"myNamespace:Add Ten"} );
```
Custom Transform Example

Let’s create a simple Custom Transform to multiply a value by 1,000. We embed the function definition inside `Add Custom Functions()`.

```
Add Custom Functions(
    New Custom Function(
        "custom", // namespace in which new function resides
        "x1000", /* function name. The completely scoped name is  
                "custom:x1000".*/

        Function( {x}, x * 1000 ),// function definition

        // optional message to enables this as a custom transform
        <<Transform Category( 1 )
    )
);
```

Running the above example writes “Deploying function: custom:x1000” in the JMP log. Search for this function in the Scripting Index to show that `custom:x1000` is an existing function.

When you create a new formula column in a data table, the custom transform appears as shown in Figure 9.15.

**Figure 9.15** Custom Transform in a Data Table
Custom Format Example: Multiplication

The last type of custom function is a custom format. You create custom formats using `New Custom Function()` and by specifying the `Custom Format Category(1)` message. Here’s an example that multiplies an input variable by 2 and also displays (x2) after the value. Note that, in this example, this function persists as a custom format and in the formula category “My New Category”. This allows you to use the format in a column formula or as a custom format.

```plaintext
/* add a New Custom Function, specifying it as a Custom Format show "(x2)" after the value in the data table */
Add Custom Functions(
   New Custom Function(
      "myNamespace",
      "Times 2",
      Function( {inputVar},
                 {Default Local},
                 Char( inputVar * 2 ) || " (x2)"
      ),
      <<Description( "Multiply input by 2. Display (x2) after the new value." )
      ),
      <<Formula Category( "My New Category" ),
      <<Custom Format Category( 1 ) // enable this as a custom format
   )
);
```

By specifying the `Custom Format Category(1)` message, this format now persists under the Custom Function category in the Format menu. Here’s what this looks like when applying this new Times 2 custom format in the Column Info window:
Suppose that you want to display dates in a format that isn’t provided in JMP. The following script formats a data to show the month, year, day, and day of week.

```plaintext
Add Custom Functions(
    New Custom Function(
        "myNamespace",
        "DateYMD_Day",
        Function( {inputVar},
            {Default Local},
            Char(
                Match( Month( inputVar ),
                    1, "January ",
                    2, "February ",
...
3, "March ",
4, "April ",
5, "May ",
6, "June ",
7, "July ",
8, "August ",
9, "September ",
10, "October ",
11, "November ",
12, "December ">

) || Char( Year( inputVar ) ) || ", Day#" || Char( Day( inputVar ) )
|| "-" ||
Char(
Match( Day Of Week( inputVar ),
1, "Sunday",
2, "Monday",
3, "Tuesday",
4, "Wednesday",
5, "Thursday",
6, "Friday",
7, "Saturday"
)
)
);

),
<<Description(
"Date format showing Month, Year, Day and Day of Week \nFor example, April 1930, Day#29-Tuesday"
),
<<Custom Format Category( 1 )
);

After you run the script, you can assign the format to a column of date values. In the Cols >
Column Info window, the new date format is in the Format > Custom Function menu. You
need to widen the data table column to be wide enough to display all of the characters.

Tip: See “Display Numbers as Four Digits” on page 417 for another example of creating a
custom format.

Delete Columns

To delete columns, send a Delete Columns message and specify which column or columns to
delete. To delete more than one column, list the columns as multiple arguments or as a list.
```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Delete Columns( "weight" );
dt << Delete Columns( "weight", "age", "sex" );
dt << Delete Columns( {"weight", "age", "sex"} );

Without an argument, Delete Columns deletes columns that were previously selected. See “Column Attributes” on page 414.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column("age") << Set Selected;
dt << Delete Columns();

Get Column Names

Column Name(n) returns the name of the n-th column.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column Name( 2 );
    age

The returned value is a name value, not a quoted string. What this means is you can use it anywhere you would normally use the actual name in a script. For example, you could subscript it:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column Name( 2 )[1];
    12

If you want the name as a text string, quote it with Char:

Char( Column Name( 2 ) );
    "age"

To retrieve a list of the names of all columns in a data table, submit Get Column Names.

dt << Get Column Names( argument );

where the optional argument controls the output of the Get Column Names function, as follows:

- Specify Numeric, Character, Row State, or Expression to include only those column data types.
- Specify Continuous-Ordinal-Nominal-Multiple Response- Unstructured Text, None, and Vector to include only those modeling types.
- Specify String to return a list of strings rather than column names.

For example, if you want to get numeric and continuous columns in the Big Class jmp sample data table, proceed as follows:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
```
Column Attributes

Use a collection of message pairs for data table columns to control all of the various attributes or characteristics of a column, including its name, data, states, and metadata. The messages come in pairs, one to “set” or assign each attribute and one to “get” or query the current setting of each attribute.

For example, you can hide, exclude, label, and turn on or off the scroll lock for a column through scripting. The value is Boolean; enter a one to turn the column attribute on, and a zero to turn it off.

In the following examples, the name column is unhidden, unexcluded, labeled, and locked from horizontal scrolling.

```julia
Column( "name" ) << Hide( 0 );
Column( "name" ) << Exclude( 0 );
Column( "name" ) << Label( 1 );
Column( "name" ) << Set Scroll Locked( 1 );
```

**Note:** All the messages to set various arguments (for example, Set Name, Set Values, Set Formula) start with Set. The word Set is optional for all messages except Set Name (recall that Name is already used for something else, the command that lets you use unusual characters in a name). Use whichever form you prefer or find easier to remember. The corresponding messages to retrieve the current value of an argument (for example, Get Formula) are the same, except that they start with Get instead of Set, and the word Get is not optional.

To deselect all selected columns, send a Clear Column Selection message to the data table object.

```julia
dt << Clear Column Selection;
```

Set or Get a Column Name

Set Name lets you name or rename a column, and Get Name returns the name for a column. The following example changes the name of the second column from age to ratio. It then returns the current column name to the log.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = Column( 2 );
col << Set Name( "ratio" );
col << Get Name;
"ratio"
```
Set or Get Column Values

Similarly, Set Values sets values for a column. If the variable is character, the argument should be a list. If the variable is numeric, the argument should be a matrix (vector). If the number of values is greater than the current number of rows, the necessary rows are added to the data table. Get Values returns the values in list or matrix form. Get As Matrix is similar to Get Values but returns values in the numeric columns.

```julia
col << Set Values( myMatrix ); // for a numeric variable
col << Set Values( myList ); // for a character variable
col << Get Values; // returns a matrix, or list if character
col << Get Matrix(<list of column names>|<list of column numbers>|<column range>; // returns the specified columns as a matrix
```

The following example returns a list and a matrix of values:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "name" ) << Values( {Fred, Wilma, Fred, Ethel, Fred, Lamont} );
myList = :name << Get Values;
{"Fred", "Wilma", "Fred", "Ethel", "Fred", "Lamont", "JAMES", "ROBERT", "BARBARA", ...}
Column( "age" ) << Values( [28, 27, 51, 48, 60, 30] );
myVector = :age << Get Values;
[28, 27, 51, ... ]
myMatrix = :weight << Get as Matrix;
[95, 123, 74, ... ]
```

Set or Get Value Labels

Note: For more information about value labels, see Using JMP.

Value labels provide a method of displaying a descriptive label for abbreviated data. For example, you might have a column of 0 and 1 values, where 0 represents a male and 1 represents a female. The value label “male” for 0 and “female” for 1 are more readable.

You can specify value labels in any one of the following three ways. Using the Big Class.jmp sample data table, assume that M maps to Male, and F maps to Female.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
:sex << Value Labels( {"F", "M"}, {"Female", "Male"} ); // use two lists
:sex << Value Labels( {"F", "Female", "M", "Male"} ); // use a list of pairs
:sex << Value Labels( {"F" = "Female", "M" = "Male"} ); // use a list of assignments
```

You can activate value labels by sending Use Value Labels as a message to the column.

```julia
:sex << Use Value Labels( 1 );
```
To revert back to showing the column’s actual values:

:sex << Use Value Labels( 0 );

The same message can be used for the data table to turn value labels on and off for all columns.

dt << Use Value Labels( 1 );

Set or Get Data and Modeling Types

You can set or get the data type of a column using JSL. The choices are character, numeric, and row state. The following example adds a new column that has a character data type to the Big Class.jmp sample data table.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "New" );
Column( "New" ) << Data Type( Character );
Column( "New" ) << Get Data Type;
"Character"

To set or get the modeling type of a column:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = New Column( "New" );
col << Modeling Type( "Continuous" );
col << Get Modeling Type;
"Continuous"

You can specify the format of a column when changing its data type:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = New Column( "Date" );
Column( "Date" ) << Data Type( Numeric, Format( "ddMonYYYY" ) );

Set or Get Formats

The Format message controls numeric and date/time formatting. The first argument is a quoted string from the list of format choices shown in the Column Info window. Subsequent arguments depend on the format choice. You can also set the field width by itself.

    col << Format( "Best", 5 ); // width is 5
    col << Format( "Fixed Dec", 9, 3 ); // width is 9, with 3 decimal places
    col << Format( "PValue", 6 );
    col << Format( "d/m/y", 10 );
    col << Set Field Width( 30 );

For date formats, the Format message sets how dates appear in a data table column. To set the format that you use for entering data, or for displaying the current cell when you have it selected for entry or editing, use the Input Format message.
col << Format( "d/m/y", 10 ); // display the date in day-month-year order
col << Input Format( "m/d/y" ); // enter the date in month-day-year order

For more information about date/time formatting choices, see “Date-Time Functions and Formats” on page 150 in the “Types of Data” chapter.

**Note:** Do not confuse the Format message for columns with the Format function for converting numeric values to strings according to the format specified (typically used for date/time notation as described in “Date-Time Functions and Formats” on page 150 in the “Types of Data” chapter). Sending a message to an object has a very different effect from using a function that might happen to have the same name.

To get the current format of a column, submit a Get Format message:

col << Get Format;

**Display Numbers as Four Digits**

The Format() function and the Format message have a custom format capability that enables you to provide your own script to do the formatting. The name of the format is “Custom” (rather than “Best”, “Fixed”, and so on) and the argument is a script that works with the variable named “value” to return a string to represent that value. To make positive or negative integers always have at least four digits by adding zeros, you could do this:

```
New Table( "Untitled",
    New Column( "Column 1",
        Numeric,
        "Continuous",
        Format("Custom", // make a custom format
            Formula( // using a JSL formula
                Local( {sign, length = 4, result}, // local variables
                    sign = If( value < 0, -1, 1 ); // handle negative numbers
                    value = Char( Abs( value ) );
                    If( Length( value ) > length, // handle too big
                        value = Repeat( "#", length )
                    );
                    result = Right( value, length, "0" ); // add zeros
                    If( sign < 0,
                        result = "-" || result // re-attach sign
                    );
                    result; // return the modified value
                )
            )
        )
    ),
);
```
// sample data to test positive, negative, zero
Set Values( [0, 3, -5, 33, -55, 333, -555, 3333, -5555, 33333, -55555] )

See “Create Custom Functions, Transforms, and Formats” on page 406 for more information about creating custom formats.

**Specify the Significant Digits in a Numeric Column**

Significant digits are the first nonzero digit and all succeeding digits. For example, 3.14159 has six significant digits, and 0.00314 has three significant digits.

Set the number of significant digits with the Precision column format:

```
Format( "Precision", 12, 3 ); // 12 wide with 3 significant digits
```

**Set, Get, or Evaluate a Formula**

The following examples show how to set, get, and evaluate a formula:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = New Column( "Ratio" ); // create column and stores its reference
col << Set Formula( :height/:weight ); // set the formula
col << Eval Formula; // evaluate the formula
col << Get Formula; // return the expression :height/:weight
```

To use the values from columns in scripts, be sure to add commands to evaluate the formula. Formula evaluation timing can differ between different versions of JMP.

**Notes:**

- When formulas are added, they are scheduled to be evaluated in a background task. This can be a problem for scripts if they depend on the column having the values while the script is running.
- To force a single column to evaluate, you can send an **Eval Formula** command to the column. You can do this inside the command to create the column, right after the Formula clause:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Ratio",
    Numeric,
    Formula( :height / :weight ),
    Eval Formula
 );
```

where **Formula()** is an alias for **Set Formula()**.

However, it is best to wait until you are finished adding a set of formulas, and then use the command **Run Formulas** to evaluate all of the formulas in their proper order, as follows:
dt << Run Formulas;

- The Run Formulas command is preferable to the Eval Formula command, because while it is evaluating the formulas, Eval Formula does not suppress the background task from evaluating them again. The formula dependency system background task takes great care to evaluate the formulas in the right order, and RunFormulas simply calls this task until all the formulas are finished evaluating.

- If you use random numbers and use the Random Reset(seed) feature to make a reproducible sequence, then you have another reason to use Run Formulas, in order to avoid a second evaluation in the background.

- If formula suppression is enabled with Supress Eval, turn it off to enable Eval Formula to run.

- The Add Custom Function() function enables you to create your own functions and display them in the Formula Editor’s Functions list. See “Create Custom Functions, Transforms, and Formats” on page 406.

### Set and Get Range and List Checks

You can manipulate list and range check properties using JSL. The following examples use the Big Class.jmp sample data table.

Set and clear the list check property in the sex column:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "sex" ) << List Check( {"M", "F"} ); // set the property
Column( "sex" ) << List Check(); // clear the property
```

Range checks require the specification of a range using the syntax in Table 9.3.

<table>
<thead>
<tr>
<th>To specify this range</th>
<th>Use this function</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a \leq x \leq b$</td>
<td>LELE(a, b)</td>
</tr>
<tr>
<td>$a \leq x &lt; b$</td>
<td>LELT(a,b)</td>
</tr>
<tr>
<td>$a &lt; x \leq b$</td>
<td>LTLE(a,b)</td>
</tr>
<tr>
<td>$a &lt; x &lt; b$</td>
<td>LTLT(a,b)</td>
</tr>
</tbody>
</table>

The following example specifies that the values in the age column must be greater than zero and less than 120:

```javascript
Column( "age" ) << Range Check( LTLT( 0, 120 ) );
```
All of the functions can be preceded by `Not` and one of them can be missing. The following example specifies that the values in the age column should be greater than or equal to 12:

```
Column( "age" ) << Range Check( not( LT( 12 ) ) );
```

To clear a range check state, submit an empty `Range Check()`:

```
Column( "age" ) << Range Check();
```

To retrieve the list or range check assigned to a column, send a `Get List Check` or `Get Range Check` message to the column:

```
Column( "sex" ) << Get List Check;
Column( "age" ) << Get Range Check;
```

Here is an example of `Get Range Check` for the age column in Big Class.jmp:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "age" ) << Range Check( LTLT( 0, 120 ) );
Column( "age" ) << Get Range Check;

Range Check( LTLT( 0, 120 ) )
```

Note that you can also use `Set Property`, `Get Property`, and `Delete Property` to set, retrieve, and remove list checks and range checks. See “Column Properties” on page 421.

**Note:** Operations sent through JSL that involve range check columns show any warnings in the log rather than in interactive windows.

### Get a Column Script

**Get Script** returns a script to create the column.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Column( "Ratio", Set Formula( :height/ :weight) );
Column( "Ratio" ) << Get Script;

New Column( "Ratio", 
            Numeric, 
            "Continuous", 
            Format( "Best", 10 ),
            Formula( :height / :weight )
            );
```

### Preselect Roles

To preselect a role on a column, use the `Preselect Role` message. Choices include No Role, X, Y, Weight, Freq, and Validation. The `Get Role` message returns the current setting.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = New Column( "New" );
col << Preselect Role( X );
col << Get Role;
```
Lock a Column or Cells

To lock or unlock a column, use Lock or Set Lock with a Boolean argument. Get Lock returns the current setting.

```jsx
col << Lock( 1 ); // lock
col << Set Lock( 0 ); // unlock
col << Get Lock; // show current state
```

Column Properties

Tip: JSL choices for properties are the same as those in the Column Properties menu in the Column Info window. The arguments for each property correspond to the settings in the Column Info window. An easy way to learn the syntax is to establish the property that you want in the Column Info window first, and then use Get Property to view the JSL. See Using JMP for more information about each property.

Data columns have numerous optional metadata attributes that can be set, queried, or cleared using the messages Get Property, Set Property, and Delete Property.

```jsx
col << Set Property( "propertyName", {argument list} );
col << Get Property( "propertyName" );
col << Delete Property( "propertyName" );
```

The name of the property in question is always the first argument for Set Property, and what is expected for subsequent arguments depends on which property you set:

- Get Property and Delete Property always take a single argument, which is the name of the property.
- Get Property returns the property’s settings. Delete Property completely removes the property from the column.
- To get a list of all column property names for a column, specify the column and then use Get Properties List.

If you want to set several properties, you need to send several separate Set Property messages. You can stack several messages in a single JSL statement if you want.

```jsx
col << Set Property( "Axis",{Min(50), Max(180)} )<< Set Property( "Notes", "to get proportions" );
```

To get a property’s value, send a Get Property message whose argument is the name of the property that you want:

```jsx
Column("ratio") << Get Property( "axis" ); // return axis settings
```

To set columns as label columns:

```jsx
dt << Set Label Columns( col1, col2, col3 );
```
To clear all label columns:

   dt << Set Label Columns();

The same syntax works for Set Scroll Lock Columns, and Scroll Lock.

**Set Column Properties with Variables**

When writing JSL to script a column property, it is important to understand that the column is a repository for all column properties. The column stores the column property with the values supplied without evaluation or validation of the supplied arguments. In order to add column properties that contains variables using JSL code, the script must convert any variables to their actual values.

One way to do this is to use expressions. In the following example, the Eval Expr() function evaluates and replaces any variable wrapped in the Expr() function with its value. The outer Eval() function evaluates the entire statement after the replacement has occurred.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
// assign desired spec limits
lLimit = 55;
uLimit = 70;
tLimit = 62.5;

Eval(
   Eval Expr(
      // store the limits in the Spec Limits column property
      :height << Set Property("Spec Limits",
      {LSL( Expr( lLimit ) ), USL( Expr( uLimit ) ), Target( Expr( tLimit ) ),
      Show Limits( 0 )
      });
   )
);
```

**Set and Get Column Properties**

Table 9.4 shows examples for setting and getting popular column properties. See Using JMP for more information about each property.
Table 9.4 Common Properties for Data Table Columns

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

</tr>
<tr>
<td><strong>Caution</strong>:</td>
<td>The matrix argument is the transpose of the profit matrix as displayed in the Column Properties window.</td>
<td></td>
</tr>
<tr>
<td><strong>Expression Role</strong></td>
<td>Applies to columns that contain expressions.</td>
<td>col&lt;&lt;Set Property( &quot;Expression Role&quot;, Expression Role( &quot;Picture&quot;, MaxSize( 640, 480 ), StretchToMaxSize( 1 ), PreserveAspectRatio( 1 ), Frame( 0 ) ) )</td>
</tr>
<tr>
<td><strong>Custom property</strong></td>
<td>Provided for custom uses. Corresponds to <strong>Column Properties &gt; Other</strong> in the Column Info window. The first argument is a name for the custom property, and the second argument is an expression.</td>
<td>col&lt;&lt;Set Property( &quot;Date recorded&quot;,12Dec1999 ) ; long date( col&lt;&lt;Get Property( &quot;Date recorded&quot; ) ) ;</td>
</tr>
</tbody>
</table>

**Specify Engineering SI Units**

The Engineering SI format displays the value with an appropriate SI suffix. For example, 3,100 is displayed as 3.1k. 0.0055 is displayed as 5.5m.
Rows

This section describes the messages for adding and manipulating the rows in a data table. Row messages are directed to a data table reference, and most act on the currently selected rows. A number of row messages might not be practical in scripting (for example, Move Rows).

- “Add Rows”
- “Delete Rows”
- “Select Rows”
- “Find Rows”
- “Move Rows”
- “Assign Colors and Markers to Rows”
- “Color Cells”
- “Hide, Exclude, and Label Rows”
- “Iterate on Rows in a Table”
- “Prevent Editing Rows”
- “Row States”

Add Rows

To add rows, send an Add Rows message and specify how many rows. You can also specify after which row to insert the new rows. The arguments can either be numbers or expressions that evaluate to numbers.

```javascript
dt << Add Rows( 3 ); // add 3 rows to bottom of data table
```
A variation of `Add Rows` lets you specify an argument yielding a list of assignments. Assignments can be separated with commas or semicolons.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Rows( { :name = "Peter", :age = 14, :sex = "M", :height = 61, :weight = 124 } );

or

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Add Rows( { :name = "Peter", :age = 14, :sex = "M", :height = 61, :weight = 124 } );
```

You can send several arguments yielding lists, or even a list of lists. The following script creates a data table with `Add Rows` commands of each variety:

```javascript
dt = New Table( "Cities" );
dt << New Column( "xx", Numeric );
dt << New Column( "cc", Character, width( 12 ) );

dt << Add Rows( { xx = 12, cc = "Chicago" } ); // single list
dt << Add Rows( // several lists
    { xx = 13, cc = "New York" }, { xx = 14, cc = "Newark" } );
dt << Add Rows( // list of lists
    {{ xx = 15, cc = "San Francisco" }, { xx = Sqrt( 256 ), cc = "Oakland" } });
a = { xx = 20, cc = "Miami"};
dt << Add Rows( a ); // evaluate as single list

b={{ xx = 17, cc = "San Antonio"}, { xx = 18, cc = "Houston"}, { xx = 19, cc = "Dallas"}};
dt << Add Rows( b ); // evaluate as list of lists
```

Further information for rows can be specified with messages described under “Row States” on page 441.
Delete Rows

To delete rows, send a `Delete Rows` message and specify which row or rows to delete. To delete more than one row, give a list or matrix as the `rownum` argument, or combine `Delete Rows` with other commands such as `For`. The `rownum` argument can be a number, list of numbers, range of numbers, matrix, or an expression that yields one of these. Without an argument, `Delete Rows` returns the number of selected rows and deletes those rows. When an argument is not specified or rows are not selected, `Delete Rows` only returns the number of selected rows: 0.

```
    dt << Delete Rows( 10 ); // delete row 10
    dt << Delete Rows( {11, 12, 13} ); // delete rows 11-13
    myList = {11, 12, 13};
    dt << Delete Rows( myList ); // delete rows 11-13
    dt << Delete Rows( 1 :: 20 ); // delete first 20 rows
    dt << Delete Rows( [1 2 3] ); // delete first 3 rows
```

For example, the following script opens Big Class.jmp and deletes row 10:

```
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    Selected( Row State( 10 ) ) = 1; // select row 10
    dt << Delete Rows;  // delete row 10
```

You can list duplicate rows, and you can list rows in any order with no consequence.

Here is a general way to remove the bottom \( x \) rows of a data table of any size. The following example removes five rows from the bottom of the data table:

```
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    x = 5;
    n = N Row( dt );
    For( i = n, i > n - x, i--, 
        dt << Delete Rows( i )
    );
```

`NRow` counts the rows in the table. See “Iterate a Script on Each Row” on page 439.

Select Rows

`Select All Rows` selects (or highlights) all of the rows in a data table.

```
    dt << Select All Rows;
```

If all rows are selected, you can deselect them all by using `Invert Row Selection`. This command reverses the selection state for each row, so that any selected rows are deselected, and any deselected rows are selected.

```
    dt << Invert Row Selection;
```
**Note:** With the exception of **Invert Row Selection**, whose result depends on the current selection, any new selection message starts over with a new selection. If you already have certain rows selected and you then send a new message to select rows, all rows are first deselected.

To select a specific row, use **Go To Row**:

```classic
dt << Go To Row( 9 );
```

To select specific rows in a data table based on their row number, use the **Select Rows** command. The argument to the command is a list of row numbers. For example, to select rows 1, 3, 5, and 7 of a data table:

```classic
dt << Select Rows( {1, 3, 5, 7} );
```

To select a range of rows, specify one of the following messages:

```classic
dt << Select Rows( Index( 7, 10 ) );
dt << Select Where( Any( Row() == Index( 7, 10 ) ) );
```

Both of these examples select rows seven through 10 in the current data table.

**Select Where**

To select rows according to data values, use **Select Where**, specifying a logical test inside the parentheses.

**Tip:** For a description of the functions and operators that you can use within a **Select Where** message, see “**Operators**” on page 103 in the “JSL Building Blocks” chapter.

For example, using the **Big Class.jmp** sample data table, select the rows where the students’ age is greater than 13:

```classic
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age > 13 );
```

Or, select the rows where the students’ ages are less than 14:

```classic
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
col = Column( dt, 2 );
dt << Select Where( col[] < 14 );
```

The following example selects the rows where the student’s ages are less than 15 and the sex is “F”:

```classic
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age < 15 & :sex == "F" );
```
To select a row without deselecting a previously selected row, combine `<< Select Where` with `<< Select Where` and the `Current Selection("extend")` argument. This is an alternative to using an OR statement.

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age == 14 );
dt << Select Where( :sex == "F", Current Selection( "extend" ) );
```

To select rows that contain specific strings, follow this example:

```julia
dt = Open( "SAMPLE_DATA/Hollywood Movies.jmp" );
my_genres = {"Romance", "Comedy"};
dt << Select Where( Contains( my_genres, :Genre ) );
```

You can also create more complex conditions by using regular expressions.

```julia
// select rows where :name begins with "j" or "J".
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
/* \0 is a group reference that causes the expression to return the entire matched text. !Is Missing is needed because the regex returns the matched text if it successfully matched or missing if it failed to match. So !Is Missing means the string successfully matched */
dt << Select Where( !Is Missing( Regex( :name, "^j", \0", IGNORECASE ) ) );

// select rows where :name ends with "N" or "E".
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( !Is Missing( Regex( :name, "(N|E)$", \0") ) );
```

### Select Excluded, Hidden, or Labeled Rows

To select rows that are currently excluded, hidden, or labeled:

```julia
dt << Select Excluded;
dt << Select Hidden;
dt << Select Labeled;
```

To select rows that are not excluded, hidden, or labeled, stack a select message and an invert selection message together in the same statement, or send the two messages sequentially:

```julia
dt << Select Hidden << Invert Row Selection;
dt << Select Hidden;
dt << Invert Row Selection;
```

### Select Duplicate Rows

To select duplicate rows in a data table, use the `Select Duplicate Rows` message:

```julia
dt = Open( "SAMPLE_DATA/San Francisco Crime.jmp" );
dt << Select Duplicate Rows(); // selects rows 301 and 8864
```
The second and subsequent duplicate rows are selected. Note that the duplicate values are case sensitive.

**Note:** By default, if no matching column is specified, all of the columns are matched.

In the preceding example, the duplicate rows might have been data input errors. Exclude the duplicate rows to remove them from the analysis:

```julia
dt = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
dt << Select Duplicate Rows();
dt << Exclude();
```

To select duplicate values in the rows of selected columns, specify the column names. The following example finds duplicate values in the rows of the Incident Number and Time columns.

```julia
dt = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
dt << Select Duplicate Rows( Match( Column( "Incident Number" ), :Time ) );
```

To select duplicate rows according to data values, select the duplicate rows, specify the data values, and then restrict the duplicate rows to the current selection.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Duplicate Rows( Match( :age ) );
dt << Select Where( :age > 15, Current Selection( "restrict" ) );
```

**Refer to a Specific Cell in the Row**

To refer to a specific cell, assign a subscript to the cell’s row number. In the following example, the subscript [1] is used with the weight column. The formula then calculates the ratio between each height and the first value in the weight column.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Column( "ratio", Formula( height / weight[1] ) );
```

**Select Random Rows**

To obtain a random selection, use this syntax:

```julia
dt << Select Randomly( number );
dt << Select Randomly( Sample Size( number ) );
dt << Select Randomly( probability );
dt << Select Randomly( Sampling Rate( probability ) );
```

These commands use a conditional probability to obtain the exact count requested.

**Select Matching Cells**

The row menu command **Select Matching Cells** is also implemented in JSL.
// select matching cells in the current data table
dt << Select Matching Cells;
// select matching cells in all open data tables
dt << Select All Matching Cells;

For more complicated selections, or to store selections permanently as row state data, see “Row States” on page 441.

Find Rows

Get Rows returns a matrix of rows that match the specified condition. The following example select rows in which the age is greater than or equal to 16:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Get Rows Where( :age >= 16 );
[35, 36, 37, 38, 39, 40]
```

Get Selected Rows returns a matrix of the currently selected rows. The following example selects rows 1, 3, 5, and 7 and then returns the row numbers in a matrix:

```julia
dt << Select Rows( {1, 3, 5, 7} );
dt << Get Selected Rows;
[1, 3, 5, 7]
```

Find Selected Rows

Next Selected and Previous Selected scroll the data table window up or down so that the next selected row that is not already in view moves into view. The table wraps, so Next Selected jumps from the bottom-most selected row to the top-most, and vice versa for Previous Selected.

```julia
dt << Next Selected;
dt << Previous Selected;
```

Clear Selected Rows

To cancel a selection, leaving no rows selected, use Clear Select:

```julia
dt << Clear Select;
```

Move Rows

These commands move the currently selected rows to the indicated destination point.

```julia
dt << Move Rows( At Start );
dt << Move Rows( At End );
dt << Move Rows( After( rowNumber ) );
```
Assign Colors and Markers to Rows

You can use the `Colors` and `Markers` messages to assign (or change) colors and markers used for rows. These settings mostly affect graphs produced from the data table. Both messages expect numeric arguments to choose which color or marker to use. For more information about how numbers correspond to colors and markers, see “Colors and Markers” on page 451.

```jl
dt << Colors( 3 ); // set selected rows to red
dt << Markers( 2 ); // pick the X marker for selected rows
```

As with other row messages, you can stack selection and other messages together:

```jl
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age == 12 ) // select the youngest subjects
    << Colors( 8 ) << Markers( 8 ); // and use purple open circles for them
```

Color by Column sets colors according to the values of a column that you specify, and Marker by Column works similarly:

```jl
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Color by Column( :age );
dt << Marker by Column( :age );
```

Here are additional, named arguments:

- **Continuous Scale** (Color by Column only) Assigns colors in a chromatic sequential fashion based on the values in the highlighted column.
- **Reverse Scale** Reverses the color scheme in use.
- **Make Window with Legend** Creates a separate window with a legend.
- **Excluded Rows** Applies the row states to excluded rows.
- **Marker Theme** Specifies the marker type.
- **Color Theme** Specifies the color theme.

Color Cells

You can color individual cells in the data grid. For example, this line uses the row state color to color the cells:

```jl
dt << Color Rows by Row State;
```

You can also specify a color theme for either categorical or continuous columns:

```jl
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
:height << Set Property(
    "Color Gradient",
    {"White to Blue", Range( 40, 80 )}
);
```
You can also color specific cells. The following example sets rows 1, 5, 8 of the “name” column to red:

```julia
:name << Color Cells( red, {1, 5, 8} );
```

To remove the color from specific cells, set the color to black. The following example removes the color for row 1 of the “name” column.

```julia
:name << Color Cells( black, {1} );
```

You can color cells based on specific values. The following example colors the cells in the `height` column. All cells containing a value greater than 60 are blue. All cells containing a value equal to or less than 60 are purple.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For( i = 1, i <= N Row( dt ), i++,
    If( Column( dt, "height" )[i] > 60,
        Column( dt, "height" ) << Color Cells( 5, {i} ),
        Column( dt, "height" ) << Color Cells( 8, {i} )
    )
);
```

**Note:** The first argument for `Color Cells` represents the color value. The second argument contains the row numbers.

### Hide, Exclude, and Label Rows

**Note:** For more information about hiding, excluding, and labeling rows using row state functions, see “Row States” on page 441.

Use the `Hide`, `Exclude`, and `Label` messages to hide, exclude, and label rows. These messages are toggles, meaning that to turn the messages on you send them once, and to turn them off you send the message a second time. They also accept Boolean arguments to explicitly turn them off and on.
For example, to hide all rows in Big Class where age is greater than 13, you could do the following:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age > 13 );
dt << Hide( 1 );
```

Messages to the same object can be stacked together in a single statement, so you could simplify the preceding script.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age > 13 ) << Hide( 1 );
```

### Iterate on Rows in a Table

In addition to built-in programming functions for iterating, JSL provides functions for iterating through data table rows, groups, or conditional selections of rows.

Generally, an expression is executed on the current row of the data table only. Some exceptions are the expressions inside formula columns, `Summarize` and the pre-evaluated statistics functions, and any use of data table columns by analysis platforms.

### Set the Current Row

**Note:** The current row for scripting is *not* related to rows being selected (or highlighted) in the data table or to the current cursor position in the data table window. The current row for scripting is defined to be zero (no row) by default.

You can set the current row for a script using `For Each Row` or `Row() = X`.

```javascript
Row() = 3; ...
For Each Row( ... );
```

`For Each Row` executes the script once for each row of the current data table. Note that `Row()=1` only lasts for the duration of the script, then `Row()` reverts to its default value, which is zero. This means that submitting a script all at once can produce different results than submitting a script a few lines at a time.

Throughout this chapter, examples without an explicit current row should be assumed to take place within a context that establishes a current row. See “What is the Current Row?” on page 438.
What is the Current Row?

By default, the current row number is 0. The first row in a table is row 1, so row 0 is essentially not a row. In other words, *by default, an operation is done on no rows*. Unless you take action to set a current row or to specify some set of rows, you get missing values due to the lack of data. For example, a column name returns the value of that column on the current row. Scope the column name with the prefix `:` operator to avoid ambiguity (to force the name to be interpreted as a column name).

```plaintext
:sex; // returns ""
:age; // returns .
```

Scoping names prevents you from getting a result that might look reasonable for the whole data table but is actually based on only one row. It also protects you from accidentally overwriting data values when making assignments to ambiguous names under most circumstances. You can have even more complete protection by using the prefix or infix `:` operator to refer specifically to a data column and the prefix `::` operator to refer specifically to a global script variable. See “Advanced Scoping and Namespaces” on page 272 in the “Programming Methods” chapter.

You can use the `Row()` function to get or set the current row number. `Row()` is an example of an *L-value* expression in JSL: a function that returns its value unless you place it before an assignment operator (`=`, `+=`, and so on.) to set its value.

```plaintext
Row(); // returns the number of the current row (0 by default)
x = Row(); // store the current row number in x
Row() = 7; // make the 7th row current
Row() = 7; :age; // make the 7th row current and returns 12
```

Note that the current row setting only lasts for the portion of a script that you select and submit. After the script executes, the current row setting resets to the default (row 0, or no row). Therefore, a script submitted all at once can produce different results from the same script submitted a few lines at a time.

How Many Rows and Columns?

The `N Rows()` and `N Cols()` functions return the rows and columns in a data table.

```plaintext
N Rows( dt ); // number of rows
N Cols( dt ); // number of columns
```

`N Rows` and `N Cols` also count the number of rows in matrices. Note that `NRow` and `NCol` are synonyms. See the “Inquiry Functions” on page 208 in the “Data Structures” chapter.
Iterate a Script on Each Row

To iterate a script on each row of the current data table, put For Each Row around the script.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( If( :age > 15, Show( :age ) ) );
```

To specify the open data table, include a data table reference as the first argument.

```julia
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
For Each Row( dt1, If( :age > 15, Show( :age ) ) );
```

You can use For Each Row to set row states instead of creating a new formula column in the data table. The scripts below are similar, except that the first one creates a row state column, and the For Each Row script simply sets the row state without creating a column.

```julia
New Column( "My Row State", Row State, Formula( Color State( :age - 9 ) ) );
For Each Row( Color of( Row State() ) = :age - 9 );
```

To iterate a script on each row that meets a specified condition, combine For Each Row and If:

```julia
For Each Row( Marker of( Row State() ) = If( :sex == "F", 2, 6 ) );
```

You can use Break and Continue to control the execution of a For Each Row loop. See “Break and Continue” on page 124 in the “JSL Building Blocks” chapter.

Return Row Values

Dif() and Lag() are special functions that can be useful for statistical computations, particularly when working with time series or cumulative data.

- Lag() returns the value of a column n rows before the current row.
- Dif() returns the difference between the value in the current row and the value n rows previous.

The following lines are equivalent:

```julia
dt  <<  New Column( "htDelta" );
For Each Row( :htDelta = :height - Lag( :height, 1 ) );
For Each Row( :htDelta = Dif( :height, 1 ) );
```

Add Sequence Data

Sequence() corresponds to the Sequence function in the Formula Editor and is used to fill the cells in a data table column. It takes four arguments and the last two are optional:

```julia
Sequence( from, to, stepsize, repeat );
```
From and to are not optional. They specify the range of values to place into the cells. If from = 4 and to = 8, the cells are filled with the values 4, 5, 6, 7, 8, 4, ...

Stepsize is optional. If you do not specify a stepsize, the default value is 1. Stepsize increments the values in the range. If stepsize = 2 with the above from and to values, the cells are filled with the values 4, 6, 8, 4, 6, ...

Repeat is optional. If you do not specify a Repeat, the default value is 1. Repeat specifies how many times each value is repeated before incrementing to the next value. If repeat = 3 with the above from, to, and stepsize values, the cells are filled with the values 4, 4, 4, 6, 6, 6, 8, 8, 8, 4, .... If you specify a Repeat value, you must also specify a Stepsize value.

The sequence is always repeated until each cell in the column is filled.

```r
dt = New Table( "Sequence Example" ); // create a new data table
dt << New Column( "Count to Five" ); // add two columns
dt << New Column( "Count to Seventeen by Fours" );
dt << Add Rows( 50 ); // add fifty rows

/* fill the first column with the data sequence 1, 2, 3, 4, 5, ...
fill the second column with the data sequence 1, 1, 5, 5, 9, 9, 13, 13, 17, 17, ...
*/
For Each Row (  
  Column( 1 )[ ] = Sequence( 1, 5 );  
  Column( 2 )[ ] = Sequence( 1, 17, 4, 2 );  
);
```

Because Sequence() is a formula function, you can also set a column's formula to use Sequence() to fill the column. The following example creates a new column named Formula Sequence and adds a formula to it. The formula is a sequence that fills the column with values between 25 and 29, incremented by 1, and repeated twice (25, 25, 26, 26, 27, 27, 28, 28, 29, 29, 25, ...).

```r
dt = New Table( "Formula Sequence Example" );
dt << Add Rows( 20 );
dt << New Column( "Formula Sequence", Formula( Sequence( 25, 29, 1, 2 ) ) );
```

The following are more examples of Sequence() results:

- **Sequence(1,5)** produces 1,2,3,4,5,1,2,3,4,5,1, ...
- **Sequence(1,5,1,2)** produces 1,1,2,2,3,3,4,4,5,5,1,1, ...
- **Sequence(10,50,10)** produces 10,20,30,40,50,10, ...
- **10*Sequence(1,5,1)** also produces 10,20,30,40,50,10, ...
- **Sequence(1,6,2)** produces: 1,3,5,1,3,5, ... The limit is never reached exactly.

**Note:** If you want a matrix of values, then use the Index function, not Sequence.
Prevent Editing Rows

To prevent adding or deleting rows, use `Set Edit Lock`:

```
  dt << Set Edit Lock( "add rows", "delete rows" );
```

See “Prevent Changes to a Data Table” on page 362 for more information about preventing other data table operations.

Row States

There is a special data element type called a row state that stores various attributes in the data table. Row states can indicate the following:

- Whether a row is selected, excluded, hidden, or labeled
- Which marker type, color, shade, and hue to use for graphs

In JSL, you can use row state functions to manipulate row states.

About Row States

Row states change how JMP works with your data. Table 9.6 explains each row state. Remember that you can use several row states at once to get the combination of effects that you want.

Table 9.6  Row States

<table>
<thead>
<tr>
<th>Row states</th>
<th>How they affect results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excluded</td>
<td>If rows are excluded, JMP omits them from calculations for statistical analyses (text reports and charts). Results are the same as if the data was not entered. However, points are still included in plots. (To omit points from plots, use <code>Hide</code>. To omit points from all results, use both <code>Exclude</code> and <code>Hide</code>.)</td>
</tr>
<tr>
<td>Hidden</td>
<td>If rows are hidden, JMP does not show them in plots. However, the rows are still included in text reports and charts. (To omit points from reports and charts, use <code>Exclude</code>. To omit points from all results, use both <code>Exclude</code> and <code>Hide</code>.)</td>
</tr>
<tr>
<td>Labeled</td>
<td>If rows are labeled, JMP places row number labels, or the values from a designated Label column, on points in scatterplots.</td>
</tr>
</tbody>
</table>
### Table 9.6  Row States  *(Continued)*

<table>
<thead>
<tr>
<th>Row states</th>
<th>How they affect results</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Color</strong></td>
<td>If rows have colors, JMP uses those colors to distinguish the points in scatterplots.</td>
</tr>
<tr>
<td><strong>Marker</strong></td>
<td>If rows have markers, JMP uses those markers to distinguish the points in scatterplots.</td>
</tr>
<tr>
<td><strong>Selected</strong></td>
<td>If rows are selected, JMP highlights the corresponding points and bars in plots and charts.</td>
</tr>
</tbody>
</table>

**Note:** For row state messages, omitting the argument *toggles* the option: if the option is off, the message turns it on, and if the option is on, the message turns it off. You can also use the "*toggle"", "*switch"", or "*flip" argument, as in `r << Exclude( "toggle" )`. 
About Row State Functions

When you give a row state function a number as its argument (or an expression that evaluates to a number), the function interprets that number as an index to its possible values.

Table 9.7 shows a comparison chart of the different row state functions, so that you can see which functions convert row states to numbers and numbers to row states. It also includes the numbers that you can use with each function.

<table>
<thead>
<tr>
<th>Numbers</th>
<th>Convert from numbers to row states</th>
<th>Row states</th>
<th>Convert from row states to numbers</th>
<th>Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or 0</td>
<td>Excluded State($n$)</td>
<td>Excluded</td>
<td>Excluded(rowstate)</td>
<td>1 or 0</td>
</tr>
<tr>
<td>1 or 0</td>
<td>Hidden State($n$)</td>
<td>Hidden</td>
<td>Hidden(rowstate)</td>
<td>1 or 0</td>
</tr>
<tr>
<td>1 or 0</td>
<td>Labeled State($n$)</td>
<td>Labeled</td>
<td>Labeled(rowstate)</td>
<td>1 or 0</td>
</tr>
<tr>
<td>1 or 0</td>
<td>Selected State($n$)</td>
<td>Selected</td>
<td>Selected(rowstate)</td>
<td>1 or 0</td>
</tr>
<tr>
<td>0 to 31</td>
<td>Marker State($n$)</td>
<td>Marker</td>
<td>Marker Of(rowstate)</td>
<td>0 to 31</td>
</tr>
</tbody>
</table>
Assign Row States

To assign a row state using JSL, use `Select Where` to indicate which rows are affected, and then specify which row state to assign to the rows. In the following example, marker type 5 (a triangle) is assigned to rows in which `sex` is “F”.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :sex == "F" ) << Markers( 5 );
```

You can also use a formula to assign row states. Here is how you would do it in the data table:

1. Create a row state column.
2. Add a formula to the column that assigns a marker to each row in which sex is “F”.
3. In the Column panel, right-click the star next to the row state column and select **Copy to Row States**.

The JSL equivalent would be something like this:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Row State",
    Row State,
    Set Formula( If( :sex == "F", Marker State( 4 ) ) )
);
Column( "Row State" ) << Copy To Row States();
```

**Store Row State Information**

A row state column is a dedicated column that *stores* row state information, but does not put the information into effect. You can then use **For Each Row** to put the row state column into effect. For more information about row state columns, see *Using JMP*.

The following example creates a row state column then puts the row states into effect:

1. Submit this line to start a new data table:
   ```javascript
dt = New Table( "Row State Testing" );
```
2. Submit these lines to add row states to a column and add ten rows:
   ```javascript
dt << New Column( "Row State Data", Row State, Set Formula( Color State( Row() ) ) );
dt << Add Rows( 10 );
```
3. Submit this line to put the row states into effect:
   ```javascript
For Each Row( Row State() = :Row State Data );
```

**Figure 9.17** Table with No Row States (left) and Table with Row States (right)

This action replaces any row states in effect with the row state combination from the row state column. For more information about how to change selected attributes of a row state without changing or canceling others, see “Set One Characteristic and Cancel Others” on page 449.
Set or Get Row States

From JSL, you can set or get row states directly using the `Row State` function. You can set or get the state for row \( n \) with `Row State(n)`. If you do not supply an argument, you set or get the current row. To work with all rows, either use a `For Each Row` loop or work with formula columns.

To set a row state, place the row state expression on the left of an assignment (L-value):

\[
\text{Row State( 1 ) = Color State( 3 ); // make row 1 red}
\]
\[
\text{Row() = 8; Row State() = Color State( 3 ); // make the 8th row red}
\]
\[
\text{For Each Row( Row State() = Color State( 3 ); // make each row red}
\]

To specify the data table, include a data table reference as the first argument:

\[
\text{dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );}
\]
\[
\text{dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );}
\]
\[
\text{Row State( dt1, 1 ) = Color State( 3 ); // make row 1 red;}
\]

To get a row state, place the row state expression on the right side of an assignment:

\[
\text{x = Row State( 5 ); // put the row state of row 5 into x}
\]
\[
\text{x = Row State(); // row state of current row}
\]

Notes on Setting Row States

Be careful whether you set every aspect of `Row State()` or just one aspect of it, such as `Color Of( Row State() )`. To see how this works, first color and mark all the rows:

\[
\text{dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );}
\]
\[
\text{For Each Row(}
\]
\[
\text{\hspace{1em}Row State() = Combine States( Color State( Row() ), Marker State( Row() ) ) ;}
\]
\[
\text{)}
\]

And now observe the difference between setting one attribute of a row state:

\[
\text{Color Of( Row State( 1 ) ) = 3; // make row 1 red without changing marker}
\]

And setting every aspect of a row state to a single state:

\[
\text{Row State( 1 ) = Color State( 5 ); // make row 1 blue and remove its marker}
\]

To copy all the current row states into a row state column:

\[
\text{dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );}
\]
\[
\text{For Each Row(}
\]
\[
\text{\hspace{1em}dt1,}
\]
\[
\text{\hspace{2em}Row State() = Combine States(}
\]
\[
\text{\hspace{3em}Color State( Row() ),}
\]
\[
\text{\hspace{3em}Marker State( Row() )}
\]
\[
\text{)}
\]
dt1 << New Column( "rscol", "Row State", Set Formula( Row State() ) );

To copy several but not all of the current row states into a row state column, use a script like the following (commenting out or omitting any states that you do not want):

New Column( "rscol2",
    Set Formula(
        Combine States(
            Color State( Color Of() ),
            Excluded State( Excluded() ),
            Hidden State( Hidden() ),
            Labeled State( Labeled() ),
            Marker State( Marker Of() ),
            Selected State( Selected() )
        )
    )
);

To set a component of a row state:

    Color Of( Row State( i ) ) = 3; // change color to red for row i
    Selected( Row State( i ) ) = 1; // select the ith row state and set to 1

You can see from the example above that some of the functions convert numbers into states, and others convert states into numbers. Here are some helpful hints for remembering which are which:

**Number-to-state functions have the word “State”** Functions that take number arguments and either return states or accept state assignments all have the word “State” in their names: Row State, As Row State, Color State, Combine States, Excluded State, Hidden State, Hue State, Labeled State, Marker State, Selected State, Shade State.

**State-to-number functions are one word or have the word “Of”** Functions that take row state arguments (and assume that the argument Row State() if none is given) and functions that return or are set to numbers are either one word, or their second word is “Of”: Color Of, Excluded, Hidden, Labeled, Marker Of, Selected.

Table 9.7 on page 443 is a helpful comparison chart for these functions.

The following lines are equivalent to their interactive commands:

Copy From Row States
Add From Row States
Copy To Row States
Add To Row States

**Examples of Getting Row States**

For example, create the following table containing row states:
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Row State Data", Row State, Set Formula( Color State( Row() ) ) );
dt << Add Rows( 10 );
For Each Row( Row State() = :Row State Data );

To get row states, submit the following lines:

Row State( 1 ); // returns row state for row 1
Row() = 8; Row State(); // returns row state for current (8th) row
For Each Row( Print( Row State()) ); // returns the row states for each row

To get a row state and store it in a global, place Row State() on the right side of an assignment. Add the following lines to the preceding script:

::x = Row State( 1 ); // put the row state of row 1 in x, a global
Row() = 8; ::x = Row State(); // put the row state of the 8th row in x
Show( x ); // returns x = Color State( 8 )
dt << New Column( "rscol", Row State );
// put row states in rscol (a row state column)
For Each Row( :rscol = Row State() );

To get a component of a row state, place the row state expression on the right side of an assignment and also use one of the L-value operators:

x = Selected( Row State() ); // selection index of current row selected

**Get and Set Multiple Characteristics at Once**

You can get or set many characteristics at once by combining state settings inside Combine States(). You can also get or set each characteristic one at a time, the ultimate row state being the accumulation of characteristics. The following example sets green Y markers for males, but hides them in plots for row. It also sets red X markers for females but shows them in plots.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row(
    If( sex == "M",
        /* then */ Row State() = Combine States(
            Color State( 4 ), Marker State( 6 ), Hidden State( 1 ) ),
        /* else */ Row State() = Combine States(
            Color State( 3 ), Marker State( 2 ), Hidden State( 0 ) )
    ),
);

Get the row state for one row, such as the 6th:

Row State( 6 );
Combine States(Hidden State(1), Color State(4), Marker State(6))

Notice that JMP returns a Combine State() combination. This is because a row state datum is not just the state of one characteristic, such as color, but the cumulative state of all the characteristics that have been set: exclusion, hiding, labeling, selection, markers, colors, hues, and shades. A list of such characteristics is called a row state combination.
Just as there can be many row state characteristics in effect, a row state column can have multiple characteristic row states as its values.

**Set One Characteristic and Cancel Others**

In addition to the overall `Row State()` function for getting or setting all the characteristics of a row state, there are separate functions to get or set one characteristic at a time preemptively. That is, to give a row one characteristic, canceling any other characteristics that might be in effect. The functions that set one characteristic and cancel others are `Color State`, `Combine States`, `Excluded State`, `Hidden State`, `Hue State`, `Labeled State`, `Marker State`, `Selected State`, `Shade State`.

For example, to make row 4 be hidden only:

```plaintext
Row State( 4 ) = Hidden State( 1 );
```

**Set or Get One Characteristic at a Time**

A row state is not just one characteristic, but many. To work with just one characteristic at a time, use one of the L-value operators with `Row State` on either side of the equal sign. The side of the equal sign depends on whether you want to get or set a characteristic. There is an L-value operator for each of the following characteristics: `Color Of`, `Excluded`, `Hidden`, `Labeled`, `Marker Of`, `Selected`.

This example hides row 4 without affecting any other characteristics:

```plaintext
Hidden( Row State( 4 ) ) = 1
```

This example stores the color of row 3 without getting any other characteristics:

```plaintext
::color = Color Of( Row State( 3 ) );
```

**Identify Row State Changes**

The `MakeRowStateHandler` message (sent to a data table object) obtains a callback when the row states change. For example,

```plaintext
f = Function( {X}, Show( x ) );
obj = dt << Make Row State Handler( f );
```

Then when you select a group of rows, the row numbers of any row whose row state changed are sent to the log. For example:

```plaintext
x: [3, 4, 28, 40, 41]
```

When a group is highlighted, it might call the handler twice, once for rows whose selection is cleared, then again for the new selection.
Exclude, Hide, Label, and Select

This section discusses conditions that have Boolean states (either on or off). These conditions include: excluding, hiding, labeling, and selecting rows.

- **Excluded** gets or sets an excluded index. The index is 1 for true or 0 for false, indicating whether each row is excluded.
- **Hidden** gets or sets a hidden index, which is 1 for hidden or 0 for not hidden.
- **Labeled** gets or sets a labeled index, which is 1 for labeled or 0 for not labeled.
- **Selected** gets or sets a selected index, which is 1 for selected or 0 for not selected.

The following examples illustrate these conditions:

```plaintext
Excluded( Row State() ); // returns 1 if current row is excluded, 0 if not
Hidden();               // returns 1 if current row is hidden, 0 if not
Labeled( Row State() );  // returns 1 if current row is labeled, 0 if not
Selected();            // returns 1 if current row is selected, 0 if not

Excluded( Row State() ) = 1; // exclude current row
Hidden() = 0;              // unhide current row
Labeled( Row State() ) = 1; // label current row
Selected() = 0;            // deselect current row
```

Remember that these functions assume the argument `Row State()` if none is given.

**Excluded State**, **Hidden State**, **Labeled State**, and **Selected State** do the reverse; they get or set a row state condition as true or false according to the argument. Nonzero values set the row state to true, and zero values set it to false. Missing values result in no change of state.

```plaintext
Row State() = Excluded State( 1 ); // change current row state to excluded
Row State() = Hidden State( 0 );   // change current row state to not hidden
Row State() = Labeled State( 1 );  // change current row state to labeled
Row State() = Selected State( 0 ); // change current row state to not selected
```

Notice that the first two expressions above replace the row state with just the exclusion or just the unhiding, so that any preexisting row state characteristics are lost. More commonly, you would issue the `state` commands for all of the characteristics that you want inside a `Combine States`. The following example changes the third row to hidden and a green square marker:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Row State( 3 ) = Combine States(
    Color State( 4 ),
    Marker State( 3 ),
    Hidden State( 1 )
);```
Another common way to use a -State command would be in a row state data column whose values could be added to the row state (for cumulative characteristics). The following example excludes each odd numbered row:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "myExcl",
   Row State,
   Set Formula( Excluded State( Modulo( Row(), 2 ) ) )
);
For Each Row( Row State() = Combine States( :myExcl, Row State() ) );
```

### Clear Row States

Clear Row States() removes row states from the data table. The following script assigns a row state to each row and then removes the row state.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( Row State() = Color State( Row() ) );
Wait( 3 ); // pause for demonstration purposes
dt << Clear Row States();
```

To clear row states for selected rows, select the rows first and then clear the selected row states.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( Row State() = Color State( Row() ) );
dt << Select Rows( [ 5 ] );
Wait( 3 ); // pause for demonstration purposes
dt << Clear Selected Row States();
```

### Colors and Markers

This section discusses conditions that have many choices. These conditions include: coloring, adding markers, different hues, or different shades to rows.

Color Of() returns or sets the color index. The color index is a number from the JMP color map that corresponds to the row state, or a missing value if there is no assigned color.

```julia
Color Of( Row State() );  // returns color index for current row
Color Of() = 4;            // set current row to Color 4
```

Similarly, Marker Of returns or sets the marker index. The marker index is a number from the JMP marker map that corresponds to the active marker, or a missing value if there is no assigned marker.

```julia
Marker Of();               // returns marker index for current row
Marker Of( Row State() ) = 4; // set current row to Marker 4
```
Both `Color Of()` and `Marker Of()` accept any row state expression or column or `Row State()` as arguments. They also assume the argument `Row State()` if none is given (some examples are shown with, and some without).

`Color State()` and `Marker State()` are similar to `Color Of()` and `Marker Of()`, except they work in the opposite direction. Where the `Of()` functions turn actual states into indices, the `-State` functions turn indices into states.

```plaintext
Row State() = Color State( 4 );  // change current row to green
Row State() = Marker State( 4 ); // change current row to the diamond marker
```

Notice that the last two commands replace the row state with just the color or just the marker, so that any preexisting row state characteristics are lost. More commonly you would issue the `-State` commands for all the characteristics that you want inside a `Combine States()`.

The following example puts a green square marker in the third row and hides the row:

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Row State( 3 ) = Combine States(  
    Color State( 4 ),
    Marker State( 3 ),
    Hidden State( 1 ) );
```

The following script shows the standard JMP markers, which are numbered 0–31. Indices outside the range 0–31 have undefined behavior.

```plaintext
New Window( "Markers",  
    Graph Box(  
        FrameSize( 300, 300 ),
        Y Scale( -1, 16 ),
        X Scale( 0, 7 ),
        For(  
            i = 0;
            jj = 15;,
            i < 16;
            jj >= 0;,
            i++; jj--;  // 16 rows, 2 columns
            Marker Size( 3 );
            Marker( i, {1, jj + .2} ); // markers 0-15
            Marker( i + 16, {4, jj + .2} ); // markers 16-31
            Text( {1.5, jj}, "marker ", i ); // marker labels 0-15
            Text( {4.5, jj}, "marker ", i + 16 ); // marker labels 16-31
        )  
    ));
```
Tip: For more information about this script, see the “Display Trees” chapter on page 517.

Note the following about colors:

- JMP colors are numbered 0 through 84.
- The first 16 named colors are the basic colors. See the script below.
- Numbers higher than 16 are darker or lighter shades of the basic colors.
- Indices outside the range 0–84 have undefined behavior.
- For more information about using JMP colors, see “Specify Colors” on page 659 in the “Scripting Graphs” chapter.

The following script illustrates the standard JMP colors:

```plaintext
Text Color( 0 );
New Window( "Colors",
    Graph Box(
        FrameSize( 640, 400 ),
        Y Scale( -1, 17 ),
        X Scale( -3, 12 ),
        k = 0;
        For( jj = 1, jj <= 12, jj += 2,
            l = 15;
            For( i = 0, i <= 15 & k < 85, i++,
                thiscolor = Color To RGB( k );
                Fill Color( k );
                thisfill = 1;
                If( thiscolor == {1, 1, 1},
                    Pen Color( 0 );
                )
            )
        )
    )
);
thisfill = 0;
,
   Pen Color( k )
);
Rect( jj, l + .5, jj + .5, l, thisfill );
Text( {jj - 1, l}, "color ", k );
k++; l--;
);

jj = -2;
For(
   i = 0;
   l = 15;, i <= 15 & l >= 0,
   i++;
l--;
   Text( {jj, l}, color[i + 1] )
);
)
);

Figure 9.19 JMP Colors
If you prefer to use RGB values, each color should be a list with percentages for each color in red, green, blue order. For example, the following percentages produce a teal color:

```plaintext
Pen Color( {.38,.84,.67} ); // a lovely teal
```

**Hue and Shade Example**

Hue State and Shade State together are an alternative to Color State for choosing colors. You cannot select black, white, or the shades of gray when you use Hue State. For these, you must use Shade State alone, or Color State.

The following script demonstrates how hue and shade values relate to colors:

```plaintext
New Window( "Hues and Shades",
    Graph Box(
        FrameSize( 600, 300 ),
        Y Scale( -3, 3 ),
        X Scale( -2, 12 ),
        k = 0;
        For( h = 0, h < 12, h++,
            For( s = -2, s < 3, s++,
                myMk = Combine States( Hue State( h ), Shade State( s ), Marker State( 15 ) );
                Marker Size( 3 );
                Marker( myMk, {h, s} );
            )
        );
    Text( Center Justified, {5, 2.5}, " <--- Hues 0-11 ---> " );
    Text( Right Justified,
        {-.5, -2}, "Shade -2",
        {-.5, -2.25}, "(Very dark)",
        {-.5, -1}, "Shade -1",
        {-.5, -1.25}, "(Dark)",
        {-.5, 0}, "Shade 0",
        {-.5, -.25}, "(Basic hue)",
        {-.5, 1}, "Shade 1",
        {-.5, .75}, "(Light)",
        {-.5, 2}, "Shade 2",
        {-.5, 1.75}, "(Very light)"
    );
    );
```
There are no -Of functions for Hue and Shade. Color Of returns the equivalent Color State index for a color row state that has been set with Hue State or Shade State. For example, the following example gives rows 4 and 5 the same dark red marker:

```
Row State( 4 ) = Combine States( Hue State( 0 ), Shade State( -1 ), Marker State( 12 ) );
Row State( 5 ) = Combine States( Color State( Color Of( Row State( 4 ) ) ), Marker State( Marker Of( Row State( 4 ) ) ) );
```

**Row State and Matrices Example**

In the following example, row state values are prepared ahead and passed to the Marker routine, along with matrices of coordinates.

```
dt = New Table( "Artificial CP and CA data", Add Rows( 26 ),
    New Column( "cover_cp", Numeric, "Continuous",
         Formula( Random Uniform() / 100 + 0.94 ) ),
    New Column( "cover_ca", Numeric, "Continuous",
         Formula( Random Uniform() * 0.04 + 0.94 ) ),
    New Column( "p", Numeric, "Continuous", Formula( Random Uniform() ) ) );
```
Accessing Data Values

The typical way to work with values in a data table is to follow these steps:

1. Set up the data table whose values you want to access as the current data table. Or, if you already have a data table reference, you can simply use that reference. See “Set the Current Data Table” on page 355.
2. Specify the row or rows whose values you want to access and specify the column name that contains the values that you want to access. See “Set or Get Values by Column Name” on page 458.

The following example opens the Big Class.jmp sample data table (making it the current data table), and then specifies row 2 in the weight column. A value of 123 is returned in the log, which is the weight for Louise in row 2.

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt:weight[2];
123
```

**Set or Get Values by Column Name**

The easiest way to refer to a column is by its name. If you have a global variable and a column with the same name, to prevent ambiguity, scope the column name with the : prefix operator.

To set the value of a cell in the current row, provide the column name and the new value.

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
Row() = 5; // select row 5
dt:age = 19; // set the age in row 5 to 19
dt:name = "Sam"; // set the name in row 5 to Sam
```

To set the value of a cell in row 10, specify the row number in a subscript.

```julia
dt:age[10] = 20; // set the value of age in row 10 to 20
```

An empty subscript refers to the current row, so :age[] is the same as :age.

To get the value of a cell in row 16, specify the column name.

```julia
Row() = 16; // select row 16
myGlobal = :age; // store the age as a variable
:age; // returns 14, the age in row 16
Show( :age ); // returns age = 14;
```

To get the value of a cell in a specific row, include the column name and row number. Both of the following examples return 13, the value of age in row 12 of Big Class.jmp:

```julia
:age[12];
myGlobal = :age[12];
```

To get a value in a data column reference, use Column() and As Column() to get the value in a data column reference. See “Access Cell Values through Column References” on page 395.

**Notes:**

- If you do not specify the row number, the current row is selected.
- An empty subscript, such as :age[], refers to the current row.
• Be careful that you are subscripting to a table row that exists. The default row number is zero, so statements like :name that refer to row zero generate an Invalid Row Number error.

**Additional Ways to Access Data Values**

There are other ways to specify a data table, row, and column. You can specify all three items in one expression by using an infix operator and a subscript:

```plaintext
dt:age[2] = 12; // table, column, and row
```

If you want to target multiple rows, you can use subscripts with a list or matrix of row numbers.

```plaintext
age[i] = 3;
age[[3, 12, 32]] = 14;
list = age[[3, 12, 32]]; // results in a list
vector = age[1 :: 20];  // results in a matrix
dt[1,1] = dt[2,1]; // in Big Class.jmp, “KATIE” (row 1, column 1) is now “LOUISE” (row 2, column 1)
dt[0,{height}] = dt[0,{weight}]; // everybody’s height is their weight
dt[1,{height,weight}] = dt[2,4::5]; // row 1 height and weight is from Louise
dt[[5 3 1], 0] = .; /* set rows 5, 3, and 1 to missing. Using out-of-order subscripts makes more sense if the right hand side is a matrix or a data table with subscripts */
```

**Note about Changing Values**

Whenever you change values in a data table, messages are sent to the displays to keep them up-to-date. However, if you have thousands of changes in a script, this increases the time it takes to complete the updates.

In order to speed up changes, use `Begin Data Update` before the changes to block these update messages. Use `End Data Update` after the changes have been completed to release the messages and update the displays.

```plaintext
dt << Begin Data Update;
...<many changes>...
dt << End Data Update;
```

Be sure to always send the `End Data Update` message, otherwise the display is not updated until forced to do so in some other way.

**Note:** `Begin Data Update` does not affect the data refresh due to some other table manipulations. For example, when you delete or add columns, the data table is updated and then the data update begins.
Add Metadata to a Data Table

Data tables store observation data, or measurements of various variables on a specific set of subjects. However, JMP data tables can also store metadata, or data about the data.

- “Data Table Variables”
- “Table Scripts”
- “Formulas”
- “Delete Metadata”

Data Table Variables

Table variables are for storing a single text string value, such as “Notes”. To understand how variables work, first get its existing value by sending a Get Table Variable message:

```
dt = Open( "$SAMPLE_DATA/Solubility.jmp" );
dt << Get Table Variable( "Notes" );
"Chemical compounds were measured for solubility in different solvents. This table shows the log of the partition coefficient (logP) of 72 organic solutes in 6 aqueous/nonpolar systems."
```

Now change the existing value of the string using Set Table Variable and then use Get Table Variable again to check that the string has been updated:

```
dt << Set Table Variable( "Notes", "Solubility of chemical compounds" );
dt << Get Table Variable( "Notes" );
"Solubility of chemical compounds"
```

The following example adds two new table variables to a data table:

```
dt = Open( "$DOCUMENTS/Big Class.jmp" );
myvar = "This is my version of the JMP Big Class sample data.";
dt << Set Table Variable( "key1", myvar );
dt << Set Table Variable( "key2", myvar );
```

Notice that setting the value creates a new variable only if one by the given name does not already exist. If you add two table variables with the same name, only one variable is created.

Table Scripts

You can add a new script, run a script, or get a script using JSL.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Script( "Bivariate Example", Bivariate( Y( :weight), X( :height ) ) );
dt << Get Table Variable( "Bivariate Example" );
```
// returns Bivariate( Y( weight ), X( height ) )
dt << Run Script( "Bivariate Example" )

The following example replaces the contents of the table script that was created by the preceding script:

dt << Set Property( "Bivariate Example", Bivariate( Y( :weight ), X( :height ), Fit Line ) ); // include Fit Line in the Bivariate Example script

Suppose you want a text representation of a data table, perhaps to e-mail to a colleague or to use as part of a script. You can obtain a script that reconstructs the information in a data table with Get Script. The following example opens Big Class.jmp and prints the data, table variables, and column properties to the log. A portion of the output is shown here:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Get Script;
New Table( "Big Class",
Add Rows( 40 ),
New Script(
["en" => "Distribution",...],
Distribution(
Continuous Distribution( Column( :weight ) ),
Nominal Distribution( Column( :age ) )
)
);
```

Delete Scripts deletes one or more scripts.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Delete Scripts( "Distribution" );
```

In JMP versions prior to 14, use Delete Property to delete a script.

**Note:** The Names Default to Here setting is false by default for table scripts. If a table script specifies Names Default to Here(1), this setting lasts only as long as the table script runs. After the script finishes running, the setting is reset to whatever it was before the script ran.

## Options for Downloaded Data Tables that Contain Scripts

You are prompted to open or examine downloaded data tables that contain scripts. This helps you prevent potentially damaging scripts from running on your computer. In the Open() command, you can control this behavior.

To open the data table and enable scripts to run:

```
Open( "$DOWNLOADS/file.jmp", Quarantine Action( "Allow Scripts" ) );
```

To open the data table and block scripts:

```
Open( "$DOWNLOADS/file.jmp", Quarantine Action( "Block Scripts" ) );
```

To display the default prompt window to open or examine the file:
Open( "$DOWNLOADS/file.jmp", Quarantine Action( "Show Dialog" ) )

To enable a Try() expression to capture the error:

Try( Open( "$DOWNLOADS/file.jmp", Quarantine Action( "Do Not Open" ) ),
     Show( exception_msg ) );

If the user selects Examine, the scripts are disabled.

Notes:

• The Block Scripts and Show Dialog options don’t work if the domain that you downloaded the data table from is on your Windows Internet Options Trusted sites list.

• After you select Open for a quarantined data table, the data table is trusted until the next time you open JMP.

Prompting to Run a Script upon Opening a Data Table

You can prompt to open a table script named On Open or OnOpen when the data table opens. The choice is remembered each time you open the data table in the current JMP session.

To create an On Open script, perform one of the following actions:

• Create the script using the Save Script > To Data Table option, double-click the script name, and change the name to On Open.

• Store the script using a New Script message.

In this example, you create an OnOpen script in Big Class.jmp.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Script( "OnOpen", // create the script
                 sortedDt = Data Table( "Big Class" ) << Sort( By( :name ), Output Table Name( "Sorted Big Class" ) ) // sort the data and put it in a new data table );
```

The JMP preference called Evaluate OnOpen Scripts determines when the script runs. By default, the user is prompted to run the script. You can set the preference to always run the On Open script or to prevent it from running:

```julia
Preference( Evaluate OnOpen Scripts( "always" ) );
Preference( Evaluate OnOpen Scripts( "never" ) );
Preference( Evaluate OnOpen Scripts( "prompt" ) ); // default setting
```

On Open scripts that execute other programs are never run. As a safety precaution, you might consider suppressing automatic execution when opening data tables that you receive from others.
Notes:

- If the OnOpen script is in a downloaded data table, you must specify Quarantine Action("Allow Scripts") in the Open() expression to run the OnOpen script automatically. See “Options for Downloaded Data Tables that Contain Scripts” on page 461.
- When you create a new data table in a script and include the On Open() function, On Open() is called after the data table is created.
- Some operations in an OnOpen script are considered unsafe, such as saving the current data table. Run an external script to save that table instead of opening a table to run the OnOpen script.

Work with Groups of Table Scripts

Suppose that you want to put related table scripts in a group to save room in the list of data table scripts. Use Group Scripts, specify the group name, and then specify the script names to put in the group.

```javascript
dt = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
dt << Group Scripts(
    "Maps",
    {"Bubble Plot Street Map", "Graph Builder Street Map: Traffic Incidents", "Graph Builder Street Map Zoomed"}
);
dt << Group Scripts(
    "Tabulate",
    {"Tabulate: Category and Description", "Tabulate: Category, Summary, Percentage", "Tabulate: Category and Resolution", "Tabulate: Resolution and Description"}
);
```

Move a Script Group

Move Script Group rearranges the table script groups using the to first, to last, after(script), and after(group) arguments:

```javascript
dt << Move Script Group( "Tabulate", after( "Maps" ) );
dt << Move Script Group( "Tabulate", to last);
```

Get Groups and Group Names

To get the list of table scripts in the group, use Get Script Group. Then you can perform an operation such as running a script in the group.

```javascript
 tb = dt << Get Script Group( "Tabulate" );
dt << Run Script( tb[2] ); // runs the second script in the Tabulate group
```
Get Script Groups Names returns the group names in a list:

```java
gn = dt << Get Script Groups Names; // returns {"Maps", "Tabulate"}
```

// move the Maps group to the end of the table scripts
dt << Move Script Group(gn[1], to last);

Select a Script Group

Select Script Group selects the named table script group, a list of scripts in a group, or all scripts.

```java
dt << Select Script Group; // select all scripts groups
dt << Select Script Group( "Tabulate" ); // select Tabulate group
dt << Select Script Group( {"Tabulate", "Maps"} ); // select both groups
```

Ungroup Scripts

Ungroup Scripts removes specified table scripts or group from the group. You can send the message to the name of the script group or a list of scripts.

```java
dt << Ungroup Scripts( "Tabulate" );
dt << Ungroup Scripts( "Tabulate: Category and Description", "Tabulate: Category, Summary, Percentage",
                    "Tabulate: Category and Resolution", "Tabulate: Resolution and Description"
                );
```

Rename a Script Group

You can rename a table script group using Rename Script Group, specifying the existing group name, and specifying the new group name.

```java
dt << Rename Script Group( "Maps", "Street Maps" );
```

Delete a Script Groups

To delete a table script group, you get it first and then delete it.

```java
a = dt << Get Script Group( "Street Maps" );
dt << Delete Scripts( a );
```
Chapter 9
Scripting Guide
Add Metadata to a Data Table

Formulas

The message *Suppress Formula Eval* takes a Boolean argument to specify whether formula evaluation should be suppressed or not. You might want to suppress evaluation if you plan to make numerous changes to the data table and do not want to wait for formula updates between steps.

```julia
dt << Suppress Formula Eval( 1 );
dt << Suppress Formula Eval( 0 );
```

To accomplish the same effect for all data tables, use the *Suppress Formula Eval* command to turn off formulas globally. This is the same as the message above, except that you do not send it to a data table object.

```julia
Suppress Formula Eval( 1 ); // make formulas static globally
Suppress Formula Eval( 0 ); // make formulas dynamic globally
```

Note that formulas are not evaluated when they are installed in the column. Even when you force evaluation, they end up being evaluated again in the background. This can be a problem for scripts if they depend on the column having the values while the script is running. If you need a mechanism to control evaluation, use the *EvalFormula* command or the *Run Formulas* command.

To force a single column to evaluate, send an *Eval Formula* command to the column. You can even do this inside the command to create the column, after the formula clause:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Ratio",
    Numeric,
    Formula( :height / :weight ),
    Eval Formula
);
```

*dt << Run Formulas* performs all pending formula evaluations, including evaluations that are pending as a result of evaluating other formulas. This function is useful when you have a whole series of columns to run.

**Tip:** This method is preferred over *EvalFormula*. Although *EvalFormula* evaluates the formulas, it does not suppress the background task from evaluating them again. The background task takes great care to evaluate the formulas in the right order.
If you send the Run Formulas command to a data column, the evaluation is done at the time of the command, but it does not suppress the scheduled evaluations that are pending. Therefore, formulas might end up being evaluated twice if you also send the command to the data table and the data column. Being evaluated twice might be desirable for formulas that have random function in them, or it might be undesirable if they depend on randomization seeds being set. If you use random numbers and use the Random Reset(seed) feature to make a replicable sequence, then use the Run Formulas command, because it avoids a second evaluation.

**Note:** All platforms send a Run Formulas command to the data table to assure that all formulas have finished evaluating before analyses start.

**Set Values without a Formula**

`col << Set Each Value(expression)` evaluates the expression for each row of the data table and assigns the result to the column. It does not store the expression as a formula.

**Delete Metadata**

You can delete table variables, table properties (such as a script or a variable), and formulas from the data table, using the following commands:

```
dt << Delete Table Variable( name );
dt << Delete Table Property( name|{property1, property2, ...});
col << Delete Formula;
col << Delete Property( name|{property1, property2, ...} );
col << Delete Column Property( name );
```

**Calculations**

This section discusses functions for pre-evaluated columnwise and rowwise statistics and shows how JSL expressions work behind the scenes in the JMP formula calculator.

**Pre-Evaluated Statistics**

The following functions are special, pre-evaluated functions: Col Maximum, Col Mean, Col Minimum, Col N Missing, Col Number, Col Quantile, CV (Coefficient of Variation), Col Standardize, Col Std Dev, Col Sum, Maximum, Mean, Minimum, NMissing, Number, Std Dev, and Sum.
Note: Statistics are also computed with Summarize ("Store Summary Statistics in Global Variables" on page 364). Although the named arguments to Summarize have the same names as these pre-evaluated statistic functions, they are not calling the pre-evaluated statistic functions. The resemblance is purely coincidental.

All the statistics are pre-evaluated. That is, JMP calculates them once over the rows or columns specified and thereafter uses the results as constants. Because they are computed once and then used over and over again, they are more efficient to use in calculations than the equivalent formula-calculated results.

When JMP encounters a pre-evaluated function in a script, it immediately evaluates the function and then uses the result as a constant thereafter. Therefore, pre-evaluated functions enable you to use columnwise results for rowwise calculations. For example, if you use Col Mean inside a column formula, it first evaluates the mean for the column specified and then uses that result as a constant in evaluating the rest of the formula on each row. A formula might standardize a column using its pre-evaluated mean and standard deviation:

\[
\frac{\text{Height} - \text{Col Mean(Height)}}{\text{Col Std Dev(Height)}}
\]

For the Big Class.jmp data, Col Mean(Height) is 62.55 and Col Std Dev(Height) is 4.24. So for each row, the formula above would subtract 62.55 from that row’s height value and then divide by 4.24.

Note: Pre-evaluated functions disregard the excluded row state, meaning that any excluded rows are included in calculations. For summary statistics that obey row exclusion, use the Distribution platform.

Columnwise Functions

The functions whose names begin with “Col” all work columnwise, or down the values in the specified column, and return a single number. For example, Col Mean(height) finds the mean of the values in all the rows of the column height and returns it as a scalar result. Some examples include the following:

Average Student Height = Col Mean( height );
Height Sigma = Col Std Dev( height );

With the Col functions, column properties such as Missing Value Codes assign data values that produce incorrect calculations. Suppose that the Missing Value Codes column property is assigned to the x1 column to treat “999” as a missing value. Another column includes a formula that calculates the mean. To use the value “999” instead of a missing value to calculate the mean, refer to Col Stored Value() in the formula:

Mean( Col Stored Value( :x1 ), :x2, :x3 )
Rowwise Functions

The functions without “Col” listed below work rowwise across the values in the variables specified and return a column result. For example, Mean(height, weight) finds the mean of the height and weight for the current row of the data table. The rowwise statistics are valid only when used in an appropriate data table row context. The following are some possibilities:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );

// scalar result for row 7 assigned to JSL global variable
Row() = 7;
::scalar = Mean( height, weight );

// formula column created in data table
dt << New Column( "Scaled Ht-Wt Ratio",
    Formula( Mean( height, weight ) / age )
);

vector = J( 1, 40 ); // create a 1x40 matrix to hold results
For Each Row( vector[Row()] = Mean( height, weight ) ); // fill the vector
```

Rowwise functions can also take vector (column matrix) or list arguments:

```
myMu = Mean( [1 2 3 4] );
mySigma = Std Dev( {1, 2, 3} );
```

Calculator Formulas

You can store formulas in columns that are automatically evaluated to create the values in the cells of the column. If you open the formula, you get a calculator interface to edit the formula structurally. However, the formula is implemented with JSL, and you can obtain the text JSL form of any expression in the calculator by double-clicking it. The text can be edited, and when it is de-focused, it is compiled back into the structural form.

**Note:** There is no difference between a formula column created through the calculator window and one created directly through JSL with commands such as New Column(..., Formula(...)) or Col << Formula(...).
If you run the same analysis frequently, you can script it to automate the process. Anyone can then run the script, ensuring the same results every time. To get started, perform your analysis interactively as you normally would with JMP, and then save a script that re-creates that analysis. You can modify the script to further customize it.

**Figure 10.1** Typical Workflow for Scripting Platforms

This chapter is about scripting platforms, not reports. *Platform* object references and *report* object references receive different types of JSL messages. Platforms can run tests, draw plots, and so on. Reports can copy pictures, select display boxes, or close outline nodes. To learn about scripting reports, see the section "Navigate JMP Reports" on page 519 in the “Display Trees” chapter.

**Tip:** For additional scripting help, see the JMP Scripting Index (Help > Scripting Index) and the *JSL Syntax Reference*.

Example of Scripting a Platform

If you are not familiar with JSL, it can be helpful to start by interactively performing your analysis in JMP, and then saving the analysis to a script. JMP creates the script for you, and you can then add to it or modify it as desired, by creating a platform object and sending it messages.

Overview

This example takes you through these steps:

1. Launch the Analysis and Save the Script to a Window
2. Add a Platform Reference Object and Send Messages
3. Add a Data Table Reference and Save the Script

Launch the Analysis and Save the Script to a Window

1. Select Help > Sample Data Library and open Big Class.jmp.
   This fictional data set contains the names, ages, sex, heights, and weights for 40 students.
2. Select Analyze > Fit Y by X.
4. Select age and click X, Factor.
5. Click OK.
   A Oneway plot of students’ height by age appears.
6. Click the Oneway Analysis red triangle and select the following options:
   – Means/Anova
   – Compare Means > Each Pair, Student’s t
7. Click the Oneway Analysis red triangle and select Save Script > To Script Window.

Here is the resulting script:

```julia
Oneway(
  Y( :height ), X( :age ),
  Each Pair( 1 ),
  Means( 1 ),
  Mean Diamonds( 1 )
);
```

Notice the following:

- The script begins with a call to the `Oneway()` function, which returns a Oneway object.
• The parentheses after the `Oneway()` function contain arguments that tell the `Oneway` function how to make the object.
  – The first two arguments, `Y` and `X`, are required at launch.
  – The next three arguments are optional: `Each Pair`, `Means`, and `Mean Diamonds`.
  – When you selected the Each Pair, Student’s t option, the Each Pair feature was turned on.
  – When you selected the Means/Anova option, the Means and Mean Diamonds features were turned on.
• The scripting equivalent of turning an option on or off is the Boolean argument 0 (off) or 1 (on).

Add a Platform Reference Object and Send Messages

1. (Optional) Right-click in the script and select **Show Embedded Log**.
   Output that appears in the log is now easily visible below the script.
2. Choose a JSL variable to remember the Oneway platform object.
   In this example, use the name `oneObj`:
   ```javascript
   oneObj = Oneway(
       Y( :height ),
       X( :age ),
       Each Pair( 1 ),
       Means( 1 ),
       Mean Diamonds( 1 )
   );
   ```
   This gives you a way to address the platform object and send messages to it.
3. Click **Run Script**.
   This creates the Oneway object and sets the variable `oneObj`. Now, send a message to tell the platform to turn on the Unequal Variances report.
4. At the end of the script, add the following line: `oneObj << Unequal Variances(1)`, as shown here:
   ```javascript
   oneObj = Oneway(
       Y( :height ),
       X( :age ),
       Each Pair( 1 ),
       Means( 1 ),
       Mean Diamonds( 1 )
   );
   oneObj << Unequal Variances( 1 );
   ```
5. Highlight the Unequal Variances line of JSL and click **Run Script**.
**Tip:** You can also press Ctrl+R to run a highlighted line of JSL.

At the bottom of the report window, the Tests That the Variances Are Equal report now appears. Now, suppose that you want to see only that report (and the graph), and you want to close the other reports.

6. Add the following lines to the script:

```javascript
rep = Report( oneObj );
rep["Oneway Anova"] << Close(1);
rep["Means Comparisons"] << Close(1);
```

The `Report()` function returns the report object for the Oneway platform, and stores a reference to the report in the JSL variable called `rep`. You can send messages or perform actions on the report object, such as closing specific report outlines.

7. Highlight these last 3 lines of the script and click **Run Script**.

In the report window, the Oneway Anova and the Means Comparisons reports are now closed. Only the initial graph and the Tests that the Variances are Equal report (which includes the Welch’s Test report) appear.

If you close the `Big Class.jmp` sample data table at this point and then try to run the script, you are prompted to open a data table. A best practice is to precede the call to the Oneway platform with an `Open()` function to open the associated data table each time the script is run.

**Add a Data Table Reference and Save the Script**

1. Add the following line as the first line in the script:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
```

If the data table is not open when the script is run, this line opens the associated data table.

Your finished script should look like this:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
oneObj = Oneway(
    Y( :height ),
    X( :age ),
    Each Pair(1),
    Means(1),
    Mean Diamonds(1)
);
oneObj << Unequal Variances(1);
rep = Report( oneObj );
rep["Oneway Anova"] << Close(1);
rep["Means Comparisons"] << Close(1);
```

Once you complete your script, save it for future access.
2. From the script window, select **File > Save As**. Enter a name for your script and save it to any directory.

---

**Send Messages to a Platform**

Before you can send messages to a platform, you need to create a platform object that you can send the messages to. Use the Send operator (<<).

The following line keeps a reference to a Oneway platform in the JSL variable called `oneObj`:

```javascript
oneObj = Oneway( Y( height ), X( age ) );
```

Then, add the Send operator to send the platform object a message. In this example, the message is to turn on the Unequal Variances report:

```javascript
oneObj << Unequal Variances( 1 );
```

To see which messages can be sent to a specific object, do one of the following:

- Use the autocomplete shortcut. On a new line, enter the object name, then the Send operator (<<), and press Ctrl+space (Windows) or Ctrl+Option+space (macOS). The following example shows the messages that you can send to the platform object `oneObj` on Windows:

  ```javascript
  oneObj << (Ctrl+space)
  ```

  A list of messages appears. Click one to insert it.

- Use the `Show Properties ()` function. Specify the object in the parenthesis. The following example shows the messages that you can send to the platform object `oneObj`:

  ```javascript
  Show Properties (oneObj)
  ```

  A list of messages appears in the log.

---

**Conventions for Messages and Arguments**

- For most messages, omitting the argument for a Boolean command enables the option. For example, all of these messages create a test for unequal variances:

  ```javascript
  oneObj << Unequal Variances;
  oneObj << Unequal Variances( 1 );
  oneObj << Unequal Variances( "true" );
  oneObj << Unequal Variances( "yes" );
  oneObj << Unequal Variances( "present" );
  oneObj << Unequal Variances( "on" );
  ```

  The first three approaches are recommended.
Notes:

- The quoted arguments "present", "absent", "on", "off", "switch", and "flip" are supported for backwards compatibility.

- When the name of the JMP option contains several options separated by a comma or slash (such as the Means/Anova option or the T Square, $T^2$ option) you can use any one of the menu names. Or, you can use the full menu name, including the comma or slash, if the string is followed by n. For example, any of these messages create a Means/Anova test:

  ```
  oneObj << Means( 1 )
  oneObj << Anova( 1 )
  oneObj << "Means/Anova"n( 1 )
  ```

- When an option appears under a menu in JMP, the corresponding script message is the option itself without the parent menu. For example, in the Oneway red triangle menu, the Nonparametric menu has multiple options under it, including Wilcoxon Test. Simply use Wilcoxon Test as a function or message in a script:

  ```
  oneObj = Oneway( Y( height ), X( age ), Wilcoxon Test( 1 ));
  oneObj << Wilcoxon Test( 1 );
  ```

- When a menu in JMP contains values rather than options, in the script, specify the parent menu and the value as an argument. For example, in the Oneway red triangle menu, the Set Alpha Level menu has values, such as 0.10, 0.05, 0.01, and Other. To specify 0.01 in a script, add a line like the following:

  ```
  oneObj << SetAlphaLevel(0.01);
  ```

### Send Multiple Messages

To send several messages, just add more `<<` operators or more `Send` arguments:

```
dist << Quantiles( 1 ) << Moments( 1 ) << More Moments( 1 ) << Horizontal Layout( 1 );
Send( dist, Quantiles( 1 ), Moments( 1 ), More Moments( 1 ), Horizontal Layout(1));
```

Because `<<` is an *eliding operator*, it combines arguments and works differently than if its arguments were grouped. You can stack multiple messages with extra `<<` symbols to perform them all in order, from left to right.

Another way to stack messages is to send a list of messages:

```
dist << {Quantiles( 1 ), Moments( 1 ), More Moments( 1 ), Horizontal Layout( 1 )};
```

These approaches work well assuming that no value is returned as a result of one of your messages. However, if your goal is to send a message to the *result* of another message, add grouping parenthesis. The second line shows the wrong way to do it; the third line shows how to do it correctly:
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
/* the following line is incorrect, and sends the Fit Mean message to the original data table object */
bv = dt << Run Script( "Bivariate" ) << Fit Mean( 1 );
/* the following line is correct, and sends the Fit Mean message to the resulting Bivariate object/report */
bv2 = ( dt << Run Script( "Bivariate" ) ) << Fit Mean( 1 );

Find Messages for Objects

Some messages apply to all platform objects, and others are specific to certain platforms. Once you have created a platform object, find out what messages you can send to the object, using any of the following approaches:

Use the Scripting Index in JMP

1. Select Help > Scripting Index.
2. Enter the object type that you are interested in.
3. Click the correct object in the resulting list. Messages for the object appear in the Items list.

Once you have created a platform object, use the Show Properties( obj ) function.

Replace obj with your named platform object. A list and brief description of all the messages the object can receive appears in the Log. To understand more about the Show Properties output, see “Interpret the Show Properties List” on page 478.

Tip: The Show Properties() function also works with data tables and display boxes. See “How Can I See All of the Messages that Can be Sent to a Data Table Object?” on page 326 in the “Data Tables” chapter and “The << Operator” on page 530 in the “Display Trees” chapter.

• Examine the platform in JMP launch windows and report windows. Most options that you find there have JSL equivalents with the same names and arguments.
Interpret the Show Properties List

Show Properties lists the messages that can be sent to a scriptable object, such as a data table, an analysis platform, or a display, producing a text report in the log. Each type of message is categorized and appears in brackets, and can be any of the following:

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Action]</td>
<td>Correspond to options in the JMP interface.</td>
<td>Redo Analysis [Action] (Rerun this same analysis in a new window. The analysis will be different if the data has changed.)</td>
</tr>
<tr>
<td>[Action Choice]</td>
<td>List specific choices for their arguments.</td>
<td>Fit Polynomial [Action Choice] {2, quadratic, 3, cubic, 4, quartic, 5, 6}</td>
</tr>
<tr>
<td>[Enum]</td>
<td></td>
<td>Draw [Enum] {Filled, Outlined, Filled and Outlined}</td>
</tr>
<tr>
<td>[Boolean]</td>
<td>Turn options on or off. Arguments are usually 1 or 0. If a message is specified without an argument, sending the message changes it to the opposite state. [Default On] indicates that the option is on by default.</td>
<td>Show Points [Boolean] [Default On]</td>
</tr>
<tr>
<td>[Subtable]</td>
<td>List options within submenus. You use the option itself, not the parent item.</td>
<td>Script [Subtable] Redo Analysis [Action] (Rerun this same analysis in a new window. The analysis will be different if the data has changed.) Save Script to Datatable [Action] (Return to the launcher for this analysis.)</td>
</tr>
<tr>
<td>[New Entity]</td>
<td>Open a new window in the interface.</td>
<td>Prediction Interval [New Entity] (Prediction Interval to contain a single future observation or the mean of m future observations.)</td>
</tr>
</tbody>
</table>
For example, run the following JSL:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = Bivariate( Y( :height ), X( :age ) );
Show Properties( biv );

The object biv supports Subtable, Boolean, Action, and Action Choice type messages. Enum and New Entity messages are not supported.

### Send Messages to an Object

Suppose that you want to send a message to an object in the output. For example, in Fit Model, you want to send the Response Limits message to the Profiler object. Use the subscript operator ([ ]) to refer to the Profiler object.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );

```jl
fm = dt << Fit Model(
   Y( :height ),
   Personality( Standard Least Squares ),
   Emphasis( Effect Screening ),
   Run
);

obj = fm << Profiler(
   1,
   Confidence Intervals( 1 ),
   Desirability Functions( 1 ),
   Term Value( age( 12 ), sex( "F" ), weight( 105 ) )
);

Show( Profiler[1] << Get Desirability ); // show the limits before

Profiler[1] << (height << Response Limits(
   {Lower( 50, 0.95 ), Middle( 58, 0.7 ), Upper( 70, 0.066 ),
   Goal( "Minimize" ), Importance( 1 })
));
Wait( 0.1 ); // for demonstration purposes
Show( Profiler[1] << Get Desirability ); // show the limits after
```
Specify Which Columns to Analyze

If you created your script interactively, you already specified columns in the launch window, so there is no need to specify them again. However, when creating a script from scratch, you normally want to specify the columns to analyze. For example, the following line launches the Distribution platform and specifies the height and weight columns as the Y variables:

```
Distribution( Y( height, weight ) );
```

Create Column References

**Tip:** To see all the messages you can send to a column, go to Help > Scripting Index > Data Table > Column Scripting.

Creating a column reference enables you to access and send messages to the column. If you store each column reference in a JSL variable, you can use the variables instead of column names in the Y and X roles and elsewhere in the script.

For example, using Big Class.jmp, the following lines create Ycol as a column reference for weight, and Xcol as a column reference for height. The last line sends a message to Xcol to get the data type.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Ycol = Column( "weight" );
Xcol = Column( "height" );
Xcol << Get Data Type;
```

In the log, “Numeric” is output for the data type of the Xcol (height column).

Referring to a column reference with the : scoping operator (rather than plain text) is convenient in scripts saved to a data table. If the columns are renamed in the data table, the column references in the script are updated.

Specify Multiple Column Names at Once

If you have a lot of column names, instead of listing each one individually, you can use lists as column arguments. The following example gets the Y column names from a list and creates a Oneway analysis on each column in the list.

```
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
dt << Fit Group( Oneway( Y( {:SO2, :POP} ), X( :State ) ) );
```
If you do not know the column names when you are writing the script, use column indices, as done in the following example.

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Distribution( Y( 1::N Col( dt ) ) );
```

You can also use indices when specifying effects as shown here:

```julia
dt << Fit Model( Y( :y ), Effects( 1 :: 4 ) );
```

Here’s another example of specifying multiple column names. 5::31 selects columns 5 through 31.

```julia
Names Default To Here( 1 );
dt = Open( "SAMPLE_DATA/Baltic.jmp" );
dt << Partial Least Squares( Y( :ls, :ha, :dt ), X( 5 :: 31 ), Go );
```

### Enable Users to Specify Columns

Instead of specifying analysis columns yourself, you can enable a user to specify them, but you can still control what happens after they do so. In this case, use an empty specification. The following example runs the Distribution launch window:

```julia
Distribution();
```

In this scenario, the Distribution launch window appears and the user can choose the columns to analyze. After the user selects the columns and clicks **OK**, the Distribution report is shown as specified.

### Specify a By Variable

In many JMP platforms, you can specify columns as By variables. To do this in a script, include a By argument in the platform command, listing each column as an argument.

The following example uses the Big Class.jmp data table, which contains the names, ages, sex, heights, and weights for 40 students. Create a bivariate report of weight by height, using sex as a By variable, and adding a variety of fits.

### Create the Bivariate Report Using a By Variable

1. Select **File > New > Script**.
2. Add the following lines:

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
```
biv = dt << Bivariate( Y( weight ), X( height ), By( sex ));

The first line opens the Big Class.jmp sample data table. The second line creates a platform object called biv that runs a bivariate report of weight and height by sex.

3. Click Run Script.

The report window shows two graphs, one where sex is F and one where sex is M.

**Send Messages to the Entire Platform or to a Single By Level**

1. If you do not have the log showing, turn it on. Right-click in the script and select Show Embedded Log.

2. Add this line to the script:
   ```
   Show( biv );
   ```

3. Highlight the Show( biv ) line and click Run Script.

   In the log, rather than returning a single reference to a platform, Bivariate[], the platform object returns a list of references: `biv = {Bivariate[], Bivariate[]}`. The two references correspond to the two levels (F and M) of the By variable, sex.

   You can direct messages to each By level individually or to all By levels.

4. Send a message to all By levels to add a linear regression fit. Add this line to the script:
   ```
   biv << Fit Line;
   ```

5. Highlight the line you just created and click Run Script.

   In the report window, a linear regression line is added to both graphs, with the corresponding Linear Fit reports.

6. Send a message to only the F level, adding a cubic polynomial fit. Add this line to the script:
   ```
   biv[1] << Fit Polynomial( 3 );
   ```

   **Tip:** The number for each By level corresponds to their order in the report window, which is usually alphanumeric. If the By column contains a Value Order column property, that ordering is followed.

7. Highlight the line you just created and click Run Script.

   In the report window, a polynomial fit line is added to the F graph, with the corresponding Polynomial Fit reports.

8. Send a message only to the M level, adding a quartic polynomial fit. Add this line to the script:
   ```
   biv[2] << Fit Polynomial( 4 );
   ```

9. Highlight the line you just created and click Run Script.
In the report window, a quartic fit line is added to the M graph, with the corresponding Polynomial Fit reports.

**Figure 10.2 By Group Reports**

If you specify more than one column in By argument, graphs appear for each subgroup of each By variable. In this example, By( sex, age ) would produce graphs for females age 12, females age 13, and so on, up to age 17. It would also produce graphs for males age 12 up to age 17.
Extract Results from a Report

The following example shows how to launch a platform with By groups and extract results (in this case, variances) from each group:

```js
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );

// onew is the JSL variable holding a list of platforms
onew = dt << Oneway( x( :age ), y( :height ), by( :sex ), anova );

// r is a list of reports
r = onew << Report;

// nBy is the number of reports generated
nBy = N Items( r );

// vc is an array of as many rows as reports, one column, all set to zero
vc = J( nBy, 1, 0 );

// for each report, do the following:
For( i = 1, i <= nBy, i++,
    vc[i] = r[i] // vc[i] is the variance of the ith report
    [Outline Box( "Analysis of Variance" ), // look for this outline
     // then look for this column and get the second value
     Column Box( "Sum of Squares" )][2]
);
Show( vc ); // debugging, look in log to see this value

// byValues becomes a list of the values in the sex column
Summarize( byValues = By( :sex ) );

// make a new table with two rows (M,F) and two columns
New Table( "Variances" )
<< New Column( "Sex", // create a new column called Sex
                character,
                width( 8 ),
                values( byValues )
)
<< New Column( "Variance", Numeric, "Continuous", Values( vc ) );
```
Filter by Value using a Where Statement

You can use a `Where` statement to filter by a specific value. If you are adding a `Where` clause to a script that contains column references, you must first resolve the references. The following example limits the analysis to females and fits a line on the Bivariate report.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Ycol = Column( "weight" );
Xcol = Column( "height" );
biv2 = dt << Bivariate(
  Y( Ycol ),
  X( Xcol ),
  Fit Line( ),
  Where( :sex == "F" )
);
```

Enable User Input

When you send an `Action()` function to a platform, it evaluates an expression. For example, use `Action` messages when you want the launch window to appear. A user chooses columns in the launch window and the script continues running after the user runs the analysis.

The following example launches four platforms: Distribution, Bivariate, Oneway, and Contingency. The launch window for each platform appears, and the user chooses the analysis columns and clicks OK. The report window for each analysis appears, and then the next platform launch window comes up, until all platforms have been launched.

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Distribution( Action( doit ) );
doit = Expr(
  New Window( "Bivariate", Bivariate( Action( doit2 ) ) )
);
doit2 = Expr(
  New Window( "Oneway", Oneway( Action( doit3 ) ) )
);
doit3 = Expr(
  New Window( "Contingency", Contingency( Action( doit4 ) ) )
);
doit4 = Expr();
```
Execute Embedded Red Triangle Options

In addition to the red triangle menu at the top of a report, some report windows contain embedded red triangle menus. These appear when you select an option that has sub-options, such as profilers. To execute options in embedded red triangle menus, use the `Get Scriptable Object` message. The following example creates a Life Distribution report then turns off the Confidence Intervals option in the Hazard Profiler red triangle menu:

```julia
dt = Open( "$SAMPLE_DATA/Reliability/Fan.jmp" );

// create a Life Distribution report with a lognormal distribution
obj = dt << Life Distribution(  
    Y( :Time ),
    Censor( :Censor ),
    << Fit Lognormal
);

// get a reference to the Hazard Profiler red triangle menu
haz_prof = ( report( obj )[ "Hazard Profiler" ] << Get Scriptable Object);

// turn off confidence intervals in the Hazard Profiler
haz_prof << Confidence Intervals( 0 );
```

Make Platforms Invisible

In certain circumstances, you might want to make the platform analysis invisible. This means that no platform windows appear, and the platform runs in the background.

If you are doing a simulation or bootstrap analysis in your script, the script might call a platform hundreds or thousands of times. Perhaps you just want to pull one or two results out of each platform report. The following example performs a simulation and then creates a table of results and shows them in a Distribution report:

```julia
dt = As Table( (0 :: 10)` , << Column Names( {"X"} ) ); // create X variable

// set initial random seed to get reproducible results
Random Reset( 12345 );
dt << New Column( "Y",  
    "Continuous",
    "Numeric",
    Set Formula( :X * 2 + 1 + Random Normal() )
);
// Y values have a random component
res = []; // define results matrix (empty to start)
For( i = 1, i <= 100, i++, // loop through simulation runs
    // for each iteration, fit a regression line and save parameter estimates
    bv = dt << Bivariate( Y( :Y ), X( :X ), Fit Line( 1 ), Invisible );
    res |/= (Report( bv )["Parameter Estimates"])[
    // concatenate the results to the bottom of the results matrix
    Number Col Box( "Estimate" ) << Get as Matrix);

    // close the window (even though it's invisible)
    bv << Close Window;
    dt:Y << Eval Formula; // generate new Y values
);
// create table of results
dtres = As Table( res, << Column Names( {"Intercept", "Slope"} ) );

// show results in Distribution
dtres << Distribution( Y( :Intercept, :Slope ) );

If you want to run an analysis as an intermediate step in your script, and do not need the user
to see the analysis, hide it with the invisible option. In this case, you might want to show
only specific results from the report, which you can output to a journal or to the log.

- The following example runs the Distribution platform as invisible, and outputs only the
  CDF plot to a new journal:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dist = dt << Distribution( Y( :height ), CDF Plot( 1 ), invisible );
Report( dist )["CDF Plot"] << Journal;
dist << Close Window;
```

- The following example extracts the F-Ratio from an invisible Bivariate report, and outputs
  it to the log:

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( x( :height ), y( :weight ), invisible );
biv << Fit Line;
r = biv << Report;
fratio = r[ColumnBox( "F Ratio" )][1];
r << Close Window;
Show( fratio );
    fratio = 1.15609545178219;
```

**Tip:** Invisible windows use resources that must be manually freed. Be sure to close the
invisible window when the script is done with it.
You can also use the `invisible` option on the options in the Tables menu, such as Subset, Sort, Stack, and so on. The following example makes the Subset operation invisible:

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Select Where( :age == 14 );
dt = dt << Subset( invisible );
subDt << Bivariate( x( :height ), y( :weight ), Fit Line );
```

Note that the preceding line could also be handled using a `WHERE` clause:

```julia
subDt << Bivariate( x( :height ), y( :weight ), Where( :age == 14 ), Fit Line );
```

## Specify Report Titles

You can specify the title (shown in the title bar of a platform’s report) by adding the `title` command to the launch request. The following example replaces the standard bivariate report’s title with a user-specified one (My Title).

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << Bivariate( x( :height ), y( :weight ), Title( "My Title" ) );
```

## Common Messages for Platform Windows

For a list of common messages that you can send to most platforms, see the *JSL Syntax Reference*.

## Scripting Considerations by Platform

This section explains specific considerations when scripting the following platforms:

- “Categorical” on page 489
- “Control Charts” on page 490
- “Distribution” on page 492
- “DOE” on page 493
- “Fit Model” on page 495
- “Formula Depot” on page 500
- “Graph Builder” on page 500
- “Neural and Neural Net” on page 502
• “Partial Least Squares and PLS” on page 503
• “Process Capability” on page 503
• “Scatterplot 3D” on page 504
• “Text Explorer” on page 504
• “Explore Outliers” on page 504

Categorical

The Free Text option in Categorical displays a Text Explorer report. Scripts that call the Free Text option in Categorical should be updated to use the Text Explorer platform.

Scripting for Supercategories

When ratings are involved in a data set (for example, a five point scale), you might want to know the percent of the responses in the top two or another subset of ratings. You can define a group of ratings in the data using the supercategories scripting option (instead of the column property).

The following example creates a new column called Floss Delimited 2, and adds a supercategory called Sleep Related, which contains two values: Before Sleep and Wake.

```
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
dt << New Column( "Floss Delimited 2",
    Character,
    Set Property(
        "Supercategories",
        {Group( "Sleep Related", {"Before Sleep,"", "Wake," } )}
    ), ...);
```

In the data table, under the Columns panel at left, scroll down to the new Floss Delimited 2 column. Click the column property indicator ✪ and select Supercategories. You can see the new Sleep Related supercategory with its two values.

Supercategories can also be specified in a Categorical launch command, where the properties are listed inside parentheses after the column name:

```
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
dt << Categorical(
    Supercategories( :Floss Delimited(
        {Group( "Sleep Related", {"Before Sleep,"", "Wake," } )}
    ),
    Multiple Response( :Floss Delimited )
);
```
In the Categorical report, notice that the Sleep Related category has 203 cases. If you had run the Categorical platform without creating this supercategory, Before Sleep and Wake would appear as separate categories with 143 and 60 cases, respectively.

For more information about supercategories, see Consumer Research.

Control Charts

Using JSL, you can create control charts, customize tests, run alarm scripts, and more.

Customize Tests in Control Chart Builder

You can design custom tests and select or deselect multiple tests at once using the Customize Tests function. You specify the description, desired number, and label. This option is available only for Variables and Attribute chart types.

The following example creates a custom test called Test 1 and turns it on.

dt = Open( "$SAMPLE_DATA/Quality Control/Diameter.jmp" );
dt << Control Chart Builder(
   Variables( Subgroup( :DAY ), Y( :DIAMETER ) ),
   Customize Tests( Test 1( 2, "1" ) // test number, n, label
   Chart( Position( 1 ), Warnings( Test 1( 1 ) ) ), // turn Test 1 on
   Chart( Position( 2 ) )
);)

Run Alarm Scripts

An alarm script alerts you when the data fail one or more tests. As an Alarm Script is invoked, the following variables are available, both in the issued script and in subsequent JSL scripts:

qc_col is the name of the column
qc_test is the test that failed
qc_sample is the sample number
qc_phase is the label of the phase during which the failure occurred
qc_firstRow is the first row in the sample
qc_lastRow is the last row in the sample
**Example 1: Automatically Writing to a Log**

One way to generate automatic alarms is to make a script and store it with the data table as a data table script or column property named QC Alarm Script.

The following example automatically writes a message to the log whenever a test fails:

```julia
dt = Open( "$SAMPLE_DATA/Quality Control/Coating.jmp" );
obj = dt << Control Chart(
  Sample Size( :Sample ),
  KSigma( 3 ),
  Chart Col( :Weight, XBar, R ),
  Alarm Script(
    Write(
      "Out of Control for test ",
      qc_test,
      " in column ",
      qc_col,
      " in sample ",
      qc_sample
    )
  )
);
obj << Test 1( 1 );
```

**Example 2: Running a Chart with Spoken Tests**

You can create a control chart with tests that are spoken aloud using the Speak function. Try the following example:

```julia
dt = Open( "$SAMPLE_DATA/Quality Control/Coating.jmp" );
dt << Control Chart(
  Alarm Script(
    Speak(
      Match( QC_Test,
        1, "One point beyond Zone A",
        QC_Test, 2,
        "Nine points in a row in zone C or beyond", QC_Test,
        5,
        "Two out of three points in a row in Zone A or beyond"
      )
    ),
  ),
  Sample Size( :Sample ),
  KSigma( 3 ),
  Chart Col( :Weight, Xbar( Test 1( 1 ), Test 2( 1 ), Test 5( 1 ) ), R )
);
```
You can have either of these scripts use any of the JSL alert commands, such as `Speak`, `Write`, or `Mail`.

**Set Phase Limits**

A *phase* is a group of consecutive observations in the data table. For example, phases might correspond to time periods during which a new process is brought into production and then put through successive changes. Phases generate, for each level of the specified Phase variable, a new sigma, set of limits, zones, and resulting tests.

The following example illustrates setting the limits for the different phases of `Diameter.jmp`:

```jsl
dt = Open( "$SAMPLE_DATA/Quality Control/Diameter.jmp" );
dt << Control Chart(
    Phase( :Phase ),
    Sample Size( :DAY ),
    KSigma( 3 ),
    Chart Col( :DIAMETER,
        XBar( 
            Phase Level( "1",
                Sigma( .29 ),
                Avg( 4.3 ),
                LCL( 3.99 ),
                UCL( 4.72 )
            ),
            Phase Level( "2",
                Sigma( .21 ),
                Avg( 4.29 ),
                LCL( 4 ),
                UCL( 4.5 )
            )
        ),
        R( Phase Level( "1" ), Phase Level( "2" ) )
    ));
```

**Distribution**

You can set specification limits using the Spec Limits column property or using the `Spec Limits` argument in JSL:

```jsl
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
dt << Distribution(
```
Column( :OZONE ),
Fit Distribution(
    Weibull(
        Spec Limits( LSL( 0.075 ), Target( 0.15 ), USL( 0.25 ) )
    )
)
);

To set specification limits using K Sigma normal probabilities, use the Set Spec Limits for KSigma message. The first argument to the message is the value of K Sigma. By default, the limits are two-sided. To make them one-sided, use the optional sided argument. Specify sided=1 for LSL only and sided=2 for USL only.

dt = Open( "$SAMPLE_DATA/Cities.jmp" );
obj = Distribution( Column( :CO ) );
obj << Fit Distribution(
    LogNormal( Set Spec Limits for KSigma( 3 ) )
);

**DOE**

**Tip:** For a complete list of DOE scripting options, select Help > Scripting Index, select Objects from the menu, and search for DOE.

To reproduce your DOE work, most DOE platforms provide these approaches:

- In the red triangle menu for the DOE window, the Save Script to Script Window option provides a script that reproduces the work that you have entered. This option is not available for the Nonlinear Design and Taguchi Array platforms.
- In the output design tables created by most DOE platforms, a script called DOE Dialog reproduces the work in the DOE window that created the design table. This script also contains the random seed (and number of starts or column starts, where appropriate) that enables you to reproduce your design exactly.

For many DOE platforms, the design table that is created also contains one or more scripts that you can run to conduct an appropriate analysis. These scripts are prefilled with the appropriate settings for your design.

**The Random Seed**

In constructing designs using the DOE platform, JMP uses a random seed to control certain actions that have a random component. A random seed can control the following:

- initializing search algorithms for design generation
- randomizing Run Order for design construction
• selecting a starting design for designs based on random starts

To reproduce a design using a script, you need to specify the random seed that generated them. For designs using random starts, set a random seed in the script before making the design.

The following example creates a Custom Design, sets the random seed, and makes the design:

```doe
DOE(
    Custom Design,
    Add Factor( Continuous, -1, 1, "X1", 0 ),
    Add Factor( Continuous, -1, 1, "X2", 0 ),
    Set Random Seed( 34067086 ),
    Make Design
);
```

**Reproduce a Custom Design or a Main Effects Screening Design**

Custom designs and main effects screening designs (constructed in the Screening Design platform) are generated by allocating a maximum number of seconds (Design Search Time) spent searching for a design. The default setting for Design Search Time is based on the complexity of the design. Even when two custom or main effects screening designs are constructed using the same random seed, the designs might not be identical because of different machine processing capabilities.

When you save the script for either of these designs using the Save Script to Script Window option, or when the DOE Dialog script is saved to the data table, the script specifies the Random Seed and the Number of Starts. The Number of Starts is the number of random starts used during the Design Search Time. The combination of the Set Random Seed and the Number of Starts options enables you to reproduce the design.

**Note:** If you write your own script, be aware that the order in which you specify options in your script can affect your results. For example, you should specify the design options before you make the design. In particular, if your design is constructed using a random seed, set it before you make the design.

**Global Variables**

Here are some global variables used to initiate or tune search algorithms.

**Starting Design** Enables you to specify a starting design. The following example replaces the random starting design with a specified matrix:

```doe
DOE Starting Design = matrix;
```

If a starting design is supplied, the Custom Design platform has only one start using this design.
**K Exchange Value** The coordinate exchange algorithm considers every row of factor settings for possible replacement in every iteration. You can limit the number of rows considered for exchange in an iteration so that only a small number of most likely rows is considered. The following example tells the algorithm to consider only the three most likely rows for exchange in each iteration:

\[
\text{DOE K Exchange Value} = 3; 
\]

**Bayes Diagonal** Defines a vector that is added to the diagonal elements of the \(X'X\) matrix. This new matrix is used in finding the \(D\)-optimal design. The following example adds the elements of \text{vector} to the diagonal elements of the \(X'X\) matrix:

\[
\text{Bayes Diagonal} = \text{vector}; 
\]

**Fit Model**

When scripting the Fit Model platform, here are a few general tips for controlling the behavior of the launch window:

- To keep the launch window open and fit the model at the same time, do one of the following (they are equivalent):
  - Include the \text{Run Model} message in your script.
  - Include both the \text{Run} message and the \text{Keep Dialog Open(1)} message.
- To run the model without showing the launch window, include the \text{Run} message in your script.

**Model Scripts in the Data Table**

When a data table contains a \text{Model} script and you launch Fit Model interactively, the Fit Model launch window is pre-populated according to the roles assigned by the table script.

**Fit Group**

If you want to fit different models and see a shared Profiler so that you can compare the models, use the \text{Fit Group} function. You can fit models such as least squares, nonlinear, neural, Gaussian processing, and mixed, in the same window with a shared Profiler. The following example creates both a Standard Least Squares model and a Gaussian Process model.

\[
\text{dt} = \text{Open( "\$SAMPLE_DATA/Tiretread.jmp" );} \\
\text{obj} = \text{dt} << \text{Fit Group(} \\
\quad \text{Fit Model(} \\
\qquad \text{Y( :ABRASION ),} \\
\qquad \text{Effects(} \\
\qquad qquad :\text{SILICA & RS,} \\
\qquad \text{Bayes Diagonal = vector:} \\
\text{Bayes Diagonal} = \text{vector;} \\
\text{DOE K Exchange Value = 3;} \\
\text{Fit Model} \\
\text{when scripting the Fit Model platform, here are a few general tips for controlling the behavior of the launch window:} \\
\text{• To keep the launch window open and fit the model at the same time, do one of the following (they are equivalent):} \\
\text{– Include the Run Model message in your script.} \\
\text{– Include both the Run message and the Keep Dialog Open(1) message.} \\
\text{• To run the model without showing the launch window, include the Run message in your script.} \\
\text{Model Scripts in the Data Table} \\
\text{When a data table contains a Model script and you launch Fit Model interactively, the Fit Model launch window is pre-populated according to the roles assigned by the table script.} \\
\text{Fit Group} \\
\text{If you want to fit different models and see a shared Profiler so that you can compare the models, use the Fit Group function. You can fit models such as least squares, nonlinear, neural, Gaussian processing, and mixed, in the same window with a shared Profiler. The following example creates both a Standard Least Squares model and a Gaussian Process model.} \\
\text{dt} = \text{Open( "\$SAMPLE_DATA/Tiretread.jmp" );} \\
\text{obj} = \text{dt} << \text{Fit Group(} \\
\quad \text{Fit Model(} \\
\qquad \text{Y( :ABRASION ),} \\
\qquad \text{Effects(} \\
\qquad qquad :\text{SILICA & RS,}
\]
In the report, click the Fit Group red triangle and select **Profiler**. Scroll down to the Prediction Profiler. You can see the ABRASION row for the SLS model, and the HARDNESS row for the Gaussian Process model appearing in the same profiler.

### Effects

Effects in the model can be more than just a list of columns, and can have a specialized syntax:

```
Effects( list of effects, list of effect macros, or both lists );
```

An effect can be a column name, a crossing of several column names with asterisk (*) notation, or nested columns specified with subscript bracket ([ ]) notation. Additional effect options can appear after an ampersand (&) character. Here are some examples:

- `A`,         // a column name alone is a main effect
- `A*B`,       // a crossed effect, interaction, or polynomial
- `A[B]`,      // nested
- `A*B[C D]`,  // crossed and nested
- `effect&Random`, // a random effect
- `effect&LogVariance`, // a variance model term
- `effect&RS`,  // a response surface term
- `effect&Mixture`, // for an effect participating in a mixture
- `effect&Excluded`, // for an effect that with no model arguments
- `effect&Knotted`, // for a knotted spline effect

Effect macros are:

- `Factorial( columns )`, // for a full factorial design
- `Factorial2( columns )`, // for up to 2nd-degree interactions only
Responses and Effects for MANOVA

To address an individual response function analysis, use a subscripted Response:

```julia
manovaObj << ( Response[ 1 ] << {response options} );
manovaObj << ( Response[ "Contrast" ] << {response options} );
```

Each response function supports the Custom Test message:

```julia
Custom Test( matrix, <Power Analysis( ... )>, <Label( "..." )> )
```

where each row of the matrix specifies coefficients for all the arguments in the model.

To address an individual Effect test, use subscripted Effect with a name or number:

```julia
manovaObj << ( Response[1] << ( Effect["Whole Model"] << {effect options} ) );
manovaObj << ( Response[1] << ( Effect[i] << {effect options} ) );
```

The effects are numbered:

- 0 for the intercept
- 1, 2, and so on, for regular effects
- \(n+1\) for the “Whole Model” test, where \(n\) is the number of effects not including the intercept

Each effect in each response function supports the following messages, where each row of the matrix has coefficients for all the levels in the effect:

```julia
Test Details( 1 ),
Centroid Plot( 1 ),
Save Canonical Scores,
Contrast( matrix, <Power Analysis(...)> );
```

For example, the following JSL script adds test details for an effect to the report window:

```julia
dt = Open( "$SAMPLE_DATA/Dogs.jmp" );
manObj = dt << Fit Model(  
    Y( logHist0, logHist1, logHist3, logHist5 ),  
    Effects( dep1, drug, drug * dep1 ),  
    Personality( "MANOVA" ),  
    Run Model
);
manObj << Response Function( "Contrast" );
manObj << (Response["Contrast"] << (Effect["Whole Model"] <<

    /* send the Test Details message to the Whole Model outline
    under Contrast in the report window */
    Test Details( 1 )));
```
/* send the Test Details message to response 1 (Contrast) and effect 3 (drug*dep1) */
manObj << (Response[1] << (Effect[3] << Test Details( 1 )));

### Send Function

**Tip:** Recall that the `<<` operator is equivalent to the `Send()` function.

When you have multiple responses, you can send messages to a specific response column’s fit. Use the following JSL (where `responseName` is the specific response):

```jsl
fitObj << ( responseName << {options, ...});
```

The second `Send()` function finds the named response and sends the list of messages to it.

**Note:** If you send the messages directly to the `fitObj` with a single `Send()` function, the messages are sent to all responses.

In the following script, the last line sends a message to the AICc report for the ABRASION response:

```jsl
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
fitObj = dt << Fit Model(
    Y( :ABRASION, :MODULUS, :ELONG, :HARDNESS ),
    Personality( "Standard Least Squares" ), Run );
/* shows up under the Studentized Residuals plot*/
fitObj << (:ABRASION << {AICc( 1 )});
```

To send messages to an individual effect, nest even further:

```jsl
fitObj << ( responseName << ((effectName) << effectOption ));
```
Standard Least Squares

For Standard Least Squares models that contain only fixed effects and more than one Y response, you can choose to fit the models for the Y responses together or separately. If some of the rows have missing values, the following apply:

- In a script, the Y responses are fit together by default. The model fits each Y using only those rows that are nonmissing for all of the Y variables. For example, a row that includes one or more missing Y values is excluded from the model. You can explicitly include `Run( "Fit Together" )` in a script to get the same result.

- If you include the `Run( "Fit Separately" )` option, the model fits each Y using all rows that are nonmissing for that particular Y. For example, a row that includes one or more missing Y values is included in the model.

The following script fits the Y responses together:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Fit Model(
    Y( :height, :weight ),
    Effects( :sex ),
    Personality( "Standard Least Squares" ),
    Emphasis( "Minimal Report" ),
    Run // or Run( "Fit Together" )
);
```

The following script fits the Y responses separately:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Fit Model(
    Y( :height, :weight ),
    Effects( :sex ),
    Personality( "Standard Least Squares" ),
    Emphasis( "Minimal Report" ),
    Run( "Fit Separately" )
);
```

When running the model in JMP, the user is prompted to select fitting the responses separately or together. The Fit Model launch window contains a Fit Separately option, which is deselected by default. For more information about how missing Y values are handled, see Fitting Linear Models.

**Note:** In models that contain a random effect, Y values are fit separately by default.
Formula Depot

Sending commands via JSL to a Formula Depot platform report requires that you first create an empty Formula Depot. Once you have a reference to the Formula Depot report, you can send commands to it. The following script opens a formula depot report and adds a model to the depot.

```javascript
dt = Open( "$SAMPLE_DATA/Liver Cancer.jmp" );
fd = Formula Depot(); // open a new Formula Depot
obj1 = dt << Run Script( "Lasso Poisson, Validation Column" );
model = obj1 << (Fit[1] << Publish Prediction Formula );

/* Publish a model to the Formula Depot. The following script opens a formula depot report, adds a model to the depot, generates scoring code for the formula, saves the code to a file, and closes all windows.*/
case_name = "fitLS_prediction";
dest_dir = "c:"; //CHANGE ME to a better location
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Print( "Running " || case_name );
fm_ls = Fit Model(
    Y( :weight ),
    Effects( :age, :sex, :height ),
    Personality("Standard Least Squares" ),
    Emphasis("Minimal Report" ),
    Run
);
fd = fm_ls << Publish Prediction Formula;
Try(
    Print( "Generate Python Code" );
    code = fd << Generate Python Code( No Editor );
    Save Text File( dest_dir || case_name || ".py", code );
    Print( "Done." );
    Print( "Code generation failed for " || case_name || ", reason: " );
    Show( exception_msg );
);
fdw = Window( "Report: Formula Depot" );
fdw << Close Window( No Save );
Close( dt, No Save );
```

Graph Builder

The following is an example of the basic structure of a Graph Builder script:

```javascript
Graph Builder(
```
The following is an example of a simple Graph Builder script that creates a bar chart:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Graph Builder(
    Variables(
        X( :age ),
        Y( :weight ) ),
    Elements( Bar( X, Y, Legend( 8 ) ) )
);  // Legend is not required, but provides an internal legend ID that you can use for later customization
```

The following is a more detailed Graph Builder script that creates a bar chart:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Graph Builder(
    Size( 373, 332 ),
    Show Control Panel( 0 ),
    Variables(
        X( :age ),
        Y( :weight ),
        Y( Transform Column( "weight25", Formula( Col Quantile( :weight, 0.25, :age ) ) ),
            Position( 1 ) ),
        Y( Transform Column( "weight75", Formula( Col Quantile( :weight, 0.75, :age ) ) ),
            Position( 1 ) )
    ),
    Elements( Bar( X, Y( 2 ), Y( 3 ), Legend( 10 ), Bar Style( "Range" ) ),
        Bar( X, Y( 1 ), Legend( 8 ),
            Bar Style( "Float" ), Summary Statistic( "Median" ) )
    );  // This bar element uses the first Y variable and draws its median with the float style, which is a short horizontal line
```
Points( X, Y( 1 ), Legend( 9 ) )
// The Points element shows the raw data as markers.
)
SendToReport(
// Contains display customizations
Dispatch( {}, "400", ScaleBox,
// 400 is the fixed name
{Legend Model( 10,
  Level Name( 0, "1st to 3rd quartiles",
  Item ID( "Mean(weight25)..Mean(weight75)" ), 1 )
// Renames and changes the color for legend 10 (the Range bar)
  ),
  Properties( 0, {Fill Color( 32 )}, Item ID( "Mean(weight25)..Mean(weight75)" ), 1 )
// Changes the color for legend 10 (the range bar)
  ),
  Legend Model( 9,
  Properties( 0, {Marker Size( 4 )}, Item ID( "weight", 1 )
// Changes the marker size for legend 9 (the Points element)
  )}
),
Dispatch( {}, "graph title", TextEditBox,
  {Set Text("Weights with quartile ranges")}
// Changes the graph title
),
Dispatch( {}, "Y title", TextEditBox, {Set Text("weight")} ),
// Changes the Y axis title
Dispatch( {}, "400", LegendBox,
  {Legend Position( {10, [0], 8, [1], 9, [-1]} )}
// Hides the legend item for legend 9 by giving it a position of -1
)
);

Neural and Neural Net

The Neural platform replaces the Neural Net platform. Scripts that use Neural Net are deprecated and might not work in the future. It is recommended to use the Neural platform for new scripts and update any old scripts using Neural Net to Neural.
Partial Least Squares and PLS

The Partial Least Squares (PLS) platform has replaced the PLS platform. Scripts that use PLS might not work in the future. It is recommended to use the Partial Least Squares platform for new scripts and update any old scripts using PLS to Partial Least Squares.

Process Capability

The Process Capability platform has replaced the Capability platform. Scripts that use Capability might not work in the future. It is recommended to use the Process Capability platform for new scripts and update any old scripts using Capability to Process Capability.

Specification Limits in JSL Scripts

Specification limits can be read from JSL scripts, column properties, or from a specification limits data table. As an example of reading in specification limits from JSL, consider the following example:

```julia
dt = Open( "SAMPLE_DATA/Cities.jmp" );
dt << Process Capability(
    Process Variables( :OZONE, :CO, :SO2, :NO ),
    Spec Limits(
        OZONE( LSL( 0.075 ), Target( 0.15 ), USL( 0.25 ) ),
        CO( LSL( 5 ), Target( 7 ), USL( 12 ) ),
        SO2( LSL( 0.01 ), Target( 0.04 ), USL( 0.09 ) ),
        NO( LSL( 0.01 ), Target( 0.025 ), USL( 0.04 ) )
    )
);
```

Using a Limits Data Table and JSL

There is no extra syntax needed to differentiate between the two table types (wide and tall) when they are read using JSL. This example is based on the CitySpecLimits.jmp sample data table. It places the specification limits data table inside an Import Spec Limits() expression.

```julia
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
dt << Process Capability(
    Process Variables( :OZONE, :CO, :SO2, :NO ),
    Spec Limits(
        Import Spec Limits("$SAMPLE_DATA/CitySpecLimits.jmp"
    )));
```
Scatterplot 3D

If your machine supports acceleration, and you want to display the 3-D scatterplot faster, you can turn on the Use Hardware Acceleration option, or in JSL, specify the `Scene3DHardwareAcceleration` global variable. A value of 1 turns it on, and a value of zero turns it off.

```jsl
dt = Open( "$SAMPLE_DATA/Solubility.jmp" );
Scene3DHardwareAcceleration = 1;
dt << Scatterplot 3D(
   Y( :"1-Octanol"n, :Ether, :Chloroform, :Benzene, :Carbon Tetrachloride, 
      :Hexane )
);
```

Text Explorer

By default, text is converted to all lowercase in the Text Explorer platform. You can use the "From Source" keyword in the Save Regex Column message to save the results of a custom regex that preserve the original case of the text. The first argument is the name of the column that is created in the data table. The second argument is the string "From Source" or "From Result". The default behavior is equivalent to specifying the "From Result" keyword.

```jsl
dt = Open( "$SAMPLE_DATA/Aircraft Incidents.jmp" );
obj = dt << Text Explorer(
   Text Columns( :Airport Name),
   Tokenizing( "Regex" ),
   Save Regex Column( "Output Column", "From Source" )
);
obj << Close Window();
```

Explore Outliers

The Explore Outliers platform provides options to identify, explore, and manage outliers in your univariate or multivariate data.

In the `Probe.jmp` sample data table, several columns contain outlier values of 9999. Many industries use nines as a missing value code. The following example selects `VDP_PCOLL`, `VDP_PINNBASE`, and `VDP_PINPBASE`, the columns with the highest number of 9s, and adds the Missing Value Codes column property to the columns. The script then rescans the columns and removes these columns from the report.

```jsl
dt = Open( "$SAMPLE_DATA/Probe.jmp" );
obj = Explore Outliers(
   Y( 
      :VDP_M1,
   );
```
Some messages and arguments that can be sent to a platform object are scripting-only. This means that these options do not have corresponding options in JMP launch windows or reports. However, note that scripting-only options can appear as Preferences.

This section describes scripting-only messages and arguments for specific platforms.
Tip: For more information about any of these messages or arguments, and for specific examples, go to the Scripting Index (Help > Scripting Index).

- “Bivariate Script-Only Message”
- “Choice Script-Only Message”
- “Clustering Script-Only Messages”

### Bivariate Script-Only Message

The Fit Where message for Bivariate objects fits a curve or line to a single level of a categorical variable.

```r
biv_object << Fit Where( WHERE_clause );
```
Choice Script-Only Message

When estimating the parameters in the Choice platform, you can set the acceptable criterion for convergence using this JSL function:

```
Convergence Criterion( fraction );
```

Clustering Script-Only Messages

The following messages for a hierarchical cluster object are available only in JSL:

```
// returns the column names in cluster order (for two-way clustering)
hier_cluster_object << Get Column Names

// returns a vector of cluster numbers
hier_cluster_object << Get Clusters

/* returns a vector of the display position for each row in the cluster,
with missing values for undisplayed rows */
hier_cluster_object << GetDisplayOrder

/* returns a vector of the display position for each column
(for two-way clustering)*/
hier_cluster_object << GetColumnDisplayOrder

// returns the distance matrix used for hierarchical clustering
hier_cluster_object << Get Distance Matrix
```

KMeans Clustering

The following message for a KMeans cluster object is available only in JSL. The message returns the mean and standard deviation for each variable within each cluster.

```
kmeans_cluster_object << Get Statistics
```

Control Chart Script-Only Message

The following argument for the Control Chart() function is available only in JSL. The message includes points that are excluded in the moving range calculations.

```
Use Excluded Points on MR( Boolean )
```
Control Chart Builder Script-Only Messages

The following arguments for the Control Chart Builder() function are available only in JSL:

// reruns all tests and alarms
Rerun All Tests

// sets the width and height of the control chart
Size( width, height )

// specifies the sigma multiplier
KSigma()

Cumulative Damage Script-Only Message

The following message for a Cumulative Damage object is available only in JSL. It returns a list of model fit results.

cumulative_damage_object << Get Results

Custom Profiler Script-Only Messages

The following messages for Custom Profiler objects are available only in JSL:

// returns the current value of the objective function
profiler_object << Get Objective

// set the formula for the objective function
profiler_object << Objective Formula

// returns the formula for the objective function as an expression
profiler_object << Get Objective Formula

Distribution Script-Only Messages

The following message for a Distribution object is available only in JSL. The message creates an array of handles to the fitted distributions, so you can send commands to specific distributions:

dist_object << ( Fit Handle[n] << ...);

You can also get a reference to a fitted distribution directly if you send the Fit Distribution message to a Distribution object. This enables you to send commands to specific distributions:

fit_object = dist_object << Fit Distribution( distribution_name );
fit_object << ...;

The following message for a Distribution object is available only in JSL. The message specifies that PpK labeling be used in the Process Capability reports within the Distribution report object.

dist_object << PpK Capability Labeling( 1 );

### Fit Life by X Script-Only Messages

The following messages for a Fit Life by X object are available only in JSL:

/* set scriptable options within the profilers in different sections of the output */
fit_life_object << Set Scriptables( ... );

/* return the estimates, standard errors, covariance matrix, and convergence results for each distribution fit */
fit_life_object << Get Results

### Fit Model Script-Only Messages

The following section describes scripting-only messages for MANOVA, Generalized Linear Models, Nominal and Ordinal Logistic, and Standard Least Squares.

#### MANOVA

The following message for a Fit MANOVA object is available only in JSL:

fit_model_object << ( Response[1] << (Effect[1] << ... ) );

Where the third message could be one of the following:

- Test Details // show or hide the test details for an individual effect
- Centroid Plot // show or hide the centroid plot for an individual effect
- Save Canonical Scores // save the canonical scores for an individual effect
- Contrast /* run a customized F test contrasting different levels for an effect in the model*/

The following example saves canonical scores for the Response Function, which in this data, is Sum:

```java
dt = Open( "$SAMPLE_DATA/Dogs.jmp" );
obj = dt << Fit Model(
    Y( :LogHist0, :LogHist1, :LogHist3, :LogHist5 ),
    Effects( :drug, :dep1, :drug * :dep1 ),
    Personality( "Manova" ),
    Run( Response Function( Sum ) )
)```

```java
```
Generalized Linear Models

The following message for a Fit GLM object is available only in JSL. The message saves the parametric formula to a new column in the data table.

Parametric Formula();

Nominal and Ordinal Logistic

The following messages for Fit Nominal Logistic and Fit Ordinal Logistic objects are available only in JSL:

// create a SAS DATA step to score the data
fit_model_object << Get SAS Data Step

// create SAS code that you can register in the SAS Model Manager
fit_model_object << Get MM SAS Data Step

Standard Least Squares

The following JSL messages return the requested item from the fitted model, such as variance components, $p$-values, parameter estimates, and so on:

fit_model_object << Get Variance Components();
fit_model_object << Get Effect Names();
fit_model_object << Get Effect PValues();
fit_model_object << Get Estimates();
fit_model_object << Get Parameter Names();
fit_model_object << Get Random Effect Names();
fit_model_object << Get Std Errors();
fit_model_object << Get X Matrix();
fit_model_object << Get XPX Inverse();
fit_model_object << Get Y Matrix();

The following message for Standard Least Squares objects is available only in JSL:

obj << Get SQL prediction expression;

The following example saves prediction formulas as SQL expressions and outputs them to the log:

dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
obj = dt << Fit Model(
  Y( :ABRASION, :HARDNESS ),
  Effects( :SILICA, :SILANE, :SULFUR ),
  Personality( "Standard Least Squares" ),
  Run
);
Fit Parametric Survival Script-Only Messages

The following JSL messages return the requested item from the fitted model, such as parameter names, parameter estimates, standard error, and so on:

```javascript
survival_object << Get Parameter Names
survival_object << Get Estimates
survival_object << Get Std Errors
survival_object << Get Effect Names
survival_object << Get Effect PValues
```

K Nearest Neighbors Script-Only Messages

The following JSL message constructs a script to create a prediction formula column and returns it to the log.

```javascript
knn_object << (Response[number] << Get Prediction Formula)
```

The following JSL message returns the value of the best K neighbors.

```javascript
knn_object << Response[number] << Get Best K
```

Latent Class Analysis Script-Only Message

The following JSL message constructs a script to create probability formula columns and returns them to the log.

```javascript
latent_class_object << (Fit[number] << Get Probability Formulas)
```

The following example sets a random seed in order for it to be reproducible.

```javascript
dt = Open( "$SAMPLE_DATA/Car Poll.jmp" );
obj = dt << Latent Class Analysis(
   Y( :sex, :marital status, :country, :size, :type ),
   Set Random Seed( 12345 ),
   Number of Clusters( 3 ),
);
```
Life Distribution Script-Only Messages

The following JSL messages prevent a specified plot from appearing in the report, or return the requested item from the fitted model, such as results, estimates, or formulas.

```jsl
life_dist_object << Suppress Plot( plot_name )
life_dist_object << Get Results
life_dist_object << Get Estimates
life_dist_object << Get Formula
```

Multivariate Script-Only Messages

The following message for a Multivariate object is available only in JSL:

```jsl
// create SAS PROC Mixed code to run similar estimation methods using SAS
multivariate_object << Create SAS Job( );
multivariate_object << Get Correlation Matrix;
multivariate_object << Get Inv Correlation Matrix;
```

Naive Bayes Script-Only Messages

The following messages for a Naive Bayes object are available only in JSL:

```jsl
naive_bayes_object << Get Probability Formulas;
native_bayes_object << Prior Bias( <fraction=0.5> );
```

Neural Script-Only Messages

**Note:** The Neural platform replaces the Neural Net platform. Scripts that use Neural Net are deprecated and might not work in the future. It is recommended to use the Neural platform for new scripts and update any old scripts using Neural Net to Neural.

The following message for Neural objects is available only in JSL:

```jsl
// return the number of models used for boosting
neural_object << Get NBoost
```

The following JSL messages for Neural Fit objects return the requested item from the fitted model, such as entropy RSquare, generalized RSquare, misclassification rates, and so on:

```jsl
neural_object << ( Fit[n] << Get RSquare Training )
neural_object << ( Fit[n] << Get RSquare Validation )
neural_object << ( Fit[n] << Get RSquare Test )
neural_object << ( Fit[n] << Get Gen RSquare Training )
```
neural_object << ( Fit[n] << Get Gen RSquare Validation )
neural_object << ( Fit[n] << Get Gen RSquare Test )
neural_object << ( Fit[n] << Get Misclassification Rate Training )
neural_object << ( Fit[n] << Get Misclassification Rate Validation )
neural_object << ( Fit[n] << Get Misclassification Rate Test )
neural_object << ( Fit[n] << Get Average Log Error Training )
neural_object << ( Fit[n] << Get Average Log Error Validation )
neural_object << ( Fit[n] << Get Average Log Error Test )
neural_object << ( Fit[n] << Get RMS Error Training )
neural_object << ( Fit[n] << Get RMS Error Validation )
neural_object << ( Fit[n] << Get RMS Error Test )
neural_object << ( Fit[n] << Get Average Absolute Error Training )
neural_object << ( Fit[n] << Get Average Absolute Error Validation )
neural_object << ( Fit[n] << Get Average Absolute Error Test )
neural_object << ( Fit[n] << Get ROC Area Training )
neural_object << ( Fit[n] << Get ROC Area Validation )
neural_object << ( Fit[n] << Get ROC Area Test )
neural_object << ( Fit[n] << Get Confusion Matrix Training )
neural_object << ( Fit[n] << Get Confusion Matrix Validation )
neural_object << ( Fit[n] << Get Confusion Matrix Test )
neural_object << ( Fit[n] << Get Confusion Rates Training )
neural_object << ( Fit[n] << Get Confusion Rates Validation )
neural_object << ( Fit[n] << Get Confusion Rates Test )
neural_object << ( Fit[n] << Get Seconds )

Pareto Plot Script-Only Message

The following message for a Pareto Plot object is available only in JSL:

No Plot( Boolean );
   // close the outline for the Pareto plot

Partition Script-Only Messages

The following JSL messages for Partition objects return the requested item from the fitted model, such as entropy RSquare, generalized RSquare, misclassification rates:

partition_object << Get RSquare Training
partition_object << Get RSquare Validation
partition_object << Get RSquare Test
partition_object << Get Gen RSquare Training
partition_object << Get Gen RSquare Validation
partition_object << Get Gen RSquare Test
partition_object << Get Misclassification Rate Training
partition_object << Get Misclassification Rate Validation
partition_object << Get Misclassification Rate Test
partition_object << Get ROC Area Training
partition_object << Get ROC Area Validation
partition_object << Get ROC Area Test
partition_object << Get Average Log Error Training
partition_object << Get Average Log Error Validation
partition_object << Get Average Log Error Test
partition_object << Get RMS Error Training
partition_object << Get RMS Error Validation
partition_object << Get RMS Error Test
partition_object << Get Average Absolute Error Training
partition_object << Get Average Absolute Error Validation
partition_object << Get Average Absolute Error Test
partition_object << Get Seconds
partition_object << Get SAS Data Step
partition_object << Get Tolerant SAS Data Step
partition_object << Get MM SAS Data Step
partition_object << Get MM Tolerant SAS Data Step

Process Screening Script-Only Messages

The following JSL message for Process Screening saves the row states for the table of processes.

process_screen_object << RowStates

Surface Plot Script-Only Messages

The following messages for a Surface Plot object can also be controlled in JMP, but might not have corresponding options in the red triangle menu of another platform such as Profiler:

/* Isosurface uses three independent variables as the X, Y, and Z axes and simultaneously plots the surfaces for the dependent variables on the plot. Sheet has one Z response that is dependent upon two independent X, Y variables.*/
surface_plot_object << Mode( "Isosurface" | "Sheet" )

// set the Z axis by referencing the column
surface_plot_object << Set Z Axis( col, Current Value( n ) )

// set the independent variable axes by referencing each individual column
surface_plot_object << Set Variable Axis( col, Current Value( n ) )

// identify up to four response columns for plotting overlaid points
surface_plot_object << Response( ... )
// assign formulas to columns in the sheets in a specified order
surface_plot_object << Formula( ... )

Text Explorer Script-Only Messages

The following JSL messages for a Text Explorer object are available only in JSL:

/* specify the minimum number of occurrences a phrase must have
to be included in the phrase list */
text_explorer_object << Minimum Frequency for Phrase( n )

// alias for Save Document Term Matrix()
text_explorer_object << Save Indicators for Most Frequent Words( ... )

// alias for Save Term Table()
text_explorer_object << Save Word Table( ... )

// alias for Score Terms by Column()
text_explorer_object << Score Words by Column( ... )

// replace default regular expressions used in Regex tokenizing
text_explorer_object << Set Regex( ... )

// create a new column with tokenized results
// "From Source" keyword uses the capitalization of the source strings
text_explorer_object << Save Regex Column( string, <"From Source"> )

// add user-defined delimiter characters, specified in a single string
text_explorer_object << Add Delimiters( string )

// replace default delimiter characters, specified in a single string
text_explorer_object << Set Delimiters( string )
text_explorer_object << Add Stop Words( list )
text_explorer_object << Add Phrases( list )
text_explorer_object << Add Stem Exceptions( list )

// add a list of words that are always allowed to be stemmed
text_explorer_object << Add Stem Overrides( list )

// add a list of words to remove from the list of stop words
text_explorer_object << Add Stop Word Exceptions( list )

// add a list of phrases to remove from the list of specified phrases
text_explorer_object << Add Phrase Exceptions( list )

// add a list of pairs of words to recode
text_explorer_object << Add Recodes( list )

// add a list of recoded text strings to remove
text_explorer_object << Add Recode Exceptions( list )
text_explorer_object << Terms Alphabetical( Boolean )
text_explorer_object << Phrases Alphabetical( Boolean )

// set the width of the word cloud in pixels
text_explorer_object << Cloud Width( pixels )

// supply a function for custom stemming
text_explorer_object << Custom Stemmer( function( {string, dot}, ... ) )

**Time Series Script-Only Messages**

The following JSL messages for a Time Series object are available only in JSL:

// return a list of model results named by model description
time_series_object << Get Models

// return a list of model results named by model specification
time_series_object << Get Model Specs
After you learn the basics of scripting, you’re ready to manipulate JMP reports and create new JMP windows. This chapter focuses on the following topics:

- navigating JMP display trees to manipulate items in report windows
- building new windows with custom results
- building modal windows
- interacting with the script editor
- converting deprecated Dialog() scripts to New Window() scripts

### Display Tree Compatibility Issues

JMP platforms are generally stable from release to release. However, sometimes the structure of reports changes in major releases. When this happens, old scripts can fail because of the new structure. To avoid the continual updating of old scripts, write scripts so that they avoid dependence on the report structure. Using a string to index a box, followed by a numbered subscript to pick a specific child box, is most reliable across releases. See “Create a Reference by Subscripting” on page 526. See “Compatibility Notes” on page 913 for compatibility issues in JMP 16.

**Note:** This chapter shows how to create and use the most common display boxes. All display boxes are documented in the JMP Scripting Index, which is available in the Help menu.

Navigate JMP Reports

As shown in Table 11.1, reports in JMP are built in a hierarchical manner by nesting and concatenating different types of rectangular boxes called *display boxes*. This section shows you how to navigate reports, extract data from them, and customize them.

**Table 11.1** Common Display Boxes in JMP Reports

- **Outline Box()** creates an outline hierarchy.

- **Picture Box()** combines axes, frames, and labels to make graphs.

- **Table Box()** is a special **H List Box()** whose elements are string and number columns.

The hierarchical (or parent-child) relationships between display boxes help determine the sizing. The outermost display box is the parent; the inner display boxes are children. When a report is displayed, the parent display box detects the size of the last child box (the leaf) and then detects the size of the child box that precedes the last child box. The size is detected for each box on the way back up the tree. Then the positioning of the boxes takes places from the top down so that the boxes can be shown in an orderly arrangement.
The hierarchical (or parent-child) relationships between display boxes form a tree of display boxes, called the display tree. For (parent) boxes that contain other (child) boxes, the parent box’s size is determined by the sizes of its child boxes rather than some fixed size, which keeps the whole display resizable. Similarly, positions of boxes are determined by positions of the boxes before them rather than using fixed positions. In tree terminology, the sizing is bottom-up and the positioning is top-down.

Examples of Common Display Boxes

Figure 11.1 shows a Bivariate report that consists of several common display boxes.

Figure 11.1 Display Boxes in a Report
Run the following script to create the report:

```plaintext
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( :weight ), X( :height ), Fit Line() );
```

**View the Display Tree**

View the report structure to see how display boxes are arranged in the display tree.

1. Run the following script:

```plaintext
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(  
  Y( :weight ),
  X( :height ),
  Fit Mean( {Line Color( {57, 177, 67} )} )
);
```

2. Right-click the top disclosure icon and select **Edit > Show Tree Structure**.

**Figure 11.2 Top Disclosure Icon**

In the Show Tree Structure window, you see the display box structure of the report as nested outline boxes. Each outline box corresponds to a display box in the original report.

3. Click the Bivariate graph. In Figure 11.3, the frame box that contains the graph is highlighted.
You can also obtain the tree structure through a script. Send the `Show Tree Structure()` message to any report. Or, send the message to a piece of the report (any display box object) to see the tree structure for just that part of the report.

The newer JMP tree structure provides a flat view of the display box tree rather than an outline view. To view the classic structure, press Shift before you right-click the disclosure icon and then select `Edit > Show Tree Structure`. Note the following differences between the newer and classic tree structure views:

- The classic tree structure is not linked to the original report; you cannot highlight specific portions of the tree.
- Siblings appear to the left or right of each other in the classic tree structure. In the newer tree structure, siblings are above or below each other.
Show Display Box Properties

There is an easy way to format reports before you save them to a script. You can edit the display box properties such as color and position in the Show Tree Structure window. In the report window, select **Edit > Properties** (Windows) or **View > Show Properties** (macOS). Click the node that you want to edit.

In Figure 11.5, the Summary of Fit statistics were selected below the graph. The Background Color and Text Color were then changed in the Properties. These changes are preserved when you save the report as a script or journal the report.
Display Box Object References

When you launch a platform, the results are in two places: a visible report, made of display boxes, and an invisible object, called a platform, that accepts commands (or messages).

One of the messages that you can send a platform is the `Report` message. The `Report` message retrieves the display box that holds the report.

The red triangle menu at the top of the report is connected to the platform object and is the way you interactively send messages to the platform.

To fit the mean in the Bivariate platform, assign a reference to the Bivariate platform.

```java
dt = Open( "\$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( // biv references the analysis layer
X( height ),
Y( weight ),
Fit Mean,
Fit Polynomial( 4 )
);
```
To get a reference to the display box that represents the view of the platform, use the `Report` message. For example, add this expression to the preceding script:

```javascript
rbiv = biv << Report; // rbiv references the report layer
```

Now you can manipulate the display boxes in the report layer as described in the following sections.

**See What You Can Do with a Display Box**

The following example creates a Bivariate report and stores its reference in the `rbiv` report object. It then puts the `rbiv` report object in a frame box and assigns the `fbx` variable.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( // biv references the analysis layer
  Y( :weight ),
  X( :height ),
  Fit Mean( {Line Color( {57, 177, 67} )} )
);
rbiv = biv << Report; // assign rbiv to the report layer
fbx = rbiv[Frame Box( 1 )];
```

After `fbx` has been defined, you can send it a message.

```javascript
fbx << Set Background Color( blue ); // colors the frame box in blue
```

The `Set Background Color` message works the same as right-clicking in the graph and selecting `Background Color > Blue`.

To find out which messages you can send to a frame box, select `Help > Scripting Index` and search for “frame box”. 
Running the `Show Properties()` function is an alternative to using the Scripting Index. The messages for the specified display box are printed to the log.

```
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    biv = dt << Bivariate( Y( :weight ), X( :height ) );
    Show Properties( biv );
    Show Points [Boolean] [Default On]
    Histogram Borders [Boolean]
    Fit Mean [Action](Fits a flat line at the mean.)
    ...
```

Many messages are the same as items in the pop-up menu for a given object. The next section, “Construct Custom Windows” on page 539, discusses messages for common display boxes in more detail.

**Create a Reference by Subscripting**

Use the subscript operator to navigate to a specific display box in the report. The best practice is to refer to the display box with an index number. The following expression identifies the second outline box in the display tree:

```
    var = Outline Box[2];
```

Another way to navigate a report is to search for a text string. The following expression identifies the report that has the specified text string:

```
    var = report[text];
```
This expression finds the display box in \( rpt \) that has the title \textit{text}. Note that \textit{text} must be the complete title, not just a substring of the title. The "\textit{text}" argument can also be any expression that evaluates to a text string. This approach is less reliable than referring to the display box with a subscript because the string in a report can easily change.

Typically, you want to assign the identified part of the report to a variable so that you can send messages to it easily. For example, to find the Analysis of Variance outline box in the Bivariate report, use this expression:

\[
\text{var} = \text{rbiv["Analysis of Variance"]};
\]

The sections below describe other methods for using a subscript operator to locate display boxes.

**Wildcard String**

You can use a wildcard character (such as "?") with a substring to match the rest of the outline title. The wildcard character "?" represents places in the search string where you want to match any sequence of any characters. The following script searches for a string that ends with "Mean", finds "Fit Mean", and then opens the Fit Mean outline:

```r
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(
  Y( :weight ),
  X( :height ),
  Fit Mean( {Line Color( {57, 177, 67} )} ),
  Fit Polynomial( 4 )
);
riv = biv << Report; // return a reference to the Bivariate report
out1 = riv["? Mean"]; // find "Fit Mean" in the Bivariate report
out1 << Close( 0 ); // open the Fit Mean outline
```

**Box Type and Wildcard String**

Another method for locating display boxes is to include the display box and wildcard search string in the substring operator.

\[
\text{var} = \text{riv[Display Box( "?text" )]};
\]

This expression finds the outline box that contains the specified text string in the \textit{riv} report. The \textit{out1} variable assigns a reference to the outline box.

\[
\text{out1} = \text{riv[Outline Box( "? Mean" )]};
\]

**Box Type and Index Number**

Another method for locating display boxes uses the \textit{boxType} and an index number, \textit{n}.

\[
riv[Display Box ( n )];
\]
The expression above finds the \( n \)th of the specified display box of the type `boxType`. For example, this expression finds the first outline box in the `rbiv` report and assigns it to the `out1` variable:

```plaintext
out1 = rbiv[Outline Box( 1 )];
```

This method is less reliable across releases because the number of a display box might change.

**Tip:** To determine the index number of a display box, view the tree structure as described in “View the Display Tree” on page 521.

### Nested Display Boxes

To reference a display box that appears several layers down in a report, use this format:

```plaintext
var = rpt[arg1][arg2][arg3][...];
```

The expression above matches the last argument to a display box that is `contained by` the next to last argument’s outline node, which is in turn contained by the argument before the next to last, and so on. In other words, it is a way of digging down into the hierarchy of an outline tree to identify a nested display box.

If you want to identify an item nested several layers down in an outline box, use a subscript with more than one argument of any of the above types. After locating the first item, JMP looks `inside` that item for the next, and so on.

```plaintext
rpt[arg1][arg2][arg3] // finds the first item then the next starting after that location, and so on
rpt[arg1, arg2, arg3] // different syntax, same result
```

Note that you can string together subscripts that have text or index numbers. The expression below finds the “Parameter Estimate” inside the outline node “Polynomial Fit Degree=4” and selects the third display box in the first table of the outline node.

```plaintext
out = rbiv["Polynomial Fit Degree=4"]["Parameter Estimates"][1][3] << Select;
```

“Example of Creating a Report” on page 536 shows how to extract parameter estimates from the report.

### Subscripting Display Boxes for Compatibility

JMP might add or remove display boxes in a report from release to release, causing numbered subscripts to choose a different box. Using a string to index a box, followed by a numbered subscript to pick a specific child box, is more reliable across releases.

```plaintext
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
rp = dt << Bivariate( 
  Y( :weight ),
  X( :height ),
```
Fit Line( {Line Color( {213, 72, 87} )} )
);
Print(
  "C.Total DF=",

// string references the parent box
Report( rp )[Outline Box( "Analysis of Variance" )][
  Number Col Box( 1 )][3] // subscript references the child box
);

Figure 11.7  Subscripted Display Box

The numbered subscripts (in the preceding example) are relative to the named box, which makes them less likely to change. However, this also means that the absolute numbers in Show Tree Structure can't be used directly.

Send Messages to Display Boxes

Use the display reference to send messages to the display elements using the Send or << operator. For example, if out2 is a reference to an outline node, you can ask the node to close itself if it is open:

out2 << Close(); // close the outline node

Close() toggles an outline node back and forth between closed and open states, just like selecting items in the red triangle menu. You can include a Boolean argument (1 or 0) for “close or leave closed” or “open or leave open.”

rbiv["Fit Mean"] << Close; // toggle open and closed
rbiv["Fit Mean"] << Close( 1 ); // close or leave closed
rbiv["Fit Mean"] << Close( 0 ); // open or leave open
The << Operator

You can send messages to display boxes using the send (<<) operator. The operator makes it clear when the script is evaluating child arguments and optional arguments. It also helps make it clearer which argument is an option and which is a script to run inside the graph.

Here is an example of sending a Graph Box a message:

```julia
win = New Window( "Messages",
    gb = Graph Box(
        Frame Size( 400, 400 ),
        X Scale( 0, 25 ),
        Y Scale( 0, 25 )
    );
    gb << Background Color( "red" );
```

Nesting and Precedence

When you stack (or nest) messages, each message is evaluated left to right.

- The following expression sends message1 to box, then message2 to box, then message3 to box. Note that any of the messages can change box before the next message is sent.
  
  box << message1 << message2 << message3;

- The following expression sends message1 to box and gets the result. Message2 is sent to that result, and message3 is sent to the result of message2.
  
  ( box << message1 ) << message2 ) << message3

- The result of message3 is assigned to the variable x.
  
  x = box << message1 << message2 << message3;

Here is an example of using nested messages:

```julia
win = New Window( "Messages", gb = Graph Box() );
```
// message 1 sets the background color
sz = gb << Background Color( "red" )

// message 2 saves the graph box as a PNG file
<<Save Picture( "$DOCUMENTS/red.png", "png" )

// message 3 sets the graph box background color to white
<<Background Color( "white" )

// message 4 returns the graph box size and prints it to the log
<<Get Size();

If you nest several messages, you might want to use parentheses to group the messages to be sure your script does what you want it to.

Customize Reports with the Send To Report and Dispatch Functions

The Send To Report() and Dispatch() functions provide a way for JMP to record display box modifications inside an analysis script in a self-contained way. For example, arguments within the two functions open and close outline nodes, resize graphics frames, or customize the colors in a graphics frame. You can also specify the arguments in separate JSL statements.

Send To Report() contains a list of options that change the display tree.

Dispatch() contains four arguments that change the display tree:

- The first argument is a list of outline nodes that need to be traversed to find the desired part of the display tree.
- The second and third arguments work together. The second argument is the name of a display element, and the third argument is the display element’s type. These two arguments specify which particular part of the display tree is to be customized.
- The fourth argument is a list of options.

For example, open Big Class.jmp and run the attached Bivariate script. This generates a report with a fitted line. Open the Lack of Fit outline node, and close the Analysis of Variance outline node. Select Save Script > To Script Window. The following script appears in the script editor window:

```jss
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(
  Y( :weight ),
  X( :height ),
  Fit Line(),
  SendToReport(
    Dispatch(
      {"Linear Fit"},
      "Lack Of Fit",
```
OutlineBox,
{Close( 0 )} ),
Dispatch(
{"Linear Fit"},
"Analysis of Variance",
OutlineBox,
{Close( 1 )}
)
);

The `Send To Report()` function contains two `Dispatch()` functions that customize the default report.

- The first argument finds an outline node named “Linear Fit”.
- The second and third arguments finds an outline box named “Lack of Fit” below the “Linear Fit” outline.
- The fourth argument is the argument to send to this outline box. In this case, the message is `Close(0)`, in other words, open the node.

**Note:** If there are several outline nodes with identical names, subscripts are assigned to them. For example, if you have a Bivariate analysis with two quadratic fits (resulting in identical titles), when you dispatch a command to the second fit, the subscript [2] is added to the duplicated title.

The best way to deal with `Send to Report()` and `Dispatch()` is to first create a customized report interactively. Save the report as a script and then examine the script that JMP generates. Remember: the best JSL writer is JMP itself.

**Create a Journal**

Creating a journal enables you to capture the contents of a JMP window at a fixed moment in time. Suppose that a JMP window contains a graph and selected check boxes. The journal shows the graph and the check boxes that were selected when you created the journal.

The following examples show what you can do with a journal.

Suppose that you start with a Bivariate report.

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( weight ), X( height ) );
rbiv = biv << Report;

Journal the results:

rbiv << Journal Window;
```
Save the journal to a file:

```julia
rbiv << Save Journal(
    "$DOCUMENTS/test.jrn"
);
```

Note that the above example uses macOS pathname conventions. On Windows, you can use forward slashes (which are appropriate for all platforms) or backslashes (which are appropriate only for Windows).

When a script uses a By variable, the result is a list of references to the analysis results for each By group. In order to journal all By member parts of the report, you need to use parent messages to get to the top of the report.

For example, the following script creates a Bivariate report with a By group and then journals the entire report:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(
    Y( weight ),
    X( height ),
    By( sex )
);
    Save Journal( "test.jrn" );
```

### Journals with Grid Lines

When axes are collapsed, grid lines disappear when the report is journaled, pasted, or saved as a PDF file. Saving the report from JMP as a picture file or a Microsoft PowerPoint presentation retains the grid lines in the graph.

### Using Common Messages

#### Update a Numeric Column

To update a numeric column in a display box table, use the `Set Values` message.

```julia
win = New Window( "Numeric Column",
    num = Number Col Box( "Values", [9, 10, 11] )
);
num << Set Values( [1, 2, 3] );
```

The matrix argument specifies the new numbers for the table.

#### Add the Thousands Separator in a Numeric Column

To add the thousands separator in a numeric column, use the `Set Format` message.
New Window( "Example",
   ncb = Number Col Box( "Random Numbers",
      {Random Uniform(), Random Uniform() * 10,
      Random Uniform() * 100, Random Uniform() * 1000,
      Random Uniform() * 10000}
   );
   ncb << Set Format(10,3, "Fixed Dec", "Use thousands separator");

Update a String Column

To update a string column in a display box table, use the Set Values message.

   win = New Window( "String Column",
      str = String Col Box( "Values", {"a", "b", "c"} )
   );
   str << Set Values( {"A", "B", "C"} );

The list argument specifies the new strings for the table.

Wrap Text

Generally, JMP automatically wraps text within Text Box(). However, the default wrap point can be overridden with a Set Wrap (n) message. The following script wraps the text at 200 pixels.

   win = New Window( "Set Wrap",
      tb = Text Box(
         "Hover over a data point for more information."
      )
   );
   tb << Set Wrap( 200 );

Include Bullet Points in Text Boxes

You can add bullet points using the Bullet Point( 1 ) message.

   win = New Window( "Bullet List",
      text1 = Text Box( "Hover over a data point for more information." ),
      text2 = Text Box( "Draw a circle around a statistic for more information." )
   );
   text1 << Bullet Point( 1 );
   text2 << Bullet Point( 1 );

Sending the Bullet Point( 1 ) message to a text box places a bullet in front of the text and indents subsequent lines within that text box.

You can also send the Bullet Point( 1 ) message inline as shown in the following example:
Blink a Selected Display Box

You can use Select, Reshow, and Deselect to blink the selection highlight on a display box. As previously described, you can string together several << clauses to send an object several messages in a row. The results read left to right; for example, here Select is done first, then Reshow, then Deselect, then the other Reshow.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(
  Y( :weight ),
  X( :height ),
  Fit Mean( )
);

// assign the bivariate analysis layer to rbiv
rbiv = biv << Report;

/* find outline box with the specified string in the
rbiv report and assigns it to the out2 variable */
out2 = rbiv[Outline Box( "? Mean" )];
out2 << Close( 0 ); // open the outline box

// find the first string col box in rbiv and
assign the scbx variable */
scbx = rbiv[String Col Box( 1 )];

Wait( .25 ); // wait .25 seconds
For( i = 0, i < 20, i++, // set i to 0, iterate through the loop 20 times
  /* select the string col box and reshow it,
deselect it and reshow it */
  scbx << Select << Reshow << Deselect << Reshow
);
```

Add Shading or Borders to Table Headings

Headings are shaded and have column borders by default. To turn them off, use the Set Shade Headings ( 0 ) message and the Set Heading Column Borders ( 0 ) message. The following example shows the effect of turning shading and borders off:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Summarize(
  meanHt = Mean( Height ),
  minHt = Min( Height ),
```
Example of Creating a Report

Here is a script to build a report from start to finish.

1. Open a data table.
   ```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
```
2. Launch a Bivariate platform and assign it to the platform reference `biv`.
   ```julia
/* a reference to the platform */
biv = dt << Bivariate( Y( weight ), X( height ) );
```
3. To find out what you can do with the Bivariate platform, search for Bivariate in the Objects list of the Help > Scripting Index. Here are a few options:
   ```julia
biv << Fit Spline( 1000000 ) << Fit Mean;
```
   ```julia
// degree 4, orange curve
biv << Fit Polynomial( 4, {Line Color( RGBColor( 1, 0.5, 0 ) )});
biv << ( Curve[1] << Line Color( red ) ); // first curve is red
```
4. Assign `rbiv` to the report layer:
   ```julia
rbiv = biv << Report;
```
5. Get the frame box to a comfortable size and scroll up to the top to see the graph.
   ```julia
rbiv[Frame Box( 1 )] << Size Window( 500, 700 );
biv << Scroll Window( {0, 0} );
```
6. Get to work on the report. First, you need to create a reference, and then see what you can do with it.
   ```julia
Show Properties( rbiv ); // show the properties of the report
```
7. Open the Fit Mean node of the outline:
   
   `rbiv["Fit Mean"] << Close( 0 );`

   `Close()` is a Boolean function (true or false), and passing 0 indicates that the outline is not closed.

8. Practice selecting some results (submit each line alone to see its result):
   
   `rbiv["Summary of Fit"] << Select;`
   `rbiv["Parameter Estimates"] << Select;`
   `rbiv["Analysis of Variance"] << Select;`
   `rbiv["Polynomial Fit Degree=4", "Parameter ?", Column Box( "Estimate" )] << Select; // dig down in the outline tree`
   `rbiv << Deselect;`

9. Change the format of the Estimate column in the 4-degree polynomial Parameter Estimates report.
   
   `pe = rbiv["Polynomial Fit Degree=4", "Parameter ?"];`
   `ests = pe[Number Col Box( "Estimate" )];`
   `ests << Set Format( 12, 6 );`

   The first argument to `Set Format` sets the column width by the number of characters to display. The second argument sets how many decimal places are shown in the table.

**Figure 11.8 Applying Changes to a Report**

![Parameter Estimates before and after](image)
10. Use a `For()` loop to count down to the row for the term that you want. The second argument to `For()` is a condition; as long as the condition tests true, looping continues. Here the test is “when the string in the `Terms` column is not `"^3"` and we have not reached the tenth row.” As soon as the string does match, looping stops and `i`’s value is the number for the matching row. You then use `i` as a subscript to the `Get` message on the `Estimates` column.

11. You can also get values from boxes as a matrix, which you can then use for further computations or write to a data table. The following example also shows how to make a data table:

   ```plaintext
   // get the values in the Sum of Squares column as a matrix
   myVector = rbiv[Table Box( 5 )][Number Col Box( "Sum of Squares" )] << Get as Matrix;

   /* create a new column in Big Class.jmp named "Sum of Squares"
   insert the values of myVector in the column */
   dt << New Column( "Sum of Squares", Values( myVector ) );

   // put the values of the fifth table box into a new data table
   rbiv[Table Box( 5 )] << Make Data Table( "ANOVA table" );
   ```

12. Now adjust the scales on the axes.

   ```plaintext
   rbiv[Axis Box( 1 )] << Min( 70 ) << Max( 170 ); // set the Y axis
   rbiv[Axis Box( 2 )] << Min( 50 ) << Max( 70 ); // set X axis
   ```

---

**Note:** You can even get a single number out of the table. For example, get the estimate for the cubic term by adding the following script to the preceding script:

```plaintext

    terms = rbiv[Outline Box( "Parameter Estimates" )][String Col Box( "Term" )]; // find the Term column
    ests = rbiv[Outline Box( "Parameter Estimates" )][Number Col Box( "Estimate" )]; // find the Estimate column
    estimate = .; // in case there is no cubic term
    Try(
        For( i = 1, i < 10, i++,
            // get(i) goes off the end of the table handled by Try
            If( Contains( terms << Get( i ), "^3" ),
                estimate = ests << Get( i );
                Break();
            )
        )
    );
    Show( estimate );
    0.070394822744608
```
13. Copy the graph at the top of the report. Note that you need to select the picture box that contains the graph; selecting just the graph would leave its axes behind.

rbiv[Picture Box( 1 )] << Copy Picture;

Construct Custom Windows

You can use constructor functions to create objects and construct your own displays. For example, you might prompt the user for information, create custom reports, create custom launch windows, or add check box and radio button items to a window.

Start with a New Window(), including a title in quotes, and then construct display boxes inside the window. Make a reference to the new window by assigning it a variable so that you can send messages to it. When display objects are created or referred to by JSL, they are freely shared references until they are copied into another display box or until you close the window and they disappear. When you plug a display object into another display tree, JMP makes a copy of it that the new box owns.

The names of all display box constructors end in “Box”. There are similar objects that live inside graphics frames called display segs (segments such as markers and lines). The names of all display seg objects end in “Seg”.

Example of Creating a Graph Box

The following example creates a new window that contains a graph box:

```julia
win = New Window( "Simple Earth Map",
   gb = Graph Box(
      X Scale( -180, -60 ),
      Y Scale( 20, 80 ), // end of graph box parameters
      <<Background Map( Images( "Simple Earth" ) ) // beginning of script
   );
```

The parameters set the x-axis and y-axis scale and the frame size. The Background Map message then shows the map. Note that the parameters for Graph Box(), X Scale and Y Scale, come first. After the first comma, the script begins. If you put the script in the middle of the parameters in a New Window() function, the script might run but not produce the results you expect. Scripts are also easier for the users to read if the parameters are at the top of the new window.
Extract Values from a Window

After the user selects options in a window, you can extract those selections from the window using the `Return Result` message, `Get` message, or `Get Selected` message.

Extract Values: Method One

To have a `New Window()` script automatically return the results after the user clicks OK, include the `Return Result` message after the `Modal` message.

```plaintext
win = New Window( "Set a Value",
    <<Modal,
    <<Return Result,
    Text Box( "Set this value" ),
    variablebox = Number Edit Box( 42 ),
    Button Box( "OK" ),
    Button Box( "Cancel" )
);
Write( win["variablebox"] ); // create a subscript to the variablebox variable
33 // the user typed "33" in the number edit box
```

Extract Values: Method Two

Include the `Get` message to return 1 for a selected check box and 0 for a deselected check box. To view the selection, add a `Show()` expression at the end of the script.

```plaintext
win = New Window( "V List Box",
    <<Modal,
    V List Box( 
        kb1 = Check Box( "a" ),
        kb2 = Check Box( "b" ),
        kb3 = Check Box( "c" )
    ),
    Button Box( "OK",
        val1 = kb1 << Get; // get the value of the first check box
        val2 = kb2 << Get;
        val3 = kb3 << Get;
    )
);
Show( val1, val2, val3 ); // return variables after window closes
val1 = 1; // first and second checkboxes are selected
val2 = 1;
val3 = 0; // third checkbox is not selected
```
Extract Values: Method Three

Include the `Get Selected` message to return the selected column names and then insert the columns in a Bivariate plot.

**Note:** Method two and method three of extracting values are alternate examples of the same method. The method, in both examples, uses a JSL callback from one of the controls in the window. The JSL callback captures a value from a display box in the window into a global variable that will be available after the window closes. In method two, the JSL callback is on a button box. In method three, the JSL callback is on a list box.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
xvar = .;
yvar = .;
win = New Window( "Return Values",
<<Modal,
  // require the user to select two variables before clicking OK
  <<On Validate(
    Show( xvar, yvar );
    If( Is Missing( xvar ) | Is Missing( yvar ),
      0, // if xvar or yvar are missing, do nothing when OK is clicked
      1
    );
  ),
  Text Box( " Select two numeric columns. " ),
  H List Box(
    Text Box( " X, Factor " ),
    x = Col List Box(
      dt, // data table reference
      all, // display all columns from the data table
      xvar = (x << Get Selected)[1];
      // get the name of the selected column before the window closes
      Show( xvar );
    ),
    Text Box( "Y, Response" ),
    y = Col List Box(
      dt,
      all,
      yvar = (y << Get Selected)[1];
      Show( yvar );
    )
  )
);
xcol = Column( dt, xvar ); // get the columns
ycol = Column( dt, yvar );
```
Construct Custom Windows Scripting Guide

Constructors for New Windows

JSL supports both modal and non-modal windows.

- Modal windows must be closed before other windows can be used: clicking outside the modal window produces an error sound, and almost all script execution stops until the user closes the modal window.

- JMP reports and platform launch windows are examples of non-modal windows. Many non-modal windows can be open at once and you can switch between them freely. The Transparency dialog in a graph is an example of a modal window. After the Transparency dialog is opened, you must close it before continuing.

This section describes common display boxes that you can construct in a window. There are many other display boxes (such as axis boxes) in JMP that cannot be constructed. Display boxes that cannot be constructed are used by platforms in JMP. Even though they can’t be constructed in JSL, they still have functions and messages that can be used from JSL.

**Tip:** In the Scripting Index (Help > Scripting Index), display boxes that cannot be constructed are marked by ![x]. Display boxes that you can construct are marked by ![o].

**Notes:**

- The `Dialog()` function, which creates modal windows, is deprecated and will not work at all in future versions of JMP. Use either `New Window()` with the Modal message or `Column Dialog()` for column selection. See “Construct a Column Dialog” on page 611 and “Convert Deprecated Dialog to New Window” on page 617.

- In JMP, the following display boxes support only one direct child box: `Border Box()`, `Center Box()`, `If Box()`, `Mouse Box()`, `Scroll Box()`, and `Sheet Panel Box()`. To make a border box that appears to have multiple children, use a `V List Box()` or `H List Box()` as the only child and put multiple children in the `V List Box()` or `H List Box()`.

Container Display Boxes

Container display boxes enclose child display boxes.

**Border Box**

`Border Box()` adds space around the `displaybox` argument.

```js
Border Box (Left( pix ), Right( pix ), Top( pix ), Bottom( pix ),
Sides( int ), display box args);
```

```
dt << Bivariate( Y( ycol ), X( xcol ) ); // create a Bivariate plot
```
Left, Right, Top, and Bottom add space around the *displaybox* argument. `Sides` draws a border around the box, as described in Table 11.2. Additional effects can also be applied to the borders using `Sides`, as described in Table 11.2. To add both an effect and a border, add the two numbers.

For example, the following example produces a text box with a border at the top and bottom (Draw Border value of 5) colored blue, the default color (Effect value of 16):

```plaintext
win = New Window( "Borders",
    bb = Border Box( Sides( 5 ), // top and bottom border
        Text Box( "Hello World!" )
    )
);
bb << Set Color( "red" ); // set the border color to red
```

The `bb` variable is assigned to the border box so that the color can be set on the last line.

**Note:** Border boxes support only one display box argument. To make a border box that appears to have multiple children, use a `V List Box()` or `H List Box()` as the only child and put multiple children in the `V List Box()` or `H List Box()`.

In the `Sides()` function, add the following values to get the borders that you want. For example, “5” draws a top and a bottom border.

1: top
2: left
4: bottom
8: right

`Border Box()` provides the additional effects described in Table 11.2.

**Table 11.2** Border Box Sides() Additional Effects

<table>
<thead>
<tr>
<th>Add to Number Above</th>
<th>Additional Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Make the border lines the same color as the operating system’s highlight color. Not recommended because this color is different on different computers.</td>
</tr>
<tr>
<td>32</td>
<td>Fill the border box with white before drawing the border box’s child.</td>
</tr>
</tbody>
</table>
Table 11.2  Border Box Sides() Additional Effects  (Continued)

<table>
<thead>
<tr>
<th>Add to Number Above</th>
<th>Additional Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>Fill the border box with the background color before drawing the border box's child. This option makes a difference only if the border box's parent draws something behind the border box first.</td>
</tr>
</tbody>
</table>

Col List Box

Col List Box() returns a display box that shows a list of current data table columns.

    Col List Box( <Data Table( <name> ), <all>|<character>|<numeric>, <Width( n )>, <Max Selected( n )>, <NLines( n )>, <Max Items( n )>, <Min Items( n )>, <On Change( expression )>, <script> );

Note: To add a transform column to a custom display box, use Filter Col Selector() instead of Col List Box(). See “Filter Col Selector” on page 546.

All specifies that all columns in the current data table should be included. Width is measured in pixels. Max Selected is the maximum number of items that might be selected in the list box. NLines is the number of lines displayed in the box. Max Items is the maximum number of items displayed in col list box. Min Items is the minimum number of items displayed in the col list box. On Change is the script that runs when the selection changes.

You can send a Get Items message to a col list box to retrieve a list of all columns selected. Here is an example script showing Get Items in use. See the Scripting Index in the Help menu for other messages and examples.

    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    win = New Window( "Get Items Demonstration",
        H List Box(
            chooseme =

            // Col List Box shows all columns, 100 pixels wide with 6 lines
            Col List Box( "All", width( 100 ), NLines( 6 ) ),

            /* line up box arranges button boxes in 1 column with 2 pixels of space around the boxes*/
            Line Up Box( N Col( 1 ), Spacing( 2 ),
                Button Box( "Add Column >>" ),
            )
        )
    );
/* append the selected column to previously
selected columns */
listcols << Append( chooseme << Get Selected );

// get a list of selected columns from the col list box
Chosen Columns = listcols << Get Items;
Button Box( "<< Remove Column",
listcols << Remove Selected; // remove the selected column
Chosen Columns = listcols << Get Items; // get the selected column
);

// create another col list box with no columns inside
listcols = Col List Box( width( 100 ), NLines( 6 ) ),

Text Box( " " ),

/* at the bottom of the h list box,
show which columns Get Items returned */
stuff = Global Box( Chosen Columns )
);

The All argument for Col List Box() includes all data table columns in the display box. Because all columns are required, you cannot remove selected rows using Remove Selected or Remove All. Instead, create an empty column list box and append all columns. Then the columns that you select can be removed.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
colNames = dt << Get Column Names; // get a list of column names

New Window( "Example",
// create Col List Box with all the column names from the data table
myBox = Col List Box( width( 200 ), nlines( 10 ) ) );
myBox << Append( colNames );

myBox << Set Selected( 3 ); // select one or all of the entries in myBox
myBox << Remove Selected(); // remove selected entries in myBox

Note: To show only the character or numeric columns from the data table in the col list box, send Set Data Type(numeric|character) to the col list box.
Col Span Box

Col Span Box() creates spanned columns headers inside a table box. The top column header spans two child column headers.

    Col Span Box("title", display box args);

In the following script, the Confidence Limits header spans the Upper limits and Lower limits columns below it.

    win = New Window("Col Span Box",
        <<Modal,
        Table Box(
            Col Span Box(
                "Confidence Limits",
                neb = Number Col Edit Box("Upper limits", [0, 0] ),
                Number Col Edit Box("Lower limits", [0, 0] )
            )
        )
    );

Figure 11.9 Confidence Limits

Filter Col Selector

Filter Col Selector() creates a display box that shows a list of items, for example, columns in a data table. The display box is similar to Col List Box() except that Filter Col Selector() enables the user to filter columns by name, modeling type, data type, and so on. And Filter Col Selector() supports transform columns; Col List Box() does not.

    Filter Col Selector(<Data Table(name)>, <Width(pixels)>, <Nlines(n)>,<script>, <On Change(expr)>, display box args, ...);

Here's an example that shows how to use Get Items to display a list of selected columns from the filter col selector.

    dt = Open("SAMPLE_DATA/Big Class.jmp");
    win = New Window("Filter Col Selector Example",
        H List Box(
            chooseme =
                // filter col selector shows all columns, 100 pixels wide with 6 lines
                Filter Col Selector(width(100), NLines(6)),
        )
    );
/* line up box arranges button boxes in 1 column
with 2 pixels of space around the boxes */
Line Up Box( N Col( 1 ), Spacing( 2 ),
        Button Box( "Add Column >>"),

        /* append the selected column to previously
selected columns */
        listcols << Append( chooseme << Get Selected );

        // get a list of selected columns from the filter col selector
        Chosen Columns = listcols << Get Items;
        Button Box( "<< Remove Column",
        listcols << Remove Selected; // remove the selected column
        Chosen Columns = listcols << Get Items; // get the selected column
        ),
    ),

    // create another col list box with no columns inside
    listcols = Col List Box( width( 100 ), NLines( 6 ) ),
);

Figure 11.10 Filter Col Selector

H List Box and V List Box

H List Box() aligns boxes horizontally.

H List Box( <Align( center|bottom )>, display box args, ...);

Align specifies center or bottom alignment of the contents in the display box. The contents are
top aligned by default.

The following script aligns the check boxes horizontally:

    win = New Window( "H List Box",
        <<Modal,
        H List Box( 
            kb1 = Check Box( "a" ),
            kb2 = Check Box( "b" ),
            kb3 = Check Box( "c" )
        )
V List Box() aligns boxes vertically.

\[
\text{V List Box( } \langle \text{Align( center|right )}>, \text{ display box args, ...}\text{);}\]

Align specifies left, right, or center alignment of the contents in the display box. The contents are left aligned by default.

\[
\text{win = New Window( } \langle \text{"V List Box"}, \text{ Text Box( "Select your favorite fruit." )}, \text{ V List Box(} \langle \text{Check Box( "apple" ), Check Box( "banana" ), Check Box( "orange" )}, \text{)}\text{);}\]

\text{Note:} The default maximum width is 180 pixels. To set the width, set the width of the display box that encloses the V List Box.

Suppose that you want to enable the user to add a transform column to custom dialog box. Here is an example of how to create a horizontal list box with an Add and Remove button. The user right-clicks a column to create a transform column.

\[
\text{dt = Open( } \langle \$SAMPLE_DATA/Big Class.jmp \rangle; \text{ New Window( } \langle \text{"Example"}, \text{ H List Box(} \langle \text{ll1 = Filter Col Selector( )}, \text{ Button Box( "Add", ll1 << Append( ll1 << Get Selected() ) )}, \text{ ll2 = Col List Box( "Numeric", MaxItems( 1 ), nlines( 1 )}, \text{ Button Box( "Remove", ll2 << Remove Selected )}\text{)}\text{);}\]

\text{Note:} Transform columns use formulas or calculations to define the column values. Closing the window deletes any transform columns. See Using JMP.

\textbf{If Box}

\textbf{If Box()} creates a display box whose contents are conditionally displayed.

\[
\text{If Box( 0|1, display box args );}\]

The Boolean argument 1 displays the display boxes inside the if box. 0 does not display them.
The following script creates a splitter box with three scroll boxes. The second scroll box is enclosed in If Box(). Because If Box() is set to 1, the second scroll box appears in the window.

```julia
win = New Window( "If Box",
     H Splitter Box(
         Size( 500, 250 ),
         Scroll Box(),
         If Box( 1, Scroll Box() ), // if box sets the scroll box to show
         Scroll Box()
     )
);
```

When you set an if box to be hidden, then anything within the if box disappears from the report window. In the tree structure view, the hidden display box is no longer numbered. Hide the if box in this example, and the second scroll box is no longer numbered in the tree structure view. Scroll Box(3) becomes Scroll Box(2). Change the argument for If Box() in this script from 1 to 0 and then send the win << Show Tree Structure message to see the structure view.

**Note:** If boxes support only one display box argument.

### H Splitter Box and V Splitter Box

H Splitter Box() and V Splitter Box() create a display box that arranges the display boxes provided by the arguments in a horizontal or vertical layout (or panel). The splitter enables the user to interactively resize the panel.

```julia
H Splitter Box( <Size( h,v )>, display box args, <arguments> );
V Splitter Box( <Size( h,v )>, display box args, <arguments> );
```

Size( h, v ) specifies the size of the splitter box in pixels. Inner display boxes are proportionately sized according to the width and height of the splitter box. For a list of arguments, see the Scripting Index in the JMP Help menu.

The following example puts a Bivariate and One way graph inside an H splitter box. Splitter boxes are especially useful when the content is set to auto-stretching as shown in the example.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "H Splitter Box",
     H Splitter Box(
         Size( 900, 600 ),
         biv = dt << Bivariate( Y( :weight ), X( :height ), Fit Line(), Line Style( Dotted ) ),
         one = Oneway( Y( :height ), X( :sex ), "Means/Anova"n( 1 ), Mean Diamonds( 1 )
     )
);
```
/* make a reference to the report layers
set the x and y axes on the frame boxes to auto stretch
when the user drags the splitter */
(biv << Report)[FrameBox(1)] << Set Stretch( "Window", "Window" );
(one << Report)[FrameBox(1)] << Set Stretch( "Window", "Window" );

Line Up Box

Line Up Box() shows the display box arguments in n columns. You can specify optional spacing, in pixels, for the space between columns.

Line Up Box( NCol( n ), <Spacing( pixels )>, display box args, ... );

Spacing specifies the number of pixels around the box.

In the following example, the Distribution reports are lined up in three columns:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Line Up Box",
    Line Up Box( NCol( 3 ), // line up the Distributions in 3 columns
dist = Distribution(
    Continuous Distribution( Column( :height ) ),
    By( :age )
)
)
);

Outline Box

Outline Box() creates a display box to hold other display boxes and show them in an outline view.

Outline Box("title", display box args, ... );

In the following example, each outline contains a Distribution:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Outline Box",
    obj1 = Outline Box("Age and Weight",
        Distribution( Column( :age, :weight ) ),
    ),
    obj2 = Outline Box("Weight and Height",
        Distribution( Column( :weight, :height ) )
    )
);
To close an outline by default, send the `Close( 1 )` message to the outline object.

```plaintext
obj2 << Close( 1 );
```

The first argument for an outline box is the title. You can specify the title in the script, or the title can be based on another component, such as the value of a slider box. In the following example, as the user adjusts the slider, the title of the outline box is updated:

```plaintext
sliderValue = .6;
win = New Window( "Outline Box",
    Panel Box( "Slider Box",
        tb = Outline Box( "Value: " || Char( sliderValue ) ),
        sb = Slider Box(
            0,
            1,
            sliderValue,
            tb << Set Title( "Value: " || Char( sliderValue ) )
        )
    )
);
```

To make your own red triangle menu within an outline box, send the `Set Menu Script` message to the outline box reference. The following example also uses the `Set Submenu` message to create nested menu items.

```plaintext
win = New Window( "Red Triangle Menu Items",
    ob = Outline Box( "Outline Box" ) );
    ob << Set Menu Script(
            Print( "B3" ), "C", Print( "C" ), "Selected", Print( "Selected" )}
    );
    ob << Set Submenu( 1, 2 ); // menu A with 2 items in submenu A1 and A2
    ob << Set Submenu( 4, 3 ); // menu B with 3 items in submenu B1, B2, and B3
```

To indicate whether an item is selected, unavailable, or available, include `Set Menu Item State`. The following expression shows a check mark beside the ninth menu item ("Selected") in the preceding script.

```plaintext
ob << Set Menu Item State( 9, 1 );
```

Specify the value -1 to disable the menu item or 0 to make it available.

**Panel Box**

`Panel Box()` encloses the `displaybox` argument in a labeled border.

```plaintext
Panel Box( "title", display box args );
```
In the following example, the panel box appears around the edge of the Distribution launch window:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Panel Box",
   H List Box( Panel Box( "My Distribution", Distribution() ) )
);
```

**Display Element Boxes**

**Graph Box**

Graph Box() constructs a display box that contains a frame box and axes.

Graph Box( "title", <X Scale( low, high ), <Y Scale( low, high )>, <Frame Size( h, v )>, <XName( "name" )>, <YName( "name" )>, <SuppressAxes>, script );

X Scale() and Y Scale() specify the lower and upper limits of the x and y axes. Frame Size() specifies the size of the frame around the graph. XName and YName specify the name of the x and y axes.

The following example creates a simple graph:

```javascript
win = New Window( "Graph Box",
   Graph Box(
      Frame Size( 300, 300 ),
      Marker( Marker State( 3 ), [11 44 77], [75 25 50] );
      Pen Color( "Blue" );
      Line( [10 30 70], [88 22 44] );
   )
);
```

To remove tick marks, add two arguments to the axes.

```javascript
win = New Window( "Graph Box",
   Graph Box(
      Frame Size( 300, 300 ),
      xaxis( // remove tick marks from the x axis
         Show Major Ticks( false ),
         Show Minor Ticks( false ),
         Show Labels( false )
      ),
      yaxis( // remove tick marks from the y axis
         Show Major Ticks( false ),
         Show Minor Ticks( false ),
         Show Labels( false )
      ),
      Marker( Marker State( 3 ), [11 44 77], [75 25 50] );
   )
);
```
Pen Color( "Blue" );
Line( [10 30 70], [88 22 44] );

JMP provides a robust set of features to make your graphs interactive (such as dragging objects or capturing mouse clicks). The “Scripting Graphs” chapter on page 631 describes graph box options in detail.

H Sheet Box and V Sheet Box

Sheet Box() lets you create a grid of plots. H Sheet Box() and V Sheet Box() contain display boxes and arrange them in columns and rows.

```
H Sheet Box( <<Hold( report ), display box args );
V Sheet Box( <<Hold( report ), display box args );
```

The general approach is to first consider which display boxes you want and in which arrangement. Create either an H or V Sheet Box and send it a Hold message for each graph to specify which element the sheet box should hold. Finally, create interior H or V Sheet Boxes and tell each one which graph the sheet box should hold.

Here is an example of creating a sheet with four plots: a Bivariate plot, a Distribution, a Treemap, and a Bubble Plot.

First, open the data table and create a new window.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
nw = New Window( "Sheet Box Example" );
```

Use a V Sheet Box to organize the window into two columns.

```
V Sheet Box( 
```

Send the V Sheet Box() four Hold messages, one for each graph. The order matters.

```
<<Hold(
   dt << Bivariate( // graph 1
          Y( :weight ),
          X( :height ),
          Fit Line()
       )
   ),
<<Hold(
   Distribution( // graph 2
          Continuous Distribution(
             Column( :height ),
             Horizontal Layout( 1 ),
             Outlier Box Plot( 0 )
          )
       )
   ));
```
Finally, add two H Sheet Boxes to the V Sheet Box and tell each one which graph it should hold. Each H Sheet Box holds two side-by-side graphs. They are held by a V Sheet Box, so the H Sheet Boxes are displayed vertically.

```
H Sheet Box(
    Sheet Part(
        "",
        Excerpt Box( 1, {Picture Box( 1 )} ) // excerpt box 1
    ),
    Sheet Part(
        "Distribution of height",
        Excerpt Box( 2, {Picture Box( 1 )} ) // excerpt box 2
    ),
    H Sheet Box(
        Sheet Part(
            "",
            Excerpt Box( 3, {Picture Box( 1 )} ) // excerpt box 3
        ),
        Sheet Part(
            "My Title Here",
            Excerpt Box( 4, {Picture Box( 1 )} ) // excerpt box 4
        )
    )
);
```
The \texttt{Part()} title is required. If you include an empty string as the title, the sheet part’s title is the default report title, for example, “Bivariate Fit of weight By height”.

\textbf{Journal Box}

The \texttt{Journal Box()} constructs a display box from instructions that are stored in a journal.

\begin{verbatim}
box = Journal Box("journal text");
\end{verbatim}

where "\texttt{journal text}" is text that has been extracted from a journal file.

Since journal text has lots of rules about which boxes can be with other boxes, we recommend that you get journal text by highlighting an area of the report, selecting Edit > Journal, and save it as a journal. Open the journal in a text editor, and then paste it into your script as the \texttt{Journal Box()} argument.

We highly recommend that you use the "\[ ... \]\" quoting mechanism so that you do not have to escape double quotes within the journal text. This excerpt shows how to escape the journal text:

\begin{verbatim}
win = New Window( "Mosaic Plot",
    Journal Box("\\[ // beginning of quoting mechanism
    ...display box arguments...
    ]\\"
    ) // end of quoting mechanism
);
\end{verbatim}

Another way to get journal text is to send the \texttt{Get Journal} message to a display box. For example, run the following script and copy the journal text from the log into the \texttt{Journal Box()} function:

\begin{verbatim}
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( :weight ), x( :height ) );
rbiv = biv << Report;
Print( rbiv << Get Journal ); // print the journal to the log
\end{verbatim}

\textbf{Picture Object}

JSL has a Picture Object, which stores pictures of JMP output or formulas. You can take a picture of anything in a display box or create a picture of a text formula as it would look in the Formula Editor.

To create picture data, send a \texttt{Get Picture} message to a \textit{display box}.

\begin{verbatim}
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( :weight ), x( :height ) );
rbiv = biv << Report;
rbiv << Get Picture;
\end{verbatim}
The Expr As Picture() function evaluates its argument and creates a picture of the expression, using the same formatting mechanism as the Formula Editor. If you have a literal expression as the argument, remember to enclose it in Expr() so that JMP just takes a picture of the result. The expression then is not evaluated.

```javascript
win = New Window( "Formula",
    Expr As Picture( Expr( a + b * c + r / d + Exp( x ) ) ) );
```

After you have the picture, there are two ways of using it:

- Add the picture to a new display tree using a display box constructor.
- Write the picture to a file using Save Picture().

```javascript
picture << Save Picture( "path", type );
```

where `type` can be EMF (Windows), JPEG or JPG, GIF, PDF, or PNG.

On Windows, the Windows Specific preferences determine the resolution (or DPI), or you can run this expression:

```javascript
Pref( Save Image DPI( <number> ) );
```

On macOS, the operating system determines the DPI.

**Input Selector Display Boxes**

Input selector display boxes enable users to enter information and interact with the display box. The display box script includes a script that runs when the user interacts with the display box. See “Set Function and Set Script” on page 588 for more information about writing the scripts.

**Button Box**

Button Box() draws a button that contains text.

```javascript
Button Box( "text", <script>);
```

The following example creates a new window with an OK button and a Cancel button:

```javascript
win = New Window( "Set the Value",
    <<Modal,
        Text Box( "Set this value" ),
        variablebox = Number Edit Box( 42 ),
        Button Box( "OK" ),
        Button Box( "Cancel" ) );
```

Note that a modal window must have at least one button. If you omit the Button Box() from your script, an OK button is automatically included. To omit the OK button, set the visibility to collapse.
win = New Window( "No OK Button",
  <<Modal,
    b = Button Box( "Close Window", b << Close Window ),
    bb = Button Box( "OK", <<Visibility( "collapse" ) )
  );

You can add a tooltip for a button by sending a Set Tip message to it. The following script creates a button named “Submit”. A tooltip that contains “Send my information.” appears when you hover over the button.

  Button Box( "Submit", << Set Tip( "Send my information." ) );

You can also send the message Open Next Outline as a script command, which causes the next outline box to open. If you are sending more than one message to the button box, this must be the first command listed. When the user clicks the next button in this example, the second outline box opens.

  win = New Window( "Open Next Outline",
    Outline Box( "First",
      ex = Button Box( "Next", ex << Open Next Outline )
    ),
    Outline Box( "Second", Text Box( "Last" ), << Close )
  );

Using the Set Menu Items message, you can create a button that contains a menu:

  win = New Window( "Set and Get Menu Choice",
    bb = Button Box( "Select a dessert",
      // get menu choices when the button is clicked
      choice = bb << Get Menu Choice;
      Show( choice );
      );
    bb << Set Menu Items( {"fruit", "no thank you", "-", "chocolate bar", "ice cream"} );

The "-" in the preceding script creates a menu separator. The separator counts as an item in the list. If you select chocolate bar from the menu, 4 is returned, not 3.

To indicate whether an item is selected, unavailable, or available, include Set Menu Item State. The following example makes the fifth menu item (“ice cream”) in the preceding script unavailable:

  bb << Set Menu Item State( 5, -1 );

Specify 0 to make the menu item available or 1 to show a check mark before the menu item.
Chapter 11
Construct Custom Windows Scripting Guide

Note that, after you click the button, the button box doesn’t know where the script is stored because the button is disconnected from the script. For example, relative paths don’t work when executed from a button box because of this disconnection. An Open() script must evaluate the current directory and concatenate it to the relative file path to construct an absolute path.

```julia
nw = New Window( "Open File Example",
    Button Box( "Open",
        Open(
            Eval( Get Path Variable( "$SAMPLE_DATA" ) ) ||
            "Quality Control/Coating.jmp"
        )
    )
);
```

In the following example, the path is interpreted as an absolute path beginning with the root.

```julia
nw = New Window( "Example",
    Button Box( "Open", Open( "/MyData/Big Class.jmp" ) )
);
```

**Note:** Line-break characters are ignored in button boxes.

### Check Box

Check Box() constructs a display box to show one or more check boxes. Any number of the check box items can be selected simultaneously.

```julia
Check Box ({"item 1", "item 2", ...}, <script>);
```

The following example shows how to get the user’s selection by sending the Get Selected message to the check box. Each selection is printed to the log.

```julia
win = New Window( "Check Box",
    cb = Check Box(
        {"apple", "banana", "orange"},
        scb = cb << Get Selected();
        Show( scb );
    )
);
scb = {"banana", "orange"};
```

The following example shows one way to enable the user to click OK to close the window.

```julia
win = New Window( "Check Box",
    <<Modal,
    <<On Close(
        flagbox1 = ckbox <<Get( 1 );
        flagbox2 = ckbox <<Get( 2 );
        1; // On Close returns non-zero, so the window closes.
    ),
);
ckbox = Check Box( {"Check Box 1", "Check Box 2"} ),
ckbox << Set( 1, 1 ),
ckbox << Set( 2, 0 )
);

**Combo Box**

`Combo Box()` creates a drop-down list.

`Combo Box( {"item 1", "item 2", ...}, <script> );`

“item1” and “item2” are strings in the drop-down list.

The `Editable` argument allows the user to enter text in the combo box. The following example creates a new window and an editable combo box with the list items “one”, “two”, and “three”. The script prints the selected item name and index number to the log.

```plaintext
win = New Window( "Combo Box",
    cb = Combo Box(  
        {"One", "Two", "Three"},
        Editable,
        selection = cb << GetSelected();
        Print( "Selected: " || selection );
        Print( "Index: " || Char( cb << Get() ) );
    )
);
```

Note that closing the window for an editable combo box can produce unexpected results. On Windows, the `Print()` script runs after you select an item from the list or enter the item name. On macOS, the `Print()` script runs after you select an item from the list or enter the item name and then press Return.

For cross-platform compatibility, include `!Is Empty` to test for an existing combo box before running the script.

```plaintext
win = New Window( "Combo Box",
    cb = Combo Box(  
        {"One", "Two", "Three"},
        Editable,
        If( !Is Empty( cb ),
            selection = cb << GetSelected();
            Print( "Selected: " || selection );
            Print( "Index: " || Char( cb << Get() ) );
        )
    )
);
```

To make an item selectable or unselectable, send the `<<Enable Item` message to `Combo Box()`.
cb << Enable Item( 2, 0 ) // makes the second item unselectable

**Note:** If the editable combo box has no empty strings, nothing is selected by default. If the editable combo box has one or more empty strings, the first empty string is selected by default.

---

### Global Box

Global Box shows the name and current value of a JSL global variable.

```julia
Global Box( name );
```

The user can assign a new value to the global variable by editing the value directly in the window and pressing Enter or Return to commit the change. Global boxes automatically update the displayed value of a variable when the variable changes.

```julia
ex = Sqrt( 4 );
win = New Window( "Global", Global Box( ex ) );
```

The preceding script creates a new window named “Global” that displays the following result:

```
ex=2
```

The following example shows the value of the myGlobal variable on the graph:

```julia
myGlobal = 6;
win = New Window( "Global Box",
    V List Box(
        gr = Graph Box(
            Frame Size( 300, 300 ),
            X Scale( 0, 10 ),
            Y Scale( 0, 10 ),
            Y Function( x, x ),
            Text( {5, 5}, "My global is ", myGlobal )
        ),
        Global Box( myGlobal ) // value of myGlobal
    )
);
```

**Note:** When you are using Global Box(), remember that every time the variable is changed, JMP remeasures, reshow, and updates the window. Depending on the number of Global Box() objects, changes to the variable can affect the refresh rate of the window. JMP recommends avoiding numerous global boxes in deliverable scripts. Global boxes can be replaced with text boxes that the script can manually update when necessary.
List Box

List Box() creates a display box that shows a list box of items that can be selected.

List Box("item 1", "item 2", ...), <Width( n )>, <MaxSelected( n )>, <NLines( n )>, <script>);

Item names are case sensitive by default. Width is measured in pixels. MaxSelected is the maximum number of items that might be selected in the list box. NLines is the number of lines to display in the box, with a default value of 3.

Add items to a list box by either using Append or Insert:

```
win = New Window( "test", lb = List Box( {"a", "e"} ) );
lb << Append( {"f", "g"} ); // result is a, e, f, g
lb << Insert( {"b", "c", "a", "d"}, 1 ); // result is a, b, c, d, e, f, g
```

Append always adds the list to the end of the list box. Insert adds the list after the position specified.

You can have two mutually exclusive list boxes, so that the item you select in one box is deselected when you select an item in the other box. Send the Clear Selection message to deselect the item.

```
win = New Window( "Each Box Clears the Other Box",
    window:la = List Box( 
        {"broccoli", "pepper", "spinach"},
        <<Set Script( window:lb << Clear Selection )
    ),
    window:lb = List Box( 
        {"avocado", "pumpkin", "tomato"},
        <<Set Script( window:la << Clear Selection )
    )
);
```

A list box can also contain an image. In the following example, an image from the user’s computer appears in the “first” list item. The JMP nominal icon appears in the “second” list item.

```
win = New Window( "List Box with Image",
    List Box( 
        {"first", "$SAMPLE_IMAGES/pi.gif"}, {"second", "nominal"}},
        width( 200 ),
    )
);
```

To set the width of the list box, use the width argument.

```
listA = {"a", "b", "c",
    "This is a very, very long name like Mary Ann Johnston."};
New Window( "Example",
```
// set the width to the length of the string
V List Box( listBoxA = List Box( listA, width( 0 ) ) );

To set the font of the list box, use the Set Base Font message.

New Window( "Example",
    fontobj = lb = List Box(
        {"First Item", "Second Item", "Third Item"},
        width( 200 ),
        max selected( 2 ),
        nlines( 6 )
    );
);
Wait( 2 );
fontobj << Set Base Font( "Title" );

Set Base Font also works with Bar Seg, Col List Box(), Contour Seg, Filter Col Selector, Hier Box(), Number Edit Box(), Outline Box(), Poly Seg, Text Box(), Text Edit Box(), and Text Seg.

Mouse Box

Mouse Box() creates a box that can make JSL callbacks for dragging and dropping, marking, or clicking and tracking mouse actions.

Mouse Box( display box args, messages );

The following example is from the DragDrop.jsl sample script in the Samples/Scripts folder. One list box contains “a”, “b”, and “c”. The other list box contains “d”, “e”, “f”. You can drag a letter from one list box to the other list box.

Note: Mouse boxes support only one display box argument.

    win = New Window( "Drag and drop between list boxes",
        H List Box( MouseBox( 
            one = List Box( {"a", "b", "c"} ),
            // if the mouse is over the preceding list box, drop on the other box
            <<setTrack( 
                (two << parent) << setDropEnable( 1 );
                (one << parent) << setDropEnable( 0 );
            ),
            // watch the mouse movement (not clicks)
            <<setTrackEnable( 1 ),
        ));
    )

};
// when a drop happens...
<<setDropCommit(
    Function( {this, clickPt, text},
        // find out what is selected in the other box
        x = two << getSelected;
        If( Words( text, "\!t" ) == x,
            two << removeSelected; // and take it...
            one << append( x ); // and add it to me
            ,
                Print( "Drag from the other box please." )
        );
    )
),
Spacer Box( size( 20, 20 ) ),

/* same comments as above with reversed logic
for current box versus other box */
MouseBox(
    two = List Box( {"d", "e", "f"} ),
    <<setTrack(
        (one << parent) << setDropEnable( 1 );
        (two << parent) << setDropEnable( 0 );
    ),
    <<setTrackEnable( 1 ),
    <<setDropCommit(
        Function( {this, clickPt, text},
            x = one << getSelected;
            If( Words( text, "\!t" ) == x,
                one << removeSelected;
                two << append( x );
                ,
                    Print( "Drag from the other box please." )
            );
        )
    ),
);

Number Col Edit Box

Number Col Edit Box() creates a display box that shows editable numbers in a column. The numeric entries can be in list or matrix form.

Number Col Edit Box("title", numbers);
The following script creates number edit boxes in which the user enters values. The Return Result message extracts the values.

```plaintext
x = y = z = 0;
win = New Window( "Number Col Edit Box",
                  <<Modal,
                  <<Return Result,
                  Table Box(
                     neb = Number Col Edit Box( "values", {x, y, z} )
                  ));
{neb = {2, 4, 6}, Button( 1 )}
```

**Number Edit Box**

*Number Edit Box()* creates an editable number box that initially contains the value argument. You can also set the width of the box in characters.

```plaintext
Number Edit Box( initValue, <width>);
```

The following script shows an editable box that initially contains the number “42”. The number that the user types is printed to the log.

```plaintext
win = New Window( "Set a Value in Number Edit Box",
                  <<Modal,
                  <<Return Result,
                  Text Box( "Set this value" ),
                  variablebox = Number Edit Box( 42 ),
                  Button Box( "OK" ),
                  Button Box( "Cancel" )
                );
Write( win["variablebox"] ); // create a subscript to the variablebox variable
33 // the user typed "33" in the number edit box
```

The following script shows how to make the initial value a date, and enables the user to choose a different date.

```plaintext
New Window( "Date/Time Selector",
            <<Modal,
            neb = Number Edit Box( Today(),
                                   23,
                                   <<Set Format( Format( "m/d/y h:m:s", 23, 0 )
                                 )
                              )
          );
```
### Popup Box

Popup Box() creates a red triangle menu that contains menu item commands.

```
Popup Box( {"command1", script1, "command2", script2, ...} );
```

The following example stores a command list in a variable and then uses Popup Box() to display the items:

```plaintext
List = {
"command1", Print( "command1" ),
"command2", Print( "command2" ),
"command3", Print( "command3" ),
"command4", Print( "command4" ),
"", Empty(), // make a separator line
"command5", Print( "command5" ),
"commandThrow", Throw( "commandThrow1" ),
"commandError", Sqrt( 1, 2, 3 ),
"commandEnd", Print( "commandEnd" )};
```

```plaintext
win = New Window( "Example",
  Text Box( "Popup Test" ),
  mymenu = Popup Box( List );
);
```

**Figure 11.11** Red Triangle Menu

Note that you can disable and re-enable the menu using the `Enable( Boolean )` message. An argument of 1 turns the menu on, and an argument of 0 turns the menu off. Using the previous example, assign the popup box to a variable and then send messages to it:

```plaintext
win = New Window( "Example",
  Text Box( "Popup Test" ),
  mymenu = Popup Box( List );
);
```

```
mymenu << Enable( 0 ); // disabled menu
```
You can also add a popup menu to an outline box. See “Outline Box” on page 550 for an example.

**Radio Box**

Radio Box() creates a list of radio buttons.

    Radio Box({"item 1", "item 2", ...}, <script>);

Only one item in the radio box can be selected at any time.

The following script creates “A”, “B”, and “C” radio buttons and selects the second box.

    win = New Window( "Radio Box",
        V List Box(
            rb = Radio Box( {"A", "B", "C"}, <<Set( 2 ) ),
        )
    );

“New Window Example” on page 617 also provides an example of creating radio boxes.

**Slider Box**

Slider Box() creates a slider control for picking any value for the variable, within the minimum and maximum range that you specify.

    Slider Box( min, max, global variable, script, <Set Width( n )>, <Rescale Slider( min, max )> );

Set Width specifies the width of the slider box. Rescale Slider specifies the minimum and maximum values.

When the slider is moved, the value given by the current position of the slider is assigned to the global variable. Thus, Slider Box() is another way to parameterize a graph.

    ex = .5;
    win = New Window( "Slider Box",
        tb = Text Box( "Value: " || Char( ex ) ),
        sb = Slider Box( 0, 1, ex,
            tb << Set Text( "Value: " || Char( ex ) )
        )
    );
    sb << Set Width( 100 ) << Rescale Slider( 0, .8 );

The following script creates multiple slider boxes without using a unique global variable to hold the current value for each one:

    sb1 = Slider Box( 1, 10 );
// create a slider box with only the min and max value
sb2 = Slider Box( -10, 10 );
sb1 << Set Function( // set the script or the function
    Function( {this},
        {},
        Show( this << Get, sb2 << Get )
    ),
);
sb2 << Set Script( Show( sb2 << Get, sb1 << Get ) );
New Window( "Values", sb1, sb2 ); // place the slider boxes in a window

As you move the slider, the value is printed to the log.

See “Example of Slider Boxes and Range Slider Boxes” on page 576 for another example of slider boxes.

Spacer Box

Spacer Box() creates space between display boxes.

Spacer Box(<size(horizontal_pixels,vertical_pixels>), <color(color)>)

The following script places a 450 pixel wide and 15 pixel tall blue spacer box between the two outline boxes.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Spacer Box",
    V List Box(  
        Outline Box( "Bivariate",
            biv = dt << Run Script( "Bivariate" ),
            // Color string consists of percentages of RGB values  
            Spacer Box( Size( 450, 15 ), Color( {.53, .80, .98} ), )  
        ),
        Outline Box( "Distribution",
            V List Box( dist = dt << Run Script( "Distribution" ), )
        )
    )
);
String Col Edit Box

String Col Edit Box() creates a column named title in a table containing the string items listed. The string boxes are editable.

```plaintext
String Col Edit Box( "title", {strings} );
```

The following script creates a column of editable text boxes, preceded by the title “Names”:

```plaintext
a = b = c = "";
win = New Window( "String Col Edit Box",
<<Modal,
<<Return Result,
```
Table Box:

```plaintext
    seb =
    String Col Edit Box(
        "Names",
        {a, b, c}
    )
);
{seb = {"apple", "orange", "banana"}, Button( 1 )}
```

**Tab Box and Tab Page Box**

Tab Page Box() organizes the title and contents of the page in one display box. When Tab Page Box() is inside Tab Box(), a tabbed window with multiple tabbed pages appears.

```plaintext
Tab Box( Tab Page Box( Title( "page title 1" ), <options>, contents of page 1), Tab Page Box( "page title 2", <options>, contents of page 2), ...
```

The following script creates three tab boxes:

```plaintext
win = New Window( "Tab Box",
    Tab Box(
        Tab Page Box(
            Title( "First page" ),
            Text Box( "first line of first page" ),
            Text Box( "second line of first page" )
        ),
        Tab Page Box(
            Title( "Second page" ),
            Text Box( "first line of second page" ),
            Text Box( "second line of second page" )
        ),
        Tab Page Box(
            Title( "Third page" ),
            Text Box( "first line of third page" ),
            Text Box( "second line of third page" )
        )
    )
);
```

**Figure 11.13** Tab Boxes

<table>
<thead>
<tr>
<th>First page</th>
<th>Second page</th>
<th>Third page</th>
</tr>
</thead>
<tbody>
<tr>
<td>first line of first page</td>
<td>second line of first page</td>
<td></td>
</tr>
</tbody>
</table>
You can specify which tab should be selected by sending the `Set Selected(n)` message, where `n` is the tab number, to the tab box object.

The `Set Style` message lets you select the visual appearance of the tab box. The default value is `tab`. Other options include the following:

- `combo` creates a combo box.
- `outline` creates an outline node.
- `vertical spread` displays the tab title vertically.
- `horizontal spread` displays the tab title horizontally.
- `minimize size` bases the tab style on the width of the tab title. In the following example, the first tab title is fairly long:

```plaintext
win = New Window( "Tab Box",
    tb = Tab Box( 
        Tab Page Box(
            Title( "First page of my tab box" ),
            Text Box( "first line of first page" ),
            Text Box( "second line of first page" )
        ),
        Tab Page Box(
            Title( "Second page" ),
            Text Box( "first line of second page" ),
            Text Box( "second line of second page" )
        ),
        Tab Page Box(
            Title( "Third page" ),
            Text Box( "first line of third page" ),
            Text Box( "second line of third page" )
        )
    );
    tb << Set Style( "minimize size" );
```

Minimizing the size of the tab box converts the tab box into a combo box. Figure 11.14 compares the default and minimized tab boxes.

**Figure 11.14** Default Tab Box (Left) and Minimized Tab Box (Right)

For `Tab Page Box()` examples, see “Examples of Creating a Dashboard from Two Reports” on page 596.
Tips:

- Unlike with other display boxes, you must define the title in the Title() function.
- The Set Style message works for both bare words and quoted words. However, you cannot assign the style to a variable and then pass the variable as the argument.
- You can combine Tab Box() with Splitter Box() to create docked tabs, which can be dragged to drop zones in a window to create a different layout. See “Examples of Creating a Dashboard from Two Reports” on page 596.
- To delete a tab, you can either send Delete(index) to the tab box, or you can send Delete Box() to a tab page box. Note that the entire display box (all tabs) is deleted, not just a single tab.
- Use the Visibility(“Collapsed”) message to hide a tab.
- When tabs in a tab list are not wide enough for the titles, send the Set Overflow Enabled(1) message to Tab Box(). A triangle symbol is shown to the right of a tab list, and the tab titles are truncated using ellipses.
- When Tab Page Box() is created or dragged outside a Tab Box(), it is a stand-alone container. The title appears in a shaded box at the top of the page, similar to the title in Sheet Part(); the title does not appear in an interactive tab.
- See “Write Tab Box and Tab Page Box Scripts” on page 629 for more information about the differences between Tab Box() and Tab Page Box().
- In Bubble Plot and Graph Builder scripts, set the Fit to Window message to "On" to resize the window when you resize the graph in Tab Box().
- To close a tab, first make a tab closeable by sending Closeable(1) to the tab page box and then send the Close message.
- Closeable tabs can be closed with the middle mouse button.

TextBox

TextBox() creates a non-editable text box. Text boxes are frequently used as labels of other controls.

   Text Box( "text" );

You can format the text with HTML tags. For example, the following script formats text in bold:

   win = New Window( "Formatted Text",
      Text Box( "This is <b>bold</b> text.",
           <<Markup) );

Make sure you close nested tags correctly and escape the quotes as shown here:

   "This is <font color="Blue" face="Lucida Sans Unicode" size="24"><b>blue</b></font> text. This is a <background
The following example prints “Changed” in the log each time the text edit box is changed:

```javascript
win = New Window( "Text Edit Box",
    Text Edit Box( "Change Me", <<Script( Print( "Changed" ) ) )
);```

Assign a reference to the text edit box object to access its contents. The following example prints the value of the text edit box to the log each time the box changes:

```javascript
win = New Window( "Text Edit Box",
    teb = Text Edit Box( "Change Me",
        <<Script( Print( teb << Get Text ) )
    )
);```

Text edit boxes are empty. However, you can specify placeholder text as a visual cue for the user to enter a value in the box. The placeholder text is only a hint and does not affect the value of the text field.

The following example produces the text edit box shown in Figure 11.15. The Hint option returns "mm/dd/yyyy" and formats it as light gray text.

```javascript
win = New Window( "Text Edit Box",
    Text Edit Box( "Current Date" ),
    Text Edit Box( "", Hint( "mm/dd/yyyy" ) )
);```

**Figure 11.15** Text Edit Box with Placeholder Text
Tip: To omit the border around the editable box and the white background color, send the `White Box Style( 0 )` message to the text edit box.

If you need to use a text edit box for your user to enter passwords, you can apply a style to the text edit box to replace all characters entered with an asterisk. For example, the following example creates a text edit box whose value is the string “a”. When a user types a new string into the text edit box, each character is displayed as an asterisk, and the message “Changed!” is printed to the log.

```julia
win = New Window( "Text Edit Box",
    teb = Text Edit Box( "a",
        Password Style( 1 ),
        Set Script( Print( "Changed!" ) )
    )
);
```

You can also send a text edit box a message to either use password style or to stop using password style.

```
q << Password Style( 1 ); // set the text edit box to password style
q << Password Style( 0 ); // set the text edit box to standard style
```

Filtering Display Boxes

`Data Filter Source Box()` and `Data Filter Context Box()` work together to filter data in multiple graphs. `Data Filter Source Box()` defines which graph is the “source” of the selection filter. When data are selected in the source graph, graphs in the common `Data Filter Context Box()` are updated.

**Data Filter Context Box**

`Data Filter Context Box()` creates a display box that enables you to filter data in multiple graphs. The function determines the number of graphs that the filter applies to, for example, all graphs in a report.

```
Data Filter Context Box( display box args );
```

In the following example, the `H List Box()` that contains the graphs is wrapped in `Data Filter Context Box()`. After you run the script, select values in the filter to see both graphs update.

```
dt = Open( "$SAMPLE_DATA/Hollywood Movies.jmp" );
win = New Window( "Shared Local Filter",
    Data Filter Context Box(
        // enclose the h list box that contains distribution and graph builder
        H List Box(

```
dt << Data Filter( Local ), // add the local data filter

```
dt << Distribution(
    Weight( :Profitability ),
    Nominal Distribution( Column( :Lead Studio Name ) ),
    Nominal Distribution( Column( :Genre ) ),
    Histograms Only)
);
```

dt << Graph Builder(
    Variables(
        X( :Genre ),
        Y( :Domestic Gross ),
        Y( :Foreign Gross, Position( 1 ) )
    ),
    Show Control Panel( 0 ),
    Elements(
        Bar(
            X,
            Y( 1 ),
            Y( 2 ),
            Legend( 2 ),
            Bar Style( "Side by side" ),
            Summary Statistic( "Mean" ),
        ),
        Frequencies( 0 ),
    )
);

Data Filter Source Box

Data Filter Source Box() and Data Filter Context Box() work together to filter data in multiple graphs. Data Filter Source Box() defines which graph is the “source” of the selection filter. When data are selected in the source graph, graphs in the common Data Filter Context Box() are updated.

```
Data Filter Source Box( display box args );
```

The following script lets you select data in Distribution graphs, and only that data is shown in the Graph Builder graph:

```
import File = require( "file.js" );

dt = Open( "$SAMPLE_DATA/Hollywood Movies.jmp" );
win = New Window( "Shared Local Filter",
    Data Filter Context Box(
        // enclose data filter source box and the graph builder platform
        H List Box(
```

Data Filter Source Box(
    dt << Distribution( // use distribution as the source graph
        Weight( :Profitability ),
        Nominal Distribution( Column( :Lead Studio Name ) ),
        Nominal Distribution( Column( :Genre ) ),
        Histograms Only
    ),
    dt << Graph Builder(
        Variables(
            X( :Genre ),
            Y( :Domestic Gross ),
            Y( :Foreign Gross, Position( 1 ) )
        ),
        Show Control Panel( 0 ),
        Elements(
            Bar(
                X,
                Y( 1 ),
                Y( 2 ),
                Legend( 2 ),
                Bar Style( "Side by side" ),
                Summary Statistic( "Mean" )
            ),
            Frequencies( 0 ),
        )
    );
)

Examples of Combined Display Boxes

The following example generates a sample of many controls illustrated in the previous sections.

dt = Open( "SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Window Controls",
    Line Up Box( N Col( 2 ), Spacing( 3 ),
        Panel Box( "Panel Box",
            Check Box( {"Check Box 1", "Check Box 2"} ),
            Radio Box( {"Radio Box 1", "Radio Box 2"} ),
            Combo Box( {"Combo Box"} ),
            Button Box( "Button Box" ),
            List Box( {"List Box 1", "List Box 2"} )
        ),
        Col List Box( "all" )
);
Example of Slider Boxes and Range Slider Boxes

The following example combines a graph with two sliders and a button by gluing the graph box, two horizontal boxes, and a button together in a vertical list box:

```plaintext
// Slider LogNormal
lU = 1;
lS = 2;
win = New Window( "LogNormal Density",
    V List Box( 
        gr = Graph Box( // define the arguments and script for the graph box 
            Frame Size( 500, 300 ),
            X Scale( 0.01, 3 ),
            Y Scale( 0, 4 ),
            XAxis( Show Major Grid ),
            YAxis( Show Major Grid ),
            Y Function( 
                Exp( -(Log( x ) - Log( lU )) ^ 2 / (2 * lS ^ 2) ) / (lS * x * 
                    Sqrt( 2 * Pi() )),
                x
            );
        /* display the specified text at 1 on the x axis 
            and .5 on the y axis */
        Text( {1, .5}, "u= ", lU, " s= ", lS );
    ),
    /* define the minimum and maximum range 
        insert the value of lU and updates the display as the slider moves */
    H List Box( Slider Box( 0, 4, lU, gr << Reshow ), Text Box( "mu" ) ),
    H List Box( 
        Slider Box( 0, 4, lS, gr << Reshow ),
        Text Box( "sigma" )
    )
);
```

Figure 11.16 Example of Many Interactive Display Elements
The following script uses a `Range Slider Box()` instead of a `Slider Box()` to perform the same function:

```scripting
lLow = 1;
lHigh = 2;
win = New Window( "Range Slider",
    V List Box(
        gr = Graph Box(
            Frame Size( 500, 300 ),
            X Scale( 0.01, 4 ),
            Y Scale( 0, 4 ),
            XAxis( "Show Major Grid" ),
            YAxis( "Show Major Grid" ),
            X Function( lLow, x );
            X Function( lHigh, x );
            Text( {1, .5}, "Low= ", lLow, " High= ", lHigh );
        ),
        V List Box(
            Text Box( "Low and High" ),
            sb = Range Slider Box( 0, 4, lLow, lHigh, gr << Reshow )
        )
    )
);
Show( gr );
gr << Reshow; // update the display of the Graph Box
```

Figure 11.17  Example of Sliders and Buttons in a Report Window
Figure 11.18 Example of Using Range Slider Box

The script below is similar but uses Global Box() as an editable text box instead of two Slider Box() controls:

```
// Global LogNormal
lU = 1;
lS = 2;
win = New Window( "LogNormal Density", 
    V List Box( 
        gr = Graph Box( // define the arguments and script for the Graph Box
            Frame Size( 500, 300 ),
            X Scale( 0.01, 3 ),
            Y Scale( 0, 4 ),
            XAxis( "Show Major Grid" ),
            YAxis( "Show Major Grid" ),
            Y Function( 
                Exp( -(Log( x ) - Log( lU )) ^ 2 / (2 * lS ^ 2) ) / (lS * x *
            )
        ));
        Button Box( "Reshow",
            lLow = 1;
            lHigh = 2;
            gr << Reshow;
            sb << Reshow;
        );
        Show( gr );
        gr << Reshow;
```
\[
Sqrt( 2 \times Pi() ), \\
x \\
\]
// display the specified text at 1 on the x and y axes
Text( {1, 1}, "u= \, \, lU, \, \, s= \, \, lS, \, \, or \, \, type \, \, new \, \, values \, \, below" );

// display the lU variable value in the first H List Box
H List Box( Global Box( lU ) ),

// display the lS variable value in the second H List Box
H List Box( Global Box( lS ) )

Figure 11.19 Example of Using a Global Box Instead of Sliders

Example of a Calendar and Date Selector

You can create a calendar or date selector using Calendar Box() and Number Edit Box().

Calendar Box

With CalendarBox(), you can select dates from a calendar and input the year. The following example creates a calendar with October 5, 1989 initially selected. You can select any date 60 days before or 60 days after October 5, 1989.

```plaintext
win = New Window( "Calendar Box", cal = Calendar Box() );
date = Date MDY( 01, 04, 2021 );
```
cal << Date( date );
cal << Show Time( 0 ); // omit the time

/* earliest date that can be selected is 60 days before 01/04/2021
"start" truncates the value so the time is not included */
cal << Min Date( Date Increment(date, "Day", -60, "start" ) );

// latest date that can be selected is 60 days after 01/04/2021
// print the abbreviated date to the log
    cal << Set Function( Function( {this}, Print( Abbrev Date(this << Get Date()) ) ) );

Figure 11.20 Creating a Calendar

Number Edit Box

With Number Edit Box(), you can enter a date in the box or click the calendar button to select the date from a calendar.

The following example shows how to create an interactive calendar using Number Edit Box(). The user enters a date in the box or clicks the calendar to select a date from the calendar. The number appears in a text box below the number edit box. “01/04/2021” is initially selected.

    f = Function( {this}, // callback
        textbox << Set Text( Format( this << Get, "m/d/y" ) ) // get the date );
    win = New Window( "Date Selector",
        numbox = Number Edit Box( 0, 20, << Set Function( f ) ),
        textbox = Text Box( "" ) // specified date );
    numbox << Set Format(
        Format( "m/d/y", 12 ) // date format and number of characters displayed );
    numbox << Set( Date MDY( 01, 04, 2021 ) ); // default date
Figure 11.21 Creating a Date Selector

Note that a callback is assigned to the f variable. In the callback, this refers to the number edit box, the box that calls the function later. Referring to this prevents the need for using the numbox variable within the callback. The Get message is sent to the this argument to get the specified date.

Example of Constructing a Summary Results Report

The following example uses the Summarize() function to collect summary statistics on the Height column of Big Class.jmp and then uses display box constructors to show the results in a nicely formatted window.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Summarize(
    a = by( age ),
    c = count,
    sumHt = Sum( Height ),
    meanHt = Mean( Height ),
    minHt = Min( Height ),
    maxHt = Max( Height )
);
win = New Window( "Summary Results",
    Table Box(
        String Col Box( "Age", a ),
        Number Col Box( "Count", c ),
        Number Col Box( "Sum", sumHt ),
        Number Col Box( "Mean", meanHt ),
        Number Col Box( "Min", minHt ),
        Number Col Box( "Max", maxHt )
    )
);

This produces the summary results shown in Figure 11.22.

<td>3</td>
<td>200</td>
<td>66.6667</td>
<td>62</td>
<td>70</td>
</tr>
</tbody>
</table>
```

The following script saves the report as a Microsoft PowerPoint presentation.
Interact with a Closing Window

A user can close a window by clicking the OK or Cancel button or by clicking the red Close button in the top corner of the window. A message can also be sent to close the window. **On Validate** and **On Close** expressions determine what happens you interact with the window.

- **On Validate** evaluates its expression *when the OK button is clicked*. The expression is not evaluated for any other button click or action. If the expression evaluates as true, the window closes. If the expression evaluates as false, the window is not closed. The script for an OK button runs when you click the button, no matter what the **On Validate** expression does.

- **On Close** evaluates its expression *right before the window closes*. The **On Close** return value is like the **On Validate** return value and can prevent the window from closing. However, the best practice for **On Close** is to always return 1 so that you do not accidentally create a window that cannot be closed.

If the window closes, **On Close** is evaluated. **On Close** is not evaluated if the **On Validate** expression returns false, because the window is not closed.

**Tips:**

- **On Close** works for modal or non-modal windows. **On Validate** works only for modal windows.

- Do not use **On Close** for validation because it does not distinguish between OK and Cancel. Use **On Close** to clean up resources (such as invisible data tables) because it always runs when the window closes.

- Do not use **On Validate** to clean up resources. Use **On Close** instead or in addition to **On Validate**, because **On Validate** does not run for the Cancel button or red Close button.

**On Close() Example**

Suppose that a non-modal window is a report window, and the resource that needs cleaning up is an invisible data table. The **On Close** script closes the data table. This is good because the user might not know that the data table is open and has no easy way to close it.

```plaintext
dt = New Table( "Untitled", << Invisible,
    New Column( "x", Set Values( [1, 2, 3, 4] ) ),
    New Column( "y", Set Values( [4, 2, 3, 1] ) )
)

dt << Bivariate(
    y( dt:y ), x( dt:x ), <<On Close( Close( dt, "nosave" ) )
)
```

```plaintext
Show Properties( win );
win << Save Presentation( "$DOCUMENTS/Summary.pptx" );
```
Before the script is run, no data tables are open. The Untitled invisible table is created and displayed in the Home Window and in the Data Tables list above the script. Then the graph is created. After you close the report window, the invisible table is closed by `On Close`.

**On Validate() Example**

Suppose that a modal window contains a question that the user must answer before closing the window. The following example shows how to validate the input when the user closes the window.

```plaintext
win = New Window( "Validate Example",
    <<Modal,
    <<Return Result,
    <<On Validate(
        If( (!Is Missing( variablebox << Get ) & 40 <= variablebox << Get <= 50),
            ( 1 ), // else the user did not enter the correct answer
            tb << Set Text(
                Match( Random Integer( 1, 3 ),
                    1, "Are you sure?",
                    2, "Guess again.",
                    3, "Please read the question."
                )
            );
            ( 0);
        );
    ),
    Text Box( "I'm thinking of a number between 40 and 50. What's your guess?"
    ),
    variablebox = Number Edit Box( . ),
    H List Box( Button Box( "OK" ), Button Box( "Cancel" ) ),
    tb = Text Box( "" )
);

New Window( "Modal Window",
    <<Modal,
    Text Box( If( // user clicked Cancel or the red Close button
        win["Button"] == -1, "Try again when you feel better.",
        win["variablebox"] == 42, "Good job.", // user entered 42
            "Take the test again." // user did not enter 42 and clicked OK
    )
    )
);
```

Update an Existing Display

Sometimes, you do not know how many display boxes will appear in a future report. For example, you might write a generic script that analyzes and reports on one or more variables. You do not know how many display boxes are needed, because the number of variables can change from one run of the script to the next.

The following sections describe how to add and delete display boxes from a report using `Append()`, `Prepend()`, `Delete()`, and `Sib Append()`.

Append

Use the `Append` message to add a display box to the bottom of an existing display. In the script, construct a single, empty box, then append boxes to it for each variable in the analysis. You can also use the `Append` message to modify an existing display with custom information or organization.

The following code example assumes that there is a list of effect names in the variable `effectsList`, and that each one corresponds to a column in a matrix `varprop`. In other words, `effectsList[1]` is the label for `varprop[0,1]`; `effectsList[2]` is the label for `varprop[0,2]`; and so on.

```plaintext
varprop = [0 1 2, 3 4 5, 6 7 8];
effectsList = {"one", "two", "three"};
```

First, an empty `Outline Box` containing an `H List Box` is created. The interior empty container is given the name `hb`:

```plaintext
win = New Window( "H List Box Example",
   Outline Box( "Variance Proportions", hb = H List Box() )
);
```

Then, a `for` loop steps through the `effectsList` and adds a `Number Col Box` for each element of `effectsList`:

```plaintext
For( i = 1, i <= N Items( effectsList ), i++,
   Eval(
      Substitute(
         Expr(
            hb << Append(
               Number Col Box( effectslist[i], varprop[0, i] )
            ),
            Expr( i ), i
         )
      )
   )
);
```
Sib Append() is similar to Append() but makes the display box a sibling of the last child display box. For an example that compares Append() to Sib Append(), see Figure 11.24.

Prepend

The Prepend message works just like Append but adds the item at the beginning of the display box rather than at the end. If the display box is one of several that do not allow appending, then Prepend delegates the command to a child display box that can accept the command. It is fine to apply it to the top of the tree.

For example, the following example creates a Bivariate report with a button box at the top.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( height ), X( weight ), Fit Line );

/* select the first outline box in the biv report layer
send the Prepend message to the first outline box */
(biv << Report)(Outline Box( 1 )) << Prepend(
    // prepend a button box that fits a quadratic curve
    Button Box( "Click here for curve", biv << Fit Polynomial( 2 ) )
);
```

Click the Click here for curve button to add a quadratic curve to the graph.

You can accomplish the same thing by appending the button to the top of the tree:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( height ), X( weight ), Fit Line );
biv << Report << Prepend( // send the prepend message to the report
    // prepend the button box to the top of the report
    Button Box( "Click here for curve", biv << Fit Polynomial( 2 ) )
);
```

Delete

The Delete message removes the specified display box and all its children from the report. This is useful with the Append and Prepend messages for building completely dynamic displays. In the example below, a text box is replaced with another text box. In this case, the script could have used Set Text, but many display boxes cannot change their content.

```julia
win = New Window( "X",
    list = V List Box(
        t1 = Text Box( "t1" ),
        t2 = Text Box( "t2" )
    )
);
```
t1 << Delete;
list << Append( t1 = Text Box( "t1new" ) );

**Note:** Avoid deleting display boxes from a JMP platform. Send the `Hide( 1 )` message or the `Visibility( "Hidden" )` message to the display box that you want to hide.

---

**Sib Append**

You can use the `Sib Append` message to add a display box immediately after an existing display box. Figure 11.23 shows two picture box trees. Picture Box( 1 ) holds the Bivariate scatterplot. Picture Box( 2 ) holds the Fit Mean menu, determined by seeing the green line and the Fit Mean text box.

Suppose you wanted to insert a text box in between these two boxes. You want to append a sibling to Picture Box( 1 ), so you send it the `Sib Append` message:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate(
  Y( :weight ),
  X( :height ),
  Fit Mean( {Line Color( {57, 177, 67} )} )
);

/* the report function takes the biv object and returns a report object. append the text box immediately after the first picture box */
Report( biv )[Picture Box( 1 )] << Sib Append( Text Box( "Hello There" ) );
```
**Figure 11.23** Appending a Sibling Text Box

Note: In Figure 11.23, the appended sibling text box appears below the first picture box in the Show Tree Structure View window. In the classic Show Tree Structure View window, siblings appeared next to each other in the display tree. See “View the Display Tree” on page 521.

Figure 11.24 shows the difference between and `Append()` and `Sib Append()`. `Append()` makes the display box a *child* of the parent display box. `Sib Append()` makes the display box a *sibling* of the last display box.
**Figure 11.24** Append (Left) and Sib Append (Right)

![Diagram showing Append and Sib Append operations.](image)

**Note:** If the parent display box is not a `V List Box()`, `Sib Append()` wraps that display box in `V List Box()`.

## Set Function and Set Script

You can use the `Set Script` message to have a display box control (for example, a button box or combo box) run a script when it is clicked with the mouse.

```plaintext
win = New Window( "Set Script Example", 
ex = Button Box( "Press me" )
);
ex << Set Script( Print( "Pressed" ) );
```

The preceding script prints the following text to the log when the button box is clicked:

"Pressed"

Alternatively, you can use the `Set Function` message to have a display box control run a specific function where the first argument is the specific display box. `Set Function` enables you to build more object-oriented scripts and to create a larger system.

```plaintext
win = New Window( "Set Function Example", 
    Button Box( "Press me", 

    // functions specified with Set Function get 'this' display box 
    << Set Function(
        Function(
            {this},
            this << Set Button Name( "Thanks" )
        )
    )
    )
);
```
The preceding script creates a button box with the name “Press me”. When the button is clicked, the function called by Set Function changes the name to “Thanks”.

If you have multiple buttons that can be serviced by the same script, Set Function is much simpler than Set Script because it tells you which button was pressed. In this example, both check boxes use the script that begins on the first line.

```plaintext
f = Function( {this, idx}, // idx just changed
    Write(
      /* <<Get Items returns a list of all items; indexing that list with idx
      is the name of the item that is changing */
      "\!n changing item=" || (this << Get Items())[idx] || " to " || Char(
        // <<Get returns the new value of that item
        this << Get( idx ) ) ||
      "\!n new selection=" || Char( this << Get Selected ) || "\!n"
    ) // <<Get Selected returns a list of the currently checked (selected) items
);
New Window( "Example",
    H List Box( // 'f' is the 'named' function, used twice
        V List Box( Text Box( "Column 1" ), Check Box( {"a", "b"}, <<Set
            Function( f ) ) ),
        Spacer Box( size( 50, 50 ) ),
        V List Box( Text Box( "Column 2" ), Check Box( {"c", "d"}, <<Set
            Function( f ) ) )
    )
);
```

In the following example of Set Function, the same function is used to create the buttons.

```plaintext
New Window( "Cash Box",
    V List Box(
        H Center Box( TB = Text Box() ), // TB will show total of coins
        LB = Lineup Box( N Col( 3 ) ), // LB will hold buttons, added below
        H Center Box( // CLEAR button will reset the total
            Button Box( "CLEAR",
                total = 0;
                TB << Set Text( Char( total ) );
            )
        )
    );
coins = {1, 5, 10, 25, 50, 100}; // coins is a list of the button labels
total = 0;
```

/* loop creates the buttons and shows that the same function
is used for each */
For( iButton = 1, iButton <= N Items( coins ), iButton++,
   LB << Append( Button Box( Char( coins[iButton] ), Set Function( buttonFunction ) ) )
);
buttonFunction = Function( {this},
   total = total + Num( this << Get Button Name );
   TB << Set Text( Char( total ) );
);

The function called for any button, except CLEAR, uses the button’s name to determine what
to do. Rather than using the button’s name, you might want to use a sibling display box by
this<<sib or perhaps (this<<parent)<<child to find the first sibling of this button.

Notes:
• The Set Script and Set Function messages work for button boxes, calendar boxes,
  check boxes, combo boxes, list boxes, popup boxes, radio boxes, range slider boxes, slider
  boxes, and spin boxes.
• You cannot use both Set Script and Set Function at the same time. Use Set Function
  if you need to reference a specific display box object.

Get and Set Selected Values of Display Elements That Return Lists

You can use the Set Selected(Item Number, <State>, <Run Script(0|1)> ) message to
pre-select an item. You can use this message separately to a saved display box reference, or
you can specify it inline as a list box << message.

To retrieve the selected value, use the Get Selected message, which returns the value of the
selected item. The Get Selected Indices message returns the index number of the selected
item.

antennaList = {"Dish","Helical","Polarizing","Radiant Array"};

win = New Window( "Test List", // method 1: display box reference
   listObj = List Box( antennaList,
      Print(
         "iList",
         listObj << Get Selected,
         listObj << Get Selected Indices
      )
   )
);
listObj << Set Selected( 2, 1 );
win = New Window( "Test List", // method 2: inline
    listObj = List Box(
        antennaList,
        <<Set Selected( 2, 1 ),
        Print(
            "iList",
            listObj << Get Selected,
            listObj << Get Selected Indices
        )
    );
)

Both of these scripts print the following text to the log:

"iList"
{"Helical"}
{2}

In the preceding examples, the Print expression is executed when the Set Selected message is completed. To prevent the script from running, include Run Script(0) as the last argument. Run Script( 0|1 ) controls whether a display box on-change script runs after a Set or Set Selected message.

antennaList = {"Dish","Helical","Polarizing","Radiant Array"};
win = New Window( "Test List",
    listObj = List Box(
        antennaList,
        Print(
            "iList",
            listObj << Get Selected,
            listObj << Get Selected Indices
        )
    );
)
listObj << Set Selected( 2, 1, Run Script( 0 ) );

With Run Script( 1 ), the script is executed when the Set message is completed, even if the value is unchanged. (The script does not run again if the user selects the same value.) With Run Script( 0 ), the script does not run.

On most interactive display boxes, the script does not run on most interactive display boxes if you leave out Run Script(). However, on List Box(), the script runs by default, which is consistent with previous behavior.
Send Messages to Constructed Displays

When you assign a constructed display to a name, that name becomes a reference to the window, which in turn owns the display boxes inside it. Using subscripts, you can then send messages to the display boxes inside the window.

For example, the following script creates an interactive sine wave graph. The script automates the interaction by sending messages to the frame box inside the window. Note the frame box assignment to \( tf \) in the middle of the script.

```javascript
amplitude = 1;
freq = 1;
phase = 0;
win = New Window( "Wiggle Wave",
    Graph Box( 
        Frame Size( 500, 300 ),
        X Scale( -5, 5 ),
        Y Scale( -5, 5 ),
        Y Function( amplitude * Sine( x / freq + phase ), x );
        Handle( /* current values of phase and amplitude position */
            phase,
            amplitude,
            /* x and y have been set to the handle's position */
            script begins after the last comma after amplitude */
            phase = x;
            amplitude = y;
        );

    // Handle works similarly except that the y value is .5
    Handle( freq, .5, freq = x );

    Text( // display a text string in the graph
        {3, 4},
        "amplitude: ",
        Round( amplitude, 4 ), // display the current value
        {3, 3.5},
        "frequency: ",
        Round( freq, 4 ), // display the current value
        {3, 3},
        "phase: ",
        Round( phase, 4 ) // display the current value
    );
```

tf = win[Frame Box( 1 )]; // get the frame box (the graph)
For( amplitude = -4, amplitude < 4, amplitude += .1,// animate the amplitude
    tf << Reshow // force the graph to update
);
amplitude = 1; // use for loops for more complex movement
freq = 1;
phase = 0;
For( i = 0, i < 1000, i++,
    amplitude += (Random Uniform() - .5);
    amplitude = If(
        amplitude > 4, 4,
        amplitude < -4, -4,
        amplitude
    );
    freq += (Random Uniform() - .5) / 20;
    phase += (Random Uniform() - .5) / 10;
    tf << Reshow;
    Wait( .05 );
);

Construct Display Boxes That Contain Platforms

Another type of display that you might want to construct is your own combination of results from the analysis platforms in JMP. Write the platform script inside a display box and assemble the display boxes into a window. For ease in routing messages to it later, assign the whole script to a reference.

The following example creates several graphs and reports in one window:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
csp = New Window( "Platform Example",
    Outline Box( "Analyses of height in Big Class.jmp",
        H List Box(
            cc = Control Chart(
                Chart Col( Height, "Individual Measurement", "Moving Range" ),
                K Sigma( 3 )
            ),
            dist = Distribution( Columns( Height ) )
        )
    )
);
Now you can work with the window by sending messages to the reference \texttt{csp}. This is a display box reference, whose capabilities are similar to those of a \texttt{Report} for a platform. You can use multiple-argument subscripting to locate specific items within the outline tree:

\begin{verbatim}
csp["Control ?", "moving range ?"] << Close;
csp["Dist?", "quantiles"] << Close;
\end{verbatim}

Notice that the preceding script not only assigned the whole window to a reference (\texttt{csp}) but also assigned the platform launch scripts to names (\texttt{cc} and \texttt{dist}) within their display boxes. This makes it easy to route messages to the platforms. You could, in turn, get the reports for these and have yet another way to manipulate display boxes. The following are equivalent messages that reopen the nodes:

\begin{verbatim}
rcc = cc << Report;
rdist = dist << Report;
rcc["moving range ?"] << Close;
rdist["quantiles"] << Close;
\end{verbatim}
You can send messages directly to the platform references themselves. Find out your options by searching for “Distribution” and “Control Chart” in the JMP Scripting Index. For example, Control Chart provides a message called Needle that creates a needle chart. Distribution provides a message called Normal Quantile Plot.

To execute these options from JSL, send them as messages to the platform references:

```jsl
cc << Needle;
dist << Normal Quantile Plot;
```

Figure 11.26 Changing a Custom Report

Counting the Number of Child Boxes

Suppose that you want to count the number of child text boxes in a list box. The most reliable way is to use XPath to find a specific string in the text boxes and then use N Items() to count the number of text boxes.

```jsl
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = Bivariate(  
```
Y( :weight ),
X( :height ),
Group By( :age ),
Fit Line( {Line Width( 3 )} )
);

/* start with the root list box, find a text edit box
that starts with “Linear Fit age==”, and count the number of children */
N Items( biv << XPath( "//ListBox[starts-with(TextEditBox,'Linear Fit age==')]" ) );

Examples of Creating a Dashboard from Two Reports

In JMP, you create dashboards in Dashboard Builder. See Using JMP. This section shows how to write scripts to create dashboards.

Dashboard with One Row of Reports

In the report window, reports appear in tab page boxes. You reposition reports in a dashboard by clicking the tab title and dragging the tab page to a highlighted drop zone. The highlighted drop zones indicate how to arrange reports horizontally, vertically, or in tabs. If a valid drop zone is not selected, the box returns to its original location.

This example shows how to write a script that creates a dashboard with two reports in a row:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Window( "My Dashboard",
H Splitter Box( // place reports in a splitter box
Size( 700, 400 ),
Tab Page Box( // place report in a tab page box
Title( "Bivariate Fit of weight by height" ),
dt << Bivariate( // Bivariate report
Y( :weight ),
X( :height ),
Fit Line,
Report View( "Summary" ) // show only the graph
),
<<Moveable( 1 ) // make the report moveable
),
Tab Page Box(
Title( "Oneway Analysis of height by sex" ),
dt << Oneway( // Oneway report
Y( :height ),
X( :sex ),
Means( 1 ),
Mean Diamonds( 1 ),
Chapter 11
Display Trees
597
Scripting Guide Construct Custom Windows
Report View( "Summary" )
),
<<Moveable( 1 )
),
/* each tab box can be dragged to a different location
required for moveable display boxes */
<<Dockable( 1 )
);

Figure 11.27 Dashboard with Two Reports

Note: For dockable and moveable tabs that contain a single platform, the top-level outline box is subsumed into the tab title. This means that the red triangle options now appear in the title bar of the tabs.

Dashboard with Tabs

The following script creates a dashboard that places each report on a tab:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Window( "My Dashboard",
    Tab Box( // place reports in a tab box
        Tab Page Box( // place report in a tab page box
            Title( "Bivariate Fit of weight by height" ),
            Report View( "Summary" )
        ),
        <<Moveable( 1 )
    ),
    /* each tab box can be dragged to a different location
    required for moveable display boxes */
    <<Dockable( 1 )
);

Note: For dockable and moveable tabs that contain a single platform, the top-level outline box is subsumed into the tab title. This means that the red triangle options now appear in the title bar of the tabs.
dt << Bivariate( // Bivariate report
Y( :weight ),
X( :height ),
Fit Line,
Report View( "Summary" ) // show only the graph
),
<<Moveable( 1 ), // make the report moveable
<<Closeable( 1 ) // make the report closeable
),
Tab Page Box(
Title( "Oneway Analysis of height by sex" ),
dt << Oneway( // Oneway report
Y( :height ),
X( :sex ),
Means( 1 ),
Mean Diamonds( 1 ),
Report View( "Summary" )
),
<<Moveable( 1 ),
<<Closeable( 1 )
),
/* each tab box can be dragged to a different location
   required for moveable display boxes */
<<Dockable( 1 ),
<<Set Overflow Enabled( 0 ) // both tab pages appear
);
In a dashboard with several tabs, the window widens to show all tabbed reports. You might want to show only the first report and then let the user select the other tabbed reports from a list. Change `Set Overflow Enabled(0)` near the end of the script to `Set Overflow Enabled(1)`. Figure 11.29 shows the result.

Figure 11.28 Dashboard with Tabs

Figure 11.29 Dashboard with Overflow Tabs
How to Dock Tabs in Tab Boxes

A docking layout is a collection of `Tab Page Box()` objects and docking containers that enable reports to be rearranged. In the report window, you drag a docked tab to a highlighted drop zone to create a new layout. Figure 11.27 shows two docked reports. In Figure 11.30, the Oneway report was dragged to the highlighted drop zone to display the reports in one column.
You combine `Tab Box()` with `Splitter Box()` to create docked tabs. Tab boxes and splitter boxes must directly contain other docking containers or the tab pages that define the content. Note the stacked boxes from a portion of the preceding example:

```plaintext
H Splitter Box( // place reports in a splitter box
    Size( 700, 400 ),
    Tab Page Box( // place report in a tab page box
```
The following expressions specify that the tab box and splitter box are docking containers, within which tab pages can be docked:

\[
\text{Tab Box} \leftarrow \text{Set Dockable();}
\]
\[
\text{Splitter Box} \leftarrow \text{Set Dockable();}
\]

In the report window, you reposition tab pages by clicking the tab title and dragging the tab page to a highlighted drop zone. The highlighted drop zones indicate how to arrange reports horizontally, vertically, or in tabs. If a valid drop zone is not selected, the box returns to its original location.

### Closing Tabs

The following expression creates a close button \( \times \) to the right of the report title on a closeable tab page:

\[
\text{Tab Page Box} \leftarrow \text{Set Closeable();}
\]

Clicking the close button \( \times \) deletes the tab and its contents. Parent containers might also be removed if they are no longer necessary (for example, if there are no more tabs in a tab box or only a single child in a splitter box).

Use the \( \text{Tab Page Box} \leftarrow \text{Set Close} \) message to run a JSL script when the close button \( \times \) is clicked. A return value of “1” indicates that the tab is closed. A return value of “0” indicates that closing the tab is not allowed at that time. Closing the tab might not be allowed as the result of a user prompt or based on the state of the program.

### Controlling Wide Tabs

When a docking layout includes tab page boxes, you may place many pages in a single Tab Box() container. In this case, the titles may become wider than the actual content or wider than desired in the overall display. The \( \text{Tab Box} \leftarrow \text{Set Overflow Enabled( 0|1 )} \) message specifies that the tab titles should not cause the tab box to grow wider. If the titles do not all fit, a pop-up button appears in the upper right corner of the tab box to select tabs that are in the “overflow list”. See Figure 11.29 on page 599 for an example.

### Example of Creating a Cluster Platform Launch Window

The following example creates a simplified replica of the Cluster platform launch window, which then launches the platform with the given arguments.

**Note:** Some functions (Recall and Help) are not implemented in the script, so an alert window is shown when the Recall and Help button are clicked. In addition, switching from Hierarchical to K-Means clustering does not change anything, unlike the real Cluster launch window.
dt = Open( "$SAMPLE_DATA/Birth Death.jmp" );
nc = N Col( dt ); // number of columns in the window
lbWidth = 130; // width of the window

// define the method list
notImplemented = Expr(
  win = New Window( "Feature Not Implemented Yet", <<Modal, Button Box( "OK" ) )
);
clusterDlg = New Window( "Clustering", // create the window
  <<Modal,
  Border Box( Left( 3 ), Top( 2 ),
    V List Box(
      Text Box( "Finding points that are close, have similar values" ),
      H List Box(
        Panel Box( "Select Columns",
          colListData = Col List Box(All,
            width( lbWidth ),
            NLines( Min( nc, 10 ) )
          ),
        ),
        Panel Box( "Options",
          V List Box(
            comboObj = Combo Box(
              {"Hierarchical", "K-Means"},
              <<Set( 1 )
            ),
            Panel Box( "Method",
              methodObj = Radio Box( methodList, <<Set( 3 )
            ),
            checkObj = Check Box( {"Standardize Data"}, <<Set( 1, 1 )
          ),
        ),
        Panel Box( "Cast Selected Columns into Roles",
          Line Up Box( N Col( 2 ), Spacing( 3 ),
            Button Box( "Y, Columns",
              colListY << Append( colListData << GetSelected )
            ),
            colListY = Col List Box( width( lbWidth ),
              NLines( 5 ),
              "numeric"
          )
        )
      )
    )
  )
)
Display Trees
Chapter 11
Construct Custom Windows Scripting Guide

),

Example of Constructing a Custom Platform

An example in “Manipulating Expressions” on page 268 in the “Programming Methods” chapter, showed how to use the Substitute Into() function to input coefficients for a quadratic polynomial into the quadratic formula and then use the formula to calculate the roots of the polynomial. That example required specifying the coefficients as arguments to Substitute Into()

The section “Construct a Column Dialog” on page 611 shows an example to collect coefficients from the user using a modal dialog box.

This section further develops the example into a complete customized platform that first displays a dialog box to ask for coefficients, finds the roots, and then displays the results along with a graph in a custom window.

```plaintext
// create a window to collect coefficients from the user
myCoeffs = New Window( "Find the roots for the equation",
  <<Modal,
    H List Box(  
a = Number Edit Box( 1 ),
    Text Box( "x^2 + " ),
    b = Number Edit Box( 2 ),
    Text Box( "x + " ),
    c = Number Edit Box( 1 ),
    Text Box( " = 0" )
  ));
```
Button Box( "OK",
    a = a << Get;
    b = b << Get;
    c = c << Get;
    Show( a, b, c );
),
Button Box( "Cancel" )
);

/* calculate the results: The quadratic formula is
x=(-b + - sqrt(b^2 - 4ac))/2a. Plug the coefficients into
the quadratic formula */
x = {Expr(
    (-b + Sqrt( b ^ 2 - 4 * a * c )) / (2 * a)
), Expr(
    (-b - Sqrt( b ^ 2 - 4 * a * c )) / (2 * a)
)};
xx = Eval Expr( x );

results = Expr( // store the solution list
/* test whether real roots were found and make an appropriate display
if yes (for example, with the window's defaults), show roots and a graph */
xmin = xx[1] - 5;
xmax = xx[2] + 5;
 ymin = -20;
 ymax = 20;
win = New Window( "The roots of a quadratic function",
    V List Box(        
        Text Box( "The real roots for the equation " ),
        Text Box( "   " || Expr( po ) || " = 0" ),
        H List Box( Text Box( "are x=" ), Text Box( xxx ) ),
        Text Box( " " ), // to get a blank line
        Graph Box(            
            Frame Size( 200, 200 ),
            X Scale( xmin, xmax ),
            Y Scale( ymin, ymax ),
            Line Style( 2 ),
            H Line( 0 ),
            Line Style( 0 ),
            Y Function( polynomial, x ),
            Line Style( 3 ),
            Pen Color( 3 ),
            V Line( xx[1] ),
        )
    )
);
Marker Size( 2 ),
Marker( 0, {xx[1], 0}, {xx[2], 0} )
)
);
);
error = Expr(

/* if no (for example, with a=3, b=4, c=5), put up an error window with a helpful graph */
win = New Window( "Error",
  V List Box(  
    Text Box( " " ),
    Text Box( " Polynomial " || po || " has no real roots. " ),
    Text Box( " " ),
    Text Box( "Examine a graph of the function to get an idea why." ),
    Graph Box(  
      Frame Size( 200, 200 ),
      X Scale( -20, 20 ),
      Y Scale( -20, 20 ),
      Line Style( 2 ),
      H Line( 0 ),
      Line Style( 0 ),
      Y Function( polynomial, x )
    )
  )
);

/* either way, the script needs to have some strings ready rewrite the polynomial with the coefficients specified */
polynomial = Expr( a * x ^ 2 + b * x + c );

// store this instance of the polynomial as a string
po = Char( Eval Expr( polynomial ) );

// store the solution list as a string
xxx = Char( Eval Expr( x ) );

  error,
  results
);

When you run the preceding script, you first see a window like this:
Figure 11.32  A Custom Platform Launch Window

Clicking OK, displays a results window (Figure 11.33, left), with either the roots or an error message. Rerun the script, input 5, 4, and 5 respectively and click OK. Note that JMP displays an error message (Figure 11.33, right).

Figure 11.33  The Custom Platform’s Report

Example of Specifying Text and Background Colors

The markup argument in a display box enables you to write HTML code to specify text and background colors. The color can be a hex value (starting with “0x” or “#”) or a known JMP color. Here is an example:

```
New Window( "Colors",
    Text Box(
        "This is <font color="#Red">red text and this is <font color="#00ff00">green text and this is <font color="#0000FF">blue text</font>.",
        <<markup
    ),
    Text Box(
        "This is <background color="#ff0000"> red text and this is <background color="#Green"> green text and this is <background color="#0000FF"> blue text</background> ",
        <<markup
    )
);
```
Modal Windows

As described in “Constructors for New Windows” on page 542, modal means that the user must interact with the window immediately. Clicking outside the window produces an error sound. Script execution stops until the user responds to the window.

JMP provides two types of modal window functions:

- **New Window()** with the Modal message. This creates a new window in which you arrange other display boxes.
- **Column Dialog()** constructs a window for column role assignments as found in many launch windows. The specialized constructors for Column Dialog() mean that you have less flexibility than with New Window(). However, Column Dialog() lets you easily create a launch window.

Construct a Modal Window

When you submit a script with a modal window, JMP draws the window, waits for the user to make choices and click OK, and then stores a list of the variables with their values. Any attempt to click outside the window produces an error sound, and script execution is suspended until the user clicks OK or Cancel.

The Column Dialog() function is specifically intended to prompt users to choose columns from the current (topmost) data table. Windows created by Column Dialog() are also modal windows.

Tips:

- Put all the modal windows near the beginning of the script, if possible. This way, all the user interaction can be accomplished at once, and then users can leave JMP to finish its work unattended.
- Make sure your modal windows give the user enough information. Do not just present a number field. Tell users how the number is used. If there are limits for valid responses, say so.

A very simple modal window might request a value for one variable:

```javascript
win = New Window( "Set a Value",
<<Modal,
```

Figure 11.34 HTML Text and Background Colors

This is red text and this is green text and this is blue text.
This is red text and this is green text and this is blue text.
Text Box( "Set this value" ),
variablebox = Number Edit Box( 42 ),
Button Box( "OK" ),
Button Box( "Cancel" )
);

Notice that the argument to Number Edit Box() is the default value, 42.

Figure 11.35  Sample Modal Display Box

If you click OK, the window closes and {Button(1)} is returned. To get the value entered in the box, use the Return Result message and a subscript into the window. Note that the deprecated Dialog() returns the list of variable assignments the same way.

```plaintext
win = New Window( "Set a Value",
     <<Modal,
     <<Return Result,
     Text Box( "Set this value" ),
     variablebox = Number Edit Box( 42 ),
     Button Box( "OK" ),
     Button Box( "Cancel" )
);

// create a subscript to the variablebox variable
Write( win["variablebox"] );
```

In this example, the user typed 33 in the number edit box. That value is stored in win.

If you click Cancel, the window closes, it returns {Button(-1)}, and the script continues.

To detect whether the user clicked Cancel, add the following expression:

```plaintext
If( win["Button"] == 1,
   Print( win["variablebox"] );
   Print("Canceled")
);
```

Note that a modal window must have at least one button. If you omit the Button Box() from your script, an OK button is automatically included. To omit the OK button, set the visibility to collapse.

```plaintext
win = New Window( "No OK Button",
```
<<Modal,
b = Button Box( "Close Window", b << Close Window ),
bb = Button Box( "OK", <<Visibility( "collapse" ) )
);

**Note:** Modal windows require at least one button for dismissing the window. You can use OK, Yes, No, or Cancel to label modal window buttons. If you do not include at least one of these buttons in a modal window, JMP adds an OK button.

### Construct a Column Dialog

Column Dialog(), a variant of the deprecated Dialog() function, lets you prompt for column selections from the current data table or contextual data table. The OK, Cancel, and Remove buttons and the list of columns to choose from the data table are added automatically.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dlg = Column Dialog(
    Col ID = Col List( "X, Treatment", Max Col( 1 ) ),
    Group = Col List( "Group Factors" ),
    Split = Col List( "Y, Response" ),
    w = Col List( "Weight" ),
    H List( "Alpha", alpha = Edit Number( .05 ) )
);
```

**Figure 11.36** Column Dialog

The following example returns a list similar to this one, depending on the user’s choices:

```
{Col ID = {}, Group = {}, Split = {}, w = {}, alpha = 0.05, Button( -1 )}
```
For each destination list, a Col List clause must be a direct argument of Column Dialog() (not nested inside some other argument). An optional MaxCol(\(n\)) argument restricts the number of data columns that can be chosen to \(n\). Lists are always returned, although they can sometimes be empty lists. You can include as many as twelve Col List clauses.

Other items permitted in the deprecated Dialog() are permitted in Column Dialog() and have the same functionality. You can specify the minimum and maximum number of columns that are allowed in a column dialog box with the MinCol and MaxCol arguments.

You can also specify the modeling type of the columns that are allowed to be selected (Ordinal, Nominal or Continuous). You can set the width of the list using Select List Width(pixels) argument. To set the width of the column list, use Width(pixels) inside the Col List() function.

The following example generates a column dialog box that only allows the selection of exactly one numeric column:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
rt_dlg = Column Dialog(
    cv = Col List( "Response To Test", MaxCol( 1 ), MinCol( 1 ), DataType( "Numeric" ) )
);
```

**Figure 11.37** Restricting Selection of Columns

The Data Type choices are Numeric, Character, and Any.

In addition, use the Columns specification to pre-fill some column selections. For example, the following script assigns height to the X role and weight and age to the Y role:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dlg = Column Dialog(
    xCols = Col List( "X, Factors", Columns( :height ) ),
    yCols = Col List( "Y, Response", Columns( :weight, :age ) )
);
```
Comparison of Column Dialog and New Window

New Window() and Column Dialog() enable you to construct a launch window that has a column selector. Use Column Dialog() to construct a simple launch window. Several items are added automatically to column dialogs: the Remove and Cancel buttons, the list of columns, and an OK button (if no buttons are explicitly defined).

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dlg = Column Dialog(
   x = ColList( "X", Max Col( 1 ) ),
   y = ColList( "Y", Max Col( 1 ) )
);

// returns dlg = {x = {:weight}, y = {:height}, Button(1)};
Show( dlg );

If( dlg["Button"] == 1,
   xCol = dlg["x"];
   yCol = dlg["y"];
);

Show( xCol, yCol );
   xCol = {:height};
   yCol = {:weight};

New Window() is more flexible because of numerous optional arguments. In the following example, the user must select two columns before clicking the OK button. A Bivariate graph is then created. Validating the user’s selections is not possible in Column Dialog().

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
xvar = .;
yvar = .;
win = New Window( "Example of Returning Values",
   <<Modal,
   // require the user to select two variables before clicking OK
   <<On Validate( 
      Show( xvar, yvar );
      If( Is Missing( xvar ) | Is Missing( yvar ),
         // if xvar or yvar are missing do nothing when OK is clicked
         0,
         1
      );
   ),
   Text Box( " Select two numeric columns. " ),
   H List Box(
Text Box( "X, Factor" ),
x = Col List Box(
  dt, // data table reference
  all, // display all columns from the data table

  // get the name of the selected column before the window closes
  xvar = (x << Get Selected)[1];
  Show( xvar );
),
Text Box( "Y, Response" ),
y = Col List Box(
  dt,
  all,
  yvar = (y << Get Selected)[1];
  Show( yvar );
)
);
If (win["Button"] == 1, // if the user clicks OK...
xcol = Column( dt, xvar ); // get the columns
ycol = Column( dt, yvar );
dt << Bivariate( Y( ycol ), X( xcol ) ); // create a Bivariate plot
);

Constructors for Column Dialogs

Constructors such as Edit Number() and Check Box() can be used in column dialogs, which construct launch windows with a column selector. The following example shows a typical column dialog with an Edit Number() box:

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column Dialog(
  ex x = ColList( "X", Max Col( 1 ) ),
  HList( "Alpha",
    ex = Edit Number( .05 )
  )
);

Table 11.3 describes the column dialog constructors.

Notes:

- A column dialog automatically includes the list of columns in the data table.
- A column dialog also automatically includes OK, Cancel, and Remove buttons.
### Table 11.3 Column Dialog Constructors

<table>
<thead>
<tr>
<th>Constructor</th>
<th>Syntax</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Button</td>
<td><code>Button( &quot;OK&quot; ), Button( &quot;Cancel&quot; )</code></td>
<td>Draws an OK or a Cancel button. If OK is clicked, <code>Button(1)</code> is returned. If Cancel is clicked, <code>Button(-1)</code> is returned.</td>
</tr>
<tr>
<td>Check Box</td>
<td><code>var ( CheckBox( &quot;Text after box&quot;, &lt;1/0&gt; ) )</code></td>
<td>When OK is clicked, a selected check box assigns 1 to the variable. A check box that is not selected assigns 0 to the variable. Add an optional 1 for the check box to be selected (on), or 0 for it to be not selected (off) when the window first appears. The default value is 0 (off).</td>
</tr>
<tr>
<td>Col List</td>
<td><code>var=Col List( &quot;role&quot;, &lt;MaxCol( n )&gt;, &lt;Datatype( type )&gt; )</code></td>
<td>Creates a selection destination with a <code>role</code> button; the user’s choices are returned in a list item of the form <code>var={choice 1, choice 2, ..., choice n}</code>. You can specify the minimum and maximum number of columns using <code>MinCol( n )</code> or <code>MaxCol( n )</code>. You can specify the required data type of the column using <code>Datatype(type)</code>. The choices for <code>type</code> are Numeric, Character, or Rowstate.</td>
</tr>
<tr>
<td>Combo Box</td>
<td><code>var( ComboBox( &quot;choice1&quot;, &quot;choice2&quot;, ... ) )</code></td>
<td>Produces a menu with the choices listed. The first choice is the default. Choices evaluate to quoted text strings. Choices can also be inside a list.</td>
</tr>
<tr>
<td>Edit Number</td>
<td><code>var( Edit Number( number ) )</code></td>
<td>Produces an edit field for a number with <code>number</code> as the default value. When OK is clicked, the number entered in the field is assigned to the variable.</td>
</tr>
<tr>
<td>Constructor</td>
<td>Syntax</td>
<td>Explanation</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit Text</td>
<td>var(Edit Text(&quot;string&quot;, &lt;width(x)&gt;))</td>
<td>Produces an edit field for a string with <em>string</em> as the default value. You can also specify the minimum width of the box in pixels. The default width is 72 pixels. When OK is clicked, the text entered in the field is assigned to the variable.</td>
</tr>
<tr>
<td>HList</td>
<td>HList( <em>item</em>, <em>item</em>, ... )</td>
<td>Top aligns and spaces the <em>items</em> in a horizontal row. Placing a pair of VLists within an HList produces a top aligned, spaced pair of columns.</td>
</tr>
<tr>
<td>Line Up Box</td>
<td>Line Up Box( <em>n</em>, <em>item_11</em>, <em>item_12</em>, ..., <em>item_1n</em>, ..., <em>item_nn</em> )</td>
<td>Lines up the <em>items</em> listed in <em>n</em> columns, where <em>item_ij</em> is the <em>j</em>th item of the <em>i</em>th row.</td>
</tr>
<tr>
<td>List Box</td>
<td>var=ListBox( {&quot;item&quot;, &quot;item&quot;, ...}, width( 50 ), max selected( 2 ), NLines( 6 ) )</td>
<td>Creates a display box that contains a list of items.</td>
</tr>
<tr>
<td>Radio Buttons</td>
<td>var(RadioButtons(&quot;choice1&quot;, &quot;choice2&quot;, ...))</td>
<td>Produces a vertical, left-justified list of radio buttons with the choices specified. The first choice is the default. When OK is clicked, the button that is selected is assigned to the variable. Choices must evaluate to quoted text strings.</td>
</tr>
<tr>
<td>string</td>
<td>&quot;string&quot;</td>
<td>Draws text in the window. For example, can include a labeling string before an Edit Number field. All strings must be quoted.</td>
</tr>
<tr>
<td>VList</td>
<td>VList( <em>item</em>, <em>item</em>, ... )</td>
<td>Left aligns and spaces the <em>items</em> in a vertical column. Placing a pair of HLists within a VList produces a left-aligned, spaced pair of rows.</td>
</tr>
</tbody>
</table>
Convert Deprecated Dialog to New Window

Because `New Window()` provides more display options and better control over the content and functions of the window, rewrite your `Dialog()` scripts.

**Note:** `Dialog()` scripts will not run in the future.

The following sections illustrate how to rewrite `Dialog()` scripts as `New Window()` scripts.

- “New Window Example”
- “Example of Deprecated Dialog”
- “Differences Between New Window and the Deprecated Dialog”
- “Optional Scripts in New Window”

**New Window Example**

The following example creates a window with multiple vertical and horizontal list boxes:

```plaintext
win = New Window( "New Window Example",
                  <<Modal,
                  <<ReturnResult, // ensure that you get the same result as with Dialog
V List Box(  
    V List Box(  
        Text Box( "Radio Frequency Embolism Projection" ),
        Line Up Box(  
            NCol( 2 ),
            Text Box( "Lower Spec Limit" ),
            lsl_box = Number Edit Box( 230 ),
            Text Box( "Upper Spec Limit" ),
            usl_box = Number Edit Box( 340 ),
            Text Box( "Threshold" ),
            threshold_box = Number Edit Box( 275 )
        ),
    ),
H List Box(  
    Panel Box( "Type of Radio",
                rb_box1 = Radio Box( {"RCA", "Matsushita", "Zenith", "Sony"} ) ),
    Panel Box( "Type of Antenna",
                rb_box2 = Radio Box( {"Dish", "Helical", "Polarizing", "Radiant Array"} ) )
),
cb_box1 = Check Box( "Emission Synchronization" ),
Text Box( "Title for plot" ),
title_box = Text Edit Box( "My projection" ),
```
Example of Deprecated Dialog

Compare the previous `New Window()` example to this example of the deprecated `Dialog()`.

```plaintext
dlg = Dialog(
  Title( "Dialog Example" ),
  H List(
    V List(
      "Radio Frequency Embolism Projection",
      Lineup( 2,
        "Lower Spec Limit", lsl = Edit Number( 230 ),
        "Upper Spec Limit", usl = Edit Number( 340 ),
        "Threshold", threshold = Edit Number( 275 )
      ),
    ),
    H List(
      V List(
        "Fealty", "Loyalty", "Piety", "Obsequiousness"
      )
    ),
  ),
  H List Box(
    Align( Right ),
    Spacer Box(),
    Button Box( "OK",
      lsl = lsl_box << Get;
      usl = usl_box << Get;
      threshold = threshold_box << Get;
      radio_type = rb_box1 << Get;
      antenna = rb_box2 << Get;
      synch = cb_box1 << Get;
      title = title_box << Get Text;
      quality = cb_box2 << Get;
    ),
    Button Box( "Cancel" )
  )
)
If(win["Button"] == 1,
  // if the user clicks OK, show the selections in the log
  Show( "OK", lsl, usl, threshold, radio_type, antenna, synch, title, quality);
  ,
  Show( "Canceled" ); // if the user clicked Cancel, print "Canceled"
);
```

---

Example of Deprecated Dialog

Compare the previous `New Window()` example to this example of the deprecated `Dialog()`.

```plaintext
H List Box( Text Box( "Quality" ),
  cb_box2 = Combo Box( {"Fealty", "Loyalty", "Piety", "Obsequiousness"} )
),
H List Box(
  Align( Right ),
  Spacer Box(),
  Button Box( "OK",
    lsl = lsl_box << Get;
    usl = usl_box << Get;
    threshold = threshold_box << Get;
    radio_type = rb_box1 << Get;
    antenna = rb_box2 << Get;
    synch = cb_box1 << Get;
    title = title_box << Get Text;
    quality = cb_box2 << Get;
  ),
  Button Box( "Cancel" )
)
If(win["Button"] == 1,
  // if the user clicks OK, show the selections in the log
  Show( "OK", lsl, usl, threshold, radio_type, antenna, synch, title, quality);
  ,
  Show( "Canceled" ); // if the user clicked Cancel, print "Canceled"
);
```
"Type of Radio",
type = Radio Buttons( "RCA", "Matsushita", "Zenith", "Sony" )
),
V List(
  "Type of Antenna",
  antenna = Radio Buttons( "Dish", "Helical", "Polarizing", "Radiant Array" )
),

synch = Check Box( "Emission Synchronization", 0 ),
"Title for plot",
title = Edit Text( "My projection" ),
H List(
  "Quality",
  quality = Combo Box( "Fealty", "Loyalty", "Piety", "Obsequiousness"
)
),

V List( Button( "OK" ), Button( "Cancel" )
);

If( dlg["Button"] == 1,
  Show(
    "OK",
    dlg["lsl"],
    dlg["usl"],
    dlg["threshold"],
    dlg["type"],
   dlg["antenna"],
    dlg["synch"],
    dlg["title"],
   dlg["quality"]
  ),
  Show( "Canceled" )
);
**Figure 11.38** Results from New Window (left) and the Deprecated Dialog (right)

**Note:** Use `Return Result` to get the same result in `New Window()` as with the deprecated `Dialog()`. See “Construct a Modal Window” on page 609 for an example.

## Differences Between New Window and the Deprecated Dialog

This section shows the differences between display boxes in `New Window()` and the deprecated `Dialog()` scripts. Table 11.4 summarizes those differences. More information can be found in the sections that follow the table.

### Table 11.4 Display Boxes in New Window and Deprecated Dialog Scripts

<table>
<thead>
<tr>
<th>Box Type</th>
<th>New Window</th>
<th>Deprecated Dialog</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Strings and Lists</strong></td>
<td><code>win = New Window( &quot;Combo Box&quot;, &lt;&lt;Modal, &lt;&lt;ReturnResult, cb = Combo Box( {&quot;True&quot;, &quot;False&quot;} ), );</code></td>
<td><code>Dialog( Title( &quot;Combo Box&quot; ), cb = Combo Box( &quot;True&quot;, &quot;False&quot; ), );</code></td>
</tr>
<tr>
<td><strong>List Boxes and Check Boxes</strong></td>
<td><code>win = New Window( &quot;H List Box&quot;, &lt;&lt;Modal, &lt;&lt;ReturnResult, H List Box( kb1 = Check Box( &quot;a&quot; ), kb2 = Check Box( &quot;b&quot; ), kb3 = Check Box( &quot;c&quot; ) );</code></td>
<td><code>dlg = Dialog( Title( &quot;H List&quot; ), H List( kb1 = Check Box( &quot;a&quot;, 0 ), kb2 = Check Box( &quot;b&quot;, 0 ), kb3 = Check Box( &quot;c&quot;, 0 ) );</code></td>
</tr>
</tbody>
</table>

<td>dlgs = Dialog( Title(&quot;Radio Buttons&quot;), rb = Radio Buttons( {&quot;a&quot;, &quot;b&quot;, &quot;c&quot;} ) );</td>
</tr>
<tr>
<td><strong>Text Edit Boxes</strong></td>
<td>win = New Window(&quot;Text Edit Box&quot;, &lt;&lt;Modal, &lt;&lt;ReturnResult, V List Box( Text Box(&quot;Strings&quot; ), str1 = Text Edit Box(&quot;The&quot; ), str2 = Text Edit Box(&quot;quick&quot; ), ) );</td>
<td>dlgs = Dialog( Title( &quot;Edit Text&quot; ), V List( &quot;Strings&quot;, str1 = Edit Text(&quot;The&quot; ), str2 = Edit Text(&quot;quick&quot; )) );</td>
</tr>
</tbody>
</table>
Strings and Lists

A major difference between the `New Window()` and the deprecated `Dialog()` functions is how you specify lists and strings as arguments. In `New Window()`, the items must be placed in a list. In the deprecated `Dialog()`, items are generally separated by commas. For example, compare the following two instances of a combo box.

```
win = New Window( "Combo Box", // modal New Window
                  <<Modal,
                  <<ReturnResult,
                  V List Box(  
                      Text Box("Random Numbers"),
                      num1 = Number Edit Box( Random Uniform()),
                      num2 = Number Edit Box( Random Uniform() * 10),
                      ...);

Dialog( Title( "Combo Box" ), // modal Dialog  
        cb = Combo Box( "True", "False" ), // items are separated by commas
        ...);
```

**Note:** The script does not explicitly define the OK button. For modal windows, JMP automatically adds the OK button. Explicitly define each additional button.

Additionally, the deprecated `Dialog()` could include " " to indicate empty text. `New Window()` requires that empty text appear in a `Text Box (" ")`.

List Boxes and Check Boxes

In `New Window()`, boxes are horizontally aligned with `H List Box()` and vertically aligned with `V List Box()`. In the deprecated `Dialog()`, you use `H List` and `V List` instead.

**Note:** Boxes are vertically aligned by default if `H List Box()` or `V List Box()` are omitted.
The following example creates a window with three horizontal check boxes and an OK button:

```lisp
win = New Window( "H List Box", 
    <<Modal, 
    <<Return Result, 
    H List Box( 
        kb1 = Check Box( "a" ),
        kb2 = Check Box( "b" ),
        kb3 = Check Box( "c" )
    ),
);
```

Here is the same window created with the deprecated Dialog() and an H List():

```lisp
dlg = Dialog( Title( "H List" ),
    H List( 
        kb1 = Check Box( "a", 0 ),
        kb2 = Check Box( "b", 0 ),
        kb3 = Check Box( "c", 0 )
    ),
);
```

**Line Up Items**

In New Window(), use Line Up Box() to arrange items in the number of columns that you specify. In the deprecated Dialog(), you used Line Up.

The following example arranges the text boxes in one column and the number edit boxes in another column:

```lisp
win = New Window( "Line Up Box", 
    <<Modal, 
    <<Return Result, 
    V List Box( 
        Lineup Box( N Col( 2 ),
            Text Box( "Set this value" ),
            var1 = Number Edit Box( 42 ),
            Text Box( "Set another value" ),
            var2 = Number Edit Box( 86 ),
        ),
    ),
    H List Box( Button Box( "OK" ), Button Box( "Cancel" ) )
);
```

Clicking OK returns the following result in the log window:

```
List( 3 elements ) assigned.
```
Figure 11.39 Default Dialog Arrangements for Windows (left) and macOS (right)

Here’s the same window created with the deprecated `Dialog()` and `Line Up`:

```javascript
dlg = Dialog(
    V List(
        Line Up( 2,
            "Set this value", variable = Edit Number( 42 ),
            "Set another value", var2 = Edit Number( 86 )
        ),
        H List( Button( "OK" ), Button( "Cancel" ) )
    )
);
```

Clicking **OK** returns the following result in the log window:

```
{variable = 42, var2 = 86, Button(1)}
```

**Note:** JMP does exert some control over OK and Cancel button positions to ensure that dialog boxes are consistent with what the operating system expects. In certain cases, JMP needs to override your `H List Box()`, `V List Box()`, and `Line Up Box()` settings for `Button( "OK" )` and `Button( "Cancel" )`. Do not be alarmed if the result is slightly different from what you expect.

### Radio Boxes

Another difference between `New Window()` and the deprecated `Dialog()` is the usage of `Radio Box`. In `New Window()`, you must define the `Panel Box()` container for `Radio Box()` if you want the radio buttons in a box.

```javascript
win = New Window( "Radio Box",
    <<Modal,
    <<Return Result,
    Panel Box( "Select",
        rbox = Radio Box( {"a", "b", "c"} )
    )
);  
```

In the deprecated `Dialog()`, the `Radio Buttons()` automatically appear in a panel box.

```plaintext
dlg = Dialog( Title( "Radio Buttons" ),
             rb = Radio Buttons( {"a", "b", "c"} ),
             );
```

**Text Edit Boxes**

In `New Window()`, use `Text Edit Box()` to create editable boxes that contain specified strings. In the deprecated `Dialog()`, you used `Edit Text()`.

```plaintext
win = New Window( "Text Edit Box",
             <<Modal,
             <<Return Result,
             V List Box(
             Text Box( "Strings" ),
             str1 = Text Edit Box( "The" ),
             str2 = Text Edit Box( "quick" ),
             str3 = Text Edit Box( "brown" ),
             str4 = Text Edit Box( "fox" ),
             str5 = Text Edit Box( "jumps" ),
             str6 = Text Edit Box( "over" ),
             str7 = Text Edit Box( "the" ),
             str8 = Text Edit Box( "lazy" ),
             str9 = Text Edit Box( "dog" )
             );
```

Here is the same window created with the deprecated `Dialog()` and `Edit Text()`:

```plaintext
dlgs = Dialog( Title( "Edit Text" ),
             V List("Strings",
             str1 = Edit Text( "The" ),
             str2 = Edit Text( "quick" ),
             str3 = Edit Text( "brown" ),
             str4 = Edit Text( "fox" ),
             str5 = Edit Text( "jumps" ),
             str6 = Edit Text( "over" ),
             str7 = Edit Text( "the" ),
             str8 = Edit Text( "lazy" ),
             str9 = Edit Text( "dog" )
             );
```

Alternatively, use String Col Edit Box() to create editable boxes within in a table structure that contains specified strings. For example, the following script creates a window named “String Col Edit Box”. The window contains a column (labeled “Strings”) of editable boxes, each of which contains the specified string:

```sas
win = New Window( "String Col Edit Box",
    <<Modal,
    <<Return Result,
    steb = String Col Edit Box( "Strings",
        {"The", "quick", "brown", "fox", "jumps", "over", "the", "lazy", "dog"} )
); 
```

**Note:** In the preceding example, New Window() assigns only two elements to the list (the specified list items and the button).

---

### Number Edit Boxes

In New Window(), use Number Edit Box() to create editable boxes that contains the specified numbers. In the deprecated Dialog(), you used Edit Number().

```sas
win = New Window( "Number Edit Box",
    <<Modal,
    <<ReturnResult,
    V List Box( 
        Text Box( "Random Numbers" ),
        num1 = Number Edit Box( Random Uniform() ),
        num2 = Number Edit Box( Random Uniform() * 10 ),
        num3 = Number Edit Box( Random Uniform() * 100 ),
        num4 = Number Edit Box( Random Uniform() * 1000 )
    ),
); 
```

Here is the same window created with the deprecated Dialog() and Edit Number():

```sas
dlg = Dialog(
    Title( "Edit Number" ),
    V List( 
        "Random Numbers",
        num1 = Edit Number( Random Uniform() ),
        num2 = Edit Number( Random Uniform() * 10 ),
        num3 = Edit Number( Random Uniform() * 100 ),
        num4 = Edit Number( Random Uniform() * 1000 )
    ),
); 
```
Another method for creating the same window uses `Number Col Edit Box()` to create editable boxes within in a table structure that contains specified numbers. For example, the following script creates a window named “Number Col Edit Box”. The window contains a column (labeled “Random Numbers”) of editable boxes, each of which shows the specified type of random number:

```plaintext
win = New Window( "Number Col Edit Box",
   <<Modal,
   <<ReturnResult,
   nceb = Number Col Edit Box(
       "Random Numbers",
       {num1 = Random Uniform(), num2 = Random Uniform() * 10, num3 =
       Random Uniform() * 100, num4 = Random Uniform() * 1000}
   ),
);
```

**Note:** In the preceding example, the `Number Col Edit Box()` assigns only two elements to the list. The `New Window()` and deprecated `Dialog()` examples for `Number Col Edit Box()` assign five elements to the list.

### Optional Scripts in New Window

One of the benefits of using `New Window()` is the ability to add optional scripts to display boxes. In the deprecated `Dialog()`, the following combo box could not include an optional script. If you wanted an action associated with any of the display box controls, you had to place a script as the control’s last argument. For example:

```plaintext
win = New Window( "Combo Box",
   <<Modal,
   <<ReturnResult,
   comboObj = Combo Box(
       {"True", "False"},
       << Set( 1 ),
       Print( comboObj << Get )
   ),
);
```

When the user selects a different value, the selected item number (1 or 2 in this case, because there are two items in the combo box) is printed to the log.
Scripting the Script Editor

Even the script editor window is a display tree in JMP, which means you can write a JSL script to write and save another JSL script.

There is no `New Script` command. Instead, to open a new script window, you use the `New Window()` function and then send it a message to tell it that it’s a script window:

```js
ww = New Window( "Window Title", <<Script, "Initial Contents" );
```

The last argument is optional. If you include a string, the new script window contains that string.

In the `New Window` example above, `ww` is a reference to the display box that is the entire window. To write to a script window, you first need to get a reference to the part of the display box that you can write to, which is called a script box:

```js
ed = ww[Script Box(1)];
```

Using the reference `ed`, you can add text, remove text, and get the text that is already there.

```js
ed << Get Text();
"Initial Contents"
```

Use `Set Text` to set all the text in the script window. The following command clears all text in the Script Window and then adds `aaa=3;` followed by a return:

```js
ed << Set Text( "aaa=3;\!N" );
```

Use `Append` to add additional text to the end of the script window.

```js
ed << Append Text( "bbb=1/10;" );
ed << Append Text( "\!Nccc=4/100;" );
```

Use the `Get Line Text` command to get the text at the line of a specified line number. Use the `Set Line Text` command to replace a specified line of text with new text.

```js
ed << Get Line Text( 2 );
ed << Set Line Text( 2, "bbb = 0.1;" );
```

Use the `Get Line Count` message to get the total number of lines in the script. The `Get Lines` message returns a list of each line in the script as a string.

```js
ed << Get Line Count();
ed << Get Lines();
```

Use the `Reformat` message to automatically format a script for easier reading.

```js
ed << Reformat();
```

To run an entire script in a script window, use it the `Run` message.

```js
ed << Run();
```
To close the script window without saving the script, send the window the Close Window message, just like you can do with any JMP window.

```julia
ww << Close Window( nosave );
```

To save and view the script, use the Save Text and Load Text File messages:

```julia
ww = New Window( "Test", <<Script, "Open(\"$SAMPLE_DATA\BigClass.jmp\")");
ww << Save Text( "$TEMP/Test.jsl" );
Write( Load Text File( "$TEMP/Test.jsl" ) );
```

**Note:** When the script is loaded into the script window, the window is considered “dirty” or modified. Use `<<Set Dirty(0)` to remove this property. Otherwise, you are prompted to save the script when you close the window.

To save the script and close the window, follow this example:

```julia
ww = New Window( "Test", <<Script, "Open(\"$SAMPLE_DATA\BigClass.jmp\")");
ww << Save Text( "$TEMP/Test.jsl" );
ww << Close Window();
```

## Technical Details

### Write Tab Box and Tab Page Box Scripts

Tab Page Box() organizes the title and contents of the page in one display box. When Tab Page Box() is inside Tab Box(), a tabbed window with multiple tabbed pages appears. See “Tab Box and Tab Page Box” on page 569.

In previous versions of JMP, display boxes such as V List Box() contained tab contents. Consider the following script:

```julia
win = New Window( "Tab Box",
    tb = Tab Box(
        "First page", // name of the tab
        V List Box( // tab contents
            Text Box( "first line of first page" ),
            Text Box( "second line of first page" )
        ),
        "Second page", // name of the tab
        V List Box( // tab contents
            Text Box( "first line of second page" ),
            Text Box( "second line of second page" )
        )
    )
)
```
We recommend that `Tab Box()` contain a `Tab Page Box()` for each tab. The preceding example is rewritten as follows:

```plaintext
win = New Window( "Tab Box",
    tb = Tab Box(
        Tab Page Box( // tab contents
            Title( "First page of my tab box" ), // name of the tab
            Text Box( "first line of first page" ),
            Text Box( "second line of first page" )
        ),
        Tab Page Box( // tab contents
            Title( "Second page" ), // name of the tab
            Text Box( "first line of second page" ),
            Text Box( "second line of second page" )
        )
    )
);
```

**Note:** `Tab Page Box()` requires that the title be defined in a `Title()` function.

When a tab page box is created or dragged outside a tab box, the tab page box is a stand-alone container. The title appears in a shaded box at the top of the page, similar to the title in `Sheet Part();`; the title does not appear in an interactive tab. “Dashboard with One Row of Reports” on page 596 provides an example.

### Deprecated Tab Box and Tab Page Box Messages

Some messages previously used for `Tab Box()` are deprecated. Their counterparts are compatible with `Tab Page Box()`.

</table>

See “Tab Box and Tab Page Box” on page 569 for more information about the two display boxes.
The JSL script for a graph contains expressions that create shapes and lines, apply fill patterns, assign background colors, and so on. You can also right-click a graph and select Customize to add the same expressions.

This chapter also describes how to customize hover labels with rich text, images, and drill-down graphs.

For information about scripting three-dimensional graphs, see the chapter “Three-Dimensional Scenes” on page 723.

Add Scripts to Graphs

When you right-click a graphics frame, you can enter or paste JSL commands as shown in the following example. The script usually contains drawing commands that run in the context of the graphics frame. The context of the graphics frame includes the data range of the axes and the order that the data and scripts are drawn in.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Select Analyze > Fit Y by X.
3. Choose weight for Y and height for X, and then click OK.
4. Right-click inside the graph and select Customize.

Figure 12.1 Customizing the Graph Options

5. Click the Add button to add a new graphics script.
6. Type the following text and click OK.

   Text( {55, 160}, "Hello World" );

Now the graph has a text element at the graph’s x-coordinate 55 and y-coordinate 160.
By default, the data points appear on top of graphics.

For example, add a new script in the Customize Graph window:

```julia
Fill Color("Green"); Rect(57, 175, 65, 110, 1);
```

A solid green rectangle appears. The list of scripts shows the order in which each script is drawn, so the first item on the list is drawn first.

- If you want the rectangle behind everything, move the rectangle script above the text script: select the rectangle script and click the up button ↑.
- If you want the rectangle on top of everything, select the rectangle script and click the down button ↓.

You can arrange all the scripts in a graph into the drawing order that you prefer. Any new script is initially added directly after the item in the list that is selected.

**Tip:** To use a script that references a column name, use `Column( colname )` or a colon (`:colname`) to scope it properly.

**Hint:** To see the JSL for the above actions, select **Save Script > To Script Window** from the red triangle menu.

## Specify the Order of Graphical Elements

You can also add graphics elements using JSL instead of doing so interactively:

```julia
Frame Box <<Add Graphics Script(<order>, <"description">, script)
```

When you add graphical elements using JSL, they are drawn on top of whatever is already in the graph.
• The optional order argument specifies in what order to draw the graphics element. The order can be the keyword Back or Front or an integer that specifies the drawing order for a number of graphics elements. For example, if you add an oval to a scatterplot, the oval is drawn on top of the markers. The keyword Back or 1 cause the oval to be drawn last. Front or 2 means the object is drawn first.

• The optional Description argument is a string that appears in the Customize Graph window next to the graphics script.

To specify the drawing order for a number of graphics elements, use an integer for the order argument to determine where each is drawn in relation to the others. The following script first adds a blue oval and then adds a red oval over the blue oval. Both ovals are behind the points.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
op = dt << Bivariate(
    X( :height ),
    Y( :weight ),
);

Report( op )[Frame Box( 1 )] << Add Graphics Script(
    1, // draw the blue oval
    Description( "Blue Oval" ),
    Fill Color( "Blue" );
    Oval( 60, 140, 65, 90, 1 );
);

Report( op )[Frame Box( 1 )] << Add Graphics Script(
    2, // draw the red oval over the blue oval
    Description( "Red Oval" ),
    Fill Color( "Red" );
    Oval( 50, 120, 65, 100, 1 );
);
```
Figure 12.3 Specifying the Drawing Order

Copy and Paste Frame Contents or Settings

You can copy and paste the contents or the settings of a frame with these JSL commands:

```jsl
obj << Copy Frame Contents // contents such as a graph or line of fit
obj << Paste Frame Contents
obj << Copy Frame Settings // settings such as background color
obj << Paste Frame Settings
```

The following example creates two Bivariate graphs, adds a line of fit to the first graph, and then copies and pastes the line to the second graph.

```jsl
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( :weight ), x( :height ) );
rbiv1 = biv << Report; // create a report object
rbiv2 = rbiv1 << Clone Box; // create a copy of the Bivariate graph

/* place the cloned box below the Bivariate graph
to create a second Bivariate graph */
rbiv1 << Append( rbiv2 );

framebox1 = rbiv1[Frame Box( 1 )]; /* assign references to
the reports' frame boxes*/
framebox2 = rbiv2[Frame Box( 1 )];
biv << Fit Line; // fit a line to the first Bivariate graph

// copy the frame contents from framebox1
framebox1 << Copy Frame Contents;

// paste the frame contents to framebox2
framebox2 << Paste Frame Contents;
```
The following example creates two Bivariate graphs, sets the background of the first graph to blue, and then copies and pastes the blue background setting to the second graph:

```julia
dt = Open("$SAMPLE_DATA/Big Class.jmp");

biv1 = dt << Bivariate( y( :weight ), x( :height ) );

// create the first Bivariate graph
rbiv1 = biv1 << Report; // create a report object
rbiv2 = rbiv1 << Clone Box; // create a copy of the Bivariate graph

/* place the cloned box below the Bivariate graph
to create a second Bivariate graph */
rbiv1 << Append( rbiv2 );

framebox1 = rbiv1[Frame Box( 1 )]; /* assign a reference to the reports' frame boxes */
framebox2 = rbiv2[Frame Box( 1 )];

// assign the background color to framebox1
framebox1 << Background Color( "Blue" );
```
// copy the frame settings from framebox1
framebox1 << Copy Frame Settings;

// paste the frame settings to framebox2
framebox2 << Paste Frame Settings;

Figure 12.5 Copying and Pasting the Background

Copy and Paste Histograms
The following example shows how to create two histograms and copy the second histogram into the first histogram. A platform will not save a pasted-in segment, so you'll need to run a script like this to reproduce the graph.

dt = Open("$SAMPLE_DATA/Big Class.jmp");
dist = dt << Distribution(
   SendToByGroup( {:sex == "F"} ),
   Nominal Distribution( Column( :age ) ),
   Histograms Only,
   By( :sex ),
   ...
SendToByGroup(
{:sex == "M"},
SendToReport(
    Dispatch(
        
            
            // set the histogram color for males
            Fill Color( "Light Yellow" ),

    )
)
)
);

For( i = 2, i <= N Items( dist ), i++,
    Report( dist[i] )[FrameBox( 1 )] << Copy Frame Contents;

    // copy the the second histogram into the first histogram
    Report( dist[1] )[FrameBox( 1 )] << Paste Frame Contents;
);

New Window( "Distribution", Outline Box( "age", Report( dist[1] )[Picture Box( 1 )] ) );

Figure 12.6  Pasted Histogram
Interactively Copy and Paste Frame Contents and Settings

To interactively copy and paste the frame settings, follow these steps:
1. Right-click the graph and select Edit > Copy Frame Settings.
2. Right-click the frame to which you want to paste the settings and select Edit > Paste Frame Settings.

To interactively copy and paste the frame contents, follow these steps:
1. Right-click the graph and select Edit > Copy Frame Contents.
2. Right-click the frame to which you want to paste the contents and select Edit > Paste Frame Contents.

Create New Graphs from Scratch and Customize Them

Graphics scripts are set up inside the Graph Box() command within a New Window() command.

New Window("title", <arguments>, Graph Box( named arguments,..., script));

The following arguments are named arguments for Graph Box():

Frame Size( horizontal, vertical ), // size in pixels
X Scale( xmin, xmax ), Y Scale( ymin, ymax ), // range of x and y axes
X Name( "x" ), Y Name( "y" ), // names for x and y axes
Suppress Axes // omit the axes

For example, Graph Box() accepts named arguments as shown in the following example, which creates a graph with a red background.

```
win = New Window("Named arguments",
    Graph Box(
        Frame Size( 300, 300 ), // construct the graph box
        X Scale( 0, 190 ), // set the x-axis range
        Y Scale( 0, 190 ), // set the y-axis range
        X Name( "height" ),
        Y Name( "weight" ),
        <<Background Color( "Red" ) // set the background color
    );
```
Alternatively, you can use the send << operator to send commands to the Graph Box instead of using the named arguments. This example also creates a graph with a red background.

```julia
win = New Window( "Messages",
               Graph Box(
                  <<Frame Size( 300, 300 ),
                  <<XAxis( 0, 190 ),
                  <<YAxis( 0, 190 ),
                  <<Background Color( "Red" )
               )
          );
```

### Customize Graphs

You can also make changes to graphs in a script. For example, create a window with a graph, get a reference to the report, and then set the frame box size.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( :weight ), X( :height ), Fit Line );
rbiv = biv << Report;
rbiv[Frame Box( 1 )] << Frame Size( 400, 400 );
```
To see a list of possible messages for any given display box object, select Help > Scripting Index and select Display Boxes from the list. Running the Show Properties() command is an alternative to using the Scripting Index. For example, here is a partial list of messages that you can send to an axis:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( :weight ), X( :height ), Fit Line );
rbiv = biv << Report;
Show Properties( rbiv[Axis Box( 1 )] );
   Axis Settings [Action](Provides a way to bring up the axis dialog or set configurable axis options for a given axis.)
   Revert Axis [Action](Restore the settings that this axis had originally.)
   Add Axis Label [Action]
   Remove Axis Label [Action]
   ...
```

The following expressions change the font of both axis labels (weight and height in the example above) to 12-point, italic Arial Black:

```julia
rbiv[Text Edit Box( 1 )] << Set Font( "Arial Black", 12, Italic );
rbiv[Text Edit Box( 2 )] << Set Font( "Arial Black", 12, Italic );
```

or

```julia
rbiv[Text Edit Box( 1 )] << Set Font( "Arial Black" );
rbiv[Text Edit Box( 1 )] << Set Font Style( "Italic" );
rbiv[Text Edit Box( 1 )] << Set Font Size( 12 );
rbiv[Text Edit Box( 1 )] << Set Font( "Arial Black" );
rbiv[Text Edit Box( 2 )] << Set Font Style( "Italic" );
rbiv[Text Edit Box( 2 )] << Set Font Size( 12 );
rbiv[Text Edit Box( 2 )] << Set Font Name( "Arial Black" ) << Set Font Size( 12 ) << Set Font Style( Italic )
```

The default font specified in the Preferences is applied if the font is not installed on the computer.

### Create Shapes for a Bubble Plot

Bubble Plot supports predefined shapes and custom shapes. Shapes can give visual cues about the data or provide a more interesting shape than a circle. For example, you can show arrows (Figure 12.8) or a hurricane symbol on a map (Figure 12.9).

#### Specify a Predefined Shape

The Set Shape message specifies the predefined shape:

```julia
bp << Set Shape( "Circle"|"Triangle"|"Square"|"Diamond"|"Arrow" );
```
The following example creates the bubble plot and diamond shape shown in Figure 12.8:

```julia
dt = Open( "$SAMPLE_DATA/PopAgeGroup.jmp" );
bp = dt << Bubble Plot(
    X( :"Portion 0-19"n ),
    Y( :"Portion60+"n ),
    Sizes( :Pop ),
    ID( :Country )
);
bp << Set Shape( "Diamond" );
```

**Figure 12.8  Diamond Shapes**

Create a Custom Shape

You can create custom shapes only in JSL through a combination of two messages:

```julia
bp << Set Custom Path( pathMatrix | pathText );
bp << Set Shape( "Custom" );
```

- In Set Custom Path(), the path can consist of an Nx3 matrix or a string that contains SVG code. The default value is 0.
  ```julia
  bp << Set Custom Path(
    "M-1,-1 L-1,1 L0,0.5 L1,1 L1,-1 L0,-0.5 L-1,-1 Z, ..." );
  ```
- In Set Shape(), specify "Custom".
  ```julia
  bp << Set Shape( "Custom" );
  ```

The following script creates the map and custom hurricane shape shown in Figure 12.9.

```julia
dt = Open( "$SAMPLE_DATA/Hurricanes.jmp" );
```
dt << Bubble Plot(
  X( :Longitude ),
  Y( :Latitude ),
  Sizes( "Wind (Knots)" ),
  Time( :Date ),
  Coloring( :Landfall in USA ),
  ID( :Name and ID ),
  Speed( 220 ),
  Bubble Size( 51.43 ),
  Time Index( 729.9 ),
  Trail Bubbles( 1 ),
  All Labels( 0 ),
  No Labels( 0 ),
  /* rotate shapes in the direction of the movement
   good for animated plots */
  Orient Shapes( 1 ),

  Set Custom Path( // specify the SVG string
    "M-0.99999898,0.00921400000000006 C-0.99999898,-0.51266322
    -0.55204076,-0.93622284 -0.0001190600000000104,-0.93622284
    C0.1835362,-0.93622284 0.3556076,-0.88949112 0.5035232,-0.80766502
    C0.3236248,-1.36413554 0.02603980000000001,-1.815694896 -0.3555946,0.829164
    C0.4067376,-1.7567781 0.9372286,-0.91116206 1.0000004,0.0082972000000009
    C1.0000000,0.5301742 0.5518026,0.9548002 -0.00011905999999982,0.9547998
    C-0.18139054,0.9547998 -0.35150496,0.9090838 -0.49816916,0.8292164
    C-0.81759686,1.3771358 -0.0174124399999999,1.8176124 0.3602494,1.999999
    C-0.38991788,1.7606584 -0.92375834,0.908779 -0.99999898,0.0092140000000034
    z"
  ),

  Set Shape( "Custom" ), // set the custom shape
  Title Position( -88.679, 59.73 ),

  SendToReport(
    Dispatch(
      {},
      "Bubble Plot",
      FrameBox,
      {Frame Size( 743, 603 ), Background Map( Images( "Simple Earth" ) ),
       Grid Line Order( 3 ), Reference Line Order( 2 )}
    )
  )
);
Figure 12.9 Custom Hurricane Shape

How to Find Shapes

Search Wikimedia Commons or Google Images and include the keyword SVG. Look for SVG examples that are composed of stroke paths. SVG can be used to represent very complex drawings, with gradients and other elements. Only a path representation, which provides both outline and fill modes, is supported.

You might need to translate and scale the SVG that you find in order to get correct coordinates. Inkscape or similar tools can be useful for doing this manipulation. To copy the path from Inkscape, select Edit > XML Editor, find the svg:path element, and copy the path string from the d Attribute into Set Custom Path().
Add Lines, Arrows, Points, Shapes, and Text

- “Draw Lines”
- “Draw Arrows”
- “Draw Markers”
- “Draw Pies and Arcs”
- “Draw Regular Shapes: Circles, Rectangles, and Ovals”
- “Draw Irregular Shapes: Polygons and Contours”
- “Add Text”
- “Specify Colors”
- “Specify Transparency”
- “Add Fill Patterns”
- “Specify Line Types”
- “Draw with Pixels”

Draw Lines

Line() draws lines between points.

```
win = New Window( "Five-Point Star",
    Graph Box(  
        Frame Size( 300, 300 ),
        X Scale( -1.1, 1.1 ),
        Y Scale( -1.1, 1.1 ),
        Line(  
            {Cos( 1 * Pi() / 10 ), Sin( 1 * Pi() / 10 )},
            {Cos( 9 * Pi() / 10 ), Sin( 9 * Pi() / 10 )},
            {Cos( 17 * Pi() / 10 ), Sin( 17 * Pi() / 10 )},
            {Cos( 5 * Pi() / 10 ), Sin( 5 * Pi() / 10 )},
            {Cos( 13 * Pi() / 10 ), Sin( 13 * Pi() / 10 )},
            {Cos( 1 * Pi() / 10 ), Sin( 1 * Pi() / 10 )}
        )
    )
);
```
You can either specify the points in two-item lists as demonstrated above or as matrices of \( x \) and then \( y \) coordinates. Matrices are flattened by rows. You can use either row or column vectors, as long as you have the same number of elements in each matrix. The following expressions have the same effect:

\[
\text{Line( \{1,2\}, \{3,0\}, \{2,4\} );} \quad \text{// several \{x,y\} lists}
\]
\[
\text{Line( [1 3 2],[2 0 4] );} \quad \text{// row vectors}
\]
\[
\text{Line( [1,3,2], [2,0,4] );} \quad \text{// column vectors}
\]
\[
\text{Line( [1 3 2], [2,0,4] );} \quad \text{// one of each}
\]

The star example could also be drawn this way. Note that the script must include the full \text{Matrix( \{\ldots\} )} notation rather than [ ] shorthand because the entries are expressions. The following example uses the \text{Matrix()} function.

```plaintext
win = New Window( "Five-Point Star",
    Graph Box(
        Frame Size( 300, 300 ),
        X Scale( -1.1, 1.1 ),
        Y Scale( -1.1, 1.1 ),
        Line(
            Matrix(
                // the x coordinates
                Cos( 1 * Pi() / 10 ), Cos( 9 * Pi() / 10 ), Cos( 17 * Pi() / 10 ),
                Cos( 5 * Pi() / 10 ), Cos( 13 * Pi() / 10 ), Cos( 1 * Pi() / 10 )
            ),
            Matrix(
                // the y coordinates
                Sin( 1 * Pi() / 10 ), Sin( 9 * Pi() / 10 ), Sin( 17 * Pi() / 10 ),
                Sin( 5 * Pi() / 10 ), Sin( 13 * Pi() / 10 ), Sin( 1 * Pi() / 10 )
            )
        )
    )
);```
HLine() draws a horizontal line across the graph at the \(y\)-value that you specify. Similarly, VLine() draws a vertical line down the graph at the \(x\)-value that you specify. Both functions support drawing multiple lines by using a matrix of values in the \(y\) argument. See “Mousetrap()” on page 674.

**Draw Arrows**

Arrow() draws an arrow from the first point to the second point. The default arrowhead is scaled to 1 plus the square root of the length of the arrow. To set the length of the arrowhead, add an optional first argument, specifying the length of the arrowhead in pixels. The following example draws simple arrows.

```
win = New Window( "Arrowheads",
    Graph Box(
        Pen Size( 4 );
        /* matrix 1 defines the \(x\) coordinates of an arrow
        matrix 2 defines the \(y\) coordinates of an arrow */
        Arrow( 20, [10 30 90], [88 22 44] );
    ));
```

The following example draws arrows in a circular pattern.

```
win = New Window( "Hurricane",
    Graph Box(
        Frame Size( 100, 100 ),
        X Scale( -100, 100 ),
        Y Scale( -100, 100 ),
        For( r = 35, r < 100, r += 20,
            ainc = 2 * Pi() * 3 / r;
            For( a = 0, a < 2 * Pi(), a += ainc,
                x = r * Cosine( a );
                y = r * Sine( a );
                aa = a + ainc * 45 / r;
                rr = r - r / 6;
                x2 = rr * Cosine( aa );
                y2 = rr * Sine( aa );
                /* list 1 defines the start point for the arrow
                list 2 defines the end point for the arrow */
                Arrow( {x, y}, {x2, y2} );
            );
        );
    ));
```

**Figure 12.11** Drawing Arrows

![Diagram showing arrows drawn with and without specified length](image)

The following example compares drawing with a specified length (19 pixels) and drawing with the default arrow head size.

```plaintext
win = New Window( "Arrowheads",
    Graph Box(
        Frame Size( 300, 300 ),
        X Scale( 0, 100 ),
        Y Scale( 0, 220 ),
        x = 10;
        y1 = 10;
        y2 = y1 + 10;
        For( i = 1, i < 10, i++,
            Pen Color( "Red" );
            Arrow( {x, y1}, {x, y2} );
            y2 += 10;
            y1 += 100;
            y2 += 100;
            Pen Color( "Blue" );
            Arrow( 20, {x, y1}, {x, y2} );
        )
    )
);  
Text Color( "Red" );
Text( {10, 80}, "Without Length Arg" );

Text Color( "Blue" );
Text( {10, 200}, "With Length Arg" );
```

```
Figure 12.12 Arrowhead Sizes

As with Line(), you can either specify the points in two-item lists as demonstrated above or as matrices of x and then y coordinates.

**Draw Markers**

Marker() draws a marker of the type that you specify (1–20) in the first argument at the point that you specify in the second argument. Marker Size() scales markers from 0 to 6 (dot to XXXL). To set markers to the size that is specified in the Preferences, use a value of -1.

```plaintext
ymax = 20;
win = New Window( "Markers",
  Graph Box(
    Frame Size( 300, 400 ),
    X Scale( -2, ymax - 5 ),
    Y Scale( -2, ymax + 3 ),
    For( j = 1, j < 7, j++,
      Marker Size( j );
      For( i = 0, i < (ymax + 1), i++,
        Marker( i, {j * 2, i} );
        Text( {0, i}, i );
        Text( {j * 2, ymax + 2}, j );
      );
    )
  );
);```
You can also include a row state argument before, after, or instead of the marker ID argument. By using Combine States(), you can set multiple row states inside Marker(). Try substituting each of the following lines in the preceding script:

```
Marker( i, Color State( i ), {j * 2, i} );
Marker( Color State( i ), i, {j * 2, i} );
Marker(
    Combine States( Color State( i ), Marker State( i ), Hidden State( i ) ),
    {j * 2, i}
);
```

As with Line() and Arrow(), you can also specify points as matrices of \( x \) and \( y \) coordinates.

### Draw Pies and Arcs

Pie() and Arc() draw wedges and arc segments. The first four arguments are \( x1, y1, x2, \) and \( y2 \), the coordinates of the rectangle to inscribe. The last two arguments are the starting and ending angle in degrees, where 0 degrees is 12 o'clock and the arc or slice is drawn clockwise from start to finish.

```
win = New Window( "Pies and Arcs",
    Graph Box(
        Frame Size( 400, 400 ),
        X Scale( 0, 9 ),
        Y Scale( 0, 9 ),
```

---

**Figure 12.13** Drawing Markers

![Figure 12.13](image_url)
Fill Color( "Black" ), // top left
Pie( 1.1, 7.9, 3.9, 5.1, 45, 270 ),
Text( Erased, {1.75, 6}, "1,8,4,5,45,270" ),
Arc( 1, 8, 4, 5, 280, 35 ),
Fill Color( "Red" ), // top right
Pie( 7.9, 7.9, 5.1, 5.1, 270, 360 ),
Text( Erased, {5.75, 6}, "8,8,5,5,270,360" ),
Arc( 8, 8, 5, 5, 370, 260 ),
Fill Color( "BlueCyan" ), // bottom left
Pie( 1.1, 1.1, 3.9, 3.9, 50, 360 ),
Text( Erased, {1.75, 2}, "1,1,4,4,50,360" ),
Arc( 1, 1, 4, 4, 370, 40 ),
Fill Color( "Purple" ), // bottom right
Pie( 7.9, 1.1, 5.1, 3.9, 270, 45 ),
Text( Erased, {5.75, 2}, "8,1,5,4,270,45" ),
Arc( 8, 1, 5, 4, 55, 260 )
);

Figure 12.14  Drawing Pies and Arcs
Draw Regular Shapes: Circles, Rectangles, and Ovals

Circles

Circle() draws a circle with the center point and radius given. Subsequent arguments specify additional radii.

```plaintext
win = New Window( "Circles",
    Graph Box( Frame Size( 200, 200 ),
        Circle( {50, 50}, 10, 12, 25 )
    )
);
```

Circle() also has a final optional argument, "fill". This string indicates that all circles defined in the function are filled with the current fill color. If "fill" is omitted, the circle is empty.

**Figure 12.15** Drawing Circles

Note that a circle is always a circle, even if you resize the graph to a different aspect ratio. If you want your circle to change aspect ratios (in other words, cease being a circle) when the graph is resized, use an oval instead.

If you do not want your circle to resize if the graph is resized, specify the radius in pixels instead:

```plaintext
win = New Window( "Circles",
    Graph Box(
        Frame Size( 200, 200 ),
        Circle( {50, 50}, Pixel Radius( 10 ), Pixel Radius( 12 ), Pixel Radius( 25 )
        )
    )
);
```
Rectangles

Rect() draws a rectangle from the diagonal coordinates you specify. The coordinates can be specified either as four arguments in order (left, top, right, bottom), or as a pair of lists ([left, top], [right, bottom]).

```
win = New Window( "Rectangles", 
    Graph Box( 
        Frame Size( 200, 200 ), 
        Pen Color( 1 ); 
        Rect( 0, 40, 60, 0 ); 
        Pen Color( 3 ); 
        Rect( 10, 60, 70, 10 ); 
        Pen Color( 4 ); 
        Rect( 50, 90, 90, 50 ); 
        Pen Color( 5 ); 
        Rect( 0, 80, 70, 70 );
    )
);
```

Rect() has an optional fifth argument, fill. Specify 0 to get an unfilled rectangle and 1 to get a filled rectangle. The default value for fill is 0. The rectangle is filled with the current fill color.

Any negative fill argument produces an unfilled frame inset by one pixel:

```
win = New Window( "Framed Rectangle", 
    Graph Box( Frame Size( 200, 200 ), Rect( 0, 40, 60, 0, -1 ) )
);
```

Ovals

Oval() draws an oval inside the rectangle given by its x1, y1, x2, and y2 arguments:

```
win = New Window( "Ovals", 
    Graph Box( 
        Frame Size( 200, 200 ), 
        Pen Color( 1 ); 
        Oval( 0, 40, 60, 0 ); 
        Pen Color( 3 ); 
        Oval( 10, 60, 70, 10 ); 
        Pen Color( 4 ); 
        Oval( 50, 90, 90, 50 ); 
        Pen Color( 5 ); 
        Oval( 0, 80, 70, 70 );
    )
);
```
Oval() also has an optional fifth argument, fill. Specify 0 to get an unfilled rectangle and 1 to get a filled oval. The default value for fill is 0. The oval is filled with the current fill color.

Figure 12.16 shows rectangles and ovals, drawn both filled and unfilled. Notice that filled rectangles do not have outlines. Ovals do have outlines. If you want a filled rectangle with an outline, you must draw the filled rectangle and then draw an unfilled rectangle with the same coordinates.

**Figure 12.16** Rectangles and Ovals, Unfilled and Filled

---

**Draw Irregular Shapes: Polygons and Contours**

**Polygons**

Polygon() works similarly to Line(). They both connect points, but Polygon() returns to the first point to close the polygon and filling the resulting area. You can specify the points as individual points in two-item lists (as shown in “Draw Markers” on page 650) or as matrices of x and then y coordinates. Matrices are flattened by rows, so you can use either row or column vectors, as long as you have the same number of elements in each matrix. First set up the matrices of points and then call them inside Polygon().

```
gCoordX = [25, 23.75, 22.5, 21.25, 21.25, 22.5, 23.75, 25.625, 27.5, 18.75, 12.5, 6.25, 2.5, ...
```
1.25, -1.25, 3.125, 6.25, 12.5, 18.75, 25, 29.375, 34.375, 37.5, 38.75, 40.625, 42.5, 43.125, 42.5, 41.25, 38.75, 43.75, 50, 56.25, 60.625, 63.75, 65.625, 62.5, 56.25, 50, 45, 37.5, 32.5, 28.75, 27.5, 26.25, 25.625, 25];
gCoordY = [-2, 2, 5, 10, 15, 20, 25, 30, 33, 34, 35, 37.5, 40, 41, 43.5, 41, 40, 39, 40, 42, 45, 50, 55, 60, 64, 60, 55, 50, 47, 42, 43.5, 43, 42, 40, 38, 36, 37, 37, 36, 35, 30, 25, 20, 15, 10, 5, 2];
win = New Window( "The JMP Man", Graph Box( Frame Size( 300, 300 ), X Scale( -10, 80 ), Y Scale( -10, 80 ), Pen Color( "Black" ); Fill Color( "Blue" ); Polygon( gCoordX, gCoordY ); Fill Color( "Black" ); Circle( {18, 58}, 9, "FILL" ); ) );

Figure 12.17 Drawing a Polygon

A related command, In Polygon(), tells whether a given point falls inside the specified polygon. This code checks some points from the JMP man pictured in Figure 12.17:

In Polygon( 0,60, GcoordX,GCoordY );  // return 0
In Polygon( 30,38, GcoordX,GCoordY );  // return 1
You can add In Polygon() to the JMP man script. Run the following script, and then click various locations in the picture and watch the log window. "In" and "out" are printed to the log when you click the body.

\[
gCoordX = [25, 23.75, 22.5, 21.25, 21.25, 22.5, 23.75, 25.625, 27.5, 18.75, 12.5, 6.25, 2.5, 1.25, -1.25, 3.125, 6.25, 12.5, 18.75, 25, 29.375, 34.375, 37.5, 38.75, 40.625, 42.5, 43.125, 42.5, 41.25, 38.75, 43.75, 50, 56.25, 60.625, 63.75, 65.625, 62.5, 56.25, 50, 45, 37.5, 32.5, 28.75, 27.5, 26.25, 25.625, 25];
\]

\[
gCoordY = [-2, 2, 5, 10, 15, 20, 25, 30, 33, 34, 35, 37.5, 40, 41, 43.5, 41, 40, 39, 40, 42, 45, 50, 55, 60, 64, 60, 55, 50, 47, 42, 43.5, 43, 42, 40, 38, 36, 37, 36, 35, 30, 25, 20, 15, 10, 5, 2];
\]

\[
win = New Window( "The JMP Man",
    Graph Box(
        Frame Size( 300, 300 ),
        X Scale( -10, 80 ),
        Y Scale( -10, 80 ),
        Pen Color( "Black" );
        Fill Color( "Black" );
        Polygon( gCoordX, gCoordY );
        Mousetrap(
            {},
            Print( If( In Polygon( x, y, gCoordX, gCoordY ), "in", "out" ) )
        )
    );
\]

\section*{Contours}

Contour() draws contour lines using a grid of coordinates.

\[
\text{Contour( xVector, yVector, zGridMatrix, zContour, <zColors> );}
\]

Suppose that you have an \( n \) by \( m \) matrix \( zGridMatrix \) of values on some surface (defined across the \( n \) values of \( xVector \) by the \( m \) values of \( yVector \)). \( \text{Contour()} \) draws the contour lines that are defined by the values in \( zContour \) in the colors defined by \( zColors \). Here is an example:

\[
x = (-10 :: 10) / 5;
y = (-12 :: 12) / 5;
grid = J( 21, 25, 0 );
z = [ -.75, -.5, -.25, 0, .25, .5, .75 ];
zcolor = [ 3, 4, 5, 6, 7, 8, 9 ];
For( i = 1, i <= 21, i++,
    For( j = 1, j <= 25, j++,
        grid[i, j] = Sin( (x[i]) ^ 2 + (y[j]) ^ 2 )
    )
);
Add Text

You can use `Text()` to draw text at a given location.

```lisp
Text( <properties>, ( {x, y}|{left, bottom, right, top} ), "text" );
```

The point and text can be in any order and repeated. You can precede the point and text with an optional first argument: Center Justified, Right Justified, Erased, Boxed, Counterclockwise, or Clockwise. Erased is for removing whatever would otherwise obscure the text in a graph. It paints a background-colored rectangle behind the text.

In the following example, notice how the erased text appears inside a white box over the green `Rect()`.

```lisp
mytext = New Window( "Adding Text",
    Graph Box(
        Frame Size( 200, 200 ),
        Y Scale( 0, 15 ),
        X Scale( 0, 10 ),
        Text Size( 9 );
        Text Color( "blue" );
        Text( {5, 1}, "Left Justified" );
        Text( Center Justified, {5, 2}, "Center Justified" );
        Text( Right Justified, {5, 3}, "Right Justified" );
    )
);
```

```plaintext
Fill Color( 4 );
Rect( 5, 8, 9, 5, 1 );
Text( Erased, {6, 6}, "Erased" );
Text( Boxed, {6, 10}, "Boxed" );
Text( Clockwise, {4, 10}, "Clockwise" );
Text( Counterclockwise, {3, 5}, "Counterclockwise" );
```

**Figure 12.19** Drawing Text in a Graph Box

There is a variant of the `Text()` function that draws a string inside the rectangle that is specified by four coordinates. Here is the syntax:

```
Text( {left, top, right, bottom}, string);
```

**Specify Colors**

The following commands control colors:

- **Fill Color()** for solid areas
- **Level Color()** for categorical data
- **Pen Color()** for lines and points
- **Back Color()** for the background of text (similar to the box around the erased text in Figure 12.19)
- **Background Color()** for the graph’s background color
- **Font Color()** for added text

Fill colors overwrite pen colors for drawn shapes. You do not get both, as in some drawing packages. To get both a fill and a pen line, draw two shapes, one with fill and one without. You can select a color with a single numeric argument, a color name in quotation marks, or an RGB value. The standard colors are specified with numbers 0–15 (both 0 and 15 are black) or by their names (Table 12.1).
Tip: For more shades, add the word Dark, Medium Dark, Medium Light, or Light before a color name in quotation marks.

Table 12.1 Standard JMP Colors

<table>
<thead>
<tr>
<th>Number</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Black</td>
</tr>
<tr>
<td>1</td>
<td>Gray</td>
</tr>
<tr>
<td>2</td>
<td>White</td>
</tr>
<tr>
<td>3</td>
<td>Red</td>
</tr>
<tr>
<td>4</td>
<td>Green</td>
</tr>
<tr>
<td>5</td>
<td>Blue</td>
</tr>
<tr>
<td>6</td>
<td>Orange</td>
</tr>
<tr>
<td>7</td>
<td>BlueGreen</td>
</tr>
<tr>
<td>8</td>
<td>Purple</td>
</tr>
<tr>
<td>9</td>
<td>Yellow</td>
</tr>
<tr>
<td>10</td>
<td>Cyan</td>
</tr>
<tr>
<td>11</td>
<td>Magenta</td>
</tr>
<tr>
<td>12</td>
<td>YellowGreen</td>
</tr>
<tr>
<td>13</td>
<td>BlueCyan</td>
</tr>
<tr>
<td>14</td>
<td>Fuchsia</td>
</tr>
</tbody>
</table>

The following script creates a graph that shows all JMP colors:

```
Text Color( 0 );
New Window( "Colors",
            Graph Box( FrameSize( 640, 400 ),
                         Y Scale( -1, 17 ),
                         X Scale( -3, 12 ),
                         k = 0;
                         For( jj = 1, jj <= 12, jj += 2,
                              l = 15;
```

For( i = 0, i <= 15 & k < 85, i++,
    thiscolor = Color To RGB( k );
    Fill Color( k );
    thisfill = 1;
    If( thiscolor == {1, 1, 1},
        Pen Color( 0 );
        thisfill = 0;
        ,
        Pen Color( k )
    );
    Rect( jj, l + .5, jj + .5, l, thisfill );
    Text( {jj - 1, l}, "color ", k );
    k++;
    l--;);
jj = -2;
    "Purple", "Yellow", "Cyan", "Magenta", "YellowGreen", "BlueCyan",
    "Fuschia", "Black"};
For( i = 0;
    l = 15;, i <= 15 & l >= 0,
    i++;
    l--;
    Text( {jj, l}, color[i + 1] )
);)

Larger numbers cycle through shading variations of the same color sequence. A script demonstrating this appears under “Colors and Markers” on page 451 in the “Data Tables” chapter. Values outside the range 0–84 are not accepted.

### Table 12.2 How Numbers Map to Colors

<table>
<thead>
<tr>
<th>Number</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>16–31</td>
<td>Medium Dark</td>
</tr>
<tr>
<td>32–47</td>
<td>Medium Light</td>
</tr>
<tr>
<td>48–63</td>
<td>Dark</td>
</tr>
<tr>
<td>64–79</td>
<td>Light</td>
</tr>
</tbody>
</table>
If you prefer to use RGB values, create a list with the fraction for each color in red, green, and blue order.

    Pen Color( {.38,.84,.67} ); // teal

RGB Color() and Color to RGB() convert color values between JMP color numbers and the red-green-blue system. The following example finds the RGB values for JMP color 3 (red):

    Color to RGB( 3 );
    {0.941176470588235, 0.196078431372549, 0.274509803921569}

Likewise, HLS Color() and Color to HLS() convert color values between JMP color numbers and the hue-lightness-saturation system.

    win = New Window( "Color Wheel",
        Graph(
            Frame Size( 200, 200 ),
            For( hue = 0, hue < 360, hue += 30,
                y = 50 - 40 * Cos( hue * 2 * Pi() / 360 );
                x = 50 + 40 * Sin( hue * 2 * Pi() / 360 );
                Fill Color( HLS Color( hue / 360, 0.5, 1 ) );
                Oval( x - 10, y - 10, x + 10, y + 10, 1 );
            )
        )
    );

Finally, Heat Color() returns the JMP color that corresponds to a value in any color theme that is supported by Cell Plot, Treemap, and so on. The syntax is:

    Heat Color( n, <<"theme" )

The theme message is optional, and the default value is "Blue to Gray to Red". You can specify any color theme, including custom color themes. You can also create and use an anonymous color theme as shown in the following examples:

    Heat Color( z, <<"", {{1, 1, 0}, {0, 0, 1}} );
    Heat Color( z, <<"", {blue, green, yellow} );
Specify Transparency

In a graphics environment (like a Frame Box), use the Transparency function to set the level of transparency. The argument, alpha, can be any number between zero and one. The value 0 means clear and drawing has no effect. The value 1 means completely opaque and is the usual drawing mode. Intermediate values build semi-transparent color layers on top of what has already been drawn below it. The following example script illustrates transparency with rectangles.

```
win = New Window( "Transparency",
    Graph Box(
        Frame Size( 200, 200 ),
        Pen Color( "gray" );
        Fill Color( "gray" );
        Transparency( 0.25 );
        Rect( 0, 40, 60, 0, 1 );

        Pen Color( "red" );
        Fill Color( "red" );
        Transparency( 0.5 );
        Rect( 10, 60, 70, 10, 1 );

        Pen Color( "green" );
        Fill Color( "green" );
        Transparency( 0.75 );
        Rect( 50, 90, 90, 50, 1 );

        Pen Color( "blue" );
        Fill Color( "blue" );
        Transparency( 1 );
        Rect( 0, 80, 70, 70, 1 );
    )
);
```

Figure 12.20  Transparency and Rectangles
Add Fill Patterns

Fill Pattern() sets the pattern for filled areas.

Matrix Example

Specify a mask (a matrix of values between 0 and 1) or an image. Each value in the matrix creates a pixel.

    win = New Window( "Example",
        Graph Box(          
            Fill Pattern( [1 0.5 0 0, 0.5 0 0 1, 0 0 1 0.5, 0 1 0.5 0] );
            Polygon( [10 30 90], [88 22 44] );
        )          
    );

Named Pattern Example

Specify a name in quotation marks that corresponds to a pattern shown in Table 12.3.

    win = New Window( "Named Pattern Example",
        Graph Box(          
            Fill Pattern( "vertical light" );
            Polygon( [10 30 90], [88 22 44] );
        )          
    );

Graphic Example

Specify an image in quotation marks. If the image is not installed on the viewer's computer, question marks appear in the shape.

    win = New Window( "Graphic Example",
        Graph Box(          
            Fill Pattern( Open( "$SAMPLE_IMAGES/pi.gif", "gif" ) );
            Polygon( [10 30 90], [88 22 44] );
        )          
    );

</tbody>
</table>
Specify Line Types

You can also control Line Style() by number (0–4) or name (Solid, Dotted, Dashed, DashDot, DashDotDot). Figure 12.21 shows the numerical values for each line type.

```
linestyles = {'Solid', 'Dotted', 'Dashed', 'DashDot', 'DashDotDot'};
win = New Window( "Line Styles",
    Graph Box(
        Frame Size( 200, 200 ),
        X Scale( -1, 5 ),
        Y Scale( -1, 5 ),
        For( i = 0, i < 5, i++,
            Line Style( i );
            H Line( i );
            Text( {0, i + .1}, i );
            Text( {1, i + .1}, linestyles[i + 1] );
        )
    )
);
```

</tbody>
</table>
To control the thickness of lines, set a Pen Size and specify the line width in pixels. The default is 1 for single-pixel lines. For printing, think of Pen Size as a multiplier for the default line width, which varies according to your printing device.

```
win = New Window( "Pen Size",
    Graph Box(
        Pen Size( 2 ); // double-width lines
        Line( [10 30 90], [88 22 44] );
    )
);
```

### Draw with Pixels

You can also draw using pixel coordinates. First, set the Pixel Origin() in terms of graph coordinates, and then use Pixel Move To() or Pixel Line To() in pixel coordinates relative to that origin. The main use for Pixel() functions is for drawing custom markers that do not vary with the size or scale of the graph. You can store a marker in a script and then call it within any graph. This example uses Function() to store pixel commands in a script with its own arguments, x and y.

```
balletBox = Function( {x, y},
    Pixel Origin( x, y );
    Pixel Move To( -5, -5 );
    Pixel Line To( -5, 5 );
    Pixel Line To( 5, -5 );
    Pixel Line To( -5, 5 );
    Pixel Line To( 5, 5 );
    Pixel Move To( -5, 5 );
    Pixel Move To( 5, 5 );
    Pixel Line To( 5, -5 );
);
win = New Window( "Custom Markers",
    Graph Box(}
Interactive Graphs

Handle() and Mousetrap() are functions for making interactive graphs that respond to clicking and dragging. Handle() lets you parametrize a graph by adding a handle-marker that can be dragged around with the mouse, executing the graph’s script at each new location. Mousetrap() is similar, but it takes its arguments from the coordinates of a click without dragging a handle. The main difference is that Handle() only catches mousedowns at the handle-marker’s location, but Mousetrap() catches mousedowns at any location.

Another approach is to place buttons or slider controls outside the graph with Button Box(), Slider Box(), or Global Box().

Handle()

Handle() places a marker at the coordinates given by the initial values of the first two arguments and draws the graph using the initial values of the arguments. You can then click and drag the marker to move the handle to a new location. The first script is executed at each mousedown to update the graph dynamically, according to the new coordinates of the handle. The second script (optional, and not used here) is executed at each mouseup, similarly; see the example for “Mousetrap()” on page 674.
// Normal Density
mu = 0;
sigma = 1;
rsqrt2pi = 1 / Sqrt( 2 * Pi() );
win = New Window( "Normal Density",
    Graph Box(
        Frame Size( 500, 300 ),
        X Scale( -3, 3 ),
        Y Scale( 0, 1 ),
        Y Function( Normal Density( (x - mu) / sigma ) / sigma, x );
        Handle(
            mu,
            rsqrt2pi / sigma,
            mu = x;
            sigma = rsqrt2pi / y;
        );
        Text( {1, .7}, "mu ", mu, {1, .65}, "sigma ", sigma );
    )
);

Run demoPlotProb.jsl in the JMP Samples/Scripts folder to see Beta Density, Gamma Density, Weibull Density, and LogNormal Density graphs. The output for Normal Density is shown in Figure 12.23. Because we cannot show you the picture in motion, be sure to run this script yourself.

Figure 12.23 Normal Density Example for Handle()
If you want to use some function of a handle’s coordinates, such as in the normal density example, you should adjust the arguments for `Handle()`. Otherwise, the handle marker would run away from the mouse.

\[
Y \text{ Function}( a \times x^b );
\]
\[
\text{Handle}( a, b, a = 2 \times x, b = y );
\]

Suppose you drag the marker from its initial location to (3,4). The argument \(a\) is set to 6 and \(b\) to 4; the graph is redrawn as \(Y = 6x^4\); and the handle is now drawn at (6,4), several units away from the mouse. To compensate, you would adjust the first argument to handle, for example.

\[
\text{Handle}( a / 2, b, a = 2 \times x; b = y );
\]

To generalize, suppose you define the `Handle()` arguments as functions of the handle’s \((x, y)\) coordinates. For example, \(a=f(x)\) and \(b=g(y)\). If \(f(x)=x\) and \(g(y)=y\), then you would specify simply \(a, b\) as the first two arguments. If not, you would solve \(a = f(x)\) for \(x\) and solve \(b = g(y)\) for \(y\) to get the appropriate arguments.

You can use other functions to constrain `Handle()`. For example, here is an interactive graph to demonstrate power functions that uses `Round()` to prevent bad exponents and to keep the intercepts simple.

```r
a = 3;
b = 2;
win = New Window( "Intercepts and Powers",
    Graph Box(
        Frame Size( 200, 200 ),
        X Scale( -10, 10 ),
        Y Scale( -10, 10 ),
        Y Function( Round(b) + x ^ (Round(a)), x );
        Handle(
            a,
b,
            a = x;
b = y;
        );
        Text( {a, b}, "Move me" );
        Text( {-9, 9}, "y=", Round(b), " + x^", Round(a) );
    )
);
```
Figure 12.24  Intercepts and Powers for Handle()

Handle() and For() can be nested for complex graphs.

```plaintext
a = 5;
b = 5;
win = New Window( "Powers",
    Graph Box(
        Frame Size( 200, 200 ),
        X Scale( -10, 10 ),
        Y Scale( -10, 10 ),
        For( i = 0, i < 1.5, i += .2,
            Pen Color( 1 + 10 * i );
            Text Color( 1 + 10 * i );
            Y Function( i * x ^ Round( a ), x );
            Handle(
                a,
                b,
                a = x;
                b = y;
           );
            h = 9 - 10 * i;
            Text( {-9, h}, b, "*i*x^", Round( a ), ", i=", i );
        ));
    ));
```

Figure 12.25  Nested Handle() and For()
You can use more than one handle in a graph:

```javascript
amplitude = 1;
freq = 1;
phase = 0;
win = New Window( "Sine Wave",
Graph Box(
    Frame Size( 500, 300 ),
    X Scale( -5, 5 ),
    Y Scale( -5, 5 ),
    Y Function( amplitude * Sine( x / freq + phase ), x );
    Handle( // first handle
        freq,
        amplitude,
        freq = x;
        amplitude = y;
    );
    Handle( phase, .5, phase = x ); // second handle
    Text(
        {3, 4},
        "amplitude: ",
        Round( amplitude, 4 ),
        {3, 3.5},
        "frequency: ",
        Round( freq, 4 ),
        {3, 3},
        "phase: ",
        Round( phase, 4 )
    );
))
```
Mousetrap()

Mousetrap() takes arguments for a graph from the coordinates of a mouse click. The first script is executed after each mousedown and the second script after each mouseup to update the graph dynamically, according to the new coordinates of the handle. As with Handle, it is important to set the initial values for the Mousetrap’s coordinates. If you include both Mousetrap() and Handle() in a graph, put the Handle() before the Mousetrap(). Then Handle() has a chance to catch clicks before a Mousetrap() does.

This example uses both Mousetrap() and Handle() to draw a three-dimensional function centered on the Mousetrap() coordinates, where the single contour line takes its value from a Handle().

```plaintext
x0 = 0;
y0 = 0;
z0 = 0;
win = New Window( "Viewing a 3-D Function in Flatland",
  Graph Box(
    Frame Size( 300, 300 ),
    X Scale( -5, 5 ),
    Y Scale( -5, 5 ),
    Contour Function(
      Exp( -(x - x0) ^ 2 ) * Exp( -(y - y0) ^ 2 ) * (x - x0),
      x,
      y,
      z0 / 10
    ));
```

Figure 12.26 Two Handles

![Graph of a three-dimensional function centered on the Mousetrap() coordinates, with a single contour line taking its value from a Handle().](image)
// get the z-cut values from a handle
Handle( -4.5, z0, z0 = Round( y * 10 ) / 10 );
  V Line( -4.5 );
Text Size( 9 );
Text(
    Counterclockwise,
    {-4.6, -4},
    "Drag to set the z-value for contour cut: z = " || Char( z0 / 10 )
);
Marker Size( 2 );
Marker( 2, {x0, y0} );
Mousetrap( // set the origin to the click-point
    x0 = x;
    y0 = y;
);
Text(
    {-4.25, -4.9},
    "Click any location to set the function's centerpoint."
);
);

Note: Instead of setting x0 to x and y0 to y in the Mousetrap() expression, you might want to use Function( {xx, yy}, Show( xx, yy ); x0 = xx; y0 = yy );. xx and yy are formal parameters to the function. They come from arguments that the mousetrap passed when the user clicked on the graph. The Function( {xx, yy}...) alternative makes the xx and yy names explicit, and makes it clear the you can name them anything, not just x, y.

Figure 12.27  Mousetrap() and Handle()
You might use `Mousetrap()` to collect points in a data table, such as for visually interpolating points in a graph. The following example illustrates a script that could be adapted and added to a data plot (such as a scatterplot from Fit Y by X) for that purpose. After you run the script and click in the graph, the point at which you click is recorded in the data table.

```plaintext
dt = New Table( "dat1" );
New Column( "xx", Numeric );
New Column( "yy", Numeric );
x = 0;
y = 0;
Add Point = Expr(
    dt << Add Rows( 1 );
    Row() = N Row();
    :xx = x;
    :yy = y;
);
win = New Window( "Add Points",
    Graph Box(
        Frame Size( 500, 300 ),
        X Scale( -5, 5 ),
        Y Scale( -5, 5 ),
        For Each Row( Marker( {xx, yy} ) );
        Mousetrap( {}, Add Point );
    )
);
```

Notice that the first script argument is empty. At mousedown, nothing happens. The second script, add point, is executed at mouseup to add a data point. If you click, drag, and release, then the point that is added to your data set is the point where you let go of the mouse button; it is not the point where you pressed down the mouse button.

**Drag Functions**

There are five `Drag()` functions to perform similar functions to `Handle()` and `Mousetrap()` but with more than one point at a time. For \( n \) coordinates in matrices listed as the first two arguments:

- **Drag Marker()** draws \( n \) markers.
- **Drag Line()** draws a connected line with \( n \) vertices and \( n - 1 \) segments.
- **Drag Rect()** draw a filled rectangle using the first two coordinates, ignoring any further coordinates.
- **Drag Polygon()** draws a filled polygon with \( n \) vertices.
• **Drag Text()** draws a text item at the coordinates. Or if there is a list of text items, it draws the \(i\)th list item at the \(i\)th \((x,y)\) coordinate. If there are fewer list items than coordinate pairs, the last item is repeated for remaining points.

The syntax for these commands:

```plaintext
Drag Marker( xMatrix, yMatrix, dragScript, mouseupScript );
Drag Line( xMatrix, yMatrix, dragScript, mouseupScript );
Drag Rect( xMatrix, yMatrix, dragScript, mouseupScript );
Drag Polygon( xMatrix, yMatrix, dragScript, mouseupScript );
Drag Text( xMatrix, yMatrix, "text", dragScript, mouseupScript );
```

They all must have L-value arguments for the coordinates. The coordinates are literal matrices or names of matrix values that are modified if you click a vertex and drag it to a new position. The script arguments are optional and behave the same as with `Handle()`. However, there is no `x` nor `y` that is modified as in `Handle()`.

**Drag()** functions are ways to display data that the user can adjust and then capture the adjusted values. Consider the earlier script to draw the JMP man. **Drag Polygon()** makes it possible to draw an editable JMP man; using a matching **Drag Marker()** statement makes the vertices more visible. And, similar to the `Mousetrap()` example, you can save the new coordinates to a data table. Notice how : and :: operators avoid ambiguity among matrices and data table columns with the same names.

You could just as easily put `storepoints` in the fourth argument of **Drag Polygon()** or **Drag Marker()**, but that would create a data table after each drag. You probably just want a single data table when you are finished. Regardless, the values in `gCoordX` and `gCoordY` update with each drag.

```plaintext
::i = 1;
storepoints = Expr(
    mydt = New Table( "My coordinates" || Char( i ) );
    i++;
    New Column( "GCoordX", Numeric );
    New Column( "GCoordY", Numeric );
    mydt << Add Rows( N Row( GcoordX ) );
    ::GCoordX << Values( ::GcoordX );
    ::GCoordY << Values( ::GcoordY );
);

::GcoordX = [25, 23.75, 22.5, 21.25, 21.25, 22.5, 23.75, 25.625, 27.5, 18.75, 12.5, 6.25, 2.5, 1.25, -1.25, 3.125, 6.25, 12.5, 18.75, 25, 29.375, 34.375, 37.5, 38.75, 40.625, 42.5, 43.125, 42.5, 41.25, 38.75, 43.75, 50, 56.25, 60.625, 63.75, 65.625, 62.5, 56.25, 50, 45, 37.5, 32.5, 28.75, 25.75, 26.25, 25.625, 25];
::GcoordY = [-2, 2, 5, 10, 15, 20, 25, 30, 33, 34, 35, 37.5, 40, 41, 43.5, 41, 40, 39, 40, 42, 45, 50, 55, 60, 64, 60, 55, 50, 47, 42, 43.5, 43, 42, 40, 38, 36, 37, 36, 35, 30, 25, 20, 15, 10, 5, 2];
```
win = New Window( "Redraw the JMP Man!",
    V List Box(
        Graph Box(
            Frame Size( 300, 300 ),
            X Scale( -10, 80 ),
            Y Scale( -10, 80 ),
            Fill Color( "blue" );
            Drag Polygon( GcoordX, GCoordY );
            Pen Color( "gray" );
            Drag Marker( GcoordX, GCoordY );
            Fill Color( {0, 0, 0} );
            Circle( {18, 58}, 9, "FILL" );
        ),
        Button Box( "Store current vertices in a new data table", storepoints )
    )
);

Suppose you want the body of the JMP man to be smaller. Here is how he looks before and after some judicious vertex-dragging. Clicking the button after re-shaping the JMP Man executes the storepoints script to save his new, slender figure in a data table of coordinates.

Figure 12.28 Redraw the JMP Man

This example uses two functions discussed under “Constructors for New Windows” on page 542 in the “Display Trees” chapter:

- Button Box(), which creates controls outside the graph.
- V List Box(), which combined the graph box and the button box in the same graph window.
Troubleshoot Interactive Graphs

If your interactive graphs do not work as expected, make sure that you supply initial values for the `Handle()` or `Mousetrap()` coordinates (and other globals as needed). Also make sure that the values make sense for the graph.

Create a Color Picker

Let users select a color to apply to graphs by creating a color picker. Users can select a predefined color or create their own color. You can also specify a default color in your script.

- Use the named or numbered colors shown in “Colors and Markers” on page 451 in the “Data Tables” chapter.
  or
- Specify values between 0 and 1 for each of the red, blue, and green components in `RGB Color()`.

Examples of Creating Color Pickers

The following example does not name the window, so the default title is used. Because the script does not specify a color, Black is selected by default. If the user selects a color in the color picker window, then the lines are drawn in the selected color.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Run Script( "Bivariate" );
Wait( 0 );
pickColor = Pick Color();
Report( biv )[AxisBox( 1 )] <<
    Add Ref Line( 105, "Dashed", pickColor, "Mean" );
```

The following example creates a color picker with the window title “Select a Line Color”. BlueGreen is preselected.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Run Script( "Bivariate" );
Wait( 0 );
pickColor = Pick Color( "Select a Line Color", "BlueGreen" );
Report( biv )[AxisBox( 1 )] <<
    Add Ref Line( 105, "Dashed", pickColor, "Mean" );
```

The following example creates a color picker with the window title “Select a Background Color”. BlueGreen is preselected.

```
picked color = Pick Color( "Select a Background Color", "BlueGreen" );
New Window( "Example",
```
Clip Display Segs in Graphics

Display segs (such as reference lines, grid lines, and contours) can be clipped to conform to the natural boundaries of the underlying data. This gives you a better view of the boundaries. For example, Figure 12.29 shows contours that are clipped to the boundaries of a map of the United States.

Figure 12.29 Unclipped (Left) and Clipped (Right) Boundaries

Send the Clip Shape message to the Contour Seg object to clip the display segs.

```julia
Open( "$SAMPLE_DATA/Cities.jmp" );
gb = Graph Builder(
    Size( 653, 396 ),
    Show Control Panel( 0 ),
    Variables( X( :Longitude ), Y( :Latitude ) ),
    Elements( Contour( X, Y, Legend( 2 ) ) ),
);
```
SendToReport(
    Dispatch(
        {},
        "Graph Builder",
        FrameBox,
        {Background Map( Boundaries("US States")), Grid Line Order(2),
         Reference Line Order(3)}
    ),
);

cs = (gb << Report)[FrameBox(1)] << Find Seg( Contour Seg(1));

Wait(2);

cs << Clip Shape( Boundaries("US States"));

**Tip:** 
Clip Shape(Empty()) removes the clipping path.

Here's an example of defining the clip shape path with a matrix:

```julia
Open("$SAMPLE_DATA/Big Class.jmp");
gb = Graph Builder(
    Show Control Panel(0),
    Variables( X( :height ), Y( :weight ), Overlay( :sex ) ),
    Elements( Contour( X, Y, Legend(3) ) )
);

r = ( gb << Report );
cs = r[FrameBox(1)] << Find Seg( Contour Seg(1));

cs << Clip Shape( Path([60 80 1, 50 140 2, 65 120 2, 70 65 -2]) );
```

**Figure 12.30**  Unclipped (Left) and Clipped (Right) Contours
The matrix \([60 \ 80 \ 1, 50 \ 140 \ 2, 65 \ 120 \ 2, 70 \ 65 \ -2]\) indicates the following:

1. Start at 60, 80.
2. Draw a line to 50, 140.
3. Draw a line to 65, 120.
4. Draw a line to 70, 65.
5. Connect back to the first point.

**Create Background Maps**

Background maps can be scripted in JSL. You can write a script that creates a graph and then turns on the background map in the script.

There are two types of background maps: `Images()` and `Boundaries()`. Each of these takes a parameter, which is the name of the map to use. The name is one of the maps listed in the window.

- For `Images()`, the choices are Simple Earth, Detailed Earth, NASA, Street Map Service, and Web Map Service. If you use Web Map Service, then there are two additional parameters: the WMS URL and the layer supported by the WMS server.
- For `Boundaries()`, the choices vary since boundaries can be user-defined. A typical choice is World.

The following example uses the Simple Earth as an image and World as a boundary:

```julia
dt = Open( "$SAMPLE_DATA/Air Traffic.jmp" );
dt << Graph Builder( 
  Size( 1101, 603 ),
  Show Control Panel( 0 ),
  Variables( X( :Longitude ), Y( :Latitude ) ),
  Elements( Points( X, Y, Legend( 8 ) ) ),
  SendToReport( 
    Dispatch( 
      {},
      "Graph Builder",
      Frame Box,
      {Background Map( Images( "Simple Earth" ), Boundaries( "World" ) ),
       Grid Line Order( 3 ), Reference Line Order( 4 )}
    )
  )
);```
Figure 12.31 shows an excerpt from the map:

**Figure 12.31 JSL Scripting Example**

To change the script to use a WMS server, the command would look like this:

```js
Background Map ( Images ( "Web Map Service",
    "gpw-v3:gpw-v3-population-density_2000" ), Boundaries ( "US States" ))
```

To see which layers are available on a WMS server, install the WMS Explorer Add-In. Download the add-in from the JMP File Exchange at [https://community.jmp.com/docs/DOC-6095](https://community.jmp.com/docs/DOC-6095). Note that some WMS servers are not reliable. If the server is down, or if the user does not have an Internet connection, the WMS map does not appear.

**Tips:**

- To see the syntax for the JSL script, add a background map through the user interface. Then from the red triangle menu, select **Save Script > To Script Window** to see the script that is generated.
- To specify image and boundary names in the JSL script, use the names shown in the Set Background Map window. (Right-click a map and select **Graph > Background Map**).
- Look at sample data to find examples of background map scripts. Select **Help > Sample Data Library** and open Napoleons March.jmp, Pollutants Map.jmp, or San Francisco Crime.jmp. Right-click the map table script and select **Edit** to see the **Background Map()** function.

**Graph Elements**

You can use the following commands inside **Graph Box()** statements. This chapter focuses on the JSL that is specific to graphing, but you can also use general script commands such as **For** and **While**.
**Note:** New Window() expects window and display box commands, and platforms expect platform commands. Therefore, the general script commands such as For and While might not work inside platforms or New Window(), or you might get unexpected results.

## Plot Functions

A Y Function() function is used to draw smooth functions. The first argument is the expression to be plotted. The second argument is the name of the X variable in the expression.

```plaintext
win = New Window( "Sine Function",
    Graph Box( 
        Frame Size( 200, 100 ),
        X Scale( -10, 10 ),
        Y Scale( -1, 1 ),
        X Name( "x" ),
        Y Name( "Sine(x)" ),
        Y Function( Sine( x ), x ) ) );
```

**Figure 12.32** Sine Wave

You can use For to overlap several sine waves:

```plaintext
win = New Window( "Overlapping Sine Waves",
    Graph Box( 
        Frame Size( 200, 100 ),
        X Scale( -10, 10 ),
        Y Scale( -1, 1 ),
        For( i = 1, i <= 4, i += .1,
            Y Function( Sine( x / i ), x )
        )
    )
);```
Similarly, `X Function()` is for drawing a graph where the symbol is varied on the Y variable.

```plaintext
win = New Window( "Overlapping Sine Waves", 
    Graph Box(
        Frame Size( 100, 200 ),
        X Scale( -1, 1 ),
        Y Scale( -10, 10 ),
        For( i = 1, i <= 4, i += .2,
            X Function( Sine( y / i ), y )
        )
    );
```

Figure 12.33 Overlapping Sine Waves

An `XY Function()` draws a smooth curve using a pair of formulas (parametric equations) that depend on a third variable. The third variable's value is incremented from a minimum value to a maximum value to generate the X-Y pairs.

```plaintext
win = New Window( "Spiral", 
    Graph Box(
        Pen Color( "red" ); // red line color
        xCenter = 50; // location of the center of the curve on the x axis
        yCenter = 50; // location of the center of the curve on the y axis
        minAngle = 0;
        maxAngle = Pi() * 2 * 20;
        XY Function(
```
In this example, \( \sin() \) and \( \cos() \) use \( \alpha \) as an argument (rotates) and as a factor (expands). (\( \sin() \) and \( \cos() \) use radians, not degrees.)

**Figure 12.35** Spiral Parametric Plot

Contour Function() is an analogous way to represent a three-dimensional function in a two-dimensional space. The final argument specifies the value(s) for the contour line(s). The argument can be a value, an indexed range of values using ::, or a matrix of values.

```plaintext
win = New Window( "Bird's eye view of the egg carton function",
    Graph Box(
        Frame Size( 300, 300 ),
        X Scale( -10, 10 ),
        Y Scale( -10, 10 ),
        Pen Color( "black" );
        Pen Size( 2 );
        Contour Function( Sine( y ) + Cosine( x ), x, y, (0 :: 20) / 5 );
        Pen Color( "red" );
        Pen Size( 1 );
        Contour Function( Sine( y ) + Cosine( x ), x, y, (-20 :: 0) / 5 );
    );
)
```

Normal Contour() draws normal probability contours for $k$ populations and two variables. The first argument is a scalar probability or a matrix of probability values for the contours. Subsequent arguments are matrices to specify means, standard deviations, and correlations. The mean and standard deviation matrices have dimension $k \times 2$. The correlation matrix should be $k \times 1$, where the first row pertains to the first contour, the second row to the second contour, and so on. The first column is for $x$ and the second column for $y$. Consider the following example:

```lisp
Normal Contour(  
    [ prob1,  
      prob2,  
      prob3, ...],  
    [ xmean1 ymean1,  
      xmean2 ymean2,  
      xmean3 ymean3, ...],  
    [ xsd1 ysd1,  
      xsd2 ysd2,  
      xsd3 ysd3, ...],  
    [ xycorr1,  
      xycorr2,  
      xycorr3, ...]);
```

The following script draws contours at probabilities 0.1, 0.5, 0.7, and 0.99 for two populations and two variables. The first population has $x$ mean 0 and $y$ mean 1, with standard deviation 0.3 along the $x$ axis and 0.6 along the $y$-axis, and with correlation 0.5. The second has $x$ mean 4 and $y$ mean 6, with standard deviation 0.8 along the $x$ axis and 0.4 along the $y$-axis, and with correlation 0.9.

```lisp
win = New Window( "Normal Contours",  
    Graph Box(  
```
Normal Contour() is a general way to accomplish effects such as Bivariate’s density ellipses. The Bivariate script in the Football.jmp sample data creates an example.

Gradient Function

Gradient Function() fills a set of rectangles on a grid according to a color determined by the expression value as it crosses a range corresponding to a range of colors.

Gradient Function( expression, xname, yname, [zlow, zhigh], ZColor([colorLow, colorHigh]), <XGrid( min, max, incr)>, <YGrid( min, max, incr)>, <Transparency( t)>;)

Here are explanations of the elements in the Gradient Function() syntax:

GradientFunction(
    /* the expression to be contoured, which is a function in terms of the two variables that follow expression*/
    Expression,

    // the two variable names used in the expression
    xname, yname,

    // the low and high expression values the gradient is scaled between [zlow, zhigh],

    // the colors that correspond to the low value and the high value
    ZColor([colorLow, colorHigh])
)
// optional specification for the grid of values
<XGrid(min, max, incr),>
<YGrid(min, max, incr)> );

/* the value 0 means clear. The value 1 means completely opaque and
   is the usual drawing mode. */
<Transparency>

The ZColor() values must be numeric codes rather than names. You can use the color menu
indices (such as 0=black, 1=grey, 2=white, 3=red, 4=green, and 5=blue) found in “Specify
Colors” on page 659.

The following example uses Gradient Function() to create an animated graph.

phase = 0.7;
win = New Window( "Gradient Function",
an = Graph(
   Frame Size( 400, 400 ),
   X Scale( -5, 5 ),
   Y Scale( -5, 5 ),
   Gradient Function(
      phase * Sine( x ) * Sine( y ) + (1 - phase) * Cosine( x ) * Cosine( y ),
      x,
      y,
      [-1 1],
      zcolor( [0, 2] )
   )
);
);
b = a[FrameBox( 1 )];
For( i = 1, i <= 5, i++,
   For( phase = 0, phase < 1, phase += 0.05,
      b << Reshow;
      Wait( 0.01 );
   );
   For( phase = 1, phase > 0, phase -= 0.05,
      b << Reshow;
      Wait( 0.01 );
   );
);
);
Get the Properties of a Graphics Frame

Several functions are useful for getting properties of an existing graphics frame:

**H Size**  Returns the horizontal size of the graphics frame in pixels.

**V Size**  Returns the vertical size of the graphics frame in pixels.

**X Origin**  Returns the $x$-value for the left edge of the graphics frame.

**X Range**  Returns the distance from the left to right edges of a display box.

**Y Origin**  Returns the $y$-value for the bottom edge of the graphics frame.

**Y Range**  Returns the distance from the bottom to top edges of a display box.

In the following expressions, the first line calculates the right edge. The second line calculates the top edge.

```javascript
Oval(...,
    rightEdge = X Origin() + X Range();
    topEdge = Y Origin() + Y Range();
);
```

Add a Legend

To add a legend to a graph, send the `Row Legend` message to the frame box. In the `Row Legend` message, specify which column you want to base the legend on and whether the legend affects colors and markers.
For example, using Big Class.jmp, submit the following JSL to turn on a legend based on the age column. Set both colors and markers by values in the age column.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( :height ), x( :weight ) );
rbiv = biv << Report;
framebox = rbiv[Frame Box( 1 )];

/* make a legend with the "age" title
  display colors and markers in the legend */
framebox << Row Legend( "age", Color( 1 ), Marker( 1 ) );
```

The Color() and Marker() arguments are optional. Colors are on and markers are off by default.

To use a continuous scale if your variable is nominal or ordinal, you can use a continuous color theme with the Continuous Scale( 1 ).

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( y( :weight ), x( :height ) );
rbiv = biv << Report;
framebox = rbiv[Frame Box( 1 )];
framebox << Row Legend( "age", Color( 1 ), Continuous Scale( 1 ) );
```

To interactively add a legend, right-click the graph, select Row Legend, and change the column settings.

---

# Hover Labels

When you hover over a visual element in a graph, usually you see a basic description of the data point on a hover label.

You can customize what appears on the hover label using the following methods:

- “Add Rich Text to Hover Labels Using Textlets”
- “Add Graphs or Images to Hover Labels Using Graphlets”
- “Update Names and Values in Hover Labels Using Gridlets”
- “Create Drill-Down Graphs”
- “Work with the Hover Label Execution Context”
Add Rich Text to Hover Labels Using Textlets

A *textlet* adds richly formatted text to the hover label. You might use a textlet to describe data in an explanatory paragraph or to emphasize important information by making it bold or applying a color.

The textlet in Figure 12.39 shows text that is formatted in a gray box with red text.

**Figure 12.39** Textlet Example

The following script creates the textlet shown in Figure 12.39.

```julia
Names Default To Here( 1 );
dt = Open( "SAMPLE_DATA/Diabetes.jmp" );

// create the baseline visualization
gb = dt << Graph Builder(
   Size( 534, 456 ),
   Show Control Panel( 0 ),
   Variables( X( :Age ), Y( :LDL ), Overlay( :Y Ordinal ) ),
   Elements( Points( X, Y, Legend( 8 ) ), Line Of Fit( X, Y, Legend( 10 ) ) )
);

// get a handle to the graph frame box
rpt = gb << Report;
```
frame = rpt[Framebox( 1 )];

/* configure the textlet -- a hover label extension that adds
a rich text paragraph to the hover label. */
frame << Set Textlet(
    /* "Setup" is a JSL fragment that uses Hover Label Execution Context
    variables to define content that will be embedded in the
rich text paragraph. */
    Setup(
        // map numerical values to text
        local:gender = If( Column( local:_dataTable, "Gender" )[local:_firstRow]
            == "1",
            "Male",
            "Female"
        );
        // map a categorical value to text color
        local:color = Match( local:_Y Ordinal,
            "Low", "Medium Dark Blue",
            "Medium", "Medium Dark Red",
            "High", "Medium Dark Green"
        );
        // capture values from other columns for the current row
        local:progression = Column( local:_dataTable, "Y" )[local:_firstRow];
        local:BMI = Column( local:_dataTable, "BMI" )[local:_firstRow];
    ),
    /* markup defines the rich text template. It supports HTML-like markup such
    as bold, italic and other font tags. Variable references between braces
    ({})) are substituted with their actual value. */
    Markup(
        "{local:gender} patient, {local:_age} years old, {local:BMI} BMI,
        has <font color='{local:color}'><b>{local:_Y Ordinal}</b></font>
        disease progression (<i>{local:progression}</i>)"
    )
);

// pin a hover label to display a textlet-created rich text paragraph.
frame << Add Pin Annotation(
    Seg( Marker Seg( 2 ) ),
    Index( 64 ),
    Index Row( 344 ),
    UniqueID( 568154464 ),
    FoundPt( {96, 222} ),
    Origin( {18.68125, 156.93706122449} ),
    Tag Line( 1 )
);
Texlet Commands

See the example in “Add Rich Text to Hover Labels Using Textlets” on page 692 for more information about writing texlet expressions.

Setup

Setup() defines variables used in the rich text that is displayed on the hover label.

... frame << Set Texlet(
   /* "Setup" is a JSL fragment that uses Hover Label Execution Context variables to define content that will be embedded in the rich text paragraph. */
   Setup(
      // map numerical values to text
      local:gender = If( Column( local:_dataTable, "Gender" )[local:_firstRow] == "1",
         "Male",
         "Female",
      );
      // map a categorical value to text color
      local:color = Match( local:_Y Ordinal,
         "Low", "Medium Dark Blue",
         "Medium", "Medium Dark Red",
         "High", "Medium Dark Green"
      );
      // capture values from other columns for the current row
      local:progression = Column( local:_dataTable, "Y" )[local:_firstRow];
      local:BMI = Column( local:_dataTable, "BMI" )[local:_firstRow];
   )
...)

In the interface, Setup is called “JSL Variables” on the Textlets Markup tab.

Markup

Markup() specifies a rich text paragraph template based on a subset of HTML tags. Can contain JSL variable references enclosed in delimiters. The default delimiters are braces ({}).

... Markup(
   "{local:gender} patient, {local:_age} years old, {local:BMI} BMI, has <font color='{local:color}'>{local:_Y Ordinal}</font> disease progression (<i>{local:progression}</i>)"

)

In the interface, Markup is called “HTML Markup” on the Textlets Markup tab.
See *Using JMP* for more information about the supported font formatting tags.

**Delimiters**

`Delimiters()` specifies the delimiters that indicate variables for replacement in the Markup area. For example, you might use square bracket delimiters for JMP variables if the script contains C++ code.

```plaintext
Delimiters( "[]\" )
```

In the interface, Delimiters is on the Textlets Other tab.

**Width**

`Width()` enables you to specify a preferred width in pixels for the hover label.

```plaintext
Width( 300 )
```

In the interface, Width is on the Textlets Other tab.

**Add Graphs or Images to Hover Labels Using Graphlets**

You can add a thumbnail of a related graph or an image to a hover label using a *graphlet*. These graphs and images can have actions associated with them that are triggered by a mouse click. For example, you can click a graph to launch it, or click an image to open a related link.

**Example of a Graphlet in Graph Builder**

Click the JMP man graph shown in Figure 12.40 to open it in Graph Builder and customize the graph. See *Using JMP* for details about opening a graph in a platform, customizing the graph, and then saving the updated graph in the original graph.
The following script creates the graph and hover label that are shown in Figure 12.40.

```julia
Names Default To Here( 1 );
// open the data table
dt = Open( "$SAMPLE_DATA/JMP Man Dozen.jmp" );

// launch the baseline visualization
gb = Graph Builder(
    Size( 529, 466 ),
    Show Control Panel( 0 ),
    Variables( X( :Data Set ), Y( :X ), Y( :Y, Position( 1 ) ) ),
    Elements( Bar( X,
        Y( 1 ),
        Y( 2 ),
        Legend( 12 ),
        Error Interval( "Standard Deviation" )
    )
)
);

// get a reference to the visualization frame
```
frame = (gb << Report)[FrameBox(1)];

/* use the "Set Graphlet" command to define the visualization that will be rendered inside the hover label using the "Picture" attribute */
frame << Set Graphlet(
   /* The value of the "Picture" attribute is a JSL fragment that is evaluated to generate a thumbnail. The thumbnail is displayed inside the hover label. In this case, the hover label shows a scatterplot with a caption box. */
   Picture(
      Graph Builder(
         Show Control Panel( 0 ),
         Variables( X( :X ), Y( :Y ) ),
         Elements( Points( X, Y, Legend( 1 ) ), Line Of Fit( X, Y, Legend( 3 ) ), Caption Box( X, Y, Legend( 4 ), Summary Statistic( "5 Number Summary" ) )
      )
   )
   /* Because the optional "Click" attribute is not defined, the "Picture" attribute script is re-used to launch the associated platform when the user clicks the graphlet thumbnail. */
);

**Example of a Graphlet in Principal Components**

Create a graphlet in the Principal Components platform. When the user clicks the hover label, the Principal Components report window appears. The user can then explore and filter the data.
The following script creates the graphlet shown in Figure 12.41:

```
dt = Open( "$SAMPLE_DATA/Iris.jmp" );
geb = dt << Graph Builder(
    Size( 531, 451 ),
    Show Control Panel( 0 ),
    Variables( X( :Species ), Y( :Sepal width ) ),
    Elements( Treemap( X, Y, Legend( 4 ) ) ),
    SendToReport( Dispatch(
        {},
        "Graph Builder",
        FrameBox,
        {Set Graphlet( Picture(
            Principal Components(
                Y( :Sepal length, :Sepal width, :Petal length, :Petal width
            ),
            Z( :Species ),
            Estimation Method( "Default" ),
            "on Correlations"
        )
    )
)}
)
Graphlet Commands

**Picture**

A required script that adds a thumbnail of a graph or an image to the hover label. Picture() is always executed in a Hover Label Execution Context derived from the current visual element. The first Picture Box (outside of a local data filter) found will be used to generate the displayed image.

If Picture() is a call to a platform, a local data filter is included.

```
... Picture(
    Graph Builder(
        Show Control Panel( 0 ),
        Variables( X( :X ), Y( :Y ) ),
        Elements(
            Points( X, Y, Legend( 1 ) ),
            Line Of Fit( X, Y, Legend( 3 ) ),
            Caption Box( X, Y, Legend( 4 ),
                        Summary Statistic( "5 Number Summary" ) )
        )
    )
...)
```

See “Add Graphs or Images to Hover Labels Using Graphlets” on page 695 for a complete example.

**Click**

An optional script for user-defined actions to be executed when the user clicks the associated image.

- Clicking runs the main graph’s platform (for example, Graph Builder), which launches in its own window.
- If Click is not provided, the script provided in Picture is evaluated in a Hover Label Execution Context scope.
Skip Filters

An optional script. By default, any code executed in the context of a hover label customization (such as a graphlet) executes in a context defined in the hovered visual element (for example, a bar in a bar chart). This context includes a local data filter based on the current visual role assignment, and it is usually what you want. However, in some rare cases, you don’t want the filter, or maybe part of the filter, so that the next graph generated by the graphlet can include more of the original data.

- If the Skip Filters field evaluates to a non-0 value (usually a positive integer such as 1) the selected Skip Filters Columns will be removed from the filter that will be applied to the new graphlet.
- Otherwise (for example, if it evaluates to 0), the selected columns are ignored and the filter is created as usual.
- If the Skip Filters Flag field is empty and no columns are selected in Skip Filters Columns (the default), then no columns are skipped when creating filters for the new window. Note that Skip Filters Flag is a JSL expression, which can be as complex as needed.
- If Skip Filters Flag field is not empty, but Skip Filter Columns is empty (no columns are selected), then all columns are filtered; the graphlet or new visualization includes all the data used by the original visualization. See “Example of Defining the Context of a Scatterplot Matrix and Ellipse” on page 718.

Suppose that you are looking at crime over time in the San Francisco Crime.jmp sample data table. You use a line chart where X = Date, an overlay of Police District, and no Y assignment. Lines represent counts over time per district. Now you want to use a graphlet to look at crime over time inside each district, broken down by category. Create this new graph and select Save > to Clipboard and then Paste Graphlet on the original graph to create the graphlet. However, the hovered graph shown in Figure 12.42 is not what you expect.
Figure 12.42 Initial Filtered Data

JMP created a filter based on both roles, X and the overlay. This is easier to see if you click on the graphlet to launch the new graph, and then expand the local data filter (on the left, collapsed by default). The filter on a single day causes the line chart to collapse into what looks like a marker plot as shown in Figure 12.43.
You want the overlay value to restrict what you see in the new graph. However, you don’t want the date value to do so. You still want to filter by the “SOUTHERN” Police District, but you do not want to filter on “04/14/2012” Date.

The solution is to use the Skip Filters Flag to remove the filter on Date from your original graph. On the Hover Label Editor, the script looks like this:

After the filter is removed, the end result is what you expect as shown in Figure 12.45.
The following script creates the graph shown in Figure 12.45.

```
Names Default To Here( 1 );

dt = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
gb = dt << Graph Builder(
    Size( 528, 456 ),
    Show Control Panel( 0 ),
    Variables( X( :Date ), Overlay( :Police District ) ),
    Elements( Line( X, Legend( 4 ) ) ),
    SendToReport(
        Dispatch(
            {},
            "Graph Builder",
            FrameBox,
            {Set Graphlet( Picture(
                Graph Builder(
                    Size( 528, 456 ),
                    Show Control Panel( 0 ),
                    Variables( X( :Date ), Overlay( :Category ) ),
                    Elements( Line( X, Legend( 1 ) ), Smoother( X, Legend( 2 ) ) )
                )
            )}
        )
    )
)
```
The Skip Filters Flag field holds an expression that is evaluated in the hovered visual element context. If expression evaluates to a truthful value (usually a positive integer such as 1), the selected “Skip Filters Columns” will be removed from the filter that will be applied to the new graphlet. Otherwise (for example, if it evaluates to zero), the selected columns are ignored and the filter is created as usual.

**Title**

Title is an expression that evaluates to a string. The result is the title that appears on the title bar of the window that contains the graph. Variables defined in the Hover Label Evaluation Context can be used in the Title expression.

For example, the following expression indicates the baseline visualization type and how many drilling levels have been used so far:

```
Title("Graphlet for " || local:_displaySegName || ", depth is " || Char( local:_drillDepth ))
```

If the Title expression is not specified, the new window is named “Graphlet”.

**Note:** In the JMP interface, Title is on the Hover Label Editor Other tab of a graphlet.

**Reapply**

Reapply is an expression that indicates whether the graphlet definition should be reapplied to new graphs or platforms created by clicking on a graphlet image. This is the core mechanism behind the ability to drill down using graphlets.

```
Reapply( local:_underlyingRows > 1 )
```

**Note:** In the JMP interface, Reapply is on the Hover Label Editor “Other” tab of a graphlet.

If Reapply is empty (the default setting), the graphlet definition is not reapplied. New windows launched by clicking on this graphlet doesn’t show graphlets on its hover labels.
Update Names and Values in Hover Labels Using Gridlets

A gridlet supports the full customization of the hover label name and value pairs that reflect the underlying visual data. Data can be added, removed, or renamed. You can also change the style and numeric formats.

When you hover over a visualization in a graph, you see content in the hover label for that marker. A grid entry is text that appears on the hover label by default, either from the label columns or from the columns associated with the visualization. By default, the column names that are assigned to roles (and their corresponding values) are shown, along with columns that are labeled. You can customize these column names or values or add other content. Here are a few things you can do:

- add or remove a column name and its value
- rename a grid label
- add a new grid entry with a dynamic value and an optional click action. For example, you can insert an entry named “See also” with a clickable link to a Wikipedia page as the value.
- applying a style to text (for example, formatting text in bold)
- formatting numeric values (for example, setting the number of decimal places to 2)

Figure 12.46 shows adding Genre, Name, and Length in minutes, reformatting the minutes, and formatting “Genre” in bold.

Figure 12.46 Customized Gridlet
Example of Customizing a Gridlet

The following script creates the graph and hover label shown in Figure 12.46.

```plaintext
Names Default To Here( 1 );
dt = Open( "$SAMPLE_DATA/Movie Inventory.jmp" );

// launch the baseline visualization
dt << Graph Builder(
    Size( 534, 456 ),
    Show Control Panel( 0 ),
    Variables( X( :Year ), Y( :Length ) ),
    Elements( Points( X, Y, Legend( 3 ) ), Smoother( X, Y, Legend( 4 ) ) ),
    SendToReport(
        Dispatch(
            {},
            "Graph Builder",
            FrameBox,
            {Set Gridlet(
                // delete the Length column
                Expunge( {{Matcher( "Length" )}} ),
                // add the Name, Genre, and Length in minutes columns
                Annex(
                    {{Matcher( "Name" ), value( :Name[local:_firstRow] )},
                    {Matcher( "Genre" ), value( :Genre[local:_firstRow] )},
                    {Matcher( "Length in minutes" ), value( local:_Length * 60 )}}
                ),
                Reformat(
                    // reformat the Length in minutes format
                    {{Matcher( "Length in minutes" ), Format( "hr:m", 80 ), 80}}
                ),
                Style(
                    // format "Genre" in bold nine-point text
                    {{Matcher( "Genre", Scope( Name ) ), Font("Segoe UI", 9, "Bold")}}
                ),
                Add Pin Annotation(
                    Seg( Marker Seg( 1 ) ),
                    Index( 33 ),
                    Index Row( 33 ),
                    UniqueID( 610643713 ),
                    FoundPt( {508, 199} ),
                    Origin( {1964.8951552795, 199.00456244898} ),
                    Tag Line( 1 )
                )
            )
        )
    )
)
```
Gridlet Commands

The first argument in all Set Gridlet commands is a matcher, which identifies its scope of action (the grid entries it affects). A matcher can refer to the following:

- A single grid entry: by name, matching against a string. A grid entry is text that appears on the hover label by default, either from the label columns or from the columns associated with the visualization.

- Multiple grid entries: by column reference, regular expression or using the argument All.

For example, a grid entry for Mean(height) can be matched against the following:

- the name "Mean(height)"
- the column reference :height
- the regular expression PatReg("^.*\(height\)\$")
- the special argument All, which always matches all rows in the grid.

If there is a match, the command-associated action is carried against the matching entries using the arguments.

The exception is the Annex command, which adds a new entry to the grid if there are no matches with existing entries (to avoid unplanned naming collisions).

Example of Adding and Deleting Columns

This example describes how to use the Expunge command to remove the first entry added to the hover label when the underlying table has no Label columns, followed by two instances of the Annex command to add new rows. Note that you could have used a single Annex instance and passed to it a list of lists instead.

Figure 12.47 shows the original hover label and the updated hover label. Notice that Row was removed from the label. Name and Genre were added.

Figure 12.47 Example of the Expunge and Annex Commands

The following script creates the updated hover label shown in Figure 12.47.

`Names Default To Here(1);`
```javascript
dt = Open( "$SAMPLE_DATA/Movie Inventory.jmp" );

// create the baseline visualization
gb = dt << Graph Builder(
    Size( 526, 454 ),
    Show Control Panel( 0 ),
    Variables( X( :Year ), Y( :Length ) ),
    Elements( Points( X, Y, Legend( 3 ) ), Smoother( X, Y, Legend( 4 ) ) )
);

rpt = gb << Report();
box = rpt[Framebox( 1 )];
box << Set Gridlet(
    // delete Row
    Expunge( {{Matcher( 1 )}} ),
    Annex(
        // add the Name and Genre columns to the hover label
        {{Matcher( "Name" ), value( :Name[local:_firstRow] )},
        {Matcher( "Genre" ), value( :Genre[local:_firstRow] )}}
    )
);

Annex (Append)

Annex({matcher, value(<script>), <Click(<script>)>}) adds a new row to the hover label grid. The Annex command corresponds to the Append tab in the Hover Label Editor Gridlet panel.

This command takes three arguments:

- **Matcher**: The new name. Matcher should not match existing names.
- **Value**: Required. The script is evaluated in the Hover Label Execution Context. The result is the value that appears for the new row. See “Work with the Hover Label Execution Context” on page 713 for details.

  ```javascript
  box << Set Gridlet(
      Annex( { "LDL, HDL", value( 
          Char(:LDL[local:_firstRow]) || ", " || Char(:HDL[local:_firstRow]) 
      )}))
  ```

- **Click**: Optional. Click is evaluated in the Hover Label Execution Context when the user clicks on annexed entry value. This option is equal to the Click attribute in graphlets. If present, the value portion of the new entry is rendered using a link style (blue text color with an underline) to indicate that it can be clicked.
```
Expunge (Delete)

Expunge({Matcher}) deletes the matcher. The Expunge command corresponds to the Delete tab in the Hover Label Editor Gridlet panel.

All matching entries are removed from the grid.

```
box << Set Gridlet( Expunge( "age" ) );
```

Rename

Rename({Matcher, Value(<string>)}) replaces the name portion of the matched entry or entries with the given value. The Rename command corresponds to the Rename tab in the Hover Label Editor Gridlet panel.

```
box << Set Gridlet( Rename( {Matcher( "name" ), Value( "students" )} ) );
```

Reformat

Reformat({Matcher, <format>}) takes a matcher and an argument that specifies a format to be applied to the matched row (or rows) grid numerical value or values. Matching entries are changed to reflect the specified format.

```
box << Set Gridlet( Reformat( {:height, Format( "Scientific", 10, 4 )} ) );
```

Style

Style({Matcher, <style1>, <style2>, ...}) takes a matcher and one or more style arguments. Here are the supported styles:

- Background Color
- Text Color
- Font (which further supports font family, size and style)
- Justification (left, center, or right)

Matching entries are changed to reflect the specified styles.

```
box << Set Gridlet(
  Style(
    {{Matcher( "sex" ), Text Color( "Red" ), Font("Papyrus", 14, "Bold Underline")}}
  )
);
Create Drill-Down Graphs

A drill-down graph is created when you click on the thumbnail. Clicking on the hover graph opens it in a new window, enabling you to see the graph in more detail and also make modifications such as changing the data filter. For example, click a cell on a treemap to see details about the data in a new window (Figure 12.48). Press Ctrl and click to replace the contents of the last launched window instead of opening a new window.

- The Next in Hierarchy column property enables you to define the behavior of categorical drill downs in preset graphs. This column property defines only one level of the drill down, from a category in a grouping role in the current visualization to the category in the grouping role in the next one, launched by the graphlet.

- If the Next in Hierarchy column property is not defined, the list of categorical or nominal columns from the data table that have not been added to a filter is used.

Notes:

- The Next in Hierarchy column property is not supported in graphlets defined using Paste Graphlet. See Using JMP for details about the Paste Graphlet command.

- If there is no measurement, JMP tries to get one from the data table and uses Count (or no measurement) if there are no numeric columns in the data table.
Figure 12.48 shows drilling-down on a cell in a treemap.

**Figure 12.48** Example of a Drill-Down Graph on a Hover Label

The following script creates the simplified versions of the treemap presets shown in Figure 12.48.

```plaintext
Names Default To Here( 1 );

/* traverse the given list of column names, defining the Next in Hierarchy column property so that it creates a chain to enable the drill down */
setHierarchy = Function( {dt, cols},
  {Default Local},
  nCols = N Items( cols );
  If( nCols < 2,
      Write( "\!NsetHierarchy: Insufficient number of columns!" ),
      col = Column( dt, cols[1] );
      For( i = 2, i <= nCols, i++,
```
nextCol = cols[i];
Try(
    Column( dt, nextCol ),
    Write( "Invalid column name: " || nextCol );
    Throw();
);
// Eval() is needed for now
col = Column( dt, nextCol );
nih_name = col << Get Property( "Next in Hierarchy" );
col = Column( dt, nextCol );
);
);

// open San Francisco Data.jmp
dt = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );

// add a Next in Hierarchy chain to the data table
setHierarchy( dt, {"Police District", "Category", "Incident Description"} );

/* Graph Builder treemap based on the first level of our hierarchy, "Police District" */
gb = dt << Graph Builder(  
    Size( 495, 440 ),
    Show Control Panel( 0 ),
    Variables( X( :Police District ) ),
    Elements( Treemap( X ) )
);

// get a handle to the graph framebox
rpt = gb << Report;
frame = rpt[Framebox( 1 )];

/* configure the graphlet -- a hover label extension that adds a visualization thumbnail to the hover label. Clicking on the thumbnail launches the associated visualization in its own window (or replaces the graph in the current window on a Ctrl-click). */
frame << Set Graphlet(  
    // define the thumbnail and launch treemap
    Picture(  
        // next-level grouping is retrieved from the Next in Hierarchy property
        local:propColName = local:_groupings[1] << GetProperty( "Next In Hierarchy" );
        local:nextGrouping = Column( local:_dataTable, local:propColName );

        // define the Graph Builder graph for the thumbnail
        local:nextLevel = gb"
    )
);
Work with the Hover Label Execution Context

Hover Label Execution Context variables define the environment in which your graphlet and textlet scripts are executed.

Local Data Filter

When defining a graphlet, you specify how to visualize the data that appears as a thumbnail. But how do you specify which rows should be displayed?

This information is specified indirectly you hover over different visual elements of the baseline graph (the graph to which a graphlet definition was added). Suppose that the baseline graph is a bar chart. Hovering over one of the bars indicates that all the rows behind that bar (and only those rows) should be included in the generation of the visualization. This visualization shows up as a thumbnail on the hover label. In other words, the hovered visual element provides the data context in which the visualization is generated.

This data context is expressed in a where clause that is computed by JMP based on:

- the type of graph used in the baseline visualization
- the columns assigned to its different roles
- the current values for the particular visual element being inspected
The resulting where clause is then used to create a local data filter that is assigned to the platform specified in the graphlet definition.

The following graph roles are supported as sources for the creation of local data filters:

- X, including nested columns
- Y, if not representing a summary statistic or other calculation
- overlays

Numeric columns are used in comparison to a single value or checked for inclusion in a range, depending on the underlying visualization type. Visualizations that group numeric data in bins such as histograms and heat maps (and the box in box plots) result in the use of corresponding ranges in the where clause.

If present, the where clause of a Local Data Filter associated with the baseline visualization is captured as well.

**Local Scope Context**

The JSL expressions that configure different aspects of a graphlet and other hover label extensions (such as the textlet Setup and the gridlet Append and Click scripts) are executed inside a local namespace. This namespace is initialized with local variables that reveal information from the execution context: the hover label grid entries and references to the underlying visual element and associated data. These variables are used extensively by the graphlet presets.

Figure 12.4 describes variables that are provided in a graphlet local namespace. See “Complete Example of the Hover Label Execution Context Variables” on page 719.

**Note:** To see the variables at work, right-click on a graph, select Hover Label Editor, select the Graphlet panel, and then select one of the presets. The code that appears in the Picture field illustrates how many of the Hover Label Execution Context variables are used to control the graphlet’s behavior.
### Table 12.4 Hover Label Execution Context Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| `_mode`  | A string indicating the current evaluation context. Values include Picture, Click, Textlet, Graphlet, and Other. You can use `_mode` to customize a Graph Builder expression to show more or less information. From the JMP log:  
```json
{"_mode": "Textlet"},
```
Example from the Bar preset:  
```javascript
If( local:_mode == "Picture",  
    local:sizeDef = "Size( 200, 250 ),";  
    local:l = 0;
    
    ,  
    local:sizeDef = "";
    local:l = 1;
);
```
**Note:** Other means the other attributes that take expressions (for example, SkipFiltersFlag). |
| `_groupings` | A list of the current grouping (X or overlay roles) data column references. See “Example of Defining the Context of a Scatterplot Matrix and Ellipse” on page 718.  
```javascript
{"-_groupings", {:sex}}
```
| `_measurements` | A list of the current measurements (Y role) data column references.  
```javascript
{"-_measurements", {:height}}
```
| `_filters` | A list of the current local data filter data column references.  
```javascript
{"-_filters", {:sex}}
```

<td>Another example:</td>
</tr>
</tbody>
</table>
|             | `{"_where", ":sex == \\
|             | "F\!""}`                                                                                                                                  |
| _whereExpr  | The where clause that is associated with the hovered visual element as a JSL expression.                                                   |
|             |                                                                                                                                              |
|             | `local:_h = Round(Mean( :height[local:_dataTable << Get Rows Where( local:_whereExpr )] ), 2);`                                             |
|             | Another example:                                                                                                                           |
|             | `{"_whereExpr", :sex == "F"}`                                                                                                          |
| _displaySegName | The class name of the underlying seg. Useful when creating descriptive text or in the definition of graph-dependent drill-down logic.                  |
|             |                                                                                                                                              |
|             | `Title("Graphlet for " || local:_displaySegName || ", depth is " || Char( local:_drillDepth ));`                                              |
|             | Another example:                                                                                                                           |
|             | `{"_displaySegName", "BarSeg"}`                                                                                                          |
| _dataTable  | A reference to the underlying data table. Useful for creating subsets. See “Add Rich Text to Hover Labels Using Textlets” on page 692 for an example.    |
|             |                                                                                                                                              |
|             | `{"_dataTable", Data Table( "Big Class" )}`                                                                                               |
In addition to these variables, a variable is defined for each of the hover label grid entries. The name of this variable is taken for the grid entry name, with a `_' prefix.

**Note:** See “Example of Defining the Context of a Scatterplot Matrix and Ellipse” on page 718 for examples of these variables.

As an example, using Hover Label Execution Context variables, you can create a scatterplot matrix, hover over a point to show a close-up ellipse, and then click the ellipse to modify it in Graph Builder. The graphlet shows the same visualization as the one in the underlying scatterplot matrix cell (a scatterplot of the two columns associated with that cell).

Clicking on the thumbnail then has the effect of “extracting” the cell from the matrix and opening it up as an independent visualization.

### Table 12.4 Hover Label Execution Context Variables (Continued)

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>_summaryStatistic</code></td>
<td>A string with the current summary statistic. Useful for passing to new graphs in a drill down.</td>
</tr>
<tr>
<td></td>
<td>{&quot;_summaryStatistic&quot;, &quot;Mean&quot;}</td>
</tr>
<tr>
<td><code>_drillDepth</code></td>
<td>An integer that indicates how many drill-down levels have been opened before. Useful to limit drill-down chains or to control SkipFilters logic.</td>
</tr>
<tr>
<td></td>
<td>See “Example of Defining the Context of a Scatterplot Matrix and Ellipse” on page 718</td>
</tr>
<tr>
<td></td>
<td>{&quot;_drillDepth&quot;, 1}</td>
</tr>
<tr>
<td><code>_firstRow</code></td>
<td>The 1-based index of the first row associated with the hovered visual element. See “Example of Adding and Deleting Columns” on page 707.</td>
</tr>
<tr>
<td></td>
<td>{&quot;_firstRow&quot;, 1}</td>
</tr>
<tr>
<td><code>_underlyingRows</code></td>
<td>The count of rows associated with the visual element that appears in the hover label. You can use this variable to decide the type of the visualization based on the number of rows to display, going from the low granularity of a heat map to a dense marker plot if the number of rows is small enough (and vice versa). See “Reapply” on page 704 for an example.</td>
</tr>
<tr>
<td></td>
<td>{&quot;_underlyingRows&quot;, 18}</td>
</tr>
</tbody>
</table>
The script shown in “Example of Defining the Context of a Scatterplot Matrix and Ellipse” on page 718 enables the user to extract the matrix cells in the main scatterplot matrix.

**Figure 12.49** Viewing an Ellipse in a Scatterplot Matrix

![Image of a scatterplot matrix with ellipses]

**Example of Defining the Context of a Scatterplot Matrix and Ellipse**

The following script shows an example of using the context in which the script runs. This script creates the scatterplot matrix shown in Figure 12.49.

```julia
Names Default To Here( 1 );

dt = Open( "SAMPLE_DATA/Solubility.jmp" );
win = New Window( "Scatterplot Matrix Graphlet Example",
    plt = dt << Multivariate(
        Y( "1-Octanol"n,
            :Ether,
            :Chloroform,
            :Benzene,
            :Carbon Tetrachloride,
            :Hexane
        ),
        Estimation Method( "Row-wise" ),
        Scatterplot Matrix( Density Ellipses( 1 ),
            Shaded Ellipses( 1 ),
            Ellipse Color( 69 ),
            Horizontal( 1 )
        )
    )
);
frame = win << xpath( "//FrameBox" );
frame << Set Graphlet(
    Picture( Show( local:_displaySegName ));
```

```julia
// Expanded code here...
```
If( local:_displaySegName == "MarkerSeg",
    // scatterplot cells
    Graph Builder(
        Size( 400, 200 ),
        Show Control Panel( 0 ),
        Show Legend( 0 ),
        Variables(
            X( local:_groupings[1] ),
            Y( local:_groupings[2] )
        ),
        Elements( Points( X, Y ), Ellipse( X, Y ) )
    ),
    // else histograms in matrix diagonal
    If( local:_N > 5, /* Note: only present if baseline graph is a histogram.*/
        Graph Builder(
            Size( 400, 400 ),
            Show Control Panel( 0 ),
            Show Legend( 0 ),
            Variables( X( local:_groupings[1] ) ),
            Elements( Histogram( X ) )
        ),
        Graph Builder(
            Size( 400, 400 ),
            Show Control Panel( 0 ),
            Show Legend( 0 ),
            Variables( X( local:_groupings[1] ) ),
            Elements( Points( X ) )
        )
    )
);
// skip filters if you are at the first drill level -- the original graph
SkipFilters( local:_drillDepth == 1 ), // no list -- all filters
Title( "Graphlet" ),
Reapply( local:_displaySegName == "HistSeg" & local:_N > 5 )
);

Complete Example of the Hover Label Execution Context Variables

The following script produces the graph shown in Figure 12.50. When you hover over a bar, the hover label appears. Details about the data and the Hover Label Context Execution variables appear in the log.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Graph Builder(
    Size( 528, 450 ),
    ...
Show Control Panel( 0 ),
Variables( X( :sex ), Y( :height ) ),
Elements( Bar( X, Y, Legend( 3 ) ) ),
SendToReport(
    Dispatch(
        {},
        "Graph Builder",
        FrameBox,
        {Set Textlet(
            Setup(
                local:encodedWhere = XML Encode( local:_where );
                /* Show() provides additional information about the
                HLEC variables in the log */
                Show( Namespace( "local" ) << Get Contents() );
            ),
            Markup(
                "<b>Groupings</b>: {local:_groupings}
                <b>Measurements</b>: {local:_measurements}
                <b>Summary statistic</b>: {local:_summaryStatistic}
                <b>Filter columns</b>: {local:_filters}
                <b>Where clause</b>: {local:encodedWhere}
                <b>Graph type</b>: {local:_displaySegName}
                <b>Data table</b>: {local:_dataTable}
                <b>Drill depth</b>: {local:_drillDepth}
                <b>First Row</b>: {local:_firstRow}
                <b>Underlying Rows</b>: {local:_underlyingRows}
            )
        )
    )
);
Figure 12.50  Bar Chart with Textlet
JSL includes commands for scripting three-dimensional scenes derived from OpenGL. Although not a complete OpenGL® implementation, JSL’s 3-D scene commands enable complex, interactive plots to be constructed and viewed. The Surface Plot platform in JMP is built using JSL scene commands.

About JSL 3-D Scenes

JMP’s 3-D scene language is built on top of the OpenGL API, extending, replacing, and leaving out various parts of the OpenGL API. As such, the 3-D scene language is not certified or licensed by Silicon Graphics, Inc. under the OpenGL API.

This chapter documents JMP’s JSL commands for creating 3-D scenes but is not a tutorial on OpenGL programming. If you are not familiar with OpenGL programming, you might want supplemental material. If you are familiar with OpenGL programming, you still need to read this chapter because some items are nonstandard.

JMP is shipped with sample files in the Scene3D subfolder of Sample Scripts to get you started and give you some ideas. Some of the example scripts are similar to some of the examples in this chapter; some are almost complete applications.

The website https://opengl.org is a good source for information, as is your favorite search engine.

JMP’s Scene 3-D language does some work for you that the OpenGL API requires you to do for yourself. JMP makes text easy, gives you a built-in arcball controller, and makes sure the matrix operations that belong on the model view stack and projection stack go on their respective stacks. JMP uses its own display list manager so that your scenes can be journaled and played back later, and provides a select mechanism that calls back to your JSL code to tell you what object in your scene is under the mouse, with almost no extra effort on your part. At this time, JMP does not provide access to some features, like texturing.

JSL 3-D Scene Boxes

These commands are necessary to set up and configure a 3-D scene.

Like all displays in JMP (detailed in the “Display Trees” chapter on page 517), 3-D scenes must be placed in a display box (in this case, a Scene Box). This box is then placed in a window. Therefore, a simple 3-D scene script has the following form.

```javascript
myScene = Scene Box(300, 300); // create a 300 by 300 pixel scene box
...(commands to set up the scene)...
New Window("3-D Scene", myScene); // draw the scene in a window
...(commands that manipulate the scene)
```

The scene can be sent messages that construct elements in the scene. Typical messages alter the viewer’s vantage point, construct physical elements in the scene itself, or manipulate lights and textures. These messages are maintained in a display list and are manipulated in one of two ways:
• They are sent as messages to the scene, which immediately adds them to the scene’s internal display list.
• They are sent as messages to a display list stored in a global variable, which is called by the scene’s display list later.

Figure 13.2 Constructing Scenes

For example, of commands sent to the scene’s display list directly, consider the following small script. Each of the commands is explained in detail later in the chapter.

```plaintext
scene = Scene Box( 400, 400 ); // make a scene box
New Window( "Example 1", scene ); // put the scene in a window
scene << Perspective( 45, 3, 7 ); // define the camera
scene << Translate( 0.0, 0.0, -4.5 ); // move to (0,0,-4.5) to draw
scene << Color( 1, 0, 0 ); // set the RGB color of the text
scene << Text( center, baseline, 0.2, "Hello, World." ); // add text
scene << Update; // update the scene
```

The first two lines create a scene and place it in a window. The Perspective command defines the viewing angle and field depth. By sending it as a message to the scene, it is immediately added to the scene’s display list. Because the “Hello World” text is drawn at the origin (0, 0, 0), the Translate command is added to the display list. This command moves the camera back a bit so that the origin is in the field of vision. The color is set to red with the Color command, the text is drawn, and the Update command causes the scene to be rendered (in other words, causes the display list that contains the commands to be drawn.)
Figure 13.3 Hello World

Equivalently, the commands to construct the display can be accumulated in a display list stored in a global variable, which is then sent to the scene all at once. To define a global variable as a display list, assign it using the `Scene Display List` function. For example, to use the global `greeting` as a display list, issue the command

```javascript
    greeting = Scene Display List();
```

Display commands can then be sent as messages to `greeting`. An equivalent “Hello World” example using a display list follows.

```javascript
    greeting = Scene Display List();
greeting << Color( 1, 0, 0 ); // set the RGB color of the text
greeting << Text( center, baseline, 0.2, "Hello, World." ); // add text

    // draw the window and send it the stored display list
    scene = Scene Box( 400, 400 ); // make a scene box
    New Window( "Example 1", scene ); // put the scene in a window
    scene << Perspective( 45, 3, 7 ); // define the camera
    scene << Translate( 0.0, 0.0, -4.5 ); // move to (0,0,-4.5) to draw
    scene << Call List( greeting ); // send the display list to the scene
    scene << Update; // update the scene
```

Note which commands were separated into the display list, and which were applied to the scene directly. Those that manipulate the camera (`Translate` and `Rotate`) are applied to the scene. Those that define the object (`Color` and `Text`) were relegated to the display list. This is done so that the display list can be called many times to replicate the object at different positions.
Setting the Viewing Space

3-D scenes can be rendered in two ways. Orthographic projections place the elements in a box, where coordinates are not changed to accommodate the perspective of the viewer. Perspective projections modify the display to simulate the position of the elements in relation to the position of the viewer. For example, two parallel lines (like railroad tracks) stay parallel in orthographic projections, but seem to connect at a distance in perspective projections.

Figure 13.4 Parallel Lines in an Orthographic Projection (left) and a Perspective Projection (right)

As another example, imagine looking at a tube edge-on (like a telescope). In an orthographic projection, the tube would appear as a thin circle. In a perspective projection, the circle would have a thickness; the hole at the far end of the tube would appear smaller than the close hole, and the interior of the tube is visible.

Therefore, the viewable space of an orthographic projection is a rectangular shape. That of a perspective projection is the frustum of a pyramid (that is, a pyramid whose top has been sliced off).
In general, perspective projections give a more realistic view of the world, since it mimics the way an eye or a camera sees. Orthographic projections are important when it is essential to preserve dimensions, such as an architectural CAD program.

**Setting Up a Perspective Scene**

To set up a perspective scene in JSL, send the `Perspective` command to a display list.

```
Perspective (angle, near, far)
```

where `angle` is the viewing angle, `near` is the distance to the near plane, and `far` is the distance to the far plane, as illustrated in the drawing above. A couple of things need to be remembered when defining the viewing space.

- Items outside the viewing space (for example, closer than the `near` plane or farther than the `far` plane) are not drawn. They are clipped off.
- The ratio of `far` to `near` needs to be small. This enables the rendering engine to effectively determine which items should be drawn “on top of” other items, simulating closeness of items. The `near` argument must be greater than zero.
The “Hello World” example contains the line

```plaintext
    scene << Perspective( 45, 3, 7 ); // define the camera
```
This defines a 45-degree viewing angle, with a near plane 3 units from the viewer and a far plane 7 units from the viewer.

The viewing angle functions in the same way as a wide angle or telephoto lens on a camera. Small viewing angles zoom into a drawing; wide angles zoom out. In other words, a small viewing angle maps the screen space onto a small portion of the scene, resulting in apparently larger scene elements. A large viewing angle maps the screen space onto a large portion of the scene, resulting in apparently small screen elements. The size of scene elements can therefore be manipulated using the `angle` argument of the `Perspective` function. The picture here shows the hello world script with perspective angles of 45 and 90 degrees.

**Figure 13.6** Changing the Perspective

```
Hello, World.
```

```plaintext
    scene << Perspective( 90, 3, 7 );
```

As an alternative to the `Perspective` command, you can define the actual viewing frustum with the `Frustum` command.

```plaintext
    Frustum(left, right, bottom, top, near, far);
```

The frustum's viewing volume is defined by `(left, bottom, near)` and `(right, top, near)`, which specify the `(x, y, z)` coordinates of the lower left and upper right corners of the near clipping plane; `near` and `far` give the distances from the viewpoint to the near and far clipping planes.

**Setting up an Orthographic Scene**

Orthographic scenes are specified in ways similar to perspective scenes. Issue the command

```plaintext
    Ortho(left, right, bottom, top, near, far)
```
which specifies the four corners of the near plane, the distance to the near plane, and the
distance to the far plane.

If you are dealing with a simple 2-D environment, you can set up a two-dimensional
orthographic scene with the command

    Ortho2D (left, right, bottom, top)

which specifies the corners of the two-dimensional view.

---

**Changing the View**

One of the advantages of creating a 3-D scene is the ease that they can be viewed from
different angles and positions. The *Translate* and *Rotate* commands let you set the position
from which you view the scene.

In addition, you can use the *ArcBall* command to enable the user to change the viewing angle
interactively.

**The Translate Command**

You have actually seen the *Translate* command in earlier sample scripts. It sets the position
from which the scene is viewed. The arguments give the amount to move from the current
position in the \(x\), \(y\), and \(z\) direction.

    Translate (x, y, z)

For example,

    Translate( 0.0, 0.0, -2 );

moves the origin two units in the negative \(z\) direction.

Initially, the origin and camera were at the same place. Now, the camera can see the origin
because the camera faces down the negative \(z\) axis.

**The Rotate Command**

The *Rotate* command is used to modify the viewing angle of a scene. It has the following
format.

    Rotate (degrees, xAxis, yAxis, zAxis)

This rotates by degrees around the axis described by the vector \((xAxis, yAxis, zAxis)\). For
example, to rotate a model 90 degrees about the \(x\)-axis, use *Rotate* (90, 1, 0, 0).
You can also specify the three axis values in a matrix. For example, \texttt{Rotate( 90, [1, 0, 0] )}.

\textbf{Note:} The \texttt{Rotate} command uses degrees, in contrast to JMP’s trigonometric functions, which use radians.

\texttt{Translate} and \texttt{Rotate} are also used to position objects with respect to each other. The first \texttt{Translate} or \texttt{Rotate} can be thought of as positioning everything that follows with respect to the camera. Subsequent \texttt{Translate} and \texttt{Rotate} commands are used to position objects, such as spheres, cylinders, disks, and display lists in \texttt{Call List} and \texttt{ArcBall} commands. For example, suppose you have a display list named \texttt{table} and another named \texttt{chair}. Your scene might look like this:

\textbf{Figure 13.7 Using Translate and Rotate}

\begin{verbatim}
scene << Perspective(...); \{ Set up scene
scene << Look At (...);

scene << Call List (table); \} Draw table

scene << Translate(...);
scene << Rotate(...)
scene << Call List (chair);

scene << Translate(...);
scene << Rotate(...);
scene << Call List (chair);

scene << Translate(...);
scene << Rotate(...);
scene << Call List (chair);
\}
\end{verbatim}

The following example uses the \texttt{Rotate} command inside a \texttt{For} loop to continuously change the viewing angle of a scene. It draws a cylinder that swings around a central point. This central point is shown by a small sphere.

\begin{verbatim}
scene = \texttt{Scene Box( 600, 600 ); // make a scene box...holds an OpenGL scene.}

\texttt{New Window( "Example 1", scene ); // put the scene in a window}

\texttt{For( i = 1, i < 360, i++,}
\texttt{\}
\texttt{scene << Clear;}
\texttt{\}
\texttt{// the lens is 50 degrees, near is 1 units from the camera, far is 10.}
\texttt{scene << Perspective( 50, 1, 10 );}
\texttt{scene << Translate( 0.0, 0.0, -2 );}
\texttt{scene << Rotate( i, 1, 0, 0 );}
\texttt{scene << Rotate( i * 3, 0, 1, 0 );}
\texttt{scene << Rotate( i * 3 / 2, 0, 0, 1 );}
\end{verbatim}
```plaintext
scene << Color( 0, 1, 0 ); // green for cylinder
scene << Cylinder( 0.5, 0.5, 0.5, 40, 10 );
scene << Color( 0, 0, 0 ); // black for sphere
scene << Sphere( 0.01, 10, 5 );
scene << Update;
Wait( 0.01 );
```

Figure 13.8 Rotating a Cylinder

Note the use of the `Update` command at the end of the scene messages. This command tells JMP to make the displayed screen agree with the current state of the display list. It is important to clear the list at the beginning (so that the list does not contain the old angles as well as the current) and update the scene after each change.

The Look At Command

The `Look At` command is an alternative way to set the camera view.

```
Look At( eyeX, eyeY, eyeZ, centerX, centerY, centerZ, upX, upY, upZ )
```

The Look At command puts the camera at the `eye` coordinates and points it toward the `center` coordinates. The `up` vector describes how the camera is rotated on its line of sight. The model is typically constructed at the origin. Therefore, a JMP scene should have either a Look At or a `Translate` command near its beginning to move the camera away from the origin.
First, clear the scene box of any commands from the previous frame.

\[
\text{scene} \leftarrow \text{Clear};
\]

Then use one of these projections:

\[
\text{scene} \leftarrow \text{Perspective}(45, 2, 10);
\]
\[
\text{scene} \leftarrow \text{Frustum}(-.5, .5, -.5, .5, 1, 10);
\]
\[
\text{scene} \leftarrow \text{Ortho}(-2, 2, -2, 2, 1, 10);
\]
\[
\text{scene} \leftarrow \text{Ortho2d}(-2, 2, -2, 2);
\]

**Note:** If you use the `orth2d` projection, you should not also set the camera position using either `Translate` or `Look At`.

Finally, use either `Translate` or `Look At` to set the camera position:

\[
\text{scene} \leftarrow \text{Translate}(0.0, 0.0, -4.5);
\]
\[
/* \text{the camera faces down the negative Z axis.} \\
\text{move it back so that 0,0,0 is in view. */} \\
\text{scene} \leftarrow \text{Look At}(/\text{eye*/ } 3,3,3, /\text{center*/ } 0,0,0, /\text{up*/ } 1,0,0); \\
/*\text{this is much easier. */}
\]

Once the scene and camera position are set, add your model.

**The ArcBall**

Sometimes you want a scene to rotate based on the movements of the mouse. The Surface Plot platform in JMP is an example of a 3-D scene that rotates based on mouse movements.

An *ArcBall* creates a sphere around the 3-D scene and enables the user to click the sphere’s surface and drag it around, thus causing the scene to rotate.

Use an ArcBall instead of a `Call List` command to place the scene in an ArcBall. Scenes that are attached to an ArcBall automatically respond to clicks and drags of the mouse. Custom programming is not needed. However, rotations made in the arcball are not saved. (Technically, the ArcBall is surrounded by an implicit `Push Matrix` and `Pop Matrix` block, so the movements are gone after it returns. See “Using the Matrix Stack” on page 748 for more information about pushing and popping.)

For example, examine the script from “Primitives Example” on page 738. Change the single line

\[
\text{scene} \leftarrow \text{CallList(shape); \ // send the display list to the scene}
\]

so that it reads

\[
\text{scene} \leftarrow \text{ArcBall(shape,2); \ // send the display list to an arcball}
\]
This displays the script with an associated arcball with diameter 2. When you run the script and the window appears, right-click and select **Show ArcBall > Always** from the menu that appears.

**Note:** ArcBall comes from an article by Shoemake (1994) found in *Graphics Gems IV*, published by Academic Press.

This sets the display so that the ArcBall is always showing. Click and drag on the ArcBall to rotate the scene. The right-click menu with Background Color, Use Hardware Acceleration, and Show ArcBall is always available, whether the scene is displayed through a platform, in a journal, or through JSL.

**Note:** The ArcBall does not have to be showing to react to mouse commands. It is shown here for display purposes only.

You can also set the display state of the ArcBall in JSL using the `Show ArcBall` command.

```
scene << Show Arcball(state)
```

where `state` is *During Drag*, *Always*, or *Never*.

**Figure 13.9** Showing the Arc Ball

---

**Graphics Primitives**

All scenes in JSL are built with a small number of graphics primitives. These fundamental elements function as the building blocks for complicated scenes.

Every graphics primitive involves specifying vertices. In some cases, the vertices are simply drawn as points. In others, the vertices are connected to form polygons. To draw a primitive, you must specify the type of primitive and the coordinates and properties of the vertices involved. In JSL, this specification is accomplished through the `Begin` and `End` statements.
scene<<Begin(primitive type);
...(commands specifying vertices and their properties)...
scene<<End();

To specify the coordinates of the vertices, use the `vertex` command.

scene<<Begin(primitive type);
scene<<Vertex(x, y, z);
...
scene<<End();

The options for `primitive type` are the following. In these examples, assume that \( v_0 \), \( v_1 \), and so on, have been specified between a `Begin` and `End` pair, similar to the following.

scene<<Begin(primitive type);
scene<<Vertex(x_0,y_0,z_0) // specify vertex \( v_0 \)
scene<<Vertex(x_1,y_1,z_1) // specify vertex \( v_1 \)
...
scene<<Vertex(x_n,y_n,z_n) // specify vertex \( v_n \)
scene<<End();

### Table 13.1 Primitive Types

<table>
<thead>
<tr>
<th><strong>primitive type</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>POINTS</code></td>
<td>Draws a point at each of the vertices.</td>
</tr>
<tr>
<td><code>LINES</code></td>
<td>Draws a series of (unconnected) line segments. Segments are drawn between ( v_0 ) and ( v_1 ), between ( v_2 ) and ( v_3 ), and so on. If ( n ) is odd, the last vertex is ignored.</td>
</tr>
<tr>
<td><code>POLYGON</code></td>
<td>Draws a polygon using the points ( v_0,...,v_n ) as vertices. Three vertices must exist, or nothing is drawn. In addition, the polygon specified must not intersect itself and must be convex. If the vertices do not satisfy these conditions, the results are unpredictable.</td>
</tr>
</tbody>
</table>
### Table 13.1 Primitive Types  (Continued)

<table>
<thead>
<tr>
<th>primitive type=TRIANGLES</th>
<th>Draws a series of (disconnected) triangles using vertices v0, v1, v2, then v3, v4, v5, and so on. If the number of vertices is not an exact multiple of 3, the final one or two vertices are ignored.</th>
</tr>
</thead>
<tbody>
<tr>
<td>primitive type=LINE_STRIP</td>
<td>Draws a line segment from v0 to v1, then from v1 to v2, and so on. Therefore, n vertices specify n–1 line segments. Nothing is drawn unless there is more than one vertex. There are no restrictions on the vertices describing a line strip; the lines can intersect arbitrarily.</td>
</tr>
<tr>
<td>primitive type=LINE_LOOP</td>
<td>Same as LINE_STRIP, except that a final line segment is drawn from the last vertex to the first, completing a loop.</td>
</tr>
<tr>
<td>primitive type=QUADS</td>
<td>Draws a series of quadrilaterals (four-sided polygons) using vertices v0, v1, v2, v3, then v4, v5, v6, v7, and so on. If the number of vertices is not a multiple of 4, the final one, two, or three vertices are ignored.</td>
</tr>
<tr>
<td>primitive type=QUAD_STRIP</td>
<td>Draws a series of quadrilaterals (four-sided polygons) beginning with v0, v1, v3, v2, then v2, v3, v5, v4, then v4, v5, v7, v6, and so on. The number of vertices must be at least 4 before anything is drawn, and if odd, the final vertex is ignored.</td>
</tr>
</tbody>
</table>
Primitives Example

The following short example illustrates the use of a graphics primitive.

```plaintext
shape = Scene Display List(); // create a display list and send it commands
shape << Color( 1, 0, 0 ); // set the RGB color of the text
shape << Begin( POLYGON );
shape << Vertex( 0, 0, 0 );
shape << Vertex( 0, 3, 0 );
shape << Vertex( 3, 3, 0 );
shape << Vertex( 5, 2, 0 );
shape << Vertex( 4, 0, 0 );
shape << Vertex( 2, -1, 0 );
shape << End();

// draw the window and send it the stored display list
scene = Scene Box( 400, 400 ); // make a scene box
New Window( "Primitive", scene ); // put the scene in a window
scene << Perspective( 90, 3, 7 ); // define the camera
scene << Translate( 0.0, 0.0, -5 ); // move to (0,0,-5) to draw
scene << Call List( shape ); // send the display list to the scene
scene << Update; // update the scene
```
The first section of the script creates a display list named `shape`. Inside this display list, a polygon is defined using six vertices.

The second section of the script creates a scene box and a new window. It then uses the `Call List` message to put the list in the display.

Note that all the z-coordinates are zero, which makes sure the polygon lies in a plane. Polygons that do not lie in a plane can cause unpredictable results.

Experiment with the line

```javascript
shape <<Begin(POLYGON);
```

by changing it to some of the other primitive types. For example, changing it to

```javascript
shape <<Begin(TRIANGLES);
```

results in a different picture.

**Figure 13.10** Polygon (left) and Triangles (right)

---

**Controlling the Appearance of Primitives**

JSL has several commands that let you tailor-make the appearance of primitive drawing objects. You can also specify the widths of lines and their stippling pattern (that is, whether they are dashed, dotted, and so on.)

**Size and Width**

To set the point size of rendered objects, use the `Point Size` command.

```javascript
Point Size( n )
```

where `n` is the number of pixels. Note that this might not be the actual number of pixels rendered, depending on other settings such as anti-aliasing and your hardware configuration.

Set the line width using the `Line Width` command

```javascript
Line Width( n )
```
where \( n \) is the number of pixels. The argument \( n \) must be larger than zero and is, by default, one.

**Stippling Pattern**

To make stippled lines, use the `Line Stipple` command.

```plaintext
Line Stipple( factor, pattern )
```

*Factor* is a stretching factor. *Pattern* is a 16-bit integer that turns pixels on or off. Use `Enable(LINE_STIPPLE)` to turn the effect on.

To construct a line stippling pattern, write a 16-bit binary number that represents the stippling pattern that you desire. Note that the pattern should read from right to left, so your representation might seem backward to the way it is rendered. Convert the binary number to an integer and use this as the *pattern* argument.

For example, imagine you want the dotted line pattern 0000000011111111. This is equal to 255 in decimal notation, so use the command `Line Stipple(1, 255)`.

The *factor* argument expands each binary digit to two digits. In the example above, `Line Stipple(2, 255)` would result in 00000000000000001111111111111111.

For example, the following script draws three lines, each of different widths (the `Line Width` commands) and stippling patterns.

```plaintext
scene = Scene Box( 200, 200 ); // make a scene box...holds an OpenGL scene
New Window( "Stipples", scene ); // put the scene in a window
scene << Ortho( -2, 2, -2, 2, -1, 1 );
scene << Color( 0, 0, 0 ); // set the RGB color of the text

scene << Enable( LINE_STIPPLE );
scene << Line Width( 2 );
scene << Line Stipple( 1, 255 );

scene << Begin( LINES );
scene << Vertex( -2, -1, 0 );
scene << Vertex( 2, -1, 0 );
scene << End();

scene << Line Width( 4 );
scene << Line Stipple( 1, 32767 );

scene << Begin( LINES );
scene << Vertex( -2, 0, 0 );
scene << Vertex( 2, 0, 0 );
scene << End();
```
scene << Line Width( 6 );
scene << Line Stipple( 3, 51 );

scene << Begin( LINES );
scene << Vertex( -2, 1, 0 );
scene << Vertex( 2, 1, 0 );
scene << End();
scene << Update;

Figure 13.11 Stipples

Note: Stipple patterns “crawl” on rotating models because they are in screen pixels, not model units. Lines in the model change length on the screen even though nothing changes in model units.

Fill Pattern

Polygons are rendered with both a front and a back, and the drawing mode of each side is customizable. This enables the user to see the difference between the back and front of the polygon.

To set the drawing mode of a polygon, use the Polygon Mode command.

    Polygon Mode( face, mode )

where face can be FRONT, BACK, or FRONT_AND_BACK, and mode can be POINT, LINE, or FILL.
For example, the following script creates a display list that defines a triangle. This display list is used three times in conjunction with `Translate`, `Rotate`, and `Color` commands to draw triangles in three positions. In addition, the `Polygon Mode` command changes the drawing mode of each triangle. Note there is no explicit call to the FILL mode, since it is the default.

The following table dissects the script, showing how the `Translate` and `Rotate` commands accumulate to manipulate a single display list.

**Table 13.2 Translate and Rotate Commands**

<table>
<thead>
<tr>
<th>Code from above script</th>

<td></td>
</tr>
</tbody>
</table>

// update the scene to see the triangle

scene << Update;

And then translate it.
Some developers use the fill mode in concert with the line mode to draw a filled polygon with a differently colored border. However, due to the way the figures are rendered, they sometimes do not line up correctly. The Polygon Offset command is used to correct for this so-called “stitching” problem.

PolyOffset (factor, units)

To enable offsetting, use Enable(POLYGON_OFFSET_FILL), Enable(POLYGON_OFFSET_LINE), or Enable(POLYGON_OFFSET_POINT), depending on the desired mode. The actual offset values are calculated as \( m \times (\text{factor}) + r \times (\text{units}) \). \( m \) is the maximum depth slope of the polygon and \( r \) is the smallest value guaranteed to produce a resolvable difference in window coordinate depth values. Start with PolyOffset(1,1) if you need this.

An example of PolyOffset is in the Surface Plot platform, when a surface and a mesh are displayed on top of each other, or a surface and contours displayed on top of each other. In either case, the surface would interfere with the lines if the lines were not moved closer or the surface moved farther from the viewer.
Other Uses of Begin and End

Although vertices are typically specified between begin and end statements, there are other commands that are valid. These commands are discussed in other sections of this chapter.

- **Vertex** adds a vertex to the list
- **Color** changes the current color
- **Normal** sets the normal vector coordinates
- **Edge Flag** controls drawing of edges
- **Material** sets material properties
- **Eval Coord** and **Eval Point** generate coordinates
- **Call List** executes a display list.

Drawing Spheres, Cylinders, and Disks

There are several pre-defined commands that allow for quick rendering of spheres, cylinders, and disks. The advantage of these commands is not only their ease-of-use, but that they have special lighting properties (their “normals”) built in.

Construction

The following commands are used to construct cylinders, disks, partial disks, and spheres.

**Cylinders**

```
Cylinder( baseRadius, topRadius, height, slices, stacks )
```

- **baseRadius** is the radius of the cylinder’s base. Similarly, **topRadius** is the radius of the top.
- **height** is the height of the cylinder.

**Slices** can be 10 for a reasonably accurate cylindrical shape. Using **QuadricNormals(Smooth)** helps the appearance.

**Stacks** sets the number of vertices available for lighting reflections. Use a larger value for **Stacks** for accurate “hot-spots”.

**Disks**

The following command draws a paper-thin disk with an **innerRadius** hole in the middle.

```
Disk( innerRadius, outerRadius, slices, loops )
```
Like Cylinder, \textit{slices} controls the accuracy of the curve and \textit{loops} makes more vertices (for lighting accuracy).

\textbf{Partial Disk(} \textit{innerRadius, outerRadius, slices, loops, startAngle, sweepAngle }\textbf{)}

The \texttt{Partial Disk} command works like \texttt{Disk}, but with a slice of the disk removed. Specify the part of the disk that is showing using \textit{startAngle} and \textit{sweepAngle}.

\section{Spheres}

The following command draws a sphere with the specified \textit{radius}.

\texttt{Sphere( radius, slices, stacks )}

The \textit{slices} can be thought of as longitudes and \textit{stacks} as latitudes. About 10 of each make a nicely drawn sphere.

\section{Lighting}

It is not necessary to make specific calculations of normal vectors (as is the case for customized surfaces) for spheres, disks, and cylinders. However, you can use the following commands to customize the automatic lighting.

\texttt{Quadric Normals(} \textit{mode} \texttt{)} tells what type of normal should be automatically generated. The argument \textit{mode} can be \texttt{None}, \texttt{Flat}, or \texttt{Smooth}. \texttt{Flat} makes faceted surfaces. \texttt{Smooth} makes the normals at each vertex be the average of the adjacent polygons.

\texttt{Quadric Orientation(} \textit{mode} \texttt{)} determines which way the normals point. The argument \textit{mode} can be \texttt{Inside} or \texttt{Outside}.

\texttt{Quadric Draw Style(} \textit{mode} \texttt{)} specifies the drawing mode. The argument \textit{mode} can be \texttt{Fill}, \texttt{Line}, \texttt{Silhouette}, or \texttt{Point}.

\texttt{JMP} uses the values that you set for \texttt{Quadric Normals, Quadric Orientation, and Quadric Draw Style} for subsequently generated cylinders, disks, and spheres.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{draw_styles.png}
\caption{Draw Styles}
\end{figure}
Note: Other OpenGL documentation refers to quadric objects. JMP has only one and always uses it.

Drawing Text

As shown in the “Hello World” example above, text is added to a scene using the Text command.

\[
\text{Text( \text{horz, vert, size, string, <billboard>} )}
\]

- \text{horz} can be Left, Center, or Right justification.
- \text{vert} can be Top, Middle, Baseline, or Bottom justification.
- \text{size} represents the height of a capital letter M in model coordinates.
- \text{string} is the text to draw.
- \text{billboard} is an optional argument that causes the text to rotate with the model. Text with this option always faces the viewer.

The font is always the JMP Text font. You can change the text font from the preferences menu, but because of the way JMP caches fonts for scenes, changes might not take effect until JMP is restarted.

Note: Text is not part of the standard OpenGL definition.

Using Text with Rotate and Translate

The following example uses the text command in conjunction with the Translate and Rotate commands.

```plaintext
scene = Scene Box( 600, 600 ); // make a scene box...holds an OpenGL scene New Window( "Example 2", scene ); // put the scene in a window

// the "lens" is 45 degrees, near is 3 units from the camera, far is 7
scene << Perspective( 45, 3, 7 );

// move the world so that 0,0,0 is visible in the camera
scene << Translate( 0.0, 0.0, -4.5 );

// rotate the first text about the Y (vertical on screen) axis
scene << Rotate( 30, 0, 1, 0 );
scene << Color( 1, 0, 2 ); // magenta
scene << Text( "center", "baseline", .2, "Top magenta string" );
```

Three-Dimensional Scenes
Using the Matrix Stack

Figure 13.14 Rotating and Translating Text Strings

Note that the aqua blue string extends backward beyond the far clipping plane. Change the 7 to 10 in the Perspective command to see the complete string.

Using the Matrix Stack

JMP 3-D scenes use a matrix stack to keep track of the current transform. The stack is initialized to the identity matrix, and each time a translate, rotate, or scale command is given, the top matrix on the stack is changed.

Note: Unlike many OpenGL implementations, JMP does not use a transposed matrix.

The JSL example below uses Push Matrix and Pop Matrix to position pieces of the toy top and then return to the origin. This is faster than using the Translate command a second time in reverse.
Figure 13.15 Drawing With a Matrix Stack

toyTop = Scene Display List();
toyTop << Push Matrix;
toyTop << Translate( 0, 0, .1 );
toyTop << Color( 1, 0, 0 ); // red

// baseRadius, topRadius, height, slices, stacks
toyTop << Cylinder( 1, .2, .2, 25, 5 );
toyTop << Pop Matrix;
toyTop << Push Matrix;
toyTop << Translate( 0, 0, -.1 );
toyTop << Rotate( 180, 1, 0, 0 );
toyTop << Color( 0, 1, 0 ); // green
toyTop << Cylinder( 1, .2, .2, 25, 5 );
toyTop << Pop Matrix;

toyTop << Color( 0, 0, 1 ); // blue
toyTop << Sphere( .5, 30, 30 ); // radius, slices, stacks

toyTop << Color( 1, 1, 0 ); // yellow

// innerRadius, outerRadius, slices, rings, startAngle, sweepAngle
toyTop << Partial Disk( 1, 1.2, 25, 2, 0, 270 );

toyTop << Push Matrix;
toyTop << Translate( 0, 0, -.1 );
toyTop << Color( 1, 0, 1 ); // magenta
toyTop << Cylinder( 1, 1, .2, 25, 3 );

// baseRadius, topRadius, height, slices, stacks
toyTop << Pop Matrix;
toyTop << Push Matrix;
toyTop << Rotate( 90, 1, 0, 0 );
toyTop << Translate( 0, .5, 0 );
toyTop << Color( 0, 1, 1 ); // cyan
toyTop << Text( "center", "baseline", .2, "Toy Top" );
toyTop << Pop Matrix;

scene = Scene Box( 600, 600 ); // make a scene box...holds an OpenGL scene

New Window( "Example 3", scene ); // put the scene in a window
scene << Perspective( 45, 3, 7 );
scene << Translate( 0.0, 0.0, -4.5 );
scene << Rotate( -85, 1, 0, 0 );
scene << Rotate( 65, 0, 0, 1 );
scene << Call List( toyTop );

scene << Update; // update the display box

There are some cases where you want to replace the current matrix on the stack. For these cases, use the Load Matrix command.

Load Matrix(m)

where \( m \) is a 4x4 JMP matrix that is loaded onto the current matrix stack.

Similar is the Mult Matrix command

Mult Matrix(m)

When the Mult Matrix command is issued, the matrix on the top of the current matrix stack is multiplied by \( m \).

The following matrices perform some simple commands.

Translation:

\[
\begin{bmatrix}
1 & 0 & 0 & x \\
0 & 1 & 0 & y \\
0 & 0 & 1 & z \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

In the following rotation matrices, \( c = \cos(\text{angle}) \) and \( s = \sin(\text{angle}) \).

Rotation about X axis:

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & c & -s & 0 \\
0 & s & c & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]
Rotation about Y axis:

\[
\begin{bmatrix}
c & 0 & s & 0 \\
0 & 1 & 0 & 0 \\
-s & 0 & c & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

Rotation about Z axis:

\[
\begin{bmatrix}
c & -s & 0 & 0 \\
s & c & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

For example, here are two equivalent (except for the translation being opposite) ways to translate and rotate a display list.

```c
// first way uses matrix
gl << Push Matrix;
xt = Identity( 4 ); // translate this one left by .75
xt[1, 4] = -.75;
xr = Identity( 4 ); // rotate this one, cos needs radians, not degrees
xr[2, 2] = Cos( 3.14159 * a / 180 );
xr[2, 3] = -Sin( 3.14159 * a / 180 );
xr[3, 2] = Sin( 3.14159 * a / 180 );
xr[3, 3] = Cos( 3.14159 * a / 180 );
yr = Identity( 4 );
yr[1, 1] = Cos( 3.14159 * a / 180 );
yr[1, 3] = Sin( 3.14159 * a / 180 );
yr[3, 1] = -Sin( 3.14159 * a / 180 );
yr[3, 3] = Cos( 3.14159 * a / 180 );
zr = Identity( 4 );
zr[1, 1] = Cos( 3.14159 * a / 180 );
zr[1, 2] = -Sin( 3.14159 * a / 180 );
zr[2, 1] = Sin( 3.14159 * a / 180 );
zr[2, 2] = Cos( 3.14159 * a / 180 );

// order of multiplication matters with matrices
gl << Mult Matrix( xt * xr * yr * zr );
gl << Arcball( dl, 1 );
gl << Pop Matrix;

// second way uses functions
gl << Push Matrix;
gl << Translate( .75, 0, 0 ); // translate this one right by .75
gl << Rotate( a, 1, 0, 0 ); // rotate this one in degrees
gl << Rotate( a, 0, 1, 0 ); // order of operations also matters here
gl << Rotate( a, 0, 0, 1 );
```
It is not possible to read back the current transform matrix, because the matrix exists only while the display list is drawing, not while your JSL script is creating it. If you must know its content, create it in JSL and use `Load Matrix` to put it on the stack.

---

## Lighting and Normals

The following methods enable you to add lighting, materials, and normal vectors to your shapes. Using these methods, models can appear shiny or light-absorbing.

- “Creating Light Sources”
- “Lighting Models”
- “Normal Vectors”
- “Shading Model”
- “Material Properties”
- “Alpha Blending”
- “Fog”
- “Example”

### Creating Light Sources

Light sources are specifications of a color, position, and direction. JSL allows for up to eight lights (numbered 0 to 7) defined by the `Light` command, where $n$ is the number of the light.

```
Light( n, argument, value, ... value )
```

**Note:** To turn each light on, issue an `Enable(Lighting)` and an `Enable(lightn)` command, where $n$ is the light number. Then, move the light to a position in the scene with a `Light(n, POSITION, x, y, z)` command.

The value of `argument` can be any one of those shown in Table 13.3. The table shows default values for each argument.
Table 13.3 Light Arguments and Default Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMBIENT</td>
<td>(0, 0, 0, 1)</td>
<td>Ambient RGBA intensity</td>
</tr>
<tr>
<td>DIFFUSE</td>
<td>(1, 1, 1, 1)</td>
<td>diffuse RGBA intensity</td>
</tr>
<tr>
<td>SPECULAR</td>
<td>(1, 1, 1, 1)</td>
<td>specular RGBA intensity</td>
</tr>
<tr>
<td>POSITION</td>
<td>(0, 0, 1, 0)</td>
<td>(x, y, z, w) position</td>
</tr>
<tr>
<td>SPOT_DIRECTION</td>
<td>(0, 0, -1)</td>
<td>(x, y, z) direction of spotlight</td>
</tr>
<tr>
<td>SPOT_EXPONENT</td>
<td>0</td>
<td>spotlight exponent</td>
</tr>
<tr>
<td>SPOT_CUTOFF</td>
<td>180</td>
<td>spotlight cutoff angle</td>
</tr>
<tr>
<td>CONSTANT_ATTENUATION</td>
<td>1</td>
<td>constant attenuation factor</td>
</tr>
<tr>
<td>LINEAR_ATTENUATION</td>
<td>0</td>
<td>linear attenuation factor</td>
</tr>
<tr>
<td>QUADRATIC_ATTENUATION</td>
<td>0</td>
<td>quadratic attenuation factor</td>
</tr>
</tbody>
</table>

**Note:** The default values for DIFFUSE and SPECULAR in this table apply only to Light 0. For other lights, the default value is (0, 0, 0, 1) for both arguments.

The first three arguments (AMBIENT, DIFFUSE, and SPECULAR) are used to color the light. DIFFUSE is the argument that is most closely associated with the physical color of the light. AMBIENT refers to the property of the light when it functions as a background light. SPECULAR alters the way a light is reflected off a surface.

Specify the position of the light using the POSITION argument. Nonzero values of the fourth (w) coordinate position the light in homogenous object coordinates.

Light in the real-world decreases in intensity as distance from the light increases. Since a directional light is infinitely far away, it does not make sense to attenuate its intensity as a function of distance. However, JSL attenuates a light source by multiplying the contribution of the source by an attenuation factor

\[
\text{attenuation factor} = \frac{1}{c + ld + qd^2}
\]

where \(c = \text{CONSTANT ATTENUATION}, l = \text{LINEAR ATTENUATION}, \) and \(q = \text{QUADRATIC ATTENUATION}.\)
To create a spotlight, limit the shape of the light to a cone. Use the `SPOT_CUTOFF` argument to define the side of the cone, as shown in the following illustration.

**Figure 13.16** Spotlight

In addition to the cutoff angle, you can control the intensity and direction of the light distribution in the cone. `SPOT_DIRECTION` specifies the direction for the spotlight to point; `SPOT_EXPONENT` influences how concentrated the light is.

### Lighting Models

Lighting models are specified with the `Light Model` command.

```
Light Model( argument, value,...,value )
```

Light models specify three attributes of lights.

- The global ambient light intensity
- Whether the viewpoint is local or is an infinite distance away
- Whether lighting calculations should be performed differently for the front and back faces of objects.

Table 13.3 on page 753 shows the three valid arguments for the `Light Model` command.

### Table 13.4 Light Model Arguments and Default Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIGHT_MODEL_AMBIENT</td>
<td>(0.2, 0.2, 0.2, 1)</td>
<td>Ambient RGBA intensity of the entire scene</td>
</tr>
<tr>
<td>LIGHT_MODEL_LOCAL_VIEWER</td>
<td>0 (false)</td>
<td>how specular reflection angles are computed</td>
</tr>
<tr>
<td>LIGHT_MODEL_TWO_SIDE</td>
<td>0 (false)</td>
<td>nonzero values imply two-sided lighting</td>
</tr>
</tbody>
</table>
Normal Vectors

Normal vectors point in a direction perpendicular to a surface. For a plane, all normals are the same. For a more complicated surface, normals are more complicated. JSL enables you to specify the normal vector for each vertex. These normals specify the orientation of the surface in space, necessary for lighting calculations. Accurate normals assure accurate lighting.

The normal vector is of length 1 and is perpendicular to the vertex. Typically, a vertex is shared between several polygons. A smooth shaded effect is desired, so the perpendicular at the vertex is calculated as a (possibly weighted) average of the polygon’s normals. It is important to calculate the “outward” normal for polygons unless two-sided shading is enabled because only the outer face of the polygon is illuminated. With a scaled polygon, the normal’s length is not 1 after scaling, and the lighting is wrong.

Normal vectors are set at the same time the surface is constructed, and are specified with the Normal command. Use the Enable(NORMALIZE) command to have the normals re-normalized to 1 each time the scene is drawn.

Shading Model

The shading model of a polygon is set using the Shade Model command.

Shade Model (mode)

where mode can be SMOOTH (the default) or FLAT. SMOOTH shading interpolates the colors of the primitive from one vertex to the next. FLAT mode duplicates the color of one vertex across the entire primitive.

The following script changes the color at each of a triangle’s vertices. The FILL shade model interpolates the color of the interior automatically.

```jscript
scene = Scene Box( 200, 200 ); // make a scene box...holds an OpenGL scene.

New Window( "Shade Model", scene ); // put the scene in a window
scene << Clear;
scene << Ortho2D( -1, 1, -1, 1 );

scene << Shade Model( SMOOTH );
scene << Polygon Mode( FRONT_AND_BACK, FILL );
scene << Begin( TRIANGLES );
scene << Color( 0, 0, 0 ); // black
scene << Vertex( -1, -1, 0 );
scene << Color( 0, 1, 1 ); // cyan
scene << Vertex( 0, 1, 0 );
scene << Color( 1, 1, 1 ); // white
scene << Vertex( 1, -1, 0 );
scene << End();
```
Material Properties

To set the material properties of a surface, use the \texttt{Material} command.

\begin{verbatim}
Material( face, argument, value,...value )
\end{verbatim}

\texttt{face} can be \texttt{Front}, \texttt{Back}, or \texttt{Front_and_back}. (Note that the material properties can be set separately for the front and back faces of a polygon.)

Table 13.5 shows the arguments and default values for \texttt{Material} arguments.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|p{0.8\textwidth}|}
\hline
\textbf{Argument} & \textbf{Default Value} & \textbf{Meaning} \\
\hline
\texttt{AMBIENT} & (0.2, 0.2, 0.2, 1.0) & Ambient color of material \\
\hline
\texttt{DIFFUSE} & (0.8, 0.8, 0.8, 1.0) & Diffuse color of material \\
\hline
\texttt{AMBIENT_AND_DIFFUSE} & (0.8, 0.8, 0.8, 1.0) & Both AMBIENT and DIFFUSE \\
\hline
\texttt{SPECULAR} & (0.0, 0.0, 0.0, 1.0) & Specular color of material \\
\hline
\texttt{SHININESS} & 0 & Specular exponent that can range from 0 to 128. \\
\hline
\texttt{EMISSION} & (0, 0, 0, 1) & Emissive color of material \\
\hline
\end{tabular}
\end{table}
Alpha Blending

The `BlendFunc` command allows for alpha blending. To use it, send a `BlendFunc` message to a scene, for example:

```javascript
scene << BlendFunc(SRC_ALPHA, ONE_MINUS_SRC_ALPHA)
```

`SRC_ALPHA` and `ONE_MINUS_SRC_ALPHA` are OpenGL constants that tell `BlendFunc` to use alpha to blend against the existing display buffer. Disabling z-buffer testing or rendering primitives from back to front might be needed for some applications. By default, the z-buffer tests prevent anything from drawing behind a transparent polygon after it is drawn.

More information about all the constants available to `BlendFunc` (many of which are not useful to the JSL programmer) are available in the OpenGL documentation at opengl.org.

Fog

Fog enables figures to fade into the distance, making for more realistic models. All types of geometric figures can be fogged. To turn fog on, enable the `FOG` argument.

```javascript
Enable (FOG)
```

Example

The following example uses several of the concepts presented in this section, including lighting, fog, and normalization. It draws a spinning cylinder that is affected by two lights.

```javascript
scene = Scene Box( 300, 300 ); // make a scene box
New Window( "Cylinder", scene ); // put the scene in a window

For( i = 1, i < 360, i++,
    scene << Clear;
    // the lens is 45 degrees, near is 3 units from the camera, far is 7.
    scene << Perspective( 50, 1, 10 );
    // move the world so that 0,0,0 is visible in the camera
    scene << Translate( 0.0, 0.0, -2 );
    scene << Enable( Lighting );
    scene << Enable( Light0 );
    scene << Enable( Light1 );
    scene << Light( Light0, POSITION, 1, 1, 1, 1 ); // near viewer
    scene << Light( Light0, DIFFUSE, 1, 0, 0, 1 ); // red light
    scene << Light( Light1, POSITION, -1, -1, -1, 1 ); // behind object
    scene << Light( Light1, DIFFUSE, .5, .5, 1, 1 ); // blue-gray light
    scene << Enable( Fog );
```
Bézier Curves

A complete discussion of Bézier curves is beyond the scope of the Scripting Guide. JSL has several commands for defining and drawing curves and their associated meshes.

Figure 13.19 Bézier Curve
One-Dimensional Evaluators

To define a one-dimensional map, use the \texttt{Map1} command.

\begin{verbatim}
\texttt{Map1( target, u1, u2, stride, order, matrix )}
\end{verbatim}

The \texttt{target} argument defines what the control points represent. Values of the \texttt{target} argument are shown in Table 13.6. Note that you must use the \texttt{Enable} command to enable the argument.

\textbf{Table 13.6} Map1 Target Arguments and Default Values

<table>
<thead>
<tr>
<th>\textit{target} Argument</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAP1_VERTEX_3</td>
<td>((x, y, z)) vertex coordinates</td>
</tr>
<tr>
<td>MAP1_VERTEX_4</td>
<td>((x, y, z, w)) vertex coordinates</td>
</tr>
<tr>
<td>MAP1_INDEX</td>
<td>color index</td>
</tr>
<tr>
<td>MAP1_COLOR_4</td>
<td>R, G, B, A</td>
</tr>
<tr>
<td>MAP1_NORMAL</td>
<td>normal coordinates</td>
</tr>
<tr>
<td>MAP1_TEXTURE_COORD_1</td>
<td>(s) texture coordinates</td>
</tr>
<tr>
<td>MAP1_TEXTURE_COORD_2</td>
<td>(s, t) texture coordinates</td>
</tr>
<tr>
<td>MAP1_TEXTURE_COORD_3</td>
<td>(s, t, r) texture coordinates</td>
</tr>
<tr>
<td>MAP1_TEXTURE_COORD_4</td>
<td>(s, t, r, q) texture coordinates</td>
</tr>
</tbody>
</table>

The second two arguments (\texttt{u1} and \texttt{u2}) define the range for the map. The \texttt{stride} value is the number of values in each block of storage. In other words, the value is the offset between the beginning of one control point and the beginning of the next control point. The \texttt{order} should equal the degree of the curve plus one. The \texttt{matrix} holds the control points.

For example, \texttt{Map1( MAP1\_VERTEX\_3, 0, 1, 3, 4, <4x3 matrix> )} is typical for setting the two end points and two control points to define a Bézier line.

You use the \texttt{MapGrid1} and \texttt{EvalMesh1} commands to define and apply an evenly spaced mesh.

\begin{verbatim}
\texttt{MapGrid1( un, u1, u2 )}
\end{verbatim}

sets up the mesh with \texttt{un} divisions spanning the range \texttt{u1} to \texttt{u2}. Code is simplified by using the range 0 to 1.

\begin{verbatim}
\texttt{EvalMesh1( mode, i1, i2 )}
\end{verbatim}
actually generates the mesh from \( i_1 \) to \( i_2 \). The \textit{mode} can be either \texttt{POINT} or \texttt{LINE}. The \texttt{EvalMesh1} command makes its own \texttt{Begin} and \texttt{End} clause.

The following example script demonstrates a one-dimensional outlier. A random set of control points draws a smooth curve. Only the first and last points are on the curve. Using \texttt{NPOINTS=4} results in a cubic Bézier spline.

```plaintext
boxwide = 500;
boxhigh = 400;

gridsize = 100; // bigger for finer divisions

/* We suggest you use only values between 2 and 8 (inclusively). Numbers beyond these might be interpreted differently, depending on implementation. This value is the degree+1 of the fitted curve */
NPOINTS = 4;

point = J( NPOINTS, 3, 0 );

// create an array of x,y,z triples
For( x = 1, x <= NPOINTS, x++,
    point[x, 1] = (x - 1) / (NPOINTS - 1) - .5;
    // x from -.5 to +.5
    point[x, 2] = Random Uniform() - .5; // y is random in same range
    // z is always zero, which causes the curve to stay in a plane
    point[x, 3] = 0;
);

spline = Scene Box( boxwide, boxhigh );

// data from -.5 to .5 in x and y; this is a little larger
spline << Ortho( -.6, .6, -.6, .6, -2, 2 );

spline << Enable( MAP1_VERTEX_3 );
spline << MapGrid1( gridsize, 0, 1 );
spline << Color( .2, .2, 1 ); // blue curve

spline << Map1( MAP1_VERTEX_3, 0, 1, 3, NPOINTS, point );
spline << Line Width( 2 ); // not-so-skinny curve
spline << EvalMesh1( LINE, 0, gridsize ); // also try LINE, POINT

spline << Color( .2, 1, .2 );
spline << Point Size( 4 ); // big fat green points

// show the points and label them
For( i = 1, i <= NPOINTS, i++,
```
spline << Begin( "POINTS" );
spline << Vertex( point[i, 1], point[i, 2], point[i, 3] );
spline << End;
spline << Push Matrix;
spline << Translate( point[i, 1], point[i, 2], point[i, 3] );
spline << Text( center, bottom, .05, Char( i ) );
spline << Pop Matrix;
);

New Window( "Spline", spline );

https://www.tinaja.com/glib/bezconn.pdf offers an explanation of connecting cubic segments so that both the slope and the rate of change match at the connection point. This example does not illustrate doing so; there is only one segment here.

Two-Dimensional Evaluators

Two-dimensional evaluators follow their one dimensional counterparts, and are used in a similar way.

Map2(target, u1, u2, ustride, uorder, v1, v2, vstride, vorder, matrix)
Eval Coord2(u, v)

Values for the target argument are the same as those shown in Table 13.6 on page 759 with Map1 replaced with Map2 appropriately. The $u_1$, $u_2$, $v_1$, and $v_2$ values specify the range of the two-dimensional mesh.

For example, Map2(MAP2_VERTEX_3, 0, 1, 3, 4, 0, 1, 12, 4, <16x3 matrix>) is typical for setting the 16 points that define a Bézier surface.

Use the MapGrid2 and EvalMesh2 commands to define and apply an evenly spaced mesh.

MapGrid2(un, u1, u2, vn, v1, v2)
sets up the mesh with un and vn divisions spanning the range $u_1$ to $u_2$ and $v_1$ to $v_2$. Code is simplified by using ranges that span 0 to 1.

EvalMesh2(mode, i1, i2, j1, j2)
actually generates the mesh from $i_1$ to $i_2$ and $j_1$ to $j_2$. The mode can be POINT, LINE, or FILL. The EvalMesh2 command makes its own Begin and End clause.
Using the Mouse

Mouse activity is supported through two feedback functions. The Patch Editor.jsl sample script uses these functions to support the dragging and dropping of points. Part of that script, the call-back function for mouse activity, is explained below. To run the script, open PatchEditor.jsl in the Scene3D folder inside the JMP Sample Scripts folder.

```javascript
// topClick2d function
function topClick2d(x, y, m, k)
{
  dragfunc(x, boxhigh - y, m, 1, 2);
  1;
}

// frontClick2d function
function frontClick2d(x, y, m, k)
{
  dragfunc(x, boxhigh - y, m, 1, 3);
  1;
}

// rightClick2d function
function rightClick2d(x, y, m, k)
{
  dragfunc(x, boxhigh - y, m, 2, 3);
  1;
}

// Click3d function
function Click3d(x, y, m, k, hitlist)
{
  if (m == 1,
      if (N Items(hitlist) > 0,
          CurrentPoint = hitlist[1][3], /* first matrix in the list is the closest; 3rd element of matrix is ID*/
          CurrentPoint = 0
      );
      makePatch();
  );
  0; /* cares only about initial mouse down. return 1 if drag, release is needed, but then arcball does not happen. */
}

// dragfunc function
function dragfunc(x, y, m, ix, iy)
{
  if (CurrentPoint > 0,
      points[CurrentPoint, ix] = (x / boxwide) * (orthoright - ortholeft) + ortholeft;
      points[CurrentPoint, iy] = (y / boxhigh) * (orthotop - orthobottom) + orthobottom;
      makepatch();
  )
};
```

/* after one of the 3 Click2d functions figures out which axis of the model is represented by the screen X, Y, pass in to this common code */

dragfunc = Function({x, y, m, ix, iy}, /* ix, iy are the index of the X, Y, or Z part of the coord in the points matrix */
   if (CurrentPoint > 0,
       points[CurrentPoint, ix] = (x / boxwide) * (orthoright - ortholeft) + ortholeft;
       points[CurrentPoint, iy] = (y / boxhigh) * (orthotop - orthobottom) + orthobottom;
       makepatch();
   )
);
When a 2-D function is called, the arguments are X, Y, M, K.

- X and Y are the coordinates of the mouse.
- M shows the state of the mouse and button. M=0 says that the mouse button is up. M=1 says that the button was just pressed. M=2 says that the button is down and the mouse is moving. M=3 says that the button was just released.
- K is related to the keys Shift, Alt, and Ctrl. K=1 for the Shift key, K=2 for the Ctrl (Command) key, and K=3 for the Alt (Option) key.

The 3-D function is called similarly. The arguments are X, Y, M, K, hitlist, where hitlist is a list of matrices

\[[z_{\text{near}}, z_{\text{far}}, i_1, i_2, i_3, \ldots]\]

\(z_{\text{near}}, z_{\text{far}}\) is the Z distance from the camera of the near and far edge of the object. The matrices are sorted from near to far by the midpoint of \(z_{\text{near}}, z_{\text{far}}\). The ids in the list are the pushname, loadname, and popname values you just put in the display list.

The drag functions use a return value to tell if mouse processing should continue. That is the trailing “1” you see in the functions. Anything else stops the mouse tracking. This is needed because the 2-D and 3-D functions do not run in parallel. You might want the 2-D to return 0 and the 3-D to return 1 so the tracking would happen in 3-D rather than 2-D.

### Pick Commands

This SceneBox callback gets the 2-D mouse coordinates, and then uses Pick to determine the “named” object under the mouse. For example, hitlist is a 5x5 pixel pick box around x, y; up to 1000 items returned, but just the leaf names. The format of the return is determined by the last argument (1 returns a simple array, 0 returns a sorted (by depth) list of arrays).

```javascript
Track2d=function({x, y, m, k},
    hitlist = theSceneBox<<pick( x, y, 5, 5, 1000, 1 );
    if ( nrow(hitlist) > 0, // something IS in the pick box
        ... hitlist[1..n] // are names that you put in the display list )
);}
```

Contrast this with a callback Track3d function, where the pick rectangle is always 1x1 and picking only happens when the mouse moves. This is almost always what you want, but points are difficult to pick because the 1x1 pick area is the same small size as the point. This function lets you pick without a mouse move.

The Track3d function always provides a depth-sorted list of arrays; each array can describe multiple names in a hierarchy (pushname and popname construct a hierarchy of objects). The sorting can be very slow when thousands of objects are selected. The final argument (1, above) controls whether the pick function replaces the sorted list of arrays with a simple array. The simple array contains only the “leaf” names, not higher level names.
Three-Dimensional Arguments

Arguments enable you to specify special modes and settings. To enable an argument, use the `Enable(argument)` command. To disable an argument, use the `Disable(argument)` command. Available arguments are shown in Table 13.7.

Improve the Display of Graphics

Hardware acceleration determines how fast and smoothly graphics are drawn. On Windows, hardware acceleration is turned off by default.

**Note:** JMP uses OpenGL 1.1 to perform 3-D rendering.

If you need OpenGL and have the hardware support, turn on hardware acceleration in one of the following ways:

- Right-click the graph and select **Use Hardware Acceleration**.
- Send the `Use Hardware Acceleration(1)` message to the scene box.
• In your script, set the global variable `Scene3DHardwareAcceleration = 1`; If you want hardware acceleration to be the default across runs of JMP, add it to your `jmpStartAdmin.jsl` file. Because it is a global variable, it will remain in effect until changed.
This chapter discusses scripting features that are particularly useful for production settings, such as the following:

- a data feed for capturing real-time data from a laboratory instrument
- using SAS, MATLAB, R, or Python through JMP Scripting Language (JSL)
- using JMP with Microsoft Excel
- connecting to databases
- controlling JMP externally by OLE automation
- parsing XML
- publishing to JMP Public or JMP Live
- communicating with REST web services
- communicating with web APIs

Some general JSL commands that might be of particular interest for use in a production setting include Caption, Speak, Print, Write, and Mail. These commands are described in “Functions that Communicate with Users” on page 316 in the “Programming Methods” chapter.

Real-Time Data Capture on Windows

A data feed is a real-time method to read data continuously, such as from a laboratory measurement device connected to a serial port. A data feed object sets up a concurrent thread with a queue for input data lines that arrive in real time and are processed with background events. You set up scripts to interpret the data lines and push the data to data tables, or do whatever else your process requires.

For example, submit this to get records from com1: and list them in the log.

```js
feed = Open Datafeed(
    Connect( Port("com1:" ), Baud( 9600 ), DataBits( 7 ) ),
    Set Script( Print( feed << GetLine ))
);
```

**Figure 14.1** A Datafeed Window Shows the Status and Offers Controls

Create a Data Feed Object

To create a data feed object, use the `Open Datafeed()` function with arguments specifying details about the connection:

```js
feed = Open Datafeed( options );
```

No arguments are required. You can simply create the data feed object and then send messages to it. Messages might include connecting to a port or setting up a script to process the data coming in. However, you would typically set up the basic operation of the data feed in the `Open Datafeed()` function and subsequently send messages as needed to manage the data feed. Any of the options below work both as options inside `Open Datafeed()` or as messages sent to a data feed object.

It’s a good idea to store a reference to the object in a global variable, such as `feed` above, so that you can easily send messages to the object. You can store a reference to an existing object by using a subscript; for example, to store a reference to the second data feed created:

```js
feed2 = Datafeed[2];
```
Data Feed Options

To connect to a live data source, use `Connect( )` and specify details for the port. Each setting takes only one argument; in this syntax summary the symbol `|` between argument choices means “or.” The `Port` specification is needed if you want to connect, otherwise the object still works, but is not connected to a data feed. The last three items, `DTR_DSR`, `RTS_CTS`, and `XON_XOFF`, are Boolean to specify which control characters are sent back and forth to indicate when the data feed is ready to get data. Typically, you would turn on at most one of them.

```javascript
feed = Open Datafeed(
    Connect(
        Port( "com1:" | "com2:" | "lpt1:" | ... ),
        Baud( 9600 | 4800 | ... ),
        Data Bits( 8 | 7 ),
        Parity( None | Odd | Even ),
        Stop Bits( 1 | 0 | 2 ),
        DTR_DSR( 0 | 1 ), // Data Terminal Ready
        RTS_CTS( 0 | 1 ), // Request To Send | Clear To Send
        XON_XOFF( 1 | 0 ) // Transmitter On | Transmitter Off
    )
);
```

This command creates a scriptable data feed object and stores a reference to it in the global variable `feed`. The `Connect()` argument starts up a thread to watch a communications port and collect lines. The thread collects characters until it has a line, and then appends it to the line queue and schedules an event to call the script.

**Note:** A line of data from the feed might generate multiple rows in a data table or might be a fraction of one row. You provide JSL to parse the data lines and to add rows to a data table as needed.

`Set Script()` attaches a script to the data feed object. This script is triggered by the `Open Datafeed` message whenever a line of data arrives. The argument for `Set Script()` is simply the script to run, or a global containing a script.

```javascript
feed = Open Datafeed( Set Script( myScript ) )
feed = Open Datafeed( Set Script( Print( feed << Get Line ) ) )
```

A data feed script typically uses `Get Line` to get a copy of one line and then does something with that line. Often it parses the line for data and adds it to some data table.
Read in Real-Time Data

The term *live data feed* describes the way an external data source sends information via a physical or a logical communication link to another device. You can connect JMP to a live data feed through the serial port of your Windows computer to read a stream of incoming data in real time. Remember the following:

- The data feed must come through a standard nine-pin serial port. Data cannot be read through a USB port unless there is a driver that can simulate a serial port.
- You need to know the exact baud rate, parity, stop bits, and data bits for the attached device.

Once you obtain the numbers for your device, enter them into the `Open Datafeed()` command in the script below. (The 4800, even, 2, and 7 in the script below are examples, so replace them with your information). Then connect the data feed to your computer and open and run the script:

```julia
streamScript = Expr(
    line = feed << Get Line;
    Show( line );
    len = Length( line );
    Show( len );
    If( Length( line ) >= 1,
        Show( "Hi" );
        Show( line );
        field = Substr( line, 5, 8 );
        Show( field );
        x = Num( field );
        Show( x );
        If( !Is Missing( x ),
            dt << Add Row( {:Column1 = x} );
            Show( x );
        );
    );
);
feed = Open Datafeed(
    Baud Rate( 4800 ),
    parity( even ),
    Stop bits( 2 ),
    Data bits( 7 )
);
feed << Set Script( streamScript );
feed << Connect;
```
To ensure harmony between the communications settings for JMP and the instrument reading data from an external source, select **File > Preferences > Communications**. Refer to the documentation for your instrument to find the appropriate settings.

## Manage a Data Feed with Messages

A data feed object responds to several messages, including Connect and Set Script. These are detailed above as arguments for `Open Datafeed()`. They can also be sent as messages to a data feed object that already exists:

```javascript
feed << Connect( port( "com1:" ), baud( 4800 ), databits( 7 ), parity( odd ), stopbits( 2 ) );
feed << Set Script( myScript );
```

The following messages could also be used as arguments to `On Datafeed()`. However, it would be more common to send them as messages to a data feed object that is already present.

You can send lines to a data feed from a script. This is a quick way to test a data feed. If you do not have a device available, `Queue Line` does not send data to a device; it simulates getting data from a device. Include a text argument or a global that stores text:

```javascript
feed << Queue Line( "14" );
feed << Queue Line( myValue );
```

Here is a test script to queue five lines of data:

```javascript
feed << Queue Line( "11" );
feed << Queue Line( "22" );
feed << Queue Line( "33" );
feed << Queue Line( "44" );
feed << Queue Line( "55" );
```

**Figure 14.2** Datafeed: 5 Lines Queued

To get the first line currently waiting in the queue, use a `Get Line` (singular) message. When you get a line, it is removed from the queue. Five lines were queued with the test script above, and `Get Line` returns the first line and removes it from the queue:

```javascript
feed << Get Line
"11"
```
To empty all lines from the queue into a list, use `Get Lines` (plural). This returns the next four lines from the test script in list `{ }` format.

\[
\text{myList} = \text{feed} \ll \text{GetLines;}
\]
\[
\{ "22", "33", "44", "55" \}
\]

To stop and later restart the processing of queued lines, either click the `Stop` and `Restart` buttons in the Datafeed window, or send the equivalent messages:

\[
\text{feed} \ll \text{Stop;}
\]
\[
\text{feed} \ll \text{Restart;}
\]

To close the data feed and its window:

\[
\text{feed} \ll \text{Close;}
\]

To disconnect from the live data source:

\[
\text{feed} \ll \text{Disconnect}
\]

### Table 14.1 Datafeed Messages

<table>
<thead>

<td>Returns and removes one line from the data feed queue.</td>
</tr>
</tbody>
</table>
Examples of Data Feed

Reading Data

Here is a typical data feed script. It expects to find a string 3 characters long starting in column 11. If it does, it uses it as a number and then adds a row to the data table in the column “thickness.”

```
feed = Open Datafeed( );
myScript = Expr(
    line = feed << Get Line;
    If( Length( line ) >= 14,
        x = Num( Substr( line, 11, 3 ) );
    )
);
```
If(! Is Missing(x),
dt << Add Row( {thickness = x} )
);
);
);

Assign the script to the data feed object by using Set Script:

feed << Set Script( myScript );

Set Up a Live Control Chart

Here is a sample script that sets up a new data table and starts a control chart based on the data feed.

dt = New Table( "Gap Width" ); // make a data table with one column
dc = dt << New Column( "gap", Numeric, Best );

// set up control chart properties
dc << Set Property(
   "Control Limits",
   {XBar( Avg( 20 ), LCL( 19.8 ), UCL( 20.2 ) )}
);
dc << Set Property( "Sigma", 0.1 );

// make the data feed
feed = Open Datafeed();
feedScript = Expr(
   line = feed << Get Line;
   z = Num( line );
   Show( line, z ); // if logging or debugging
   If( !Is Missing( z ),
      dt << Add Row( {:gap = z} )
   );
);
feed << Set Script( feedScript );

// start the control chart
Control Chart Builder(
   Show Capability( 0 ),
   Variables( Y( :gap ) ),
   Set Subgroup Size( 5 )
);
/* Either start the feed from the device or test-feed some data to see it work (comment out one of the lines):
feed << Connect( Port( "com1:" ), Baud( 9600 ) ); */
For( i = 1, i <= 20, i++,
    feed << Queue Line( Char( 20 + Random Uniform() * .1 ) );
    Wait( .1 ); // simulate a delay in the feed
);

Store the Script in a Data Table

You can further automate the production setting by placing a data feed script such as the one above in an On Open data table property. A property with this name is run automatically each time the table is opened (unless you set a preference to suppress execution). If you save such a data table as a template, opening the template runs the data feed script and creates a new data table.

Dynamic Link Libraries (DLLs)

Note: 64-bit JMP cannot load 32-bit DLLs. You must recompile a 32-bit DLL for JMP to be able to load it.

You can extend JMP functionality by using JMP Scripting Language (JSL) to load a DLL and call functions exported by that DLL. There is one JSL command and six messages that implement this functionality.

dl_obj = Load DLL("path" <, AutoDeclare(Boolean | Quiet | Verbose) |Quiet | Verbose > )

Load DLL() loads the DLL in the specified path. Use the AutoDeclare(Quiet) argument to suppress log window messaging.

Use the Declare Function message to declare a function that is defined in the DLL. After you declare the function, you can call it.

dl_obj <<Declare Function("name", Convention(named_argument),
    Alias("string"), Arg(type, "string"), Returns(type), other_named_arguments)

The Alias defines an alternate name that you can use in JSL. For example, if you declared Alias("MsgBox") for a function that is named "Message Box" in the DLL, then you would call it as follows:

result = dll_obj <<MsgBox(...)

Here are the named arguments for Convention:

• STDCALL or PASCAL
• CDECL

The type argument for both Arg and Returns can be one of the following:

### Table 14.2 Types for Arg and Returns

<table>
<thead>
<tr>
<th>Int8</th>
<th>UInt8</th>
<th>Int16</th>
<th>UInt16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int32</td>
<td>UInt32</td>
<td>Int64</td>
<td>UInt64</td>
</tr>
<tr>
<td>Float</td>
<td>Double</td>
<td>AnsiString</td>
<td>UnicodeString</td>
</tr>
<tr>
<td>Struct</td>
<td>IntPtr</td>
<td>UIntPtr</td>
<td>ObjPtr</td>
</tr>
</tbody>
</table>

See the JSL Syntax Reference for the Declare Function message arguments.

Finally, use the UnLoadDLL message to unload the DLL:

```plaintext
dll_obj << UnLoadDLL
```

**Note:** Refer to the documentation for that function provided by the DLL author when you declare a function. If the argument types and calling convention declared do not match the actual function in the DLL, calling the function could cause JMP to terminate.

### Example

In the following example, the DLL contains a function named `netPresentValue`, which takes four parameters. Declare Function() defines these parameters and the data type that the function returns so that JMP can successfully call the function.

```plaintext
xtfdll = Load Dll( "c:\ExtFunctionTests\ExtFunctionTests_x64.dll" ),
Show( xtfdll );

xtfdll << Declare Function(  
   "netPresentValue",  
   Convention( CDECL ),  
   Alias( "npv" ), // use this name to call the function in JMP  
   Arg( Double, "discount rate" ),  
   Arg( Double, "cash flows per period" ),  
   Arg( Int32, "number of cash flows" ),  
   Arg( Double, Array, "array of cash flow values" ),  
   Returns( Double )  
);

result = xtfdll << npv( 0.10, 1, 10, [100, 100, 100, 100, 100, 100, 100, 100, 100, 100] );
```

```
Other DLL Messages

The Show Functions message sends any functions that have been declared using Declare Function to the log:

\[
\text{dll\_obj} \ll \text{Show Functions};
\]

If you are writing your own DLL, you can create functions in it using JSL. The Get Declaration JSL message sends any JSL functions in your DLL to the log:

\[
\text{dll\_obj} \ll \text{Get Declaration JSL};
\]

Use Sockets in JSL

Another tool that can be useful in establishing a live data feed is JSL Sockets. You can create two types of sockets using JSL:

**Stream**  Stream sockets create a reliable connection between JMP and another computer. The other computer might be running JMP, or it might be a vending machine, data collector, printer, or other device that is capable of socket communication. Some devices implement their interface as an HTTP web server.

**Datagram**  Datagram sockets create a less reliable connection between JMP and another computer. Datagrams are connectionless and information might arrive multiple times, not at all, and out of order. A datagram connection does not include all the overhead of a stream connection that does guarantee reliability. Because datagrams are connectionless, the destination address must be supplied each time (and for the same socket that can be different each time).

Once a socket is created, it can do two things: wait for a connection from another socket, or make a connection to another socket. Here is a simple example program that makes a connection to another computer’s web server to get some data:

\[
\begin{align*}
\text{tCall} & = \text{Socket}() ; \\
\text{tCall} & \ll \text{Connect}( \text{"www.jmp.com", "80"} ) ; \\
\text{tCall} & \ll \text{Send}( \text{Char To Blob( "GET / HTTP/1.0~0d~0a~0d~0a~0d~0a", "ASCII~HEX" ) )} ; \\
\text{tMessage} & = \text{tCall} \ll \text{Recv( 1000 )} ; \\
\text{text} & = \text{Blob To Char( tMessage[3] )} ; \\
\text{Show( text )} ; \\
\text{tCall} & \ll \text{Close( )} ;
\end{align*}
\]
The first line creates a socket and gives it a reference name (tCall). By default, a stream socket is created. You can designate the type of socket to create with an optional argument: socket(STREAM) or socket(DGRAM).

The second line connects the tCall socket to port 80 (which is generally the HTTP port) of the JMP website.

The third line sends a GET request to the JMP web server; this message tells the JMP web server to send the JMP home page back. The / that follows the word GET should be the path to the page to be opened. A / opens the root page.

The fourth line receives up to 1000 bytes from the JMP web server and stores a list of information in tMessage. Each socket call returns a list. The first element of the list is the name of the call, and the second is a text message, which might be ok or a longer diagnostic message. Additional elements, if present, are specific to the call. In this case, the third element in the list is the data received.

The fifth line converts the binary information received into a character string. tMessage[3] is the third item in the list returned by Recv; it is the data from the JMP web server.

The sixth line displays the data in the log.

The last line closes the socket. The web server has already closed the far end, so this socket either needs reconnecting or proper disposal (close).

See the Scripting Index in the Help menu for more examples. The JMP Samples/Scripts folder also contains several examples of scripts using sockets.

**Socket-Related Commands**

Before creating and using a socket, you might need to retrieve information about the end that you want to connect to. GetAddrInfo( ) and GetNameInfo( ) each takes an address argument and an optional port argument and returns a list of information. For example:

```julia
Print( Get Addr Info( "www.sas.com" ) );
Print( Get Addr Info( "www.sas.com", "80" ) );
Print( Get Name Info( "149.173.5.120" ) );
{ "Get Addr Info", "ok", { "PF_INET", "SOCK_0", "IPPROTO_0", "149.173.5.120", "0" } }
{ "Get Addr Info", "ok", { "PF_INET", "SOCK_0", "IPPROTO_0", "149.173.5.120", "80" } }
{ "Get Name Info", "ok", { "PF_INET", "SOCK_0", "IPPROTO_0", "chess.exnet.sas.com", "0" } }
```

Sometimes there can be more than one answer. In that case, the sublist might be repeated one or more times. These functions can be quite slow; you probably should not try to build a data table of every website name with it. For IPV6 compatibility, you should generally use names like “www.sas.com” rather than the numerical form of an address.
Messages for Sockets

Once you have created a socket with `Socket()`, there are many messages that you can send to it.

**connect**  Connects to a listening socket. Returns a list: `{"connect", "ok"}` if the connection was successful; or an error if not (for example, `{"connect", "CONNREFUSED: The attempt to connect was forcefully rejected. "}`).

**close**  Closes the connection when you are finished with it. Returns a list (for example, `{"Close", "ok"}`).

**send**  Sends a STREAM message to the other end of the socket.

**sendto**  Sends a DGRAM message to the other end of the socket.

**recv**  Receives a STREAM message. The data comes back in a list, along with some other information. `Recv` takes a required numeric argument that specifies the number of bytes to accept.

**recvfrom**  Receives a DGRAM message.

**ioctl**  Controls the socket’s blocking behavior. By default, JMP sockets block if no data is available; the socket does not return control to the JSL program until data is available. This makes scripts easy to write, but not particularly robust if the remote end of the connection fails to supply the data. A socket that is set for non-blocking behavior always returns immediately, either with an `ok` return code and some data, or with a “WOULDBLOCK: ...” return code, which means if it were a blocking socket, it would have to wait (block progress of the next JSL statement) until data became available.

**Important:** Background operations that use a JSL callback avoid this issue; a socket used in a background `recv`, `recvfrom`, or `accept` is set to non-blocking and is polled during `wait` statements and when JMP is otherwise idle.

`Ioctl` returns a list. For example, `{"ioctl", "ok"}`, or `{"ioctl", "NOTCONN: The socket is not connected. "}` if the socket has not been bound (see `bind`, below) or connected already.

**bind**  Tells the server socket what address the client socket listens on. `Bind` associates a port on the local machine with the socket. This is required before a socket can `Listen`. (See below). `Bind` is not usually used on sockets that connect; the operating system selects an unused port for you. `Bind` is needed for a server because anyone that wants to connect to the server needs to know what port is being used. A common port is 80, the HTTP port. `Bind` returns a list. For example, `{"bind", "ok"}`, or `{"bind", "ADDRNOTAVAIL: The specified address is not available from the local machine. "}` if you try binding to a name that is not on your machine. Another socket can connect to this socket if it knows your machine name and the number.
**Database Access**

**Run Query Builder Queries**

Query Builder is the preferred method for selecting and importing data from a SQL database without writing SQL statements. You can preview the data before importing it into a data table. Share your queries so that other users can customize and run the queries.

After you create the query, you can run the query with a JSL script. Use `Include()` to include the query in your script without opening it.

```javascript
query = Include( "$DOCUMENTS/Airline.jmpquery" );
query << Run Foreground( );
```

Instead of running the query in the foreground, you can use `Run Background()` to run the query in the background or `Run()` to use the Query Builder preference for running queries. By default, queries run in the background.
Open Database Function

JMP supports ODBC access to SQL databases through JSL with the Open Database function.

```
dt = Open Database(
   "Connect Dialog" | "DSN=...", // data source
   "sqlStatement" | "dataTableName" | "SQLFILE=...", // SQL statement
   Invisible, //Optional keyword to hide the table upon importing it
   "outputTableName" // new table name
);
```

**Note:** The characters $# -+/%&|;? in a database table name must be quoted with square brackets [].

The first argument is a quoted connection string to specify the data source. It should be either of the following:

- "Connect Dialog" to display the Select Data Source window (Windows) or Choose DSN window (macOS).
- "DSN=" and then the data source name and any other information needed to connect to the data source. On Windows, the data source name is shown in the name column of the User DSN or System DSN tab of the ODBC Data Source Administrator. On macOS, the DSN is shown in the ODBC Manager or iODBC Driver Manager. The rest of the string depends on the ODBC data source.

For example:

"DSN=dBASE Files;DBQ=C:/Program Files/SAS/JMP/16/Samples/Import Data;"

The second argument is a double-quoted string that can be one of the following:

1. An SQL statement to execute. For example, the second argument might be a SELECT statement in a quoted string like the following:

   "SELECT AGE, SEX, WEIGHT FROM BIGCLASS"

   The SQL must conform to the SQL that the data source supports. That is, a table named "Big Class" would need to be appropriately quoted because of the space between “Big” and “Class” (if whitespace is supported). The method for quoting depends on the data source and is usually done with ",", '.', or [] characters.

2. The name of a data table. In this case, the effect is an SQL "SELECT * FROM" statement for the data table indicated. For example, Open Database would in effect execute the statement "SELECT * FROM BIGCLASS" if you specify this for the second argument:

   "BIGCLASS"
3. "SQLFILE=" and a path to a text file containing an SQL statement to be executed. For example, with the following argument, JMP would attempt to open the file mySQLFile.txt from the C:\ directory and then execute the SQL statement in the file.

"SQLFILE=C:\mySQLFile.txt"

The optional Invisible argument creates a hidden data table. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To close the hidden data table, call Close(dt), where dt is the data table reference.

The optional outputTableName argument is optional and specifies the name of the output table to be created, if any. Note that Open Database does not always return a data table. The return value might be null. Whether it returns a data table depends on the type of SQL statement executed. For example, a SELECT statement would return a data table, but a DROP TABLE statement would not.

To save a table back to a database through JSL, send the data table reference a Save Database( ) message:

    dt << Save Database( "connectInfo", "TableName" );

The first argument works the same way as it does in Open Database. Note that some databases do not allow you to save a table over one that already exists. If you want to replace a table in a database, use a DROP TABLE SQL statement in an Open Database command:

    Open Database ( "connectinfo", "DROP TABLE TableName" );

**Note:** JMP 13 or later can save tables with spaces and mixed case in the names if the data source supports them. Most data sources do support spaces, except Apache Hive and Apache Hadoop. Mixed case is preserved, but for the most part, SQL is case insensitive.

The following script opens a database with an SQL query, saves it back to the database under a new name, and then deletes the new table.

    dt = Open Database(  
        "Connect Dialog",  
        "SELECT age, sex, weight FROM !"Bigclass$\!"",  
        "My Big Class"  
    );  
    dt << Save Database( "Connect Dialog", "MY_BIG_CLASS" );  
    Open Database( "Connect Dialog", "DROP TABLE BIGCLASS.MY_BIG_CLASS" );

**Note:** When you import data from an ODBC database, a table variable is added that can contain user ID and password information. To prevent this from happening, set the following preference: pref(ODBC Hide Connection String(1)). You can also select the File menu (Windows) or JMP menu (macOS), Preferences > Tables, and then select ODBC Hide Connection String. See Using JMP.
Creating a Database Connection and Executing SQL

You can use the following functions to handle more complex database operations:

```jython
   db = Create Database Connection( "Connection String With Password" );
   Execute SQL( db, "SQL statement", <invisible>, <"New Table Title"> );
   Close Database Connection( db );
```

Using these three functions, you can open a connection, call `Execute SQL` several times, and then close the connection. `Create Database Connection` returns a handle for use in `Execute SQL` and `Close Database Connection`.

Depending on the SQL submitted, a table might or might not be returned. A SELECT statement typically returns a JMP table. INSERT INTO would not return a table, because it is modifying one in the database.

**Examples**

Open a connection to your database:

```jython
   dbc = Create Database Connection(
      "DSN=dBASE Files;DBQ=$SAMPLE_IMPORT_DATA/;"
   );
```

Execute one or more SQL statements using this connection:

```jython
   dt = Execute SQL( dbc,
      "SELECT HEIGHT, WEIGHT FROM Bigclass", "NewTable"
   );
```

When you are finished, close your connection.

```jython
   Close Database Connection( dbc );
```

You might want to create a database connection without selecting a table. The script would open the Database Open window with the connection already showing. We strongly recommend that you encrypt this script. Here's an example:

```jython
   dbc = Create Database Connection(
      "DSN=dBASE Files;DBQ=$SAMPLE_IMPORT_DATA/;UID=MyDatabase;pwd=MyPassword"
   );
   Main Menu( "Open Table" );
```

**Note:** `Execute SQL()` creates a connection string that includes the cleartext password in the resulting data table. We encourage you to create the SQL query in Query Builder and then run the query in JSL. Then the password is not included in the data table.
Write a SQL Query

The `Query()` function enables you to manipulate JMP data tables using SQL statements. The SQL statement is the only required argument to `Query()`. However, most interesting SQL statements refer to one or more data tables. Any data table that the SQL statement refers to must be passed in using a table reference argument.

A table reference argument can be a data table reference (`dt` in the following example):

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query( dt, "SELECT * FROM 'Big Class' WHERE age > 14;" );
```

The SQL statement in the preceding example includes the name of the JMP data table. If the data table path is long, you might want to use an alias for the data table in the SQL statement. To use an alias, pass the table reference as a `Table()` argument:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query( Table( dt, "t1" ), "SELECT * FROM t1 WHERE age > 14;" );
```

Using `Table()` to alias your data tables also enables you to write SQL statements for multiple queries with tables that have different names without rewriting the statements.

Private and Hidden Data Tables

If you want the data table that is produced by `Query()` to be either private or hidden, you can pass either `Private` or `Invisible` as arguments to `Query()`.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query( dt, invisible, "SELECT * FROM 'Big Class' WHERE age > 14;" );
```

Returning a Single Value

The `Query()` function normally returns the result of the query as a JMP data table. However, sometimes you might write a SQL query that returns a single value; you would rather have `Query()` return that value instead of placing the value in a JMP data table. You can do that by passing the `Scalar` argument.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query(
    Table( dt, "t1" ),
    Scalar,
    "SELECT AVG(height) FROM t1 WHERE age > 14;"
);
```

The preceding query returns 65, the average height of students older than 14.
Work with SAS

Make a SAS DATA Step

Sending Make SAS Data Step to a data table returns the text for a SAS DATA Step that can re-create the data table in SAS. For example,

```sas
dt << Make SAS Data Step
```

prints a DATA Step to the log that can be used in the SAS Program Editor.

Sending Make SAS Data Step Window produces this code in a window with a .SAS suffix, so that it can be easily sent to SAS.

Create SAS DATA Step Code for Formula Columns

Sending Get SAS Data Step for Formula Columns to a data table includes column formulas in the SAS data step code. Here is an example that outputs the formula for the Ratio column:

```sas
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "Ratio", Formula( :height / :weight ));
dt << Get SAS Data Step for Formula Columns;
```

This script output the following code to the log:

```sas
/*%PRODUCER: JMP - DataTable Formulas */
/*%TARGET: Ratio */
/*%INPUT: height */
/*%INPUT: weight */
/*%OUTPUT: Ratio */
/* Code to score Ratio */
Ratio =height/weight
drop ;
```

To get formulas for all columns, omit the column names as shown here:

```sas
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Get SAS Data Step for Formula Columns;
```

You can also include column formulas in scoring code for SAS Model Manager. Send Get MM SAS Data Step for Formula Columns to the data table.

```sas
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Get MM SAS Data Step for Formula Columns;
```

The results of this script are also shown in the log.

As with Get SAS Data Step for Formula Columns, specifying column names is optional.
SAS Variable Names

SAS Open For Var Names() opens a SAS data set only to obtain the names of its variables, returning those names as a list of strings.

The rules for SAS variable names are more strict than those of JMP. The SAS Name function converts JMP variable names to SAS variable names, changing special characters and blanks to underscores, and various other transformations to produce a valid SAS name.

```
result = SAS Name(name);
result = SAS Name({list of names});
```

If the argument is a list of names, the result is a blank-separated character string of names. For example,

```
SAS Name({“x 1”, “x 2”})
```

produces

```
“ x_1 x_2”
```

Connect to a SAS Metadata Server

You can connect to a SAS server and work directly with SAS data sets. Making connections and interacting with SAS data sets is scriptable through JSL. For information about connecting to a metadata server in the JMP interface, see Using JMP.

**Note:** If you connect to a physical workspace server, there is no metadata server involved, so metadata security is never applied. You must connect to a SAS Metadata Server and then connect to a logical workspace server. Then metadata security is enforced on the metadata-defined libraries you access.

Make the Connection

First, use the Meta Connect() function to connect to a SAS metadata server:

```
connected = Meta Connect( "MyMetadataServer", port );
```

To specify the SAS version for the metadata server, use the SASVersion named argument:

```
connected = Meta Connect( "MyMetadataServer", port, SASVersion("9.4") );
```

If you supply only the machine name (for example, myserver.mycompany.com) and the port, you are prompted to provide the authentication domain, your user name, and your password. You can also specify all that in JSL:

```
connected = Meta Connect( "MyMetadataServer", port, "authdomain", "user name", "password" );
```
When you are finished using the SAS metadata server, use Meta Disconnect() to disconnect the connection. No arguments are necessary; the command closes the current metadata server connection.

You can see the repositories that are available on a metadata server and set the one that you want to use:

```
Meta Get Repositories();
  {"Foundation"}
Meta Set Repository( "Foundation" );
```

Note that if there is only one repository available, it is selected automatically and you do not need to explicitly set it.

Once your repository is set, you can view the servers that are available:

```
mylist = Meta Get Servers();
  {"SASMain", "Schroedl", "SASMain_ja", "SASMain_zh", "SASMain_ko", "SASMain_fr", "SASMain_de", "SASMain_Unicode"}
```

Next, set your SAS connection. You can also use this command to connect directly to a local or remote server instead of using a metadata server.

```
conn = SAS Connect( "SASMain" );
```

Now you can send Disconnect and Connect messages to the conn object to close and open the SAS connection.

```
conn << Disconnect();
conn << Connect();
```

This is an example of using an object and messages with SAS server connections. You might have also connected to SAS servers using global functions. If so, the Disconnect and Connect messages do not affect those global connections. However, if there is no active global connection, that global connection is set to the connection opened by the object.

### Automatically Connect SAS Libraries

When you connect to a SAS server, use Connect Libraries to automatically connect metadata-defined libraries.

```
conn = SAS Connect( "SASMain", Connect Libraries( 1 ) );
```

All metadata-defined libraries are connected, which can slow down your connection.

To connect specific libraries later, use the SAS Connect Libref() function or Connect Libref message to a SAS server object.
View SAS Libraries

After you connect to a SAS server, use the `Get Lib Ref()` function to view the libraries on that server:

```julia
conn << Get Lib Refs();
  {"BOOKS", "EGSAMP", "GENOMICS", "GISMAPS", "JMPSAMP", "JMptest",
   "MAILLIB", "MAPS", "OR_GEN", "ORION_RE", "ORSTAR", "SASHelp",
   "SASUSER", "TEMPDATA", "TSERIES", "V6LIB", "WORK", "WRSTEMP"}
```

If the library containing the data that you want is not assigned, assign it:

```julia
conn << Assign Lib Refs( "MyLib", "$DOCUMENTS/data" );
```

Open SAS Data Sets

First, assign a SAS library reference:

```julia
conn << Assign Lib Refs( "MyLib", "$DOCUMENTS" );
```

The first argument is any name that you want to use to refer to the library reference. The second is the path on the server where the data sets are located.

Next, get the list of data sets in the selected library:

```julia
datasets << Get Data Sets( "MyLib" );
  {"ANDORRA", "ANDORRA2", "ANYVARNName", "BOOKS", "BOOKSCOPYNOT", "BOOKS_VIEW",
   "CATEGORIES", "DATETIMETESTS", "MOREUGLY", "NOTTOOGULY", "PAYPERVIEW",
   "PUBLISHERS", "PURCHASES", "PURCHASES_FULL",
```

Now you can open a data set:

```julia
conn << Import Data( "MyLib", "PURCHASES" );
```

or

```julia
conn << Import Data( librefs[1], datasets[12] );
```

or

```julia
conn << Import Data( "MyLib.PURCHASES" );
```

Now you can get information about any SAS data set in that library. For example, you can get a list of variables:

```julia
conn << Get Var Names( "MyLib.PURCHASES" );
  {"purchaseyear", "purchasemonth", "purchaseday", "bookid", "catid",
   "pubid", "price", "cost"}
```

With that information, you can choose to import only part of the data set by specifying the variables to import.

```julia
conn << Import Data( librefs[1], datasets[12], columns( bookvars[1], bookvars[2] ) );
```
Save SAS Data Sets

To save a JMP data table or an imported SAS Data Set, use the SAS Export Data() command:

```
conn << Export Data( dt, librefs[1], datasets[4], ReplaceExisting );
```

Run a Stored Process

To get a reference to a stored process:

```
stp = Meta Get Stored Process( "Samples/Stored Processes/Sample: Hello World" );
```

There is no way to acquire a list of stored processes through JSL; you must know the path to the stored process that you want to run.

To run it, send the stored process a message:

```
stp << Run();
```

Submit SAS Code from JMP

You can also directly submit SAS code and get back SAS results. For example:

```
conn << Submit( "proc print data=sashelp.class; run;" );
```

Two optional arguments control whether you see the output and the SAS log in JMP:

```
conn << Submit( "SAS Code" <,No Output Window(True|False)> <,Get Log(True|False )> );
```

You can also see the SAS Log at any time using the command

```
conn << Get Log();
```

Get Log() returns the contents, which can be placed in a JSL variable and used like any JSL string.

Get the Values of SAS Macro Variables

JMP provides several methods for querying SAS macro variables.

To show the systime value:

```
systime = sas << Get Macro Var("SYSTIME");
show(systime);
```
To show the defined SAS macro variables:

```sas
macro_names = sas << Get Macro Var Names();
show(macro_names);
```

To iterate through the SAS macro variables and print out the values:

```sas
macro_names = sas << Get Macro Var Names();
For( i = 1, i <= N Items( macro_names ), i++,
    macro_value = sas << Get Macro Var( macro_names[i] );
    output = macro_names[i] || " " || Char( macro_value );
    Show( output );
);
```

To submit SAS code that defines “test” as a SAS macro variable and then gets the value from SAS:

```sas
sas << Submit( "%let test = 1;" );
test = sas << Get Macro Var( "test" );
Show( test );
```

All macro variable values will evaluate to numbers, if possible, otherwise they will be characters.

**Preferences**

To get the current SAS version preference, use:

```sas
Get SAS Version Preference();
```

To set the current SAS version preference, use:

```sas
Preference( SAS Integration Settings( SASVersion( "9.4" ) ) );
```

**Sample Scripts**

The JMP Samples/Scripts/SAS Integration folder contains sample scripts. To run the stored process scripts successfully, the stored processes need to be placed on your SAS Metadata Server. The stored processes can be found in the sampleStoredProcesses.spk file, also in this folder.

**To import sampleStoredProcesses.spk into your SAS Metadata Server:**

**Caution:** We recommend that you import these stored processes into a SAS Metadata Server that is used for testing rather than into a production system.

1. Run SAS Management Console.
2. Connect to your SAS Metadata Server using an account with administrative privileges.

3. Expand the BI Manager node in the left pane of the SAS Management Console.

4. Navigate to the folder in the tree under which you would like to create the imported sample stored processes.

5. Right-click that folder in either the left pane or the right pane of the SAS Management Console and select **Import**.
   
   The Import Wizard appears.

6. Enter the full path to `sampleStoredProcesses.spk` or use the **Browse** button to navigate to it.

7. Select **All Objects** in the Import Options section of the wizard.

8. Click **Next**.

   The next panel reports that during the import process, you must specify values for **Application servers** and **Source code repositories**.

9. Click **Next**.

   Select which of the application servers defined in your SAS Metadata Server that you would like to use to execute the imported stored processes.

10. Select an application server from the drop-down list under **Target**.

11. Click **Next**.

    Select the source code repository (directory) defined on your SAS Metadata Server where you would like the SAS code for the imported stored processes to be placed.

12. Select a source code repository from the drop-down list under **Target Path**.

13. Click **Next**.

    The next panel gives a summary of what occurs if you click **Import**.

14. Review the information about the panel, and if it looks correct, click **Import**.

15. During the Import process, you might be asked to provide login credentials for connecting to the metadata server to perform the import. Provide credentials with administrative privileges and click **OK**.

After the import completes, you will find a folder named **BIP Tree** under the folder that you imported the stored processes into. Under **BIP Tree** is a folder named **JMP Samples**, and in the **JMP Samples** folder are two sample stored processes: **Shoe Chart** and **Diameter**.

Please note that the paths to the sample stored processes needs to be adjusted in the sample scripts `storedProcessHTML.jsl` and `storedProcessJSL.jsl` to match the folder into which you imported the sample stored processes. Otherwise, these scripts will not work correctly.
Work with MATLAB

MATLAB, a product of MathWorks Inc., provides an interactive working environment for analyzing and visualizing computational models. MATLAB is available for Windows, Mac OS X, and Linux (64-bit). JMP supports MATLAB on both Windows and macOS platforms.

You can interact with MATLAB using JMP Scripting Language (JSL):

- Submit statements to MATLAB from within a JSL script.
- Exchange data between JMP and MATLAB.
- Display graphics produced by MATLAB.

See the JSL Syntax Reference for more information about using MATLAB functions in JMP. Textual output and error messages from MATLAB appear in the log window.

Install MATLAB

MATLAB must be installed on the same computer as JMP. For the supported version of MATLAB, see the JMP website: https://www.jmp.com/system/.

How JMP Finds MATLAB

JMP delays loading MATLAB until a JSL-based script requires access to it. When you run a JSL script that calls MATLAB, JMP locates the software based on the operating system’s PATH environment variable (for example, C:\Program Files\MATLAB\R2012a\).

Test Your Install

To verify that your computer is able to run JSL-based scripts using MATLAB:

1. Run the following JSL script:

   ```jsl
   MATLAB Init();
   MATLAB Submit( "m = magic(3)" );
   magicMat = MATLAB Get( m );
   Show( magicMat );
   MATLAB Term();
   ```

   The MATLAB function \( M = \text{magic}(3) \) returns a 3-by-3 matrix using integers in the range of 1 to \( 3^2 \) with equal row and column sums. This matrix is called a magic square.

2. Select View > Log.

   You should see the following response in the log window:

   ```plaintext
   m =
   ```
If you see the following message in the log window:

An installation of MATLAB cannot be found on this system.

1. Add a new environment variable with the name of MATLABROOT and a value of C:\Program Files\MATLAB\R2012a or C:\Program Files (x86)\MATLAB\R2012a.  

   Note: The path entered depends on the MATLAB installation path.

2. Verify that the MATLAB path is included in the PATH variable.

3. Run the script again to ensure JMP can access MATLAB.

---

**Work with R**

You can interact with R using JSL:

- Submit statements to R from within a JSL script.
- Exchange data between JMP and R.
- Display graphics produced by R.

Text output and error messages from R appear in the log window.

---

**Installing R**

Install R on the same computer as JMP. You can download R from the Comprehensive R Archive Network website:

https://cran.r-project.org

Note: For macOS Catalina and later versions, download the notarized and signed package.
Because JMP is a 64-bit application, you must install the corresponding 64-bit version of R. For the supported version of R, see the system requirements on the JMP website: https://www.jmp.com/system.

Override Default R Install Location on Windows

Normally JMP determines the R_HOME environment variable internally if it is not defined in the Windows system registry:

\texttt{\textbackslash{}HKEY\_LOCAL\_MACHINE\\SOFT\_WARE\\R\_code\R\InstallPath}

You might have installed more than one version of R on your computer. To override the default R installation location, define the R_HOME environment variable using either of the two following methods:

1. Create the variable in your system environment variables using the Control Panel, select \texttt{Start > Control Panel > System > Advanced system settings}.
2. Click \texttt{Environment Variables}.
3. In the System variables pane, click \texttt{New}.
4. Type \texttt{R\_HOME} for the \texttt{Variable name}.
5. Type the path to the R .\texttt{exe} file (for example, \texttt{C\:\Program Files\R\R-2.15.3}).
6. Click \texttt{OK} and click \texttt{OK} again to close the System Properties window.

or

Create the variable using the JSL \texttt{Set Environment Variable()} function:

\begin{verbatim}
Set Environment Variable( "R\_HOME", "C:\Program Files\R\R-2.15.3" );
\end{verbatim}

Override the Default R Install Location on macOS

You might have installed more than one version of R on your computer. To use an older version, change the R_HOME environment variable to point to the R version that you want to use.

To specify the R_HOME location, follow these steps:

1. Open a terminal window.
2. Type the following code, where \texttt{value} is the location of R.
   \begin{verbatim}
   export R\_HOME=value
   \end{verbatim}
3. Press Enter.
How JMP Finds R on Windows

JMP delays loading R until a JSL-based script requires access to it. When JMP needs to load R, it follows the standard steps for finding R on a Windows computer:

1. Look up the environment variable R_HOME.
   If the variable exists, load R from the specified directory.
2. If the environment variable R_HOME does not exist, look up the InstallPath value in the Windows registry under the following key:
   HKEY_LOCAL_MACHINE\SOFTWARE\R-core\R
   If the InstallPath value exists, load R from the specified directory.
3. If the InstallPath value does not exist, an error message states that R could not be found.

How JMP Finds R on macOS

JMP uses the value of the R_HOME environment variable if the variable exists. Otherwise, it looks in /Library/Frameworks/R.framework/Versions/Current/Resources for R.

Testing Your Setup

To test that your computer is able to run JSL-based scripts that use R, run the following JSL script:

```
R Init( );
R Submit( "
x <- 1:5
x
"");
R Term( );
```

You should see the following output in the log:

```
[1] 1 2 3 4 5
```

JMP to R Interfaces

The following JMP interfaces are provided to access R. The basic execution model is to first initialize the R connection, perform the required R operations, and then terminate the R connection. In most cases, these functions return 0 if the R operation was successful, or an error code if it was not. If the R operation is not successful, a message is written to the log. The single exception to this is R Get(), which returns a value.
R JSL Scriptable Object Interfaces

The R interfaces are also scriptable using an R connection object. A scriptable R connection object can be obtained using the R Connect() JSL function.

Conversion Between JMP Data Types and R Data Types

Table 14.3 shows what JMP data types can be exchanged with R using the R Send() function. Sending lists to R recursively examines each element of the list and sends each base JMP data type. Nested lists are supported.

<table>
<thead>
<tr>
<th>R Data Type</th>
<th>JMP Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double</td>
<td>Numeric</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
</tr>
<tr>
<td>Double Matrix</td>
<td>Matrix</td>
</tr>
<tr>
<td>List</td>
<td>List</td>
</tr>
<tr>
<td>Data Frame</td>
<td>Data Table</td>
</tr>
<tr>
<td>Integer</td>
<td>Row State</td>
</tr>
<tr>
<td>Date and Time</td>
<td>Datetime</td>
</tr>
<tr>
<td>Time/Duration</td>
<td>Duration</td>
</tr>
<tr>
<td>Paired List</td>
<td>Associative Array</td>
</tr>
</tbody>
</table>

Example

```r
R Init();
X = 1;
R Send(X);
S = "Report Title";
R Send(S);
M = [1 2 3, 4 5 6, 7 8 9];
R Send(M);
R Submit("
X
S
M"");
```
The `R Term();`;

Table 14.4 shows what JMP data types can be exchanged with R using the `R Get()` function. Getting lists from R recursively examines each element of the list and sends each base R data type. Nested lists are supported.

<table>
<thead>
<tr>
<th><strong>R Data Type</strong></th>
<th><strong>JMP Data Type</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Double</td>
<td>Numeric</td>
</tr>
<tr>
<td>Logical (Boolean)</td>
<td>Numeric (0</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
</tr>
<tr>
<td>Integer</td>
<td>Numeric</td>
</tr>
<tr>
<td>Date and Time</td>
<td>Datetime</td>
</tr>
<tr>
<td>Time/Duration</td>
<td>Duration</td>
</tr>
<tr>
<td>Factor</td>
<td>Expanded to a list of Strings or a Numeric matrix</td>
</tr>
<tr>

<td>Data Table</td>
</tr>
<tr>
<td>List</td>
<td>List of converted R data types</td>
</tr>
<tr>
<td>Matrix</td>
<td>Numeric Matrix</td>
</tr>
<tr>
<td>Numeric Vector</td>
<td>Numeric Matrix</td>
</tr>
<tr>
<td>String Vector</td>
<td>List of Strings</td>
</tr>
<tr>
<td>Graph</td>
<td>Picture</td>
</tr>
<tr>
<td>Time Series</td>
<td>Matrix</td>
</tr>
<tr>
<td>Paired List</td>
<td>Associative Array</td>
</tr>
</tbody>
</table>

**JMP Scoping Operators and R**

A JMP object sent to R using `R Send()` uses the same JMP reference as the name of the R object that gets created. For example, sending the JMP variable `dt` to R creates an R object named `dt`. The colon and double colon scoping operators (`:` and `::`) are not valid in R object names, so these are converted as follows:

- A single colon scoping operator is replaced with a period (`.`).
  
  For example, sending `nsref:dt` to R creates a corresponding R object named `nsref.dt`. 
• A double colon scoping operator (designating a global variable) is ignored. For example, sending ::dt to R creates a corresponding R object named dt.

Using R Name() with R Send()

The R Name() option to R Send() has an argument that is a quoted string that contains a valid R object name. The JMP object sent to R becomes an R object with the name specified. For example:

```r
R Send( jmp_var_name, R Name( "r_var_name") );
R Submit( "print(r_var_name)" )
```

Example

This example creates a variable x in the Here namespace, a variable y in the global namespace, and a variable z that is not explicitly referenced to any namespace. The variable z defaults to Global unless Names Default To Here(1) is on. These variables are then passed to R.

```j.mp
Here:x = 1;
::y = 2;
z = 3;

R Init(); // initiate the R connection
/* send the Here variable to R
Here:x creates the R object Here.x */
R Send( Here:x );

/* note that the JMP log labels the output with the original JMP variable reference Here:x */
R Submit( "print(Here.x)" );

R Send( ::y ); // ::y create the R object y
R Submit( "print(y)" );

// to use a different name for the R object, use the R Name() option
R Send( Here:x, R Name( "localx" ) );

/* The R Name option to the R Send() command creates the R object named "localx" corresponding to the JMP variable "Here:x". Again the log shows the original corresponding JMP variable name. */
R Submit( "print(localx)" );
R Send( z ); // z creates the R object z
R Submit( "print(z)" );
```
Troubleshooting

Recording Output

On Windows, if you want to record output to the graphics window, send the following R code using R Submit( ).

```r
windows.options( record = TRUE );
```

Character Vectors

A JMP list of strings is not the same as an R character vector. If you send a list of strings to R, it becomes a list of strings in R, not a character vector. You can use the R function Unlist to convert it:

```r
R Init();
X = {"Character", "JMP", "List"};
R Send( X );

/* R output is:
[1] "list"
*/
R Submit( "class(X)" );

/* Object Y is now a character vector. The R output is:
[1] "character"
*/
R Submit( "Y<-unlist(X)
            class(Y)" );
R Term();
```

Element Names

A feature of an R list (called attributes) lets you associate a name with each element of the list. You can use the name to access that element instead of having to know the position of it in the list.

In the following example, the list that is created in R has two elements named x and y that are created using the List() function of R. When your bring the R list into JMP and then send it back to R, the names are lost. Therefore in R, you cannot access the first matrix using pts$x. Instead, you must use the index using pts[[1]].

```r
R Init();
R Submit("
  pts <- list(x=cars[,1], y=cars[,2])
  summary(pts)
  ");
```
JMP_pts = R Get( pts );

R Send( JMP_pts );
R Submit("Summary( JMP_pts )
");
R Term();

Examples

Sending a Data Table to R

This example initiates an R connection, sends a data table to R, prints it to the log, and closes the R connection.

R Init();
dt = Open( "$SAMPLE_DATA/Big Class.jmp", invisible );
R Send( dt ); // send the opened data table represented by dt to R;
R Submit( "print( dt )" );
R Term();

Creating Objects in R

This example initiates an R connection, creates an R object, retrieves the object into JMP, and closes the R connection.

R Init();
R Submit("L3 <- LETTERS[1:3]
d <- data.frame(cbind(x=1, y=1:15), Group=sample(L3, 15, repl=TRUE))
" );
R Get( d ) << NewDataView;
R Term();

Using R Functions and Graphics

This example initiates an R connection and plots the normal density function in R using the R graphics device. Then the graph is retrieved from R and displayed in JMP. Finally, the R connection is closed.

R Init();
R Submit("\[plot(function(x) dnorm(x), -5, 5, main = "Normal(0,1) Density") \]");
Simple Matrix Addition in R

This example initiates an R connection, sends a matrix to R, creates a matrix in R, adds them together, returns the new matrix to JMP, and closes the R connection.

```r
R Init();
X = J( 2, 2, 1 );
R Send( X );
R Submit("X                                     #prints X to the log
Y <- matrix(1:4, nrow=2, byrow=TRUE)  #makes a 2x2 matrix object Y
Y                                     #prints Y to the log
Z <- X + Y #matrix object Z is addition of X and Y
");
Z = R Get( Z );
R Term();
Show( Z );
```

A Bootstrap Sample

See the file JMPtoR_bootstrap.jsl in the sample scripts folder for an example script.

This script performs a bootstrap simulation by using the JMP to R Project integration.

The script produces a JMP window that asked the user to specify the variable to perform bootstrapping over. Then the user selects a statistic to compute for each bootstrap sample. Finally, the data is sent to R using the R interface in JSL.

The boot package in R is used to call the `boot()` function and the `boot.ci()` function to calculate the sample statistic for each bootstrap sample and the bootstrap confidence interval.

The results are brought back to JMP and displayed using the JMP Distribution platform.
Work with Python

The JMP-Python integration allows JMP users to interact with a large amount of scientific, statistical, and data analysis tools written in Python. JMP implements this capability by loading the Python shared library into the running JMP process. JSL gives Python access to JMP.

The JMP installer does not contain Python. Several Python implementations are available. Visit https://www.python.org/download/alternatives to view the options.

JMP has several methods for finding an instance of Python installed on the computer. You should not need to set any environment variables or additional arguments to the JSL Python Init() statement. See “Troubleshooting the JMP Python Integration” on page 806 for more information.

The Python integration enables you to perform the following tasks:

- submit statements to Python from within a JSL script
- exchange data between JMP and Python
- display graphics produced by Python

Text output and error messages from Python appear in the log window.

Install Python

JMP 16 is a 64-bit program; only 64-bit Python is supported

- Python.org 3.6 through 3.9.1 distributions are supported on Windows and macOS. On Apple silicon, you will not have full functionality until third-party packages have been updated.
- Anaconda 3.6 distribution is supported on Windows only.
- Anaconda 3.7 distribution is not supported on Windows.
- The way Python is built from versions 3.6 to 3.7 changed. In Python 3.7, Python must be installed for all users. Otherwise, the libraries that the Python DLL depend on cannot be located at DLL load time. Other Python distributions might work fine installed for a single user or might also require a system-wide install.
- JMP does not currently support Python virtual environments.

Notes:

- Python is not distributed with JMP. Download Python from the Python web site at https://python.org.
Several Python implementations are available. Visit https://www.python.org/download/alternatives to view the alternatives.

On macOS, installing Python 3.6.x from https://python.org installs in /Library/Frameworks/Python.framework.

**Required Python Packages**

For the JMP-to-Python interfaces to work properly, you must install certain Python packages and their prerequisites. In many Python installations, such as Anaconda, these packages are already installed. If you install Python from Python.org, also install the following packages:

- **numpy**  https://www.numpy.org
- **pandas**  https://pandas.pydata.org
- **matplotlib**  https://matplotlib.org
- **scipy**  https://www.scipy.org
- **sqlite3**  https://www.sqlite.org
- **PyQt5**  https://pypi.org/project/PyQt5/

Use the standard Python update tools to install these packages for your Python configuration. You must use the correct pip-tool for your installation. The pip-tool name is dependent on the what product has installed Python. The installation instructions for Python have instructions on using pip tools.

**Troubleshooting the JMP Python Integration**

Sometimes JMP has trouble locating the correct version of Python. The first thing to try is running Python from the command line. If Python doesn’t run from a terminal or console window, something is wrong with the Python installation.

**Note:** Before you proceed with troubleshooting, verify that you’re running a supported version of Python. See “Install Python” on page 805.

**How JMP Finds Python on Windows**

JMP delays loading Python until a JSL-based script requires access to it. When JMP loads Python, it needs to be able to find the Python shared library and any of the shared libraries that the Python DLL depends on. Once the Python interpreter is loaded, Python needs to be able to find the distribution’s standard Python modules. To guide this process, JMP uses registry entries, environment variables, and user-specified paths.
Python also looks for certain environment variables. Avoid using any user-specified paths or environment variables, and let JMP find Python in the registry. The following methods help JMP locate Python if the automatic location doesn’t work:

- **JMP_PYTHON_MODULE_PATH** is a JMP-specific version of PYTHONPATH. This variable is the replacement for Python Sys Path. In JMP_PYTHON_MODULE_PATH, specify standard OS paths. Separate the paths with a colon on macOS. Separate the paths with a semicolon on Windows.

- **JMP_LIB_PYTHON_PATH** is a JMP-specific version of PYTHONHOME. The variable contains the full path to the Python shared library, or the parent directory to the shared library.

Windows finds Python in the following order of precedence:

1. JMP looks at the environment variables Python Sys Path (deprecated), PYTHONINSTALLPATH (deprecated), and JMP_PYTHON_MODULE_PATH, in that order. JMP uses the first variable that is found.
2. JMP checks JMP_LIB_PYTHON_PATH for a path to the Python shared library.
3. JMP checks for options that are specified in the Python Init() or Python Connect() function calls. Path() corresponds to the location of the Python shared library. Use Python Version() allows you to specify the version of Python to look for.

   Python Sys Path provides the mechanism to set Python’s sys.path variable. If present, script parameters take precedence over the environment variables. There is one caveat. After JMP loads the Python shared library, the library is unloaded only when JMP shuts down. As a result, the Path() portion is only effective on the first load of Python, and does not allow for running different versions of Python in different scripts without shutting down JMP and restarting.

4. JMP reads the Windows registry to determine if Python has been installed. It looks at appropriate locations based on whether the installation was for an individual user or for all users on the Windows machine. If you have specified a Python version, other versions of Python will not be considered.

If JMP cannot locate Python, try the following option in the Python Init() expression:

```python
Python Init( Init Trace( "TRUE" ) );
```

JMP prints details to the log about where it detects Python, including paths and registry entries for Python.

Typically, JMP determines the equivalent to the PYTHONHOME environment variable automatically if it is defined in the Windows registry.

```python
Computer\<root>\SOFTWARE\Python\PythonCore\<version>\InstallPath
```

<root> is either the root key HKEY_LOCAL_MACHINE or HKEY_CURRENT_USER depending on where and how you installed Python. <version> is the Python version number.
If multiple versions of Python are installed on your computer, you must specify which installation for JMP to use.

- The easiest method is to specify the version using the `Use Python Version()` argument in `Python Init()` or `Python Connect()` functions.
- Use the `Path("path to an installed Python DLL or shared library")` argument with the `Python Init()` or `Python Connect()` function.
- Define the `JMP_LIB_PYTHON_PATH` environment variable as described below.

**Change the Default Python Install Location on Windows**

Create the variable in your system environment variables using the Control Panel.

1. Select **Start > Control Panel > System > Advanced system settings**.
2. Click **Environment Variables**.
3. In the System variables pane, click **New**.
4. Type `JMP_LIB_PYTHON_PATH` for the Variable name.
5. Type the path to the `Python<version>.dll` file, for example:
   
   
   `C:/Program Files/Python/<version>/Python<version>.dll`
   
6. Click **OK** and click **OK** again to close the System Properties window.
macOS: Override How JMP Finds Python

Locating Python on the Mac works the same as on Windows except for the step of looking in the registry. JMP looks in a couple of typical installation directories so see if it can locate Python. Python typically installs in `/Library/Frameworks/Python.framework`. A compatible version of Python located in the standard system location should work without any changes to environment variables or parameters passed to JSL.

If Python is installed in an alternate location, set configuration variables in your shell environment as needed. JMP on macOS uses the same environment variables as described in “How JMP Finds Python on Windows” on page 806.

`JMP_LIB_PYTHON_PATH` is the path to the Python shared library `libpython3.x.dylib`, where \( x \) is the minor version. If environment variables are needed, you typically only need to set `JMP_LIB_PYTHON_PATH`.

If JMP is unable to find install Python packages, you might also need to set the variable `JMP_PYTHON_MODULE_PATH`. The `JMP_PYTHON_MODULE_PATH` contains the same paths that the Python call `print(sys.path)` outputs. When you set an environment variable, use host OS path conventions. When the variable is passed in JSL, use a JSL list.

One way is to have Python tell you what it thinks its `sys.path` should be. In the example in this section, the same Python commands can be run on Windows to determine `sys.path`.

In the terminal or console window, enter the following boldface commands to get a string that specifies the location of the Python packages:

```
MDz320:~ shlori$ python --version
Python 3.6.4 :: Anaconda, Inc.
MDz320~ shlori$ python3
Python 3.6.4 |Anaconda, Inc.| (default, Jan 16 2018, 12:04:33) [GCC 4.2.1 Compatible Clang 4.0.1 (tags/RELEASE_401/final)] on darwin Type "help", "copyright", "credits" or "license" for more information.
>>> import sys
>>> print(sys.path)
```

Test Your Setup

To test that your computer is able to run JSL scripts that use Python, run the following script:

```javascript
Python Init();
Python Submit( \[basket = ['apple', 'orange', 'pear']
print(basket)\]" );
Python Term();
```
You should see the following output in the log:

```
['apple', 'orange', 'pear']
0
```

## JMP-to-Python Interfaces

JMP provides the interfaces to access Python that are described in the following sections. The basic execution model is to first initialize the Python connection, perform the required Python operations, and then terminate the Python connection. In most cases, these functions return 0 if the Python operation was successful or an error code if it was not. If the Python operation is not successful, a message is written to the log. The single exception to this is `Python Get()`, which returns a value.

### Python JSL-Scriptable Object Interfaces

The Python interfaces are also scriptable using a Python connection object. A scriptable Python connection object can be obtained using the `Python Connect()` function.

```python
// return a Python connection scriptable object
PythonConnection = Python Connect();

// return 1 if a Python connection is active. Otherwise, returns 0.
x = PythonConnection << Is Connected;
Show( x );
PythonConnection << Disconnect;
x = 1;
0
```

### Equivalent Data Types for Python Send()

Table 14.5 shows what JMP data types can be exchanged with Python using the `Python Send()` function. Sending lists or associative arrays to Python recursively examines each element of the list or associative array and sends each base JMP data type. Nested lists and associative arrays are supported.

<table>
<thead>
<tr>
<th>JMP Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Boolean</td>
</tr>
<tr>
<td>Data Table</td>
<td>Pandas.DataFrame</td>
</tr>
<tr>
<td>Associative Array</td>
<td>Dictionary</td>
</tr>
</tbody>
</table>
Table 14.5 Equivalent JMP and Python Data Types for Python Send() (Continued)

<table>
<thead>
<tr>
<th>JMP Data Type</th>

</tr>
<tr>
<td>Matrix</td>
<td>Float Matrix</td>
</tr>
<tr>
<td>List</td>
<td>List</td>
</tr>
<tr>
<td>String</td>
<td>Unicode String</td>
</tr>
</tbody>
</table>

Python Send() Example

```python
Python Init();
X = 1;
Python Send( X );
S = "Report Title";
Python Send( S );
M = [1 2 3, 4 5 6, 7 8 9];
Python Send( M );
Python Submit( "\[
print(X)
print(S)
print(M)
]\" );
Python Term();
```

Equivalent Data Types for Python Get()

Table 14.6 shows which JMP data types can be exchanged with Python using the Python Get() function. Getting lists from Python recursively examines each element of the list and gets each base Python data type. Nested lists are supported.

Table 14.6 Equivalent Python and JMP Data Types for Python Get()

<table>
<thead>
<tr>
<th>Python Data Type</th>
<th>JMP Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Numeric Matrix</td>
</tr>
<tr>
<td>Date and time</td>
<td>Numeric</td>

<td>String</td>
</tr>
</tbody>
</table>

Python Get() Example

```python
Python Init();
x1 = [1, 2, 3];
Python Send( x1 );
x2 = Python Get( x1 );
Show( x1, x2 );
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
Python Send( dt1 );
dt2 = Python Get( dt1 );
dt2 << New Data View;
Close( dt1 );
Python Term();
```

JMP Scoping Operators and Python

A JMP object sent to Python with `Python Send()` uses the same JMP reference as the name of the Python object that gets created. For example, sending the JMP variable `dt` to Python creates a Python object named `dt`.

The colon and double colon JSL scoping operators (`:` and `::`) are not valid in Python object names, so the colons are converted as follows:

- A single colon scoping operator is replaced with an underscore (`_`). For example, sending `nsref:dt` to Python creates a corresponding Python object named `nsref_dt`.
- A double colon scoping operator (designating a global variable) is ignored.
For example, sending ::dt to Python creates a corresponding Python object named dt.

**Note:** The Python Name option for Python Send() has a quoted string argument that contains a valid Python object name. The JMP object sent to Python becomes a Python object with the specified name.

### Python Name() and Python Send() Examples

The following example creates the jmp var name variable, assigns it to the Python name python_var_name, submits the print statement, and closes the connection.

```python
Python Init();
jmp var name = 25;
Python Send( jmp var name, Python Name( "python_var_name" ) );
Python Submit( "print(python_var_name)" );
Python Term();
25.0
```

The following example creates a variable x in the Here namespace, a variable y in the global namespace, and a variable z that is not explicitly referenced to any namespace. The variable z defaults to Global unless Names Default To Here(1) is on. These variables are then passed to Python.

```python
Here:x = 1;
::y = 2;
z = 3;

Python Init(); // initiate the Python connection

/* send the Here variable to Python
   Here:x creates the Python object Here_x */
Python Send( Here:x );

Python Submit( "print(Here_x)" );

Python Send( ::y ); // ::y creates the Python object y
Python Submit( "print(y)" );

// to use a different name for the Python object, use the Python Name() option
Python Send( Here:x, Python Name( "localx" ) );

/* The Python Name option to the Python Send() command creates the Python object named "localx", which corresponds to the JMP variable "Here:x". */
Python Submit( "print(localx)" );
```
Additional Python Integration Examples

Send a Data Table to Python

This example initiates a Python connection, sends a data table to Python, prints it to the log, and closes the Python connection.

```python
Python Init();
dt = Open( "$SAMPLE_DATA/Big Class.jmp", invisible );
Python Send( dt ); // send the opened data table represented by dt to Python
Python Submit( "print( dt )" );
Python Term();
```

<p>| | | | | |</p>

</tr>
</tbody>
</table>

Create Objects in Python

This example initiates a Python connection, creates a Python object, retrieves the object into JMP, and closes the Python connection.

```python
Python Init();
Python Submit("\[
import numpy as np
import pandas as pd
# Generate basic series
ss = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
print(ss)
sn = pd.Series(np.random.randn(5))
print(sn)
# Generate Data Frames from Series
```

```python
import numpy as np
import pandas as pd
# Generate basic series
ss = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
print(ss)
sn = pd.Series(np.random.randn(5))
print(sn)
```
s1 = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
print(s1)
dfs1 = pd.DataFrame(s1)
print(dfs1)

d1 = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
      'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
print(d1)
dfd1 = pd.DataFrame(d1)
print(dfd1)

d2 = {'one': [1., 2., 3., 4.],
      'two': [4., 3., 2., 1.]}    
print(d2)
dfd2 = pd.DataFrame(d2)
print(dfd2)"
);
ss = Python Get( ss );    
Show( ss );
sn = Python Get( sn );    
Show( sn );
dfs1 = Python Get( dfs1 );
dfs1 << New Data View;
dfd1 = Python Get( dfd1 );
dfd1 << New Data View;
dfd2 = Python Get( dfd2 );
dfd2 << New Data View;
Python Term();
   a   -0.384649
   b    0.455864
   c   -2.214405
   d    0.260955
   e    1.342286
dtype: float64
...

Matrix Operations in Python

In JMP, a simple matrix looks like this:

xx = [1 2 3, 4 5 6, 7 8 9 ];

In numpy, the matrix is an array:

xx = numpy.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

In order to submit a matrix as a numpy array, you must translate the JMP matrix.

q = "new = numpy.array (";
Work with Microsoft Excel

You can script the Profiler interface to Microsoft Excel, although not the Transfer to JMP interface. Here is the basic syntax:

```javascript
For( i = 1, i <= N Items( xx ), i++,
    zz = Matrix( xx[i] );
    q = q || Char( zz ) || ",";
);
q = q || "");
Show( q );
```

```python
Python Submit( "import numpy
" || q );
Python Submit( "print(new)" );
```

**Parse XML**

JSL has several commands available to parse XML.

```javascript
Parse XML( string, On Element( "tagname", Start Tag( expr ), End Tag( expr ) ) );
```

parses an XML expression using the On Element() expression for specified XML tags.

```javascript
value = XML Attr( "attribute name" );
```

extracts the string value of an XML argument when evaluating a Parse XML() expression.

```javascript
value = XML Text();
```

extracts the string text of the body of an XML tag when evaluating a Parse XML() expression.
Example of Parsing XML

Suppose that a Microsoft Excel file contains one row of data from Big Class.jmp. The file is saved as the valid XML document BigclassExcel.xml, shown here and also saved in the JMP Samples/Import Data folder.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Workbook xmlns="urn:schemas-microsoft-com:office:spreadsheet"
xmlns:o="urn:schemas-microsoft-com:office:office"
xmlns:x="urn:schemas-microsoft-com:office:excel"
xmlns:ss="urn:schemas-microsoft-com:office:spreadsheet"
xmlns:html="http://www.w3.org/TR/REC-html40">
  <Worksheet ss:Name="Bigclass">
    <Table ss:ExpandedColumnCount="5" ss:ExpandedRowCount="41"
      x:FullColumns="1"
      x:FullRows="1">
      <Row>
        <Cell><Data ss:Type="String">name</Data></Cell>
        <Cell><Data ss:Type="String">age</Data></Cell>
        <Cell><Data ss:Type="String">sex</Data></Cell>
        <Cell><Data ss:Type="String">height</Data></Cell>
        <Cell><Data ss:Type="String">weight</Data></Cell>
      </Row>
      <Row>
        <Cell><Data ss:Type="String">KATIE</Data></Cell>
        <Cell><Data ss:Type="Number">12</Data></Cell>
        <Cell><Data ss:Type="String">F</Data></Cell>
        <Cell><Data ss:Type="Number">59</Data></Cell>
        <Cell><Data ss:Type="Number">95</Data></Cell>
      </Row>
    </Table>
  </Worksheet>
</Workbook>
```

The following script reads BigclassExcel.xml and creates a JMP data table with the information in it. This script, named ParseXML.jsl, is in the JMP Samples/Scripts folder.

```javascript
file contents = Load Text File( "$SAMPLE_IMPORT_DATA/BigclassExcel.xml" );
Parse XML( file contents,
  OnElement("urn:schemas-microsoft-com:office:spreadsheet^Worksheet",
    StartTag( sheetname = XML Attr("urn:schemas-microsoft-com:office:spreadsheet^Name",
      "Untitled"
    ),
    dt = New Table( sheetname ),
    row = 1;
```
OLE Automation

Most of JMP can be driven through OLE automation. Please see the Automation Reference.pdf at https://www.jmp.com/en_us/support/jmp-documentation.html for more information about automating JMP. This document introduces how to automate JMP through Visual Basic and using Visual C++ with MFC. It also contains more information about the methods and properties that JMP exposes to automation clients like Visual Basic and Visual C++.

Share Reports on JMP Live

Write JSL scripts to automate the generation of JMP analyses and publish them to JMP Live.

**JMP Live Prerequisites**

Before you can use JSL to publish reports to JMP Live, do the following:

1. Get an API key (if required by a JMP Live administrator). See [Get an API Key](#).
2. Establish a connection to a JMP Live server. See [Using JMP](#). When you add a JMP Live server, you need to enter your API key (if required).

   When you establish a connection, a JMP Live Connection is created in JSL:
   ```javascript
   liveconnection = New JMP Live( Connection( "My JMP Live" ), Prompt( If Needed ));
   ```
   where "My JMP Live" is the name of the JMP Live server connection you created. If authentication is required, an interactive prompt appears. You can change the `Prompt` to `No`, but if authentication is required, the connection fails.

**Get an API Key**

Before you can script reports and publish them to JMP Live, you might need an API key. JMP Live administrators determine whether an API key is required for scripting.

An API key is unique for a user and a JMP Live server. That means that if you obtain a new API key, it overrides the previous one, and any scripts using the previous API key will need to be updated to use the new API key.

To obtain an API key:

1. Log into JMP Live.
2. At the top, click your user icon and select **Settings**.
3. Click **Generate API Key**. Make a note of your key.
Publish a Single Report to JMP Live

Publish a single report to JMP Live using a JMP Live Report.

The following example creates a Bivariate report and an empty JMP Live Report called webreport, adds the Bivariate report to the webreport, and publishes the webreport to JMP Live:

```julia
dt = Open( "$SAMPLE_DATA\Big Class.jmp" );
// Create a Bivariate report.
biv = Bivariate( X( :Height ), Y( :Weight ));
// Create an empty JMP Live Report.
webreport = New Web Report();
/* Add the Bivariate report to the webreport. A title is required and a description is optional.*/
webreport << Add Report( biv, Title( "Bivariate Report" ), Description( "A test of the new scripting" ));
/* Publish the webreport to JMP Live as a private report. Use the JMP Live Connection you established and return a JMP Live object called liveresult. */
liveresult = liveconnection << Publish( webreport );
```

You can use JSL to make the report visible to everyone or share the report with groups in JMP Live. See the Set Public and Share With Groups messages in the JMP Scripting Index at Help > Scripting Index.

Work with a JMP Live Result

The Publish function returns a JMP Live Result (liveresult). Use JSL scripting functions on a JMP Live Result to get information, such as whether the publishing succeeded or failed, failure codes, and more:

```julia
// Return the outcome of the last action.
liveresult << Succeeded();
// Return any error messages from the last action.
liveresult << Get Error Message();
```

The JMP Live Result can be made scriptable and turned into a JMP Live Report (for a single report) or a JMP Live Folder object (for multiple reports) so that you can send commands to it. The following example changes a JMP Live Result into a scriptable JMP Live Report and then changes the report access from private to public:

```julia
livereport = liveresult << As Scriptable();
livereport << Set Public( 1 );
```

See the JMP Live Report object in the JMP Scripting Index at Help > Scripting Index.
Publish Several Reports to a JMP Live Folder

Publish several reports to JMP Live by creating a JMP Live Folder and adding the JMP Live Report to the folder. A JMP Live Report object can hold a single report or multiple reports.

The following example creates a scriptable JMP Live Folder and a JMP Live Report called `webreport`, adds a Bivariate and a Oneway report to the `webreport`, and adds the reports to a folder:

```jsl
/* Create a folder in JMP Live. A title is required and a description is optional. Use the JMP Live Connection you established and return a JMP Live object called liveresult. */
liveresult = liveconnection << Create Folder( Title( "Test Folder" ),Description( "Folder created for script testing" ));
// Make the liveresult scriptable.
folder = liveresult << As Scriptable();
// Create an empty JMP Live Report.
webreport = New Web Report();
// Add a Bivariate report to the webreport.
webreport << Add Report( biv, Title( "Bivariate Report" ));
// Add a Oneway report to the webreport.
webreport << Add Report( oneway, Title( "Oneway Report" ));
// Add the reports to the folder.
liveresult = folder << Add Reports To Folder( webreport );
```

You can use JSL to share the folder with JMP Live groups. See the Share With Groups object in the JMP Scripting Index at Help > Scripting Index.

Delete Reports in a JMP Live Folder

You can delete reports and folders using JSL. Folders must be empty before they can be deleted.

```jsl
returncode = liveconnection << Delete Report( report << Get ID() );
returncode = liveconnection << Delete Folder( folder << Get ID() );
```

In both of these cases, a value of 1 (True) or 0 (False) will indicate if the operation was successful.

Replace the Contents of a JMP Live Report

You can replace the contents of an existing report rather than creating a new report with updated content. You need to know the ID of the report you want to replace. If you have the report object available, you can use the Get ID( ) function to return the ID.
The following example creates a new JMP Live Report called `webreport2`, adds an updated Oneway report, and replaces an existing Oneway report using the report ID:

```julia
// Create an empty JMP Live Report.
webreport2 = New Web Report();
/* Add a Oneway report to webreport3. A title is required and a description is optional. */
webreport2 << Add Report( oneway, Title( "New Oneway Report" ), Description( "Replace a report" ));
/* Use the JMP Live Connection you established to replace the report with the specified ID with webreport2. */
liveconnection << Replace( webreport2, ID(report << Get ID() ));
```

### Search for a JMP Live Report or Folder ID

For many JSL functions, you need to know the report or folder ID. Using JSL, you can search by keyword (in the title or description) or by the publisher of the report or folder. If your search may return many results, you can specify how many results to return at a time.

The following example searches all reports that contain the word "Production" in the title or description, and are published by a user with the display name "dianesmith". It also specifies that the search will return up to ten items at a time.

```julia
/* Search for reports with the keyword Production that are published by the user dianesmith. Return no more than 10 results at a time. */
liveresult = liveconnection << Find Reports( Search( "Production" ), Publisher( "dianesmith" ), ( PageSize( 10 ));
// Change the liveresult into JMP Live Reports and make them scriptable.
livereports = liveresult << As Scriptable();
// Show how many results are returned.
show( livereports << Get Number Of Items());
// Return the first report in list of results.
report1 = livereports[ 1 ];
// Show the title of the first report.
show( report1 << Get Title());
```

In the example above, if you might have more than ten results, you can page through them using the Next and Previous functions:

```julia
// Put the next 10 results into the next page.
nextpage = livereports << Next();
// Show the current page number.
show( livereports << Get Current Page Number());
// Get the first item in the list of items in the next page.
next1 = nextpage[ 1 ];
// Show the title of the first report.
show( next1 << Get Title());
```
// Show the number of items in the current page.
show( nextpage << Get Number Of Items());

If Next() finds no further pages, an error appears, which you should catch to proceed with further processing.

**Tip:** If you know the number of pages to expect, you can jump directly to a page. See the Get Page function in the JMP Scripting Index at [Help > Scripting Index](#).

**Update Data in JMP Live Reports**

If the data behind a JMP Live report changes, you can update the data and regenerate the report. You can update the data for a standalone report (using the report ID) or for all the reports in a folder (using the folder ID).

The following example updates data for an individual report. Suppose that in the Big Class.jmp data table, a subject’s age changed and you want to update an associated age report on JMP Live.

```julia
dt:Age[1] = 77;
/* Use the JMP Live Connection you established to update the data for the report with the specified ID based on the updated Big Class.jmp data table. */
updateresult = liveconnection << Update Data( report << Get ID( ), Data( dt, "Big Class.jmp") );
// Show the outcome of the update.
show( updateresult << Succeeded );
```

Similarly, you can also specify the folder that the report resides in:

```julia
updateresult = liveconnection << Update Data( folder << Get ID( ), Data( dt, "Big Class.jmp") );
```

Only reports in the folder using the specified data table update.

**Work with Other Content in JMP Live Reports**

Primarily in JSL, you work with JMP Live folders and reports. However, you can publish images to JMP Live reports. In JSL, you can use a generic object called a JMP Live Post to manage images or other content that does not fall under reports or folders. See the JMP Live Post function in the JMP Scripting Index at [Help > Scripting Index](#).
Communicate with REST Web Services

Representational state transfer (REST) or RESTful web services is a way of providing interoperability between computer systems on the Internet. Use JSL to communicate with a RESTful application program interface (API) that uses HTTP requests to GET, POST, PUT, and DELETE data. For example, you can get data from a web service and return it as a data table. Some web services are Amazon Web Services (AWS), DropBox, and Text-Processing.com.

Notes:

- Strings that contain “&” are truncated. “+” is converted to a space.
- New HTTP Request() supports redirects, for example, from HTTP to HTTPS.

Examples of HTTP Requests

The following examples communicate with the National Aeronautics and Space Administration (NASA) API. You must request a key from https://api.nasa.gov/index.html#apply-for-an-api-key and assign it to the key variable to run the scripts successfully.

Write Data to the Log

```julia
url = "http://technology.nasa.gov/api/query/patent/all";
request = New HTTP Request( URL( url ), Method( "Get" ) );
data = request << Send();
Write( data );
{"results":[["59fa04859600022b4d2e076f","LAR-TOPS-48","All-Organic Electroactive Device","NASA's Langley Research Center offers you an all-organic electroactive device system fabricated with single-wall carbon nanotube (SWCNT)....

// JSON output written to the log
```

Notes:

- The query string is at the end of the URL, following “?” For example, in https://www.google.com/search?q=jmp, “q=jmp” is the query string. New HTTP Request() automatically URI-encodes key/value pairs in a query string (and FORM).
- When you put an associative array in either a query string or a form, the key/value pairs get URI encoded. Spaces, ampersands, and other characters get encoded to ASCII, and the ampersand is escaped. The encoding is a “%” encoding.
- The web service defines the valid key/value pairs that it accepts. Refer to the API documentation for valid key/value pairs.
Return Data as an Associative Array and Write it to the Log

```
url = "http://technology.nasa.gov/api/query/patent/all";
request = New HTTP Request( URL( url ), Method( "Get" ) );
json = request << Send();
jsl_json = Parse JSON( json );
// turns JSON data into a JSL associative array
results = jsl_json["results"];
Write( results );
{{"59fa04859600022b4d2e076f", "LAR-TOPS-48", "All-Organic Electroactive Device", "NASA's Langley Research Center offers you an all-organic electroactive device system fabricated with single-wall carbon nanotube (SWCNT)...."}}
// associative array
```

Return Data as a JMP Data Table

```
url = "http://technology.nasa.gov/api/query/patent/all";
request = New HTTP Request( URL( url ), Method( "Get" ) );
json = request << Send();
jsl_json = Parse JSON( json );
json = As JSON Expr( jsl_json["results"] );
dt = JSON To Data Table( json,
    JSON Settings(
        Stack( 0 ),
        Col("/root",
            Column Name( "root" ),
            Fill( "Use Once" ),
            Type( "Pandas Values" ),
            Format( {"Best"} ),
            Modeling Type( "Continuous" )
        )
    )
);
dt << Set Name( "NASA Patents" );
```
OAuth 2.0 for Web APIs

OAuth 2.0 is an authorization standard for accessing personal user information through web APIs. An authorization standard is an agreed upon set of rules by many major web companies that are responsible for authorizing who can access information, and what scope of information they can access. This authorization is granted in the form of a limited time access token (a unique identifier specific to the individual and the scope of information they can access). Due to this two-pronged approach of limiting both users and scopes, OAuth is the current standard for securing personal information. Web sites such as Google, Salesforce, Reddit, and Dropbox use OAuth 2.0.

Since OAuth secures your personal information, it can appear to be fairly complex. OAuth is even more complicated due to the variety of ways it is implemented, which are called grant types. We’ll walk through the different ways you can get an OAuth token in JSL. Please note that not all methods will work with all companies, so you’ll have to do a little research to find out which grant type to use. Usually, the company will have documentation of this either with their APIs or possibly in a separate OAuth section.
We recommend that you familiarize yourself with the OAuth protocol at the official website (https://oauth.net/2/).

**Note:** Only OAuth 2.0 is supported in JSL. OAuth 1.0 and 1.0a are still used by a handful of companies (such as Twitter) but are largely regarded as inferior to 2.0.

**Security**

OAuth tokens can contain sensitive information. Depending on the grant type, you might need to provide your password or a client secret. JMP automatically handles this information for you.

Information that Google uses to authenticate your account is stored in C:/Users/<username>/AppData/Roaming/SAS/JMP/OAuthTokens.jmp. (Your Google password is not stored.) After using an OAuth token on your personal account, you can delete all columns except for User and Client ID. Keep in mind that if you need to share your script, others won’t have the User and Client ID columns saved on their machine. We recommend moving this information to an encrypted JSL script before sharing the OAuth script.

**Using Postman for Redirect URLs**

JMP does not provide a redirect URL for free. However, using Postman, it is easy to set one up yourself. Some examples that follow use Postman to redirect requests.

2. Click the orange sign-in button in the top right corner.
3. Sign in with your Google account, or proceed to create your own account.
4. You can then use https://app.getpostman.com/oauth2/callback as a redirect URL.

**Authorization Code Grant**

The Authorization Code grant usually sends refresh tokens. Refresh tokens are unique in that they act as a sort of pseudo, permanent access token. Although you won’t access sensitive information with them, a refresh token is all you need to get more access tokens. Treat it like you would your password.

The following code snippet creates an OAuth token using the Authorization Code grant. Notice this requires Request Auth(), Client Secret(), and Redirect URL(). Remember, after you make the token once, you can remove everything but the User and Client ID from OAuthTokens.jmp.

```jscript
token = New OAuth2 Token(
```
User( "Test User" ),
Client ID( "12ab" ),
Client Secret( "3456dEfG" ),
Request Auth(
  Scope("history"),
  Auth URL( "https://example.com/services/oauth2/authorize" ),
),
Redirect URL( "https://www.getpostman.com/oauth2/callback" ),
Token URL( "https://example.com/services/oauth2/token" )
);

Note: See your API documentation for more information about how to get values such as the client secret and token URL.

After you run this code once, clean it up and make it secure.

token = New OAuth2 Token(
  User( "Test User" ),
  Client ID( "12ab" ),
);

Existing Refresh Tokens

You might already be familiar with OAuth and have saved a refresh token to your script. The following snippet creates an OAuth token with that existing token.

token = New OAuth2 Token(
  User( "yourgoogleaccount@gmail.com" ),
  Refresh Token( "1a2b3c4e5F" ),
  Token URL( "https://www.example.com/oauth2/token" ),
  Client ID( "12ab" ),
  Client Secret( "3456dEfG" )
);

After you run this code once, clean it up and make it secure.

token = New OAuth2 Token(
  User( "yourgoogleaccount@gmail.com" ),
  Client ID( "12ab" )
);

Implicit Grant

The Implicit grant type doesn’t require any sensitive information. If you’re going to share a script with other people, it would be easiest to use this grant type. Note, however, that because sensitive information isn’t required, services are less likely to implement this flow.
The following code snippet creates an OAuth token using the Implicit grant. This requires Redirect URL().

```javascript
token = New OAuth2 Token(
    User( "Implicit Flow"),
    Client ID( "123abc" ),
    Redirect URL( "https://www.getpostman.com/oauth2/callback" ),
    Token URL( "https://example.com/services/oauth2/token" )
);
```

**Resource Owner Grant**

The Resource Owner grant is the only type that doesn’t require a redirect URL. If setting up Postman (the API development platform) is proving difficult, try this grant type.

The following snippet will create an OAuth token using the Resource Owner grant. This requires Client Secret() and Password().

```javascript
token = New OAuth2 Token(
    User( "yourgoogleaccount@gmail.com" ),
    Password( "wordP@ss0192" ),
    Client ID( "1234abcd" ),
    Client Secret( "5678EfGh" ),
    Token URL( "https://example.com/services/v1/token" )
);
```

After you run this code once, clean it up and make it secure.

```javascript
token = New OAuth2 Token(
    User( "yourgoogleaccount@gmail.com" ),
    Client ID( "1234abcd" ),
);
```

**Using a Token**

In order to access a web API that requires OAuth, pass the token to HTTP Request() using the OAuth2 field.

```javascript
request = HTTPRequest(
    URL( apiEndpoint ),
    Method( "POST" ),
    OAuth2( token ),
);
```
OAuth 2.0 Resources

The official website for OAuth 2.0 is https://oauth.net/2/.
https://auth0.com/docs/protocols/oauth2 provides more information about the OAuth 2 protocol.

Google provides comprehensive documentation and examples of OAuth 2.0 at https://developers.google.com/identity/protocols/OAuth2.

Communicate with SAS Cloud Analytic Services

SAS Viya uses Cloud Analytic Services (CAS) code to perform calculations in the cloud. This feature provides a way for SAS Viya users and JMP users to collaborate. You can write CAS code in JMP to import data from and export data to the CAS server, convert CAS JSON text to a JMP data table, get a list of available CAS libraries, and more.

- See the SAS CAS documentation at https://developer.sas.com/apis/cas/rest/current/apidoc.html for more information.
- The SAS CAS documentation for CAS actions cover CASL, R, Python, Lua.
This section covers the following topics:

- "About CAS Actions"
- "Connect to the CAS Server"
- "Create and Submit a CAS Action"
- "Create and Submit a CAS DATA Step Action"
- "Create a New CAS Server"
- "Import Data from the CAS Server"
- "View a CAS Dataset"
- "Get a List of Available CAS Libraries"
- "Export Data from a Data Table to a CAS Server"
- "Convert a CAS Table to a Data Table"
- "Delete a CAS Table"
- "Remove a CAS Table"
- "Verify the CAS Server Connection"
- "Get Details about the Current Connection"
- "Disconnect from the CAS Server"
- "Terminate All CAS Sessions"

**About CAS Actions**

The smallest unit of work for the CAS server is a CAS action. CAS actions can load data, transform data, compute statistics, perform analytics, and create output.

You configure each action by specifying a set of input parameters. Running a CAS action on the CAS server processes the action’s parameters and the data, and creates an action result. See CAS Actions at https://developer.sas.com/apis/cas/actions.html.

The JSON parameters are specified in the CAS documentation CAS REST API. See https://developer.sas.com/apis/cas/rest/current/apidoc.html. For JSON, you can look at the Lua format and make the appropriate adjustments.

For example, in Figure 14.6, notice the difference between the JSON syntax and the Lua syntax. JSON uses the "name" : value format. Lua uses the name = value syntax.
Connect to the CAS Server

You can show the login window and prompt the user to provide the URL for the CAS server and their login information.

```javascript
CAS Connect( Prompt( "Never"|"Always"|"IfNeeded" ) );
```

To add the login details to the script, follow this example:

```javascript
CAS Connect( URL( URL ), Username( username ), Password( password ) );
```

Information about the CAS server appears in the log after the user logs in.

To specify a trusted certificate for https connections to the CAS server, use the optional Certificates argument.

```javascript
CAS Connect( URL( URL ), Certificates( string ) );
```

Create and Submit a CAS Action

```javascript
New CAS Action( Action( "builtins.echo" ), JSON( echo ) );
```

`Action` is the JSL variable name. `builtins.echo` is the name of the CAS action that SAS created. `echo` contains the JSL arguments.

Create and Submit a CAS DATA Step Action

```javascript
New CAS DATA Step action( Code( code ) );
```

code defines the contents of the DATA step. `Action` is the JSL variable name.
cas = Current CAS Connection();

code =
"[
    data temp;
    x = 9.1; y = 6; z = sqrt(x**2 + y**2);
    A = "SAS"; B = "Statistics";
    put _ALL_;              /* display all variables and values */
    run;
]"

action = New CAS DATA Step action( Code( code ) );
cas << Submit( action );

---

Create a New CAS Server

New CAS Server() creates a new CAS server.

url = "URL";
cas = New CAS Server( Connect( URL( url ), Prompt( "Never"|"Always"|"IfNeeded" ) ) ) ;

---

Import Data from the CAS Server

CAS Import Data() imports data from the CAS server:

CAS Import Data( libref.dataset, <Private|Invisible>, <!Use Labels for Var Names>);

• invisible hides the data table from view but shows it in the JMP Home Window.
  private hides the data table completely. Specify private if the user doesn’t need to
  interact with the data table.
• "Use Labels for Var Names" indicates that the table name and the column names will
  be set to the SAS dataset label and the column labels. The appropriate column property,
  SAS Name SAS Label, is used.

---

View a CAS Dataset

CAS datasets are on the CAS file system. Datasets in memory are not listed.

To see the datasets on the CAS server that you want to import, use CAS Get Data Sets() after you connect to the server.

The following example shows how to list datasets that are only in casuser:

datasets = CAS Get Data Sets( casuser ); // quote the argument
Show( datasets );
The following example shows how to lists datasets that you have permissions to view:

```julia
datasets = CAS Get Data Sets();
Show( datasets );
```

### Get a List of Available CAS Libraries

Libraries are namespaces, just like SAS libraries, librefs, or libnames. Use `CAS Get Libraries()` to get libraries from the CAS server.

```julia
libraries = CAS Get Libraries();
Show( libraries );
```

### Export Data from a Data Table to a CAS Server

`CAS Export Data()` exports a data table to a CAS server to run an action on it.

```julia
CAS Export Data(
    Open( "$SAMPLE_DATA/Big Class.jmp" ),
    "casuser",
    "Big Class"
);
```

`CAS Export Data()` also has two arguments:

- `Save(0)` saves the data in memory.
- `Save(1)` saves the data to the file system.

### Convert a CAS Table to a Data Table

`CAS Table To Data Table()` converts JSON data to a data table. A JSON element in the results of an action contains "_ctb". This is a marker indicating that it is formatted to represent a CAS table. You can send the JSON results to `CAS Table To Data Table()`. JMP will create a JMP data table from the JSON.

If there’s more than one result, you might need to perform a little extra work as shown with `Get Results` at the end of the following example. This example shows how to export data, run an action, and save the data in several data tables.

```julia
cas = Current CAS Connection();
If( IsEmpty( cas ),
    cas = CAS Connect( URL( url ), Username( username ), Prompt( "IfNeeded" ) );
);
dt = Open( "$SAMPLE_DATA/Animals.jmp" );
cas << Export Data( dt, "CASUSER.Animals" );
```
json = "\[
{
  "table": {

action = New CAS Action(
  Action( "mixed.mixed" ),
  json
);
Get Results enables you to examine the results of a CAS action; it’s a JSL associative array. Get JSON gives you the raw JSON; it’s a JSL string.

The JSON data is in the format discussed at https://developer.sas.com/apis/cas/rest/current/apidoc.html. Search for “ResultsTable”.

In CAS Table to Data Table(), specify the JSON string, open the data table as invisible or private, and control the table name and column names.

```json
json = "jsonstring";
CAS Table to Data Table( json, <Invisible(Boolean)|Private(Boolean)>, <"Use Labels For Var Names">);
```

- **Invisible** hides the data table from view but shows it in the JMP Home Window.
- **private** hides the data table completely. Specify Private if the user doesn’t need to interact with the data table.
- "Use Labels for Var Names" indicates that the table name and the column names will be set to the SAS dataset label and the column labels. The appropriate column property, SAS Name SAS Label, is used.

**Note:** CAS ResultsTable attribute values (peers to "_ctb") found in the "_ctb" JSON are also set as table variables. The "CREATETIME" attribute creates a character table variable with a locale-formatted timestamp (for example, 04/03/2019 4:38:05 PM).

### Delete a CAS Table

CAS Delete Table() deletes the underlying file from the CAS file system.

```cas
CAS Delete Table( table name, <remove> ); // quote the table name
```

The CAS Delete Table() function has a remove option, which removes an in-memory table from the CAS server. CAS Remove Table() serves the same purpose.
Remove a CAS Table

Remove CAS Table() removes an in-memory table from the CAS server.

CAS Remove Table( casuser, Big Class ) // quote both arguments

Verify the CAS Server Connection

CAS Is Connected() determines whether the CAS server is connected.

connected = CAS Is Connected();
Show( connected );
connected = 1;

Get Details about the Current Connection

Current CAS Connection() obtains details about the current connection: the URL of the CAS server, your user name, and the session ID.

connection = Current CAS Connection();
Show( connection );

Disconnect from the CAS Server

CAS Disconnect() disconnects from the current CAS server and optionally terminates the session. By default, the session is terminated when disconnected.

CAS Disconnect(<"Terminate"|"NoTerminate">);

Terminate All CAS Sessions

CAS Terminate Sessions() ends all sessions owned by the current user except for the current session.

CAS Terminate Sessions();

You can also specify the session ID to terminate the specified session.

CAS Terminate Sessions(session ID);

Use Get Session() to get the session ID.

url = "http://myCASserver"; // quoted string
cas = CAS Connect(
    URL( url ),
    Username( "my_username" ), // quoted string
    Prompt( "IfNeeded" )
)
);  
    session_id = cas << Get Session;

To terminate the current session, use CAS Disconnect().
A JMP project provides a way to organize files that you use in an analysis. You can add JMP files (reports, data tables, scripts, journals, and so on) and non JMP files, such as Microsoft Word or Adobe PDF files. After you perform an analysis, the data table, report, and graph appear in the project on tabs. You can display multiple reports or graphs, display the project or script editor log, and run scripts from the project. Reports and graphs remain linked to the data table.

Projects help you avoid the clutter of several open JMP windows. You can maximize the project window to have a bigger view of the project. And when you save the project, the state of the project is saved (for example, the open reports and the layout of the window).

Create a Simple Project

A JMP project provides a way to organize files that you use in an analysis and display the output. A simple project might display the data table, graphs, and reports on separate tabs in the project window.

```julia
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
);
```

Figure 15.1 shows the project with selected bars, showing that the graph is still linked to the data table.

**Figure 15.1** Example of a Simple Project
Note: The best way to learn how to script a project is to create it interactively, change the project file’s extension to .jsl, and open the file in JMP.

Create a Project with a Bookmarks Pane and Log

A more complicated project might include a Bookmarks pane (to show file, folders, and groups that use frequently), and a project log. The data table and output are in separate tabs.

Begin by creating a new project and creating a bookmark.

```julia
project = New Project();
project << Add Bookmarks(
   File( "SAMPLE_DATA/Big Class.jmp" )
);
```

Run Script opens the data table and creates output inside the project.

```julia
project << Run Script(
   Open(
      "SAMPLE_DATA/Big Class.jmp",
      Set Window ID( "data" ) // unique window ID
   );
   Distribution(
      Set Window ID( "distrib" ),
      Continuous Distribution( Column( :weight ) ),
      Nominal Distribution( Column( :age ) )
   );
   Graph Builder(
      Set Window ID( "graphbuilder" ),
      Size( 443, 409 ),
      Show Control Panel( 0 ),
      Fit to Window( "Maintain Aspect Ratio" ),
      Variables( X( :age ), Y( :height ), Y( :weight ) ),
      Elements( Position( 1, 1 ), Line( X, Y, Legend( 1 ) ) ),
      Elements( Position( 1, 2 ), Bar( X, Y, Legend( 2 ) ) )
   );
);
```

Set Layout specifies the layout of the tabs that show the data table and output.

```julia
project << Set Layout(
   V Splitter Box(
      Size( 1215, 700 ),
      <<Set Sizes( {0.77, 0.23} ),
      <<Dockable(),
      V Splitter Box(
```

```julia```
Size( 1215, 540 ),
<<Set Sizes( {1} ),
<<Dockable(),
H Splitter Box(
  Size( 1215, 540 ),
  <<Set Sizes( {0.11, 0.42, 0.47} ),
  <<Dockable(),
  Tab Page Box(
    Title( "Window List" ), // show the Window List
    Window ID( "Window List" )
  ),
  Tab Page Box(
    Title( "Bookmarks" ), // show the Bookmarks pane
    Window ID( "Bookmarks" )
  ),
  Tab Page Box(
    Title( "Recent Files" ), // show the Recent Files pane
    Window ID( "Recent Files" )
  ),
),
Tab Page Box( // show the data table
  Title( "Big Class" ),
  Window ID( "data" )
),
Tab Box(
  <<Dockable(),
  Tab Page Box( // show the Distribution graph and reports
    Title( "Big Class - Distribution" ),
    Window ID( "distrib" )
  ),
  Tab Page Box( // show the Graph Builder graph
    Title( "Big Class - Graph Builder" ),
    Window ID( "graphbuilder" )
  )
)
Creating Projects
Chapter 15
Create a Project with a Bookmarks Pane and Log

Save saves the project.

```plaintext
// if the project has already been saved, the Save message
// with no argument saves the file to the existing location
project << Save( "$DOCUMENTS/Big Class.jmpprj" );
```

**Note:** If you’re saving a project with unsaved documents in JSL, the project doesn’t close and you get a log message that the project has unsaved documents. All files in a project must be saved or closed before the project can be saved. However, if you interactively save a project with unsaved documents, you are prompted to save the documents.

**Figure 15.2 Example of a Complex Project**

Open the project from another script:

```plaintext
project = Open( "Big Class.jmpprj" );
```

In this example, the script that you are running to open the project is in the same folder as the project.
Running Scripts in a Project

When you run a script outside of a project, the reports generated by the script appear in different windows. When you run a script inside a project, the reports appear in different tabs inside the project.

Running a JSL script outside of a project

Open a Script Editor window by selecting File > New > Script. Paste and run the following script:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Run Script( "Bivariate" );
dt << Run Script( "Distribution" );
Wait( 2 );
Get Window( "Big Class - Distribution" ) << Close Window();
```

Note that this script opens three JMP windows: one for the data table and one for each report. Close the reports and then the data table.

Running a JSL script inside of a project

Create a new project by selecting File > New > Project. From the project window, create a new script editor window by selecting File > New > Script. Note that the script editor window opens as a tab in the project. Paste the same JSL script you previously ran into the script editor and run it:

```julia
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
    Wait( 2 );
    Get Window( "Big Class - Distribution" ) << Close Window();
)
```

Note that this time, the data table and the reports all opened as tabs in the project, and that `Get Window()` correctly found the distribution tab. In general, all JSL functions that open, find, manipulate, and close JMP windows, tables, and reports work from within a project the same as they would outside projects.

Running a JSL script using a project’s Run Script message

You can use the Run Script message to run JSL in the project’s context. Open a Script Editor window, then paste and run the following code:

```julia
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
)
```
Creating Projects

Chapter 15

Create a Bookmark Group

You can create bookmark groups to organize the bookmarks in a project. A bookmark group can contain bookmarked files, folder, and additional bookmark groups. The bookmark group exists only in the project, not on your computer. Use `Group()` to create the bookmark group.

```jl
project = New Project();
project << Add Bookmarks(
    Group(
        "Sample Data",
        Expanded( 1 ), // open the group
        {File( "$SAMPLE_DATA/Air Traffic.jmp" ),
         File( "$SAMPLE_DATA/Big Class.jmp" )}
    ),
);
project << Set Layout(
    H Splitter Box(
        <<Set Sizes( {0.15, 0.85} ),
        Tab Page Box( Window ID( "Bookmarks" ), )
    ),
);
project << Save( "$DOCUMENTS/My Project.jmpprj" );
```

Figure 15.3 “Sample Data” Group in a Project
Close Tabs in Projects

Close a tab in a project by identifying the window with `Get Window()` and then closing it with `Close Window`.

```js
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
);

Wait( 2 ); // for demonstration purposes

// returns a reference to the open "Big Class - Distribution" window
dist = Get Window( Project( project ), "Big Class - Distribution" ) ;
dist << Close Window();
```

To close all tabs in a project, use `Get Window List << Close Window()`.

```js
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
);

Wait( 2 ); // for demonstration purposes

Get Window List( Project( project ) ) << Close Window();
```

Get a Project

When running a JSL script from within a project, you can use the `This Project()` function to obtain that project. The following example displays the name of the current project in a new window.

```js
project = This Project();
If( Is Empty( project ),
    /* if the script is not run from a project, display this sentence in the new window */
    New Window( "My Project", Text Box( "Script isn't running in a project." ) ),
);
Reset the Window Layout

Suppose that you create a project and customize the layout of the windows. For example, you might hide the Window List. Use the Reset Layout message to return the windows to their original layout.

```plaintext
project = New Project();
project << Run Script( // open data table and create a graph
    Open( "$SAMPLE_DATA/Big Class.jmp", Set Window ID( "data" ) );
    New Window( "Big Class – Bivariate of weight by height", Set Window ID( "bivariate" ), Bivariate(Y( :weight ), X( :height ), ) ) << Set Window Icon( "Bivariate" );
);

Wait(3); // for demonstration purposes
project << Set Layout( // set a custom layout
    H Splitter Box( <<Set Sizes( {0.2, 0.8} ), Tab Page Box( Window ID( "Bookmarks" ) ),
```

/* if the script is run from a project, display the window title in the new window */
    New Window( "My Project", Text Box( project << Get Window Title() ) )
);

Get Project() takes the same arguments as the Window() function. Omit the arguments to get a list of the currently open projects, include a string to find a specific project by title, or include a number to get the ith open project.

```plaintext
Open( "$SAMPLE_PROJECTS/Big Class.jmpprj" );
Open( "$SAMPLE_PROJECTS/Sports.jmpprj" );

// print the title of Sports.jmpprj
Print( Get Project( 2 ) << Get Window Title() );
```

Get Project() is also helpful when you want to save a project or set the layout from within the project.

```plaintext
Get Project() << Save(...);
Get Project() << Set Layout(...);
```
Run Startup Scripts to Control Workspaces

A workspace is either a project window or the windows that are not in a project (for example, the home window). A default workspace loads when JMP starts, and then each time you create or open a project, JMP creates another workspace.

Consider writing a workspace startup script to customize variables for a specific project. You might also construct a new customized window in a workspace startup script to put a copy of that window in each project. This is an alternative to having a single copy of the script that runs outside of projects.

The workspace startup script runs each time a new workspace loads. This means that the workspace startup script runs once when JMP starts (when the “default workspace” loads) and then runs again each time a new project is loaded. The workspace startups script runs in the context of the project, so any windows it opens or variables it sets are for that project only.

Name the script `workspaceStart.jsl` and place it in one of the following folders, as appropriate for your operating system. When JMP starts, JMP looks for the `workspaceStart.jsl` script in these folders in the order in which they are listed here. The first one that is found is run, and the search immediately stops.

**Note:** Some path names in this section refer to the “JMP” folder. On Windows, in JMP Pro, the “JMP” folder is named “JMPPro”.

On Windows:
1. C:/Users/<username>/AppData/Roaming/SAS/JMP/16
2. C:/Users/<username>/AppData/Roaming/SAS/JMP

On macOS:
1. /Users/<username>/Library/Application Support/JMP/16
2. /Users/<username>/Library/Application Support/JMP

The workspaceStart.jsl script runs only for a particular user on a computer. You can add a script named workspaceStartAdmin.jsl in one of the following places, as appropriate for your operating system. This script is run for every user on a computer. JMP runs workspaceStartAdmin.jsl first if found. Then JMP runs workspaceStart.jsl if found.

On Windows:
1. C:/ProgramData/SAS/JMP/16
2. C:/ProgramData/SAS/JMP

On macOS:
1. /Library/Application Support/JMP/16
2. /Library/Application Support/JMP
In addition to providing platforms for quickly analyzing data, JMP lets you create applications to support your specific needs. You often perform the same tasks every day (such as running Distribution and Fit Model analyses on a data table and viewing the results). In JMP’s Application Builder, you can create an application that shows the results for both analyses in one window. Application Builder’s drag-and-drop interface reduces the amount of scripting required to create an application.

Add-In Builder visually guides you through creating an add-in that users can install in JMP. And after creating an application in Application Builder, use Add-In Builder to save the application as an add-in. This allows users to install the application and quickly run it inside JMP.

**Figure 16.1 Creating Customized Reports in Application Builder**

Create Applications with Application Builder

Application Builder’s drag-and-drop interface lets you visually design windows with buttons, lists, graphs, and other objects. This saves you the step of writing scripts to create these objects.

Application Builder also helps boost the productivity of experienced JMP Scripting Language (JSL) programmers. You can start designing a program in Application Builder and edit the automatically generated scripts. Integrate your own scripts to create even more powerful custom applications.

You can use Add-In Builder with Application Builder. First, use Application Builder to write complex scripts that create new platforms and interact with users and JMP. Then, use Add-In Builder to easily distribute your complex scripts so that any JMP user can access them without having to open and run the scripts. See “Compile Add-Ins with the JMP Add-In Builder” on page 889.

Notes:

• Creating simple applications in Application Builder requires little to no JSL programming. However, to create most simple applications, Dashboard Builder might be sufficient. Dashboard Builder provides a subset of features that are found in Application Builder. See Using JMP.

• In each version of JMP, Application Builder takes advantages of new features that are not supported in earlier releases. For maximum compatibility, we recommend that you create applications in the earliest version of JMP that the application will be run in.

Example of Creating an Application

Application Builder helps you create instant applications without writing JSL. One example is a JMP window in which you arrange reports, graphs, and other objects to make them easy to interact with at once.

This example shows how to create a simple instant application for a Distribution report. This application lets you analyze preselected variables rather than having to select them in a launch window.

1. Select Help > Sample Data Library and open Big Class.jmp.
2. Run the Distribution table script to generate the report.
4. Click the Blank Application box.

A new blank application appears. Notice the Distribution report in the left column.
5. In the Sources panel, drag the Distribution report onto the application workspace (the blank area on the Module1 tab).

6. Click the Application Builder red triangle and select **Run Application**.

The Distribution report appears in a new window. Note that the histograms are interactive and still associated with the data table. When the data changes, you run the application again, and the Distribution report is updated.
An application consists of modules. A module contains the objects and scripts that are compiled into an application. When you run an application, JMP can show a separate window for each module. For example, one window might show a Create Graphs button. After the user clicks the button, the graphs appear in a new window.

There are terms you should become familiar with before using Application Builder. Knowing these terms helps you understand how a module works, even if you need to minimally edit an automatically generated script.

**Application**  The top-level file that consists of one or more modules.

**Module**  A collection of objects, messages, instances, and other JSL statements that are compiled into an application to create new JMP features.

**Instant Application**  An application that typically consists of reports and does not require JSL scripting. You can also create an instant application, or “dashboard”, in Dashboard.
Builder. Similar to Application Builder, Dashboard Builder has a drag-and-drop interface but with pre-configured display boxes.

**Custom Application**  An application that demonstrates custom behavior through JSL scripting.

**Objects and Messages**  An object is a dynamic entity in JMP, such as a data table, a data column, a platform results window, a graph, and so on. Most objects can receive messages that instruct the object to perform some action on itself.

A message is a JSL statement that is directed to an object. That object knows how to evaluate the message.

**Module Instance**  The occurrence of a module in the application. In a complex application, you might create a start-up script that creates multiple instances of one or more modules.

**Namespace**  A collection of unique variable names and corresponding values that prevents collisions among scripts.

JMP creates the Application namespace and the ModuleInstance namespace automatically. Symbols in the Application namespace are visible only to scripts in the application; the namespace is not available to scripts not created in the application. For more information about namespaces, see “Advanced Scoping and Namespaces” on page 272 in the “Programming Methods” chapter.

**Variable**  A unique name to which you assign a value. JMP creates the thisApplication and thisModuleInstance variables automatically.

- The thisApplication variable (used in the Application namespace) contains module names, which are available in any script in the application.
- The thisModuleInstance variable (used in the ModuleInstance namespace) contains box and script names, which are valid only in their own modules.

**Container**  A display box object (such as a tab or outline) into which you drag other objects.

### Design an Application

Before creating the application, you must identify its purpose, decide on which graphical elements to include, and figure out which JSL scripts you need to write.

**Purpose**  What do you want the application to accomplish? Which features of JMP do you need to customize (for example, a launch window, report, or graph)?

**Graphical Elements**  How many modules do you need? Look at the list of graphical objects in Application Builder and decide which objects to include in your application. The Sources panel shows dozens of boxes and icons that you can drag and drop into a module. Also look at the preinstalled samples to see whether a similar module exists.
Scripting Depending on the complexity of the application, you write JSL scripts. See “Write Scripts” on page 868 for more information about writing scripts for an application.

A non-interactive application that only shows objects does not require scripts. One example is a window showing reports that you have already generated in JMP.

Application Builder Window

Figure 16.4 shows an application under development in Application Builder.

The Application Builder window provides the following features:

- The toolbar provides quick access to many features, such as aligning objects and inserting common display boxes. (Select View > Toolbars > Application Builder to show the toolbar.)
• The Sources panel shows objects that you can include in the application, including open reports and graphs. Right-click an object and select **Scripting Help** for information about the object and its properties.

• The workspace in the middle shows dotted grid lines, which help you line up objects. Drag objects onto one or more Module tabs in the workspace and write scripts on the Scripts tab to control the objects’ functionality.

• The Objects panel shows a hierarchical view of the application. Along with the application, each module and its nested objects are listed. You can click an object to show its properties or to select it on the workspace.

• In the Properties panel, you set properties for each object, such as the location, width, or name of an object. The properties vary depending on the type of object.

**Tip:** To hide the grid and turn off snap-to-grid for all applications that you create, select **File > Preferences > Platforms > JMP App** and deselect these options. You can also deselect these features in the Application Builder red triangle menu.

### Application Builder Red Triangle Options

The Application Builder red triangle menu provides options for running and debugging the application, opening sample applications, showing the grid, and more.

**Run Application** Starts the application. A window for each module opens, and you can interact with the application as the user will.

**Debug Application** Opens the script in the JSL Debugger to troubleshoot errors. See “**Debug or Profile Scripts**” on page 77 in the “Scripting Tools” chapter.

**Snap to Grid** Aligns (or snaps) objects to the nearest dotted grid lines as you drag them on the workspace. Selected by default.

**Show Grid** Displays dotted grid lines on the workspace. Selected by default.

**Show Properties** Shows or hides the Objects and Properties panels.

**Auto Scroll** Automatically scrolls horizontally or vertically as you drag an object near the edges of the workspace. Selected by default.

**Dashboard Mode** Displays the application in the simpler Dashboard Builder window. When you drag a report, data filter, or data table to the application, it is automatically placed in splitter and tab page boxes. You cannot add scripts in Dashboard Mode.

Be aware that switching back and forth does not change anything that you have already added to the application. Switching modes changes the way the interface works when you add new content.
Source Panel  Shows or hides the Sources panel (the left column in which application components are displayed) and categorizes the icons. Both settings are selected by default.

Save Script  Lets you save the application to a data table, journal, script window, template, or add-in. See “Options for Saving Applications” on page 872.

Create an Application

After writing the application specifications, you create a blank application in JMP and begin adding objects and scripts.

This section provides the basic steps for creating an application:

- “Create a New Application” on page 860
- “Arrange and Remove Objects” on page 863
- “Customize Object Properties” on page 866
- “Write Scripts” on page 868

Note: In each version of JMP, Application Builder takes advantages of new features that are not supported in earlier releases. For maximum compatibility, we recommend that you create applications in the earliest version of JMP that the application will be run in.

Create a New Application

To create a new blank application, follow these steps:

1. Select File > New > Application (or File > New > New Application on macOS).
2. Select the Blank Application.
   The Application Builder window appears.
3. Select File > Save and save the file as a JMP Source File. The extension is .jmpappsource.

After you create the blank application, you add open reports, display boxes, and other objects to the workspace. See “Example of Creating an Application” on page 853.
Manage Modules

When you create a new application, a Module tab appears by default. You can add objects to this module to create interface items. To create additional windows for your application, you can add and customize new modules.

Add Objects to a Module

Follow these steps to add objects to a module:

1. In the Sources panel, select the type of object that you want to add.
2. Drag the object onto the Module1 tab (or double-click the object).
4. Add scripts to scriptable objects. See “Write Scripts” on page 868.
5. (Optional) To prevent a module from launching when you run the application, select the module in the Objects panel and deselect Auto Launch. (You might do this while testing one out of multiple modules.)
6. Click the Application Builder red triangle and select Run Application to test your application.

Depending on how the modules are used, it may not be possible to test one module without creating the other modules.

Create a Module

1. Select Format > Add Module.
2. In the Properties panel, select the Module Type:
   - Dialog
   - Dialog with Menu
   - Modal Dialog
   - Launcher
   - Report
   - Display Box

Tip: When you run an application, the window title is the name of the data table, if applicable, followed by a hyphen and the application name. Change the application name by modifying text in the JMP App object’s Name property.

Rename a Module

Change the Variable Name in the module’s object properties.
Delete a Module

Select **Format > Delete Module.**

Delete a Data Table

Select the Data Table object, right-click and select **Delete.**

**Note:** You cannot delete the data table if it has any associated objects. Delete any objects and then delete the data table.

Modal Dialog Modules

Modal Dialog modules have some special behaviors to be aware of when using them.

- **ret = Module1 << Create Instance()** will not return until the dialog is complete. By this time, the dialog has been destroyed. Therefore, the return value will not be a handle to the Module Instance. Like **New Window(),** the return will instead be of the form `{Button(1 | -1), User Data}. (1 | -1) indicates whether the OK (1) or Cancel (-1) button was pressed.

- **User Data()** is a new property on the Module Instance. During execution of the dialog, the Module script can set the user data:

  ```
  thisModuleInstance << Set User Data(...);
  ```

  to store something to be parsed by the caller. The user data will be evaluated at the time that it is set. There is also a corresponding **Get User Data().**

- Like **New Window(),** if there is no OK or Cancel button included, an OK button will be added.

- There is an optional **Validate** script property on the Module Instance. This script is only used for Modal dialogs and behaves like **On Validate()** in **New Window().** It is called when the OK button is pressed, and returns 1 to accept the input or 0 to disallow the close.

  **Tip:** If you use the Validate property, you can call **thisModuleInstance << Set User Data().**

- Unlike other module types, a Modal Dialog will not show until the module script has completed. For other module types, the window is created during the call to **thisModuleInstance << Create Objects.** JMP cannot display a Modal Dialog here because control would stop and there would be no way to initialize the contents of the boxes in the display. Since the window is not created yet, you will not be able to do actions like set the window title or set an on-close script.
Arrange and Remove Objects

Drag objects from the Sources panel onto the workspace or double-click them. A blue border appears around the edge of a selected object. Then you can position the selected object in several ways. You can also change the container of an object or insert an object into a new container.

**Tip:** To quickly select an object, select it in the Objects panel. This method is particularly helpful when the internal object completely covers the container, as with a border that has an internal text box.

Drag an Object

One way to position objects is by dragging them around the workspace.

- The top and left edges of an object align (or snap) to the nearest dotted grid lines as you drag them on the workspace. For a more precise placement, click the Application Builder red triangle and deselect **Snap to Grid**. You can also turn off **Snap to Grid** for all applications in the JMP Preferences. Select File (Windows) or JMP (macOS) > Preferences > Platforms > JMP App to change the option.

- Position objects in containers instead of positioning them independently on the workspace. For example, place two button boxes in a V List Box to align them vertically.

- When you drag an object, press Shift to restrict movement to a single axis (for example, to move the object horizontally without moving the vertical position).

- When you drag an object into a container, the arrow indicates where you can drop the object.

- When you drag an object over another one, a blue line shows where you can drop the object.

Figure 16.5 shows the various methods for dragging objects inside a container.
Change the X and Y Positions on a Container Object

- To position a container object precisely, select the object and then change the **X Position** and **Y Position** properties. After you enter a new X position, press Tab to see the object move to the new position and then enter the new Y position.

- To place an object in the upper left corner, right-click the object and select **Move to Corner**. This is a shortcut to setting the X and Y positions to 0. On macOS, press Ctrl+Command and then select **Move to Corner**.

Line Up Multiple Objects

To line up objects horizontally or vertically, select the objects and then select an option from the **Format > Align Boxes** menu.

Tips:

- The **Align Boxes** options are unavailable when you select a container rather than the internal objects.
• If you right-click a container, you might inadvertently select one of the internal objects instead. Right-click in the workspace instead.

Change the Type of Container

After inserting some containers, you can change them to a different type of container without having to re-create the object. Suppose that you create a panel that contains text and a button. To see what the panel looks like as an outline, select the panel, right-click in the module, and then select **Change Container > Outline Box**.

![Figure 16.6 Change a Panel to an Outline](image)

In this example, you would also change the outline title to match that of the panel.

**Tip:** To change the orientation of a list box quickly, select or deselect **Horizontal** in the object properties.

Insert Objects into a New Container

The toolbar at the top of the Application Builder window provides buttons for containers such as border boxes and mouse boxes (Figure 16.7).

To insert selected objects into a container, click the appropriate button on the toolbar or select **Format > Add Container**.

![Figure 16.7 Container Toolbar](image)

Duplicate Objects

When you copy and paste an object, the second instance of the object is renamed. The scripts attached to the object are also renamed. Pressing Ctrl (or Command on macOS) and dragging the object also creates duplicates of the originals.

Delete an Object

• Remove one or more objects by selecting them and then pressing Delete.
• Drag the objects outside of the module.
• On macOS, select the objects, press Ctrl+Command, and then select **Delete**.
• On Windows, select **Edit > Clear** to delete all objects in a module.
• Select the object and then press Backspace.

If you no longer need the object’s script, you can delete the script also.

**Customize Object Properties**

After you drag an object from the Sources panel onto a module, customize the object properties in the Properties panel. Editing the object properties saves you the step of writing JSL for list items, button names, and so on.

Variable names are case- and space-insensitive. When a script contains an object named “Button1”, Application Builder warns if you try to rename another object “Button 1”.

To create the radio box list items in Figure 16.8, double-click the placeholder items “Item1” and “Item2” and enter the new list item.

**Figure 16.8 Radio Box Object Properties**

For more information about an object, right-click the object and select **Scripting Help**. The JMP Scripting Index appears, and the object that you selected is highlighted. The Scripting Index often includes a script that you can run to see an example of the object.

To read more about values in the Properties panel, hover over the value.
Application Properties

The Application properties identify the run password, data table name, and more. Select the application in the Objects list.

Name  Appears after the data table name in the application’s title bar.

Description  Enter a description of the application.

Auto Launch  Shows a launch window in which the user selects the arguments that have been defined in the application. This launch window is not one of the defined modules; the modules will be instanced based on their own Auto Launch property.

Encrypt  Prevents users from editing the application in a text editor. Only applications that the user runs are encrypted (the .jmpapp file and the application in a JMP add-in). Scripts that you save to a data table, journal, and add-in are encrypted. For more information about encryption, see “Encrypt and Decrypt Scripts” on page 304 in the “Programming Methods” chapter.

Run Password  Enter the password required to run the application. To test the password, run the application outside Application Builder.

Table Module Properties

Inserting the Data Table object creates a data table object. To define properties such as the data table path, select the data table module in the Objects panel. Then modify the following options in the Properties panel.

Variable Name  Specifies the name of the data table object. This name appears in the Properties and Objects panels and in the application’s JSL script.

Path  Specifies the absolute or relative filepath for the data table used in the application. You can precede the data table name with a path variable (such as $HOME or $USER_APPDATA).

Application Builder opens the specified data table when you edit the application. If the Path property is empty or the data table cannot be found, you are prompted to open the table.

When you close a data table and objects in the application depend on the data table, the objects are removed from the application and a warning message appears. To restore the objects, reopen the application.

Label  Specifies the string used when prompting the user to open a data table. Figure 16.9 shows the default value.
Figure 16.9 Label in Data Table Prompt Window

**Location** Determines how the data table used in the application is selected when the user runs the application.

- **Current Data Table**: Uses the current data table. If no data tables are open, the user is prompted to open one. This option gives users the flexibility to use their own data.
- **Full Path**: Uses the data table specified in the Path property.
- **Name**: Uses the first open data table with the specified name. Otherwise, JMP uses the data table specified in the Path property. Note that if the application is moved to another computer, the link to the data table is broken. Consider storing the data table in a shared location.
- **Prompt**: Asks the user to select an open data table or browse to select a data table.
- **Script**: Uses the data table defined in the application or module script.
- **Embedded Script**: Reads the Source script in the data table that was used to generate the report. The Source script is run when you open the application.

**Invisible** Hides the data table from view but lists it in the JMP home window. This option is available for the Full Path and Name locations.

**Write Scripts**

After adding an object to the module, you write a script for the object to provide functionality. For example, you might want the user to click a button, select a directory, and then select a data table. Or you might have an application that displays a different graph based on which radio button the user selects.

**Application and Module Namespaces**

To prevent variable names and values from conflicting among scripts, Application Builder automatically creates the Application namespace and a namespace for each module:

- In the Application namespace, you write scripts that are executed when the user runs the application. Functions defined in the Application namespace can be used in any module.
In the Module namespaces, you write scripts that are run when an instance of that module is created. If clicking a button in the application opens a new launch window, that launch window is an instance of the module. Two instances of the same module have their own copies of any variables or functions.

To see the scripts in these namespaces, click the Scripts tab and then select the namespace in the Namespace list (or in the Objects panel).

**Figure 16.10** Application and Module Namespaces

There are two types of scripts: named scripts and anonymous scripts.

**Write a Named Script**

A named script is a function that several controls can use. The this argument tells which control is calling the function. In the following example, Get Button Name is sent to the this argument to print the button name to the log when the button is clicked:

```
Button1Press = Function({this}, Print(this <<Get Button Name))
```

On another button, use Button1Press script to produce the same results.

Two other advantages of named scripts: when you add a named script to an object, JMP inserts a placeholder script on the Scripts tab, which you then edit. On the Scripts tab, you can also select a script from the Method list to navigate to that code, which is particularly helpful in long scripts.

Add a named script:

1. Right-click the object, select Scripts, and then select the script that you want to add. In this example of creating a button, select the Press script. (On macOS, press Control, and then select Scripts > Press.)
The object’s placeholder script appears on the **Scripts** tab (Figure 16.11). The name of the named script, *Button1Press*, shows up in both the script and the object properties.

**Figure 16.11** New Script and Script Properties

2. Edit the object’s placeholder script and properties to provide the necessary functionality. For example, the button box shown in Figure 16.11 was renamed. The Title property was changed to *Submit*, the text that appears on the button.

**Tip:** After you add a script to an object and then delete the object, delete the object’s script from the **Scripts** tab if you no longer need the script. This feature prevents scripts that you might want in the future from being deleted.

If you rename the script in the object properties, rename it on the **Scripts** tab also. And if the script is used in another part of the application, rename it there as well.

### Write an Anonymous Script

An **anonymous script** is available only to the object that defines it. For example, you might want a simple `Print` statement for one button that is not used elsewhere. By writing an anonymous script, you reduce the number of names to manage in the script. Anonymous scripts also reduce clutter among more important named scripts in the Scripts tab, because you add them to the object properties.

The following examples show two types of anonymous scripts:

```
Print(Button1 <<GetButtonName) // simple anonymous
Function({this}, Print(this <<GetButtonName)) // parameterized anonymous
```

Notice that the simple script sends a message to the “Button1” variable, but this is the control in the parameterized script.

Objects such as check boxes might provide additional arguments after `this` that are not otherwise available. One example is an argument that tells which check box in a column of check boxes just changed.

**Write an anonymous script:**

1. Select the object and click ![script icon] in the object properties.
   The anonymous script editor appears.
2. Enter the script and click **OK**.

The text of the anonymous script appears in the object’s properties (rather than the name of a named script).

**Tip:** Avoid copying and pasting anonymous functions to simplify code maintenance; use a named script instead if the script is needed in more than one place.

---

**Show Specific Scripts**

There are several ways to view a script for a specific object:

- Double-click the object on the **Module** tab.
- When an object has multiple scripts, right-click the object, select **Scripts**, and then select the script name. You can also select the **Scripts** tab, select the module name from the **Namespace** list and then select the script name from the **Method** list. Likewise, to see the application scripts, select **Application** from the **Namespace** list.

In each case, the **Scripts** tab appears with the cursor in the first line of the object’s script.

**Tip:** To make a poorly formatted script easier to read, right-click and select **Reformat Script**.

---

**Copy and Paste Objects with Scripts**

When you copy and paste an object that has a script, the second instance of the object and script are renamed.

---

**Edit a Platform Script**

You can select the object for a platform in an application and edit the script for that platform. For example, you might edit the script for the Multivariate platform to show the scatterplot matrix or to use different columns.

Right-click the platform object on the workspace and select **Edit Platform Script**. After you edit the script and click OK, the object on the workspace is updated.

---

**Edit or Run an Application**

To open an application for editing, select **File > Open**, select the .jmpappsource file, and then select **Open**.

**Note:** If the Table property is empty or the specified data table cannot be found, the application runs anyway but objects requiring the data table will fail to create and JMP displays a warning.
To run an open application, click the Application Builder red triangle and select **Run Application**.

To run a closed application, select **File > Open**, select the .jmpapp file, and then select **Open**.

On Windows, you can also open or run an application from the JMP Home Window by doing one of the following:

- Drag the file from Windows Explorer onto the JMP Home Window or onto a blank application window.
- Double-click the file in Recent Files list.
- Right-click either the .jmpappsource or the .jmpapp file and select either **Edit Application** or **Run Application**.

**Options for Saving Applications**

JMP provides several options for saving application files.

- When you select **File > Save As** on Windows, you can save the application as an application source file (.jmpappsource), an application (.jmpapp), or a script.
- Selecting **File > Export** on macOS enables you to save the application as an application file or a script. To save the application as an application source file on macOS, select **File > Save As**.

The .jmpappsource file allows an application developer to save the application as is, in order to continue editing the application later. When reopened, the App Builder interface remains in the same state as when it was saved. The data tables used to create the application must still be available.

The .jmpapp file is used to distribute applications for others to use. The application runs immediately after opening the file. The application resolves the data tables using the current data tables, files on disk, or by prompting the user, depending on the application settings.

The Save Script red triangle menu provides additional options for saving scripts. When an encrypted script is saved, JMP encloses the script in the JSL `Encrypted()` function to preserve white space and comments.

**To Data Table**  Saves the script to the data table that was used to produce the report. This enables you to run the script again from the data table to recreate the results. When you edit this script from the data table, the application opens in Application Builder, not the script editor.

**To Journal**  Saves a button that runs the script in a journal. The script is added to the current journal. The script contains the path to the data table. Note that if the data table cannot be found, the script does not run.
To Script Window  Opens a script editor window and adds the script to it. If you have already saved a script to a script window, additional scripts are added to the bottom of the same script window. Note that if you modify the application significantly in a script window, you might not be able to edit the application in Application Builder. This option is useful when you want to embed the application in a larger JSL process.

**Tip:** This can also be accomplished by saving as a .jmpapp file and using Open() to run the application. However, saving the script can reduce the number of files.

To Add-In  Lets JMP users install the application and launch it from a JMP menu. See “Compile Add-Ins with the JMP Add-In Builder” on page 889.

To Template  Saves the application as a template from which you can create new applications. The templates are saved in the following locations based on your operating system and JMP version:

- Windows (JMP): "C:/Users/<username>/AppData/Roaming/SAS/JMP/<version number>/ApplicationTemplates"
- Windows (JMP Pro): "C:/Users/<username>/AppData/Roaming/SAS/JMPPro/<version number>/ApplicationTemplates"
- macOS: "~/Users/<username>/Library/Application Support/JMP/<version number>/ApplicationTemplates"

**Additional Examples of Creating Applications**

The following examples illustrate various uses for applications in JMP.

**Parameterizing Variables**

The following example shows how to create an application with parameterized variables. Users select the variables in a launch window, and then predefined reports are generated.

1. Select Help > Sample Data Library and open Quality Control/Steam Turbine Historical.jmp.
2. Run the Principal Component Analysis and Loading plot table scripts to generate the reports.
4. Select Blank Application.
   The Application Builder window appears.
5. Enlarge the window.
6. In the Sources panel, drag each Multivariate report onto the application workspace in a single row.
7. Select Edit > Select All.
8. Select Format > Add Container > H List Box to align the reports horizontally.
9. Select each report and type yvar next to Y Variable in the Objects panel.
10. Click the Application red triangle and select Run Application.
11. Select the Fuel, Steam Flow, Steam Temp, and MW variables and then click the Y button.
12. Click OK.

New Multivariate reports appear in one window.

Figure 16.12 Multivariate Application

Tip: The absolute path to the data table is inserted automatically in the application’s Table property. If the data is sample data, the $SAMPLE_DATA path variable is automatically used in the path. You can also enter an absolute or relative path. Remember that the user must have access to this path.

Filtering Data in Multiple Reports

In an application that contains several reports, you can select data in one report and then view only that data in all other reports contained in the same window.
To set up the filter, follow these steps:

1. Create the application and add two reports to the workspace.
2. Select both reports. From the toolbar, select the HListBox icon.
3. Right-click the primary report and select **Use as Selection Filter**.
   This places the primary report display box in a Data Filter Source Box and the parent report display box in a Data Filter Content Box.
4. Click the Application Builder red triangle and select **Run Application**.
   The reports appear in one window (Figure 16.13).
5. Test the application by selecting a histogram bar in the primary report.
   Only data for the selected bar appears in the second report.

**Figure 16.13 Example of Filtered Content**

Filtering Data in Separate Reports Using a Local Data Filter

The following example illustrates how to add a Local Data Filter to multiple reports and then filter each report separately.

1. Select **Help > Sample Data Library** and open SATByYear.jmp.
2. Run these scripts: Bubble Plot by Region and Graph Builder Map.
3. Resize the report windows to make them smaller, so that a 2x2 arrangement will fit on the screen.
4. Select **File > New > Application** and choose **Blank Application**.
5. Double-click **Data Filter Context Box**.
   This adds a data filter context box to the workspace. Everything placed in this box will share the same Local Data Filter.

**Figure 16.14** Adding a Data Filter Context Box

6. Under Containers, drag a **H List Box** into the Data Filter Context Box.
   This allows you to put multiple objects in this box and arrange them horizontally.
Figure 16.15  Adding a H List Box

7. Now drag a Data Filter (local), the Bubble Plot, and the Tabulate report into the H List Box.
8. Select the entire Data Filter Context Box. Press Ctrl and drag it below itself, to place a copy below the original set of reports.

9. Select both Data Filter Context boxes, then on the toolbar, click the V List Box icon.
   This arranges both reports into a single list box for display purposes.
10. Click the Application Builder red triangle and select **Run Application**.

11. In the Local Data Filter on the top, click SAT Math, then click the Add button . Move the slider to see how it only impacts the reports at top. Do the same for the bottom set of reports.

**Selecting Dates**

To insert a date selector window into an application, follow these steps:

1. Drag a Number Edit Box from the Sources panel to the workspace.
2. Select the Number Edit Box and then click the button next to Format in the Properties panel.
3. Select **Date** from the list and then select **m/d/y**.
4. Click outside the list.
5. Click the Application Builder red triangle and select **Run Application**.

The Number Edit Box, which shows a date, appears in a new window.
6. Click the calendar icon to view the date selector window.

**Figure 16.18** Example of a Date Selector

The date selector enables you to select the month and year as well as the date and time for the box.

**Creating a Launch Window and Report**

The Launcher with Report sample application combines a platform launch window with the resulting report. The sample application is displayed when you select **File > New > Application**.

The following example shows you how to arrange objects and include scripts that make up the application. You will recreate the Launcher with Report sample application so that you can create your own applications similarly.

**Note:** In the Launcher with Report sample application, the variable names of display boxes are customized to describe the display box. For example, “Text1” was renamed “Description” in the sample application. To reduce the number of steps in this example, you do not rename the variables unless one of the scripts refers to the variable name.

1. Select **File > New > Application** and click the **Launcher with Report** sample. You will copy and paste JSL from this sample into your copy. Notice that the iris jmp sample data table opens when you open the application.

2. Select **File > New > Application** and click **Blank Application**.
Create the Launch Module

The Launch Module contains objects that create a launch window.

1. In the Objects panel of the blank application, select Application.
2. In the Properties panel:
   - Change the Name from Application to “Radviz” and press Enter. This name appears in the title bar when you run the application.
   - Change the Description to “Launch Window with Report”.

![Figure 16.19 Customizing the Application](image)

3. Click the Scripts tab and select Radviz from the Namespace list.
4. After the green comments, on a new line, type the following expression:
   ```
   dt = Current Data Table();
   ```
   One of the scripts that you add to this application refers to `dt` to identify the data table.
5. In the Objects panel, select Module1.
6. In the Properties panel:
   - Change the Variable Name to “LaunchModule” and press Enter.
   - Change the Module Type to Launcher.
   - Make sure that Auto Launch is selected so that the launch window opens when you run the application.
Create Applications with Application Builder Scripting Guide

**Figure 16.20** Customizing the LaunchModule

7. Click the **LaunchModule** tab and drag a V List Box (under Containers) onto the workspace.
8. Drag a Text Box (under Display) over the arrow of the V List Box.
9. Double-click Text1, change it to “Radviz”, and then press Enter.
10. Drag an H List Box (under Containers) below the border of the Text Box until a blue line appears.

**Figure 16.21** Adding the H List Box

7. Because you have made many changes, select **File > Save** and rename the file. Make sure that .jmpappsource is selected as the file type.

**Create the Select Columns Box**

1. Drag a Panel Box (under Containers) over the H List Box arrow.
2. In the Properties panel, change the Title to “Select Columns” and press Enter.
3. Drag a Col List Box(All) (under Input) over the Panel Box arrow.
4. In the Properties panel, change the Variable Name to “ColumnList” and press Enter. The script you add later refers to this variable name.

5. Select **DataTable1** in the Objects panel. The current data table, iris.jmp, appears in the Path box.

**Create the Cast Selected Columns into Roles Box**

1. Drag a Panel Box (under Containers) to the right of the existing Panel Box until a blue line appears.

**Figure 16.22** Adding the Panel Box

![Image of Panel Box](image)

**Note:** Make sure that you drag the Panel Box to the H List Box shown in Figure 16.22.

2. In the Properties panel, change the Title to Cast Selected Columns into Roles and press Enter.

3. Drag an H List Box (under Containers) over the Panel Box arrow.

**Create the Contents of the Cast Selected Columns into Roles Box**

1. Drag a Button Box (under Buttons) over the H List Box arrow.

2. In the Properties panel:
   - Change the Title to “Y” and press Enter.
   - In the Press box, type “SetY” and press Enter. You copy and paste the script for this button later.

3. Drag a Col List Box (under Input) inside the right border of the Y Button Box.
Figure 16.23  Adding the Col List Box

4. In the Properties panel:
   - Change the Variable Name to “YList” and press Enter.
     The script that you add later refers to this variable name.
   - Change the Data type to Numeric.
     The words “optional numeric” appear in the Col List Box.

   **Tip:** Change Min Items to display the minimum number of required items in the Col List Box. If you type 3, then “required numeric” appears three times in the box as a hint to the user.

Create the Action Panel

1. Drag a Panel Box (under Containers) to the right of the Panel Box that you just added.

Figure 16.24  Adding a Panel Box

2. In the Properties panel, change the Title to “Action” and press Enter.
3. Drag a Button Box (under Buttons) over the Panel Box arrow.
4. In the Properties panel:
   - Change the Title to OK and press Enter.
   - In the Press box, type “OnOK” and press Enter.
5. Drag another Button Box (under Buttons) below the OK button.
Figure 16.25 Adding a Cancel Button

6. In the Properties panel:
   - Change the Title to “Cancel” and press Enter.
   - In the Press box, type “OnCancel”.
7. Drag a Spacer Box (under Spacers) below the Cancel button.
8. Drag a Button Box (under Buttons) below the Spacer Box.
9. In the Properties panel:
   - Change the Title to “Remove” and press Enter.
   - In the Press box, type “OnRemove” and press Enter.
10. Select the outer border of the objects on the workspace.
11. Right-click and select Move to Corner.
   The extra space around the selected object is removed.
12. Select **File > Save** to save your changes in the jmpappsource file.

Create the Launch Module Script

1. Go back to the Launcher with Report sample application window.
2. Click the Scripts tab.
3. Select LaunchModule as the Namespace and copy the script.
4. Go back to your application window and click the Scripts tab.
5. Delete the script in the LaunchModule namespace and paste the script from the sample application.
6. Select **File > Save** to save your changes in the jmpappsource file.

Create the Report Module

The Report Module contains an object that builds a graph.

1. In your application window, click the button to the right of the LaunchModule tab to add a new module.
2. In the Properties panel, change the Variable Name to “ReportModule” and press Enter.
3. Make sure that the Module Type is Report.
4. Deselect Auto Launch to prevent the report from opening when the application is run.
5. Drag an Outline Box (under Containers) to the workspace.
6. In the Properties panel, change the Title to “Radviz” and press Enter.
7. Drag a Graph Box (under Display) over the Outline Box arrow.
8. In the Properties panel, change the Variable Name to “Graph” and press Enter.
9. Select the outer border of the objects on the workspace.
10. Right-click and select Move to Corner.
   The extra space around the selected object is removed.
11. Select **File > Save** to save your changes in the `jmpappsource` file.

*Create the Report Module Script*

1. Go back to the Launcher with Report sample application window.
2. Make sure that the Scripts tab is displayed.
3. Select ReportModule as the Namespace and copy the script.
4. Go back to your application window and click the Scripts tab.
5. Delete the script in the ReportModule namespace and paste the script from the sample application.
6. Select **File > Save** to save your changes in the `jmpappsource` file.

Your application should look like the Launcher with Report sample application.

*Create the Radviz Script*

1. Go back to the Launcher with Report sample application window.
2. Make sure that the Scripts tab is displayed.
3. Select Radviz as the Namespace and copy the script.
4. Go back to your application window and click the Scripts tab.
5. Delete the script in the Radviz namespace and paste the script from the sample application.
6. Select **File > Save** to save your changes in the `jmpappsource` file.

*Test and Save the Final Application*

1. In your application window, click the Application Builder red triangle and select **Run Application**.
2. Select the Sepal length and width and Petal length and width columns, click **Y**, and then click **OK**.
A graph of the data should appear.

Figure 16.26 Iris.jmp Graph

If the graph does not appear or errors are generated, make sure that you typed in the correct variable names when necessary. Also make sure that you added the scripts to the Scripts tab for each module.

3. On Windows, select File > Save As, select JMP Application File from the Save as type list, and then click Save.

On macOS, select File > Export, select JMP Application, and click Next to save the application.

Your newly created application should match the Launcher with Report sample application.

4. Distribute the .jmpapp file to users. This file cannot be modified.

5. Save the .jmpappsource file so you can edit the application and resave it as a JMP application.

About the Application Scripts

When you create an application, you write scripts to provide functionality to display boxes. You can right-click a display box and select a script from the Scripts menu.
Create Applications with Application Builder Scripting Guide

Figure 16.27 Adding a Script Interactively

Selecting a script from the Scripts menu adds a placeholder script to the Scripts tab for the selected module. For example, the Press script shown in Figure 16.27 adds the following script to the Scripts tab:

```js
Button5Press = Function({this},
   // This function is called when the button is pressed
   name = this << Get Button Name;
);
```

Fill in the placeholder script with your own JSL. In the application that you previously created, you named two variables `SetY` and `ColumnList`. Rewrite the preceding placeholder script:

```js
SetY = Function({},
   // This function will be called when the Y button is pressed
   items = ColumnList << Get Selected;
   YList << Append(items);
);
```

`Get Selected` is passed to the `ColumnList` because you gave the Col List Box this variable name (`ColumnList`) in the object properties. `Get Selected` returns a list of the selected columns. `Append(items)` appends the selected columns to `YList`, the variable assigned to the Col List Box in the Cast Selected Columns into Roles window.

As shown when you previously created the application, you can write the script from scratch and indicate the script name in the object properties. To get help with syntax for a selected object, right-click the object and select Scripting Index.
Compile Add-Ins with the JMP Add-In Builder

A JMP add-in is a JSL script that you can run anytime from the JMP Add-Ins menu. You can create submenus to group your JMP add-ins and have many levels of menus, if desired.

Experienced JSL script writers can create scripts that extend JMP in many ways (for example, add a custom analytical tool or a user interface to communicate with a database). The JMP add-in architecture simplifies deploying and using these complicated scripts.

You can send co-workers a suite of scripts and tell them how to run them. Another option is sending a single add-in file that any JMP user can install and then use just like any other part of JMP.

As a JMP user, you might be given add-ins to use by co-workers. You can also find add-ins on the JMP website at https://www.jmp.com/addins.

Compile Scripts into an Add-In Using Add-In Builder

To create a JMP add-in, you write the scripts and gather files that are used in the add-in. Then you compile the scripts into an add-in.

- On Windows, select File > New > Add-In.
- On macOS, select File > New > New Add-In.
- In Dashboard Builder, click the red triangle and select Save Script > To Add-In.

The process of compiling scripts into an add-in involves the following steps:

- “Add General Information” on page 889
- “Create Menu Items” on page 891
- “Create Toolbars (Windows Only)” on page 892
- “Specify Start-up and Exit Scripts (Optional)” on page 893
- “Add Additional Files” on page 893
- “Save the Add-In” on page 893
- “Test the Add-In” on page 893

Add General Information

First, in the General Info tab, add the general information that identifies and sets up your add-in.
Figure 16.28 Add-In Builder General Info Tab

1. Enter a name for the add-in.
   This is the name of the registered add-in, which appears in the View > Add-Ins window.

2. Enter a unique identifier string.
   Unique ID strings are case-insensitive. To ensure uniqueness, it is strongly recommended to use reverse-DNS names (for example, com.mycompany.myaddin). The ID string must meet the following requirements:
   - It can be up to 64 characters in length.
   - It must begin with a letter.
   - It should consist only of letters, numbers, periods, and underscores.
   - It should contain no spaces.
   In JSL, use this string to refer to the add-in (for example, in calls to Get Addin() or as an argument to $ADDIN_HOME).

3. Enter the version of the add-in.
   If you decide to make changes to the add-in at a later date, you can update the version number and then verify that users have the correct version.

4. Select the minimum version of JMP that the add-in works on.

   **Note:** Add-ins were introduced in JMP 9, so no prior versions are supported. And when saving an application as an add-in, select 10 or 11 as the JMP minimum version.

5. Select whether you want the add-in to be supported on Windows, macOS, or both.

6. (Optional) Select the check box next to **Install after save** if you want to install the add-in after saving it.
   If you do not select this option, the add-in is not installed once you save it, and it does not appear as a selectable menu item in the **Add-Ins** menu.
Create Menu Items

1. Click the **Menu Items** tab.

**Figure 16.29 Add-In Builder Menu Items Tab**

2. (Optional) Click **Add Submenu**.
   
   If you have multiple add-ins, you can group them under a submenu.

3. If you add a submenu, next to **Menu item name**, enter the name of the submenu.
   
   This name appears in the **Add-Ins** menu.

4. Click **Add Command**.

5. Next to **Menu item name**, enter the name of the add-in command.

6. (Optional) Next to **Tooltip for menu item**, enter the content that appears as a tooltip when the users place their cursor over the menu item.

7. Add the script. Select either **Run this JSL** and copy and paste in your script, or select **Run JSL in this file** and click **Browse** to find the file containing your script.

8. (Optional) Select **Use the “Here” namespace for unqualified JSL variable names** to ensure that all unqualified JSL variables are in the **Here** namespace, and local only to the script.
Notes:

- If your script creates a custom menu or toolbar, the variables are in the Here namespace by default.

- For more information about the Here namespace, see “Advanced Scoping and Namespaces” on page 272 in the “Programming Methods” chapter.

9. (Optional) Browse to add an icon that appears next to the menu item in the Add-Ins menu.

10. (Optional, Windows only) Create a keyboard shortcut for the add-in.

11. To add multiple menu items, repeat the steps.

   You can add multiple levels of submenus and add-in commands.

12. Click Save and save the add-in to the desired directory.

13. Click Close.

Create Toolbars (Windows Only)

1. Click the Toolbar tab.

Figure 16.30 Add-In Builder Toolbar Tab

2. Click Add Command.

3. Next to Caption, type the name of the toolbar item. This name is only for internal use. The user does not see it.
4. Add the script. Select either **Run this JSL** and copy and paste in your script, or select **Run JSL in this file** and click **Browse** to find the file containing your script.

5. (Optional) Select **Use the “Here” namespace for unqualified JSL variable names** to ensure that all unqualified JSL variables are in the Here namespace, and local only to the script.

6. Click **Save** and save the add-in to the desired directory.

7. Click **Close**.

**Note:** For more information about customizing menus in JMP, see *Using JMP*.

### Specify Start-up and Exit Scripts (Optional)

Click the **Start-Up Script** tab to add a script that runs when JMP starts up (and the add-in starts). You can select an existing script (**Run JSL in this file**) or copy and paste in a script (**Run this JSL**). For example, you could provide a message telling the user that the add-in is installed upon start-up.

Click the **Exit Script** tab to add a script that runs when JMP exits or when you disable the add-in. You can select an existing script (**Run JSL in this file**) or copy and paste in a script (**Run this JSL**). For example, you could provide a prompt for the user to export a JMP data table upon exiting or disabling the add-in.

### Add Additional Files

If your script calls other scripts, or contains graphics or data tables, add those files here.

### Save the Add-In

Save the add-in by clicking the **Save** button on any tab. This effectively creates the add-in.

- If you selected the **Install after save** option in the General Info tab, then the add-in menu item appears in the **Add-Ins** menu immediately.

- If you did not select the **Install after save** option, when you open the saved add-in file, you are prompted to install the add-in.

### Test the Add-In

Once your add-in is installed, test your add-in:

1. Select **View > Add-Ins**.
2. Select your add-in and click **Unregister**.
3. Reinstall your add-in by either selecting **File > Open** in JMP, or by double-clicking your **.jmpaddin** file.
4. Ensure that the menu and toolbar button run your script correctly and that the script itself runs correctly.
Edit an Add-In

To edit a saved add-in:
1. Select **File > Open**.
2. Navigate to and select the add-in file.
3. Select one of the following options:
   - On Windows click the arrow to the right of the **Open** button and select **Open using Add-In Builder**.
   - On macOS, select the **Edit after opening** option.
4. Click **Open**.

The file opens in the Add-In Builder. Update the arguments and then save the changes.

Share an Add-In

Once you have a .jmpaddin file, you can share the file with other users. Email the file or you place it in a shared location, such as a network folder, or on the JMP File Exchange (located online in the [JMP User Community](https://community.jmp.com)).

When JMP users open the file, the add-in files are extracted into the appropriate folder, and the add-in is registered and installed. The add-in now appears in the user’s JMP Add-Ins menu.

Installing Multiple Add-Ins

If you want to install multiple add-ins, copy the add-ins into the following location:

- **Add-In files on Windows are located here:**
  - `%ALLUSERSPROFILE%/SAS/JMP/AddIns` (any user on this machine can access the add-in)
  - `%APPDATA%/SAS/JMP/AddIns` (only the current user on this machine can access the add-in)

- **Add-In files on macOS are located here:**
  - `/Library/Application Support/JMP/AddIns` (any user on this machine can access the add-in)
  - `~/Library/Application Support/JMP/AddIns` (only the current user on this machine can access the add-in)
When JMP starts, the addinRegistry.xml file is read, which contains information about previously registered JMP add-ins. Then JMP looks in the add-in folders for any other add-ins and installs them automatically.

**Notes:**

- The Home Folder for discovered add-ins does not have to be the AddIns subfolder in which the addin.def file was found. The addin.def file can be the only file in that subfolder and have a Home setting that points to some other location where the add-in files actually reside.
- If an automatically discovered add-in has the same unique ID as an add-in that was explicitly registered, the automatically discovered add-in is used.

### Register an Add-In Using JSL

If your add-in files are not contained within a .jmpaddin file, you can use the Register Addin() JSL function to manually register the addin.def file. This installs and registers the add-in.

- For information about the JSL functions, see the JSL Syntax Reference.
- For information about creating the addin.def file, see “Create an Add-In Manually” on page 895.

**Notes:**

- JMP might find a file named addin.def in the specified home folder. If so, values from that file are used for any optional arguments that are not included in the Register Addin() function.
- The addin.def file is used only for values that are not provided in the Register Addin() function. This function is useful while developing, but not necessary, since the addin.def file is enough to register an add-in.

### Create an Add-In Manually

The addin.def file is a simple text file containing name-value pairs that provide registration information about a JMP add-in. Here are the name-value pairs to include in the addin.def file:

- **name**  Optional. The name that can be displayed in the JMP user interface wherever add-in names are displayed, instead of the unique ID. This name is displayed if no localized names are provided or when JMP is run under a language for which you did not provide a localized name. Named Add-In Name in Add-In Builder.

- **name_xx**  Optional. Allows the user-friendly name to be localized for different languages, where xx is the two-letter ISO 639-1 code for the language. If you include localized names,
you should still include a language-neutral name in case JMP is running under regional settings for which you do not have a localized name. Not available in Add-In Builder.

**id**  Required. The unique ID for your add-in. The string can contain up to 64 characters. The string must begin with a letter and contain only letters, numbers, periods, and underscores. Reverse-DNS names are recommended to increase the likelihood of uniqueness. Named *Add-In ID* in Add-In Builder.

**home**  Optional. The path to the add-in files. The Home Folder for the add-in is assumed to be the folder where addin.def is located. You need to include a setting for home only if the Home Folder is somewhere else (for example, a network shared folder). Not available in Add-In Builder.

**home_win**  Optional. The path to the add-in files to be used when JMP is running on Windows. Overrides the value specified for home on Windows, if any. Not available in Add-In Builder.

**home_mac**  Optional. The path to the add-in files to be used when JMP is running on the macOS. Overrides the value specified for home on macOS, if any. Not available in Add-In Builder.

**autoload**  Optional, Boolean. The default value is True (1). Determines whether this add-in is initially configured to load automatically during JMP start-up. Named *Install after save* in Add-In Builder.

**host**  Optional. Valid values are Win and Mac. Named *Supported Host* in Add-In Builder.

**minJMPVersion**  Optional. Valid values are integers corresponding to the JMP major version that is the minimum version that the add-in supports. Named *Minimum JMP Version* in Add-In Builder.

**maxJMPVersion**  Optional. Valid values are integers corresponding to the JMP major version that is the maximum version that the add-in supports. Use this setting *only* if there is a known incompatibility between your add-in and a specific version of JMP. You should provide a new version of the add-in for later versions of JMP. Not available in Add-In Builder.

### Example of a addin.def File

```plaintext
id="com.mycompany.myaddin"
name="My Add-In’s Friendly Name"
name_fr="My Add-In’s French Name"
name_de="My Add-In’s German Name"
home="\server\share\myjmpaddin"
Autoload=1
MinJMPVersion=9
```
Example of a JMP Add-In

A sample add-in named Simple Calculator.jmpaddin is located in one of the following folders:

- On Windows: C:/Program Files/SAS/JMP/16/Samples/Scripts
- On macOS: /Library/Application Support/JMP/16/Sample/Scripts

**Note:** On Windows, in JMP Pro, the “JMP” folder is named “JMPPro”.

To see what the add-in contains, change the extension to .zip and unzip it into a new folder. To see how it works, change the extension back to .jmpaddin and install.

The add-in contains the following files:

**addin.def**

Provides the specification for JMP to register the add-in. It contains only these two lines:

```plaintext
id="com.jmp.sample.calculator"
name="Simple Calculator"
```

**addin.jmpcust**

Provides the menu customization file that is created when you interactively create a custom menu. Your customizations are shown only to the current user; other users who log on to the computer and open JMP do not see your personal toolbars and menus. This example places the add-in menu item into the default **Add-Ins** menu.

**calculator.jsl**

A JSL script that creates a basic calculator.

**calc_icon.gif**

The image used as the calculator’s icon.

Manage JMP Add-Ins

Install Add-Ins

A JMP add-in is a file that has the .jmpaddin extension. You can install it in one of two ways:

1. Select **File > Open**.
2. Navigate to the .jmpaddin file and select it.
3. Click **Open**.

You can also double-click the .jmpaddin file or drag it onto the JMP Home Window.

**View Your Add-Ins**

Select **View > Add-Ins** to see the add-ins that you have already installed.

**Reorder Your Add-Ins**

Select **View > Add-Ins**, then use the Load Order arrows to move each add-in where you want it to appear in the Add-Ins menu.

**Update Add-Ins**

If you are given an update to an add-in you already have installed, you can just install the update as you did the original add-in. Doing so overwrites the old version with the new one.

**Disable, Enable, and Remove Add-Ins**

*To temporarily disable an add-in without removing it*

1. Select **View > Add-Ins**.
2. Select the add-in that you want to disable.
3. Deselect the **Enabled** check box.

*To enable a disabled add-in*

1. Select **View > Add-Ins**.
2. Select the add-in that you want to enable.
3. Select the **Enabled** check box.

*To unregister an add-in*

1. Select **View > Add-Ins**.
2. Select the add-in that you want to remove.
3. Click **Unregister**.
Examining working scripts line-by-line is one of the best ways to learn JSL. This chapter describes common tasks in JMP, such as converting date/time values and extracting specific values from reports. Sample scripts that address these issues are installed with JMP in the Samples/Scripts folder so you can run them yourself.
Contents

Run a Script at Start Up ................................................................. 901
Convert Character Dates to Numeric Dates ......................................................... 902
Format Date-Time Values and Subset Data ......................................................... 903
Create a Formula Column ........................................................................... 904
Extract Values from an Analysis into a Report .................................................. 906
Create an Interactive Program ....................................................................... 910
Run a Script at Start Up

You can run the same script every time you start JMP. For example, you might include the definitions of some utility functions or a namespace that you want available throughout your JMP session. You might also set some preferences in a startup script to keep preferences consistent. Preferences persist across JMP sessions, but you could explicitly reset some preferences in case they were changed at some point in the previous session.

Name the script `jmpStart.jsl` and place it in one of the following folders, as appropriate for your operating system. When JMP starts, JMP looks for the `jmpStart.jsl` script in these folders in the order in which they are listed here. The first one that is found is run, and the search immediately stops.

**Note:** Some path names in this section refer to the “JMP” folder. On Windows, in JMP Pro, the “JMP” folder is named “JMPPro”.

On Windows:
1. `C:/Users/<username>/AppData/Roaming/SAS/JMP/16`
2. `C:/Users/<username>/AppData/Roaming/SAS/JMP`

On macOS:
1. `/Users/<username>/Library/Application Support/JMP/16`
2. `/Users/<username>/Library/Application Support/JMP`

The `jmpStart.jsl` script runs only for a particular user on a computer. You can add a script named `jmpStartAdmin.jsl` in one of the following places, as appropriate for your operating system. This script is run for every user on a computer. JMP runs `jmpStartAdmin.jsl` first if found. Then JMP runs `jmpStart.jsl` if found.

On Windows:
1. `C:/ProgramData/SAS/JMP/16`
2. `C:/ProgramData/SAS/JMP`

On macOS:
1. `/Library/Application Support/JMP/16`
2. `/Library/Application Support/JMP`
Convert Character Dates to Numeric Dates

Data might appear to be numeric in the data table. However, the column properties may specify a character data type. To manipulate the data as date/time values, convert the column to a numeric column and specify how you want the values to appear.

Convert Dates.jsl creates a data table, specifies the data input format, changes the column to a numeric continuous column, and applies the m/d/y format (Figure 17.1).

```julia
// Create a data table with character dates.
dt = New Table( "Example",
    Add Rows( 3 ),
    New Column( "Dates",
        Character, Nominal,
        Set Values( {"25/01/2010", "30/09/2009", "15/12/2013"} )
    );

// Display a modal dialog for the user to confirm the format conversion.
nw = New Window( "Date Conversion",
    <<Modal,
        tb = Text Box( "Notice the d/m/y format of the character dates.
        Click OK to convert the column to a numeric column and apply the m/d/y format."
    );

/* Apply the Numeric data type.
Specify the Informat (input format) value "d/m/y".
Specify the Format (display format) value "m/d/y".
Apply the Continuous modeling type */
col = Column( dt, "Dates" );
col << Data Type( "Numeric", Informat( "d/m/y" ), Format( "m/d/y" ) );
col << Modeling Type( "Continuous" );
```
When you change the column’s data type from character to numeric, defining the format in which the data were entered is important. In this example, `Informat("d/m/y")` defines the input format. `Format("m/d/y")` defines the new display format. If `Informat()` is omitted, the `Format()` value is applied as both the input and display format. This results in missing values for some data.

Modify `Convert Dates.jsl` to see for yourself.

1. Open `Convert Dates.jsl` from the sample scripts folder.
2. Right-click the script window and select `Show Line Numbers`.
3. On line 9, change "25/01/2010" to "01/25/2010".
4. On line 27, delete `Informat("d/m/y")`, (including the comma).
5. Run the script.

`Format("m/d/y")` is applied to the column. Only "01/25/2010" appears in the column. The other values are missing; "30/09/2009" and "15/12/2013" are not valid m/d/y values.

### Format Date-Time Values and Subset Data

How can you work with dates in JMP? JMP provides a number of formats that you can use to make comparisons and then subset data based on the date.

Select Where Using Dates.jsl applies the Date MDY format to a column of departure dates and subsets the data. A summary table of mean net costs by departure date then appears (Figure 17.2).

```julia
/*  How can you work with dates in JSL? JMP provides a number of formats that you can use to make comparisons and then subset data based on the date.
*/

hdt = Open( "$SAMPLE_DATA/Travel Costs.jmp" );
```
/* Apply the Date MDY format to Departure Date values and then select only February dates. */
hdt << Select Where(
    (Date MDY( 02, 01, 2007 ) <= :Departure Date < Date MDY( 03, 1, 2007 ))
);

/* Subset the selected rows into two tables: one table contains February departure dates, the other contains all data for those departure dates. */
nt1 = hdt << Subset( Columns( :Departure Date ),
Output Table Name( "February Departure Date" ) );
nt2 = hdt << Subset( Output Table Name( "February Data" ) );

/* Create a summary table, grouping mean cost by day of week that departure took place. */
sumDt = nt2 << Summary(
    Group( :Departure Day of Week ),
    Mean( :Net Cost ),
    Output Table Name( "Mean Net Cost by Departure Date" )
);

Figure 17.2  The Original Table and the Final Summary Table

Create a Formula Column

How do you create a formula column that combines conditional expressions with value comparisons? Create a Formula Column.jsl shows how to create a new formula column that evaluates ages in Big Class.jmp and returns the result in the new column (Figure 17.3).
/* Scenario: 
How do you create a formula column that combines conditional expressions with value comparisons? This script shows how to create a new formula column that evaluates ages in Big Class.jmp and returns the conditional result in the new column. */

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );

/* Create a new character column for the formula. Insert "early" in the new column if the age is less than or equal to 12. Insert "mid" if the age is less than or equal to 15 but greater than 12. For ages greater than 15, insert "late". */

dt << New Column( "Adolescent Phase",
    Character,
    Formula(
        If( :age <= 12, "early",
            12 < :age <= 15, "mid",
            "late"
        )
    ));
Extract Values from an Analysis into a Report

How do you capture specific results of an analysis into a custom report using JSL?

The JMP platforms in the Analyze and Graph menus contain two objects known as the analysis and report layers. Messages are sent to the analysis layer that generate the desired results.

Extract Values from Reports.jsl performs a Bivariate analysis and shows results such as the sample size, RSquare, and Correlation in a new report window. Figure 17.4 shows the Bivariate report along with the customized report, though the Bivariate report window closes after the script is finished.
/* Scenario: How do you capture specific results of an analysis in a report using JSL? 

The JMP platforms in the Analyze and Graph menus contain two objects known as the analysis and report layers.

Messages are sent to the analysis layer that generate the desired results.

This script performs a Bivariate analysis and shows results such as the sample size, RSquare, and Correlation in a new report window. */

sd = Open("$SAMPLE_DATA/Lipid Data.jmp");

biv = Bivariate( // biv is the analysis layer.
   Y( :Triglycerides ),
   X( :LDL ),
   Density Ellipse( 0.95, {Line Color( {213, 72, 87} )} ),
   Fit Line( {Line Color( {57, 177, 67} )} ),
);

/* Make sure the second Outline Box (called "Correlation") in the Bivariate report is open. You can then see which content is extracted into the Custom report. */
report(biv) [Outline Box( 2 )] << Close( 0 );

reportbiv = biv << Report; // reportbiv is the report layer.

/* The density ellipse is generated first. 
Extract the correlation coefficient. */
corrvalue = reportbiv[Outline Box( 2 )][Number Col Box( 3 )] << Get( 1 );

/* ...followed by Fit Line 
Extract the numeric values from the Summary of Fit report and place them in a matrix. */
sumfit = reportbiv[Outline Box( 4 )][Number Col Box( 1 )] << Get as Matrix;

// Extract the values of RSquare and AdjRSquare as one by one matrices.
rsquare = sumfit[1];
adjrsq = sumfit[2];
avg = sumfit[4];
samplesize = sumfit[5];

/* Extract the first column of the Parameter. 
Estimates report as two objects. */
term = reportbiv[Outline Box( 7 )][String Col Box( 1 )] << Get();
// Clone the report layer as a String Col Box.
cloneterm = reportbiv[Outline Box( 7 )][String Col Box( 1 )] << Clone Box;

// Extract the Parameter Estimates values as a matrix.
est = reportbiv[Outline Box( 7 )][Number Col Box( 1 )] << Get as Matrix;

// Extract the Standard Error values as a matrix.
stde = reportbiv[Outline Box( 7 )][Number Col Box( 2 )] << Get as Matrix;

dvalues = [];
dvalues = samplesize |/ adjrsq |/ rsquare |/ corrvalue;
sfactor = term[2];

dlg = New Window( "Custom Report",
Outline Box( "Selected Values",
/* The Lineup box defines a two-column layout, each of which contains
a Text Box. */
Lineup Box( N Col( 2 ),
Text Box( "Factor of Interest: " ),
Text Box( sfactor ), ),
tb = Table Box( /* Display an empty string in the first column
and the text in the second column. */
String Col Box( " ",
{"Sample Size: ","Adjusted RSquare: ","RSquare: ",
"Correlation:"}

Figure 17.4  Customized Report from the Bivariate Analysis
How do you gather numeric input from the users, perform a calculation on that input, and show the results in a new window?

Prime Numbers.jsl asks the user to enter a number and then factors the number or confirms it as a prime number (Figure 17.5). This script is a good example of aligning several types of display boxes, concatenating text, and working with conditional functions.

/* How do you gather numeric input from the users, perform a calculation on that input, and show the results in a new window? 

This script demonstrates how to create an interactive program that asks the user to enter a number and then factors the number or confirms it as a prime number. */

// Ask the user to enter a name and number.
new = New Window( "Factoring Fun",

Appendix A

 Compatibility Notes
Changes in Scripting in 16.0

This appendix provides information about changes that affect compatibility in JSL scripts. Please update your scripts accordingly so that the scripts run correctly in the latest version of JMP.

Compatibility Issues in 16.0

**Copy File(), Move File(), Rename File(), and Delete File()**

In JMP 15.0, copying a file, moving a file, renaming a file, and deleting a file that didn’t exist threw an error. Now, it returns 0.

**Row Selection() and Case Sensitivity**

Match Case, Match Case(), Match Case(1) and a missing Match Case do a case sensitive match in Row Selection(). Match Case(0) does a case insensitive match. Previously, Row Selection() always matched case sensitively even if Match Case was not supplied.

**Target Level Column Property**

You can use the new Target Level column property to specify the level of interest in binary logistic regression models. The default level is High. The main effects will be in the slope of the logistic probability curve, the signs of the linear model estimates, the profiler shape, and the ROC target. Be aware that some scripts that assume the target level in Fit Model or Fit Y by X logistic regression models should be checked.

**Opening Multiple Data Tables**

Open() returns a list of data tables if multiple data tables are created (for example, when importing PDF, HDF5, or Excel files). Previously, the Open() command returned a single table, even if multiple tables were created in the process.

**Format(), Informat(), and Variations**

The results of Format(), Informat() and their variations are written to the log if the format is invalid. Previously, they returned m/d/y when the format was invalid.
Graph Background Color Preference in Contour Plots

The Graph Background Color preference no longer affects the Contour Plot legend background color. Previously, the background color was applied to both the graph background and the legend background.
This appendix provides ideas for writing scripts that run faster and more efficiently. For example, it is possible to control how much time is allocated to finding an optimal design. You can collapse outlines in a report that are not necessary. Or you can write static matrices, which is faster than developing them dynamically.
Contents

Using Matrices ................................................................. 917
Design of Experiments .......................................................... 918
Scripting Data Tables ............................................................ 918
Scripting Graphs and Display Boxes .......................................... 919
Scripting Numbers, Strings, Arrays, and Lists .............................. 920
Programming Tips ............................................................. 920
Troubleshooting ............................................................... 920
Using Matrices

- The matrix concatenation operators, || and |/, add columns or rows to a matrix dynamically. However, the script runs faster if you define a matrix in a static fashion instead.

```plaintext
// faster example
t1 = Tick Seconds();
A = J( 10, 10000, . );
For( i = 1, i <= 10000, i++,
    a2 = J( 10, 1, Random Gamma( 1, 1 ) );
    // define a2 to be a 10 by 1 vector of random gamma values.
    A[0, i] = a2;
    /* populate the ith column of the matrix A to have the
    values in a2. The first argument, 0, means "all rows". */
); t2 = Tick Seconds();
Show( t2 - t1 );
t2 - t1 = 0.0166666666627862;

// slower example
t3 = Tick Seconds();
B = J( 10, 0, . );
For( i = 1, i <= 10000, i++,
    a2 = J( 10, 1, Random Gamma( 1, 1 ) );
    B = B || a2;
); t4 = Tick Seconds();
Show( t4 - t3 );
t4 - t3 = 3.1333333333605;
```

- If you know the size of a matrix that you’re going to need, it’s typically better to allocate the matrix in its entirety first and then populate it. In the example below, the J() function is doing the allocation of the 100000x1 matrix all at the same time.

```plaintext
Delete Symbols( a1, a2 );
// faster example
    t1 = Tick Seconds();
    a1 = J( 100000, 1, Random Uniform() );
    t2 = Tick Seconds();
    Show( t2 - t1 );
    Delete Symbols( a1 );
    t2 - t1 = 0;

// slower example
t3 = Tick Seconds();
a2 = J( 0, 0 );
```
Design of Experiments

In DOE, there are options such as Number of Starts and Design Search Time that enable you to control how much time is allocated to finding an optimal design.

```javascript
// Number of Starts example
DOE(
    Custom Design,
    Add Factor( Continuous, -1, 1, "X1", 0 ),
    Add Factor( Continuous, -1, 1, "X2", 0 ),
    Add Factor( Continuous, -1, 1, "X3", 0 ),
    Number of Starts( 1000 ),
    Make Design
);

// Design Search Time example
d = DOE( Screening Design );
dt2 = Open( "$SAMPLE_DATA/Design Experiment/Weld Factors.jmp" );
d << Load Factors;
Close( dt2 );
d << {Set Random Seed( 12345 ), Screening Type( 1 ),
        Suppress Cotter Designs, Design Search Time( 8 ),
        Number of Column Starts( 50 ), Set Sample Size( 12 ), Make Design};
```

Scripting Data Tables

- Displaying a large data table can cause scripts to run slower. To speed things up, you can make a data table invisible, especially if you need to reference numbers in a report that will be used for future calculations or used in another platform. In this case, there isn’t a need to see the current data table.

  ```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp", invisible);
```

- Drawing objects is slow. Suppose that you have a graph with a lot of data. The platform does complicated calculations or the data table contains a formula. Adding a row can require a lot of processing. Use `Begin Data Update()` so you only redraw the graph once
instead of for each change. Begin Data Update() saves all update messages until End Data Update() is reached.

dt = Open("MyData.jmp");
dt << Distribution(
    Column("N=1"n, "N=5"n), "N=10"n )
);
Wait(1);
dt << Begin Data Update;
dt << Add Rows(2000);
dt << End Data Update;

• The use of functions might help speed things up, for example, using the Summarize() function rather than creating a Summary table. Maintaining a data table can be too much overhead. See “Store Summary Statistics in Global Variables” on page 364 in the “Data Tables” chapter.

• Data tables are great for keeping tabular data.
  – Keep data table strings under 23 characters. Longer strings have additional overhead.
  – Numeric values use less memory than character values.

Scripting Graphs and Display Boxes

• When displaying large numbers in graphs, you can set a preference to use Fast Markers.
  Preferences( Fast Marker Threshold(25000)); // 50000 is the default.

• Collapse some of the outline nodes in a report to speed up the script.
  SendToReport(
      Dispatch(
          {"Fit Life by X - Hours BY Arrhenius Celsius (Temp) Regression ",
            "Scatterplot",
            OutlineBox,
            {Close(1) }
      ),
  ),

• Construct your display boxes outside New Window() and then include them by reference in New Window(). This method saves the drawing until the end.
  tb = TextBox("Select:" );
  lb = ListBox({"One", "Two", "Three"});
  New Window("test", tb, lb);

• The user might not need to see a report if the numbers will be used in another platform or for a future calculation. You can hide the report.
  dt= Open("$SAMPLE_DATA/Big Class.jmp");
  obj = Bivariate( Y( :Weight ), X( :Height ) );
obj << Show Window( 0 ); // hide the window
obj << Fit Line( {Confid Curves Fit( 1 )} );

Submit the following script to see the report window. Notice that the confidence curves were fit even though the window was not shown.

obj << Show Window( 1 );

---

Scripting Numbers, Strings, Arrays, and Lists

- Use a faster algorithm. Replacing an O(n^2) algorithm with an O(n) algorithm is faster than anything else. See https://en.wikipedia.org/wiki/Big_O_notation.
- Avoid concatenating long strings. 100s of characters is OK; 1,000,000s of characters will be slow if you build the string in 1,000,000s of operations.
- Use numeric arrays (matrices, not lists).
  - Use numeric arrays with operators that operate on the entire array.
  - Avoid writing loops to manipulate numeric arrays.
- Use associative arrays for lookups.

---

Programming Tips

- Avoid Break(), Continue(), and Return() functions for speed. Using them might make it easier for you to read the script.
- Functions versus expressions:
  - User-defined functions have overhead for calling them but might make it easier for you to read the script.
  - Expressions have no overhead for calling but might make it more difficult for you to read the script.

---

Troubleshooting

Use the JSL Debugger to discover where the script is expending the most time. See “Debug or Profile Scripts” on page 77 in the “Scripting Tools” chapter.

Glossary
Terms, Concepts, and Placeholders

| In syntax summaries, | means “or” and separates possible choices. Usually choices separated by | are mutually exclusive. In other words, you have to pick one and cannot list several.

**argument**  An argument is something specified inside the parentheses of a JSL function, message, and so forth. Big Class.jmp is the argument in Open("Big Class.jmp").

You can often infer the meaning by the argument’s position. For example, the values 200 and 100 in size(200, 100) are implicit arguments. The first value is always interpreted as the width; the second value is always interpreted as the height. See also named argument.

**Boolean**  A Boolean value is a yes/no value, something that is on or off, shown or hidden, true or false, 1 or 0, yes or no. A value listed as being a Boolean value is one that evaluates to true or false (or missing).

**col**  In syntax summaries, a placeholder for any reference to a data table column. For example, Column("age").

**command**  A generic description for a JSL statement that performs an action. The Scripting Guide prefers the more specific terms function and message when they are applicable.

**current data table**  The current data table is the data table that Current Data Table() either returns or is assigned.

**current row**  The current row for scripting is defined to be zero (no row) by default. You can set a current row with Row() or For Each Row, and so forth.

**database**  Although the term is much more general, for JMP’s purposes, the word “database” describes any external data source (such as SQL) accessed through ODBC with JSL’s Open Database command.

**Datafeed**  A Datafeed is a method to read real-time data continuously, such as from a laboratory measurement device connected to a serial port.

**db**  In syntax summaries, a placeholder for any reference to a display box. For example, report(Bivariate[1]).

**dt**  In syntax summaries, a placeholder for any reference to a data table. For example, Current Data Table() or Data Table("Big Class.jmp").
**eliding operator**  An eliding operator is one that causes arguments on either side to combine and evaluate differently than if the statement were evaluated strictly left to right. For example, \(12 < a < 13\) is a range check to test whether \(a\) is between 12 and 13: JMP reads the whole expression before evaluating. If \(<\) did not elide, the expression would be evaluated left to right as \((12 < a) < 13\). In other words, it would check whether the result of the comparison (1 or 0, for false or true) is below 13, which of course would always yield 1 for true. The \(<\!\!<\) operator (for `object<<message`, which is equivalent to `Send(object, message)` is another example of an eliding operator.

**function**  A function takes an argument or series of arguments inside parentheses after the function name. For example, the infix operator `+` has a function equivalent `Add()`. The statements `3 + 4` and `Add(3, 4)` are equivalent. All JSL’s operators have function equivalents, but not all functions have operator equivalents. For example, `Sqrt(a)` can be represented only by the function. Also see the `Function` operator for storing a function under a name.

**global variable**  A global variable is a name to hold values that exists for the remainder of a session. Globals can contain many types of values, including numbers, strings, lists, or references to objects. They are called globals because they can be referred to almost anywhere, not just in some specific context.

**head**  The head of a JSL expression is the expression without any of its arguments. For example, the head of the expression `Assign( x, 100.1 )` is `Assign()`.  

**infix operator**  An infix operator takes one argument on each side, such as `+` in arithmetic, `3 + 4`, or the `=` in an assignment, `a=7`.

**L-value**  Something that can be the destination of an assignment. In this manual, L-value describes an expression that normally returns its current value but that can alternatively receive an assignment to set its value. For example, you would ordinarily use a function such as `Row()` to get the current row number and assign it to something else. For example, `x=Row()`. However, since `Row` is an L-value, you can also place it on the left side of an assignment to set its value. For example, `Row()=10`.

**list**  A list is a multiple-item data type entered in special brace `{ }` notation or with the `List` function. Lists enable scripts to work with many things at once, often in the place of a single thing.

**matrix**  A matrix is a JMP data type for a rectangular array of rows and columns of number. In JSL, matrices are entered in bracket `[ ]` notation or with the `Matrix` function.

**message**  A message is a JSL statement that is directed to an `object`, which knows how to execute the message.

**metadata**  In JMP data tables, metadata are data about the data, such as the source of the data, comments about each variable, scripts for working with the data, and so on.
mousedown  An event generated by pressing down the mouse button. See “Handle()” on page 669 and “Mousetrap()” on page 674.

mouseup  An event generated by releasing the mouse button. See “Handle()” on page 669 and “Mousetrap()” on page 674.

name  A name is a reference to a JSL object. For example, when you assign the numeric value 3 to a global variable in the statement `a=3`, “a” is a name.

namespace  A namespace is a collection of unique names and corresponding values. Namespaces are useful for avoiding name collisions between different scripts.

class argument  A named argument is an optional argument that you select from a predetermined set and explicitly define. For example, `HexToNumber(hextext, <Base(number)>)` has a single named argument, `Base`. This is the fixed name that must directly be in the `HexToNumber` argument.

ODBC database  The Microsoft standard for Open DataBase Connectivity. JSL supports access to any ODBC-enabled data source through the `Open Database` command.

obj  In syntax summaries, a placeholder for any reference to an analysis platform. For example, `Bivariate[1]`.

object  An object is a dynamic entity in JMP, such as a data table, a data column, a platform results window, a graph, and so forth. Most objects can receive messages telling them to act on themselves in some way.

operator  Usually operator refers to a one- or two-character symbol such as + for addition or <= for less than or equal to.

POSIX  POSIX is an acronym for Portable Operating System Interface and is a registered trademark of the IEEE. POSIX pathnames enable you to use one syntax for paths for any operating system, instead of having to use a different syntax for each.

postfix operator  A postfix operator takes an argument on its left side (before the operator), such as `a++` for postincrement or `a--` for postdecrement.

pre-evaluated statistics  Statistics that are calculated once and used as constants thereafter.

prefix operator  A prefix operator takes one argument on its right side (after the operator), such as `!a` for negation.

reference  A way to address a scriptable object in order to send it messages. For example, `column("age")` or `Current Data Table()` or `Bivariate[1]`. Typically a reference is stored in a `global variable` for convenience.

collected state  A data element type to store any combination of the following attributes for data rows: excluded, hidden, labeled, selected, color, marker, hue, shade.
**scalar**  A simple non-matrix numeric value.

**scoping operator**  A scoping operator forces a name to be interpreted as a particular type of data element, for example the `:` operator in `:name` forces `name` to be resolved as a column; the `::` operator in `::name` forces `name` to be resolved as a global variable. In the rare case that you do want to share specific variables among all opened projects, use the `:::` root operator.

**toggle**  Omitting the Boolean argument for a row state command toggles the setting. If the option is off, the message turns it on. If the option is on, the message turns it off. Sending such a command repeatedly flips back and forth between on and off. If you include the Boolean argument, the command sets an absolute on or off state, and sending the command repeatedly has no further effect. For all other messages, omitting the Boolean argument enables the option.

**vector**  A matrix with only one column or row.

Assignment Functions

JSL also provides operators for in-place arithmetic, or assignment operators. These operations are all done in place, meaning that the result of the operation is assigned to the first argument. The most basic assignment operator is the = operator (or the equivalent function Assign). For example, if \( a \) is 3 and you do \( a+=4 \), then \( a \) becomes 7.

The first argument to an assignment function must be something capable of being assigned (an L-value). You cannot do something like \( 3+=4 \), because 3 is just a value and cannot be reassigned. However, you can do something like \( a+=4 \), because \( a \) is a variable whose value you can set.

---

**Add To** (\( a, b \))

\( a+=b \)

**Description**

Adds \( a \) and \( b \) and places the sum into \( a \).

**Returns**

The sum.

**Arguments**

- \( a \) Must be a variable.
- \( b \) Can be a variable, a list, a number, or a matrix.

**Notes**

The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.

For **Add To()**: Only two arguments are permitted. If one or no argument is specified, **Add To()** returns a missing value. Any arguments after the first two are ignored.

For \( a+=b \): More than two arguments can be strung together. JMP evaluates pairs from right to left, and each sum is placed in the left-hand variable. All arguments except the last must be a variable.

**Example**

\( a+=b+=c \)

JMP adds \( b \) and \( c \) and places the sum into \( b \). Then JMP adds \( a \) and \( b \) and places the sum into \( a \).
**Assign**

\[ a = b \]

**Description**
Places the value of \( b \) into \( a \).

**Returns**
The new value of \( a \).

**Arguments**
- \( a \) Must be a variable.
- \( b \) Can be a variable, number, or matrix.

**Notes**
\( a \) must be a variable, because it must be able to accept a value change. A number as the first argument produces an error. If \( b \) is some sort of expression, it’s evaluated first and the result is placed into \( a \).

**Divide To**

\[ a \div b \]

**Description**
Divides \( a \) by \( b \) and places the result into \( a \).

**Returns**
The quotient.

**Arguments**
- \( a \) Must be a variable.
- \( b \) Can be a variable, number, or matrix.

**Multiply To**

\[ a \times b \]

**Description**
Multiplies \( a \) and \( b \) and places the product into \( a \).

**Returns**
The product.

**Arguments**
- \( a \) Must be a variable.
- \( b \) Can be a variable, number, or matrix.

**Notes**
The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.
For `Multiply To()`: Only two arguments are permitted. If one or no argument is specified, `Multiply To()` returns a missing value. Any arguments after the first two are ignored.

For `a*=b`: More than two arguments can be strung together. JMP evaluates pairs from right to left, and each product is placed in the left-hand variable. All arguments except the last must be a variable.

**Example**

```
a*=b*=c
```

JMP multiplies `b` and `c` and places the product into `b`. Then JMP multiplies `a` and `b` and places the product into `a`.

---

**PostDecrement(a)**

```
a--
```

**Description**

Post-decrement. Subtracts 1 from `a` and places the difference into `a`.

**Returns**

`a-1`

**Argument**

`a` Must be a variable.

**Notes**

If `a--` or `Post Decrement(a)` is inside another expression, the expression is evaluated first, and then the decrement operation is performed. This expression is mostly used for loop control.

---

**Post Increment(a)**

```
a++
```

**Description**

Post-increment. Adds 1 to `a` and places the sum into `a`.

**Returns**

`a+1`

**Argument**

`a` Must be a variable.

**Notes**

If `a++` or `Post Increment(a)` is inside another expression, the expression is evaluated first, and then the increment operation is performed. Mostly used for loop control.
Subtract To(a, b)

\[ a -= b \]

**Description**
Subtracts \( b \) from \( a \) and places the difference into \( a \).

**Returns**
The difference.

**Arguments**
- \( a \) Must be a variable.
- \( b \) Can be a variable, number, or matrix.

**Notes**
The first argument must be a variable, because its value must be able to accept a value change. A number as the first argument produces an error.

For SubtractTo(): Only two arguments are permitted. If fewer than two or more than two arguments is specified, SubtractTo() returns a missing value.

For \( a -= b \): More than two arguments can be strung together. JMP evaluates pairs from right to left, and each difference is placed in the left-hand variable. All arguments except the last must be a variable.

**Example**
\[ a -= b -= c \]

JMP subtracts \( c \) from \( b \) and places the difference into \( b \). Then JMP subtracts \( b \) from \( a \) and places the difference into \( a \).

---

**Character Functions**

Most character functions take character arguments and quoted return character strings, although some take numeric arguments or return numeric data. Arguments that are literal character strings must be enclosed in quotation marks.

**BLOB To Char(blob, <Encoding="enc">)**

**Description**
Reinterpret binary data as a quoted Unicode string.

**Returns**
A quoted string.

**Required Argument**
- \( \text{blob} \) A binary large object.
Optional Argument

Encoding A quoted string that specifies an encoding. The default encoding for the character string is "utf-8". "utf-16le", "utf-16be", "us-asci"l, "iso-8859-1", "ascii-hex", "shift-jis", and "euc-jp" are also supported.

Notes

The optional argument "ascii-hex" is intended to make conversions of blobs containing normal ASCII data simpler when the data might contain CR, LF, or TAB characters (for example) and those characters do not need any special attention.

BLOB To Matrix(blob, type, bytes, endian, <nCols>)

Description

Creates a matrix by converting each byte in the blob to numbers.

Returns

A matrix that represents the blob.

Required Arguments

blob A blob or reference to a blob.
type A quoted string that contains the named type of number. The options are "int", "uint", or "float".
bytes Byte size of the data in the blob. Options are 1, 2, 4, or 8.
endian The quoted endian-ness of your system: "Big" (the first byte is most significant), "Little" (the first byte is the least significant), or "Native" (the machine's native format).

Optional Argument

<nCols> The number of columns in the matrix. The default value is 1.

Char(x, <width>, <decimal>, < <<Use Locale(Boolean)>>)

Description

Converts an expression or numeric value into a quoted character string.

Returns

A quoted string.

Required Argument

x an expression or a numeric value. An expression must be quoted with Expr(). Otherwise, its evaluated value is converted to a quoted string.

Optional Arguments

width A number that sets the maximum number of characters in the quoted string.
decimal A number that sets the maximum number of places after the decimal that is included in the quoted string.
Use Locale(Boolean) Preserves locale-specific numeric formatting.
Example

Char( Pi(), 10, 4)
"3.1416"

Char( Pi(), 3, 4)
"3.1"

Notes
The width argument overrides the decimal argument.

Char To BLOB(string, <encoding="enc">)

Description
Converts a quoted string of characters into a binary (blob).

Returns
A binary object.

Required Argument
string A quoted string or a reference to a string.

Optional Argument
encoding A quoted string that specifies an encoding. The default encoding for the blob is "utf-8","utf-16le","utf-16be","us-ascii","iso-8859-1","ascii~hex","shift-jis", and "euc-jp" are also supported.

Notes
Converting BLOBs into printable format escapes \ (in addition to ~ " ! and characters outside of the printable ASCII range) into hex notation (~5C for the backslash character).

x = Char To BLOB( "abc\def\!n" );
y = BLOB To Char( x, encoding = "ASCII~HEX" );
If(
    y == "abc~5Cdef~0A", "JMP 12.2 and later behavior",
    y == "abc\def~0A", "Pre-JMP 12.2 behavior"
);    
"JMP 12.2 and later behavior" // output

Char To Hex(value, <integer|encoding="enc">)

Hex(value, <integer|encoding="enc"|Base(number)|Pad To(number)>)

Description
Returns the hexadecimal (or other base number system) text corresponding to the given value and encoding, which can be a number a quoted string or a blob. If the value is a number, IEEE 754 64-bit encoding is used unless one of the optional arguments, integer, or Base, is provided.

Required Argument
value Any number, quoted string, or blob.
Optional Arguments

- integer  A quoted switch that causes the value to be interpreted as an integer.
- encoding  A quoted string that specifies an encoding. The default encoding is "utf-8". "utf-16le", "utf-16be", "us-ascii", "iso-8859-1", "ascii~hex", "shift-jis", and "euc-jp" are also supported.

Base(number)  An integer value between 2 and 36 inclusive. If base is specified, the function returns the text corresponding to the specified number in that base number system instead of hexadecimal.

Pad To(number)  A value to specify the padded width of the hex output.

Collapse Whitespace(text)

Description
Trims leading and trailing whitespace and replaces interior whitespace with a single space. That is, if more than one white space character is present, the Collapse Whitespace function replaces the two spaces with one space.

Returns
A quoted string.

Required Argument
- text  A quoted string.

Concat(a, b)
Concat(A, B)

a || b
A || B

Description
For quoted strings: Appends the string b to the string a. Neither argument is changed.
For lists: Appends the list b to the list a. Neither argument is changed.
For matrices: Horizontal concatenation of two matrices, A and B.

Returns
For quoted strings: A quoted string composed of the string a directly followed by the string b.
For lists: A list composed of the list a directly followed by the list b.
For matrices: A matrix.

Arguments
Two or more quoted strings, quoted string variables, lists, or matrices.

Example
a = "Hello"; b = " "; c = "World"; a || b || c;
"Hello World"

d = {"apples", "bananas"};
e = {"peaches", "pears"};
Concat( d, e );
{"apples", "bananas", "peaches", "pears"}
A = [1 2 3]; B = [4 5 6];
Concat( A, B );
[1 2 3 4 5 6]

Notes
More than two arguments can be strung together. Each additional quoted string is appended to the end, in left to right order. Each additional matrix is appended in left to right order.

Concat Items

See “Concat Items({string1, string2,...}, <delimiter>)” on page 169.

Concat To(a, b)

Description
For quoted strings: Appends the string b to the string a and places the new concatenated string into a.
For matrices: Appends the matrix b to the matrix a and places the new concatenated matrix into a.
For lists: Appends the list b to the list and places the new concatenated list into a.

Returns
For quoted strings: A string composed of the string a directly followed by the string b.
For matrices: A matrix.
For lists: A list composed of the list a directly followed by the list b.

Arguments
Two or more quoted strings, quoted string variables, matrices, or lists. The first variable must be a variable whose value can be changed.

Notes
More than two arguments can be strung together. Each additional quoted string, matrix, or list is appended to the end, in left to right order.

Example
a = "Hello"; b = " "; c = "World";
Concat To( a, b, c );
Show( a );
a = "Hello World"
A = [1 2 3]; B = [4 5 6];
Concat To( A, B );
Show( A );
A = [1 2 3 4 5 6];
d = {"apples", "bananas"}; e = {"peaches", "pears"}; Concat to(d,e); Show( d );
d = {"apples", "bananas", "peaches", "pears"};

Contains(whole, part, <start>)

Description
Determines whether part is contained within whole.

Returns
If part is found: For lists, quoted strings, and namespaces, the numeric position where the first occurrence of part is located. For associative arrays, 1.

If part is not found, 0 is returned in all cases.

Required Arguments
whole A quoted string, list, namespace, or associative array.
part For a quoted string or namespace, a string that can be part of the string whole. For a list, an item that can be an item in the list whole. For an associative array, a key that can be one of the keys in the map whole.

Optional Argument
start A numeric argument that specifies a starting point within whole. If start is negative, contains searches whole for part backwards, beginning with the position specified by the length of whole – start. Note that start is meaningless for associative arrays and is ignored.

Example
nameList={"Katie", "Louise", "Jane", "Jaclyn"};
r = Contains(nameList, "Katie");
The example returns a 1 because “Katie” is the first item in the list.

Contains Item(x, <item | {list} | pattern>, <delimiter>)

Description
Identifies multiple responses by searching for the specified item, list, pattern, or delimiter. The function can be used on columns with the Multiple Response modeling type or column property.

Returns
Returns a Boolean that indicates whether the word (item), one of a list of words (list), or pattern (pattern) matches one of the words in the text represented by x. Words are delimited by the characters in the optional quoted delimiter (delimiter) string. A comma is the default delimiter. Blanks are trimmed from the ends of each extracted word from the input text string (x).
Example

The following example searches for “pots” followed by a comma and then outputs the result.

```julia
x = "Franklin Garden Supply is a leading online store featuring garden decor, statues, pots, shovels, benches, and much more.";
b = Contains Item( x, "pots", "," );
If( b,
   Write( "The specified items were found." ), Write( "No match." )
);
```

The specified items were found.

---

**Ends With**(string, substring)

**Description**

Determines whether the quoted substring appears at the end of string.

**Returns**

1 if quoted string ends with a quoted substring, otherwise 0.

**Required Arguments**

- **string** A quoted string or a quoted string variable. Can also be a list.
- **substring** A quoted string or a quoted string variable. Can also be a list.

**Equivalent Expression**

\[
\text{Right(string, Length(substring))} == \text{substring}
\]

---

**Hex(value, <integer|encoding="enc"|Base(number)|Pad To(number)>)**

See “Char To Hex(value, <integer|encoding="enc">)” on page 30.

---

**Hex To BLOB**(string)

**Description**

Converts the quoted hexadecimal string (including whitespace characters) to a blob (binary large object).

**Example**

```julia
Hex To BLOB( "4A4D50" );
Char To BLOB("JMP", "ascii~hex")
```

---

**Hex To Char**(string, <encoding>)

**Description**

Converts the quoted hexadecimal string to its character equivalent.

**Example**

```julia
Hex To Char( "30" ) results in “0”.
```
Notes

The default quoted encoding for character string is "utf-8". "utf-16le", "utf-16be", "us-ascii", "iso-8859-1", "ascii-hex", "shift-jis", and "euc-jp" are also supported.

Hex To Number(string, <Base(number)>)

Description
Returns the number corresponding to the hexadecimal (or other base number system) text.

Required Argument

string A quoted hexadecimal string.

Optional Argument

Base(number) An integer between 2 and 36 inclusive. If base is specified, the text is treated as a quoted string representing the number in that base.

Example

Hex To Number( "80" );
128

Notes

– 16-digit hexadecimal numbers are converted as IEEE 754 64-bit floating point numbers. Otherwise, the input is treated as a hexadecimal integer.

– Whitespace between bytes (or pairs of digits) and in the middle of bytes is permitted (for example, FF 1919 and F F1919).

Insert

See “Insert(source, item, <position>)” on page 170.

Insert Into

See “Insert Into(source, item, <position>)” on page 170.

Item(n|[first last], string, <delimiter>, <Unmatched(result string)>, <Include Boundary Delimiters(Boolean)>)

Description
Returns the n_th item or the span from the first to last item of the quoted string according to the quoted string delimiters given. If you include a third argument, any and all characters in that argument are taken to be delimiters.

Required Arguments

n The position of the word being extracted.

[first last] A matrix that defines the beginning and end word range to return.

string The quoted string that is evaluated.
Optional Arguments

*delimiter* The character used as a boundary. If *delimiter* is absent, an ASCII space is used. If *delimiter* is the quoted empty string, each character is treated as a separate word.

Unmatched(*result string*) The quoted string to print if no match is found.

Include Boundary Delimiters(*Boolean*) Determines how delimiters on the front and back of string are treated. The default value is false, which means that the delimiters on these boundaries are ignored. If the value is true, delimiters on these boundaries produce an empty element (similar to consecutive delimiters within a string).

Example

Consecutive delimiters are treated as though they have a word between them. In this example, the delimiters are a comma and a space.

```
Item( 4,"the quick, brown fox", ", " ); // quick is preceded by two spaces
```

The expression is processed as follows:

```
the<delim[space]>quick<delim[comma]>quick<delim[space]>brown<delim[space]>fox
```

Because word4 is empty, this expression returns a quoted empty string.

*Item()* is the same as *Word()* except that *Item()* treats each delimiter character as a separate delimiter, and *Word()* treats several adjacent delimiters as a single delimiter.

```
Word( 4,"the quick, brown fox", ", " ); // quick is preceded by two spaces
```

This expression is processed as follows:

```
the<delim[2 spaces]>quick<delim[comma + space]>brown<delim[space]>fox
```

It returns "fox".

---

**Left**(string, *n*, <filler>)

**Left**(list, *n*, <filler>)

**Description**

Returns a truncated or padded version of the original quoted *string* or list. The result contains the left *n* characters or list items, padded with any *filler* on the right if the length of *string* is less than *n*.

**Length**(string)

**Description**

Returns the length of the given quoted string (in characters), list (in items), associative array (in number of keys), BLOB (in bytes), matrix (in elements), namespace (in number of functions and variables), or class (in number of methods, functions, and variables).
Chapter 2
JSL Syntax Reference

JSL Functions
Character Functions

Lowercase(string)

Description
Converts any uppercase character found in quoted string to the equivalent lowercase character.

Matrix to BLOB(matrix, type, bytesEach, endian(value))

Description
Makes a BLOB from a matrix by converting the matrix elements to 1-byte, 2-byte, or 4-byte signed or unsigned integers or 4-byte or 8-byte floating point numbers.

Required Arguments
- matrix The matrix.
- type The quoted type of BLOB: int, uint, or float.
- bytesEach The number of bytes in each int, uint, or float. Integers can be 1, 2, or 4 bytes each, and floats can be 4 or 8 bytes each.
- endian(value) The quoted endian-ness of your system: "Big" (the first byte is most significant), "Little" (the first byte is the least significant), or "Native" (the machine’s native format).

Munger(string, start position, find|length, <replacement string>)

Description
Computes new quoted character strings from the quoted string by inserting or deleting characters. It can also produce substrings, calculate indexes, and perform other tasks depending on how you specify its arguments.

Required Arguments
- start position A numeric expression that specifies the starting position to search in the quoted string. If the start position is greater than the position of the first instance of the find argument, the first instance is disregarded. If the start position is greater than the search string’s length, Munger() uses the string’s length as the start position.
- find|length Specifies the string or number of characters to find.

Optional Argument
- replacement string The quoted replacement string. If replacement string is omitted, a substring between start position, and position and length, is returned.

Num(string)

Description
Converts a quoted character string into a number.
Regex(source, pattern, (<replacement string>, <format, "GLOBALREPLACE", "IGNORECASE">>>)

**Description**
Searches for the quoted pattern within the quoted source string.

**Returns**
The matched text as a quoted string or numeric missing if there was no match.

**Required Arguments**
- **source** A quoted string.
- **pattern** A quoted regular expression.
- **replacement string** The replacement string.

**Optional Arguments**
- **format** A backreference to the capturing group. The default is \0, which is the entire matched quoted string. \n returns the \n\n returns the \n
"IGNORECASE" The search is case sensitive, unless you specify "IGNORECASE".
"GLOBALREPLACE" Applies the regular expression to the quoted source string repeatedly until all matches are found.

---

Remove
See “Remove(source, position, <n>)” on page 172.

---

Remove From
See “Remove From(source, position, <n>)” on page 172.

---

Repeat(source, a)
Repeat(matrix, a, b)

**Description**
Returns a copy of source concatenated with itself a times. Or returns a matrix composed of a row repeats and b column repeats. The source can be text, a matrix, or a list.

---

Reverse
See “Reverse(source)” on page 172.

---

Reverse Into
See “Reverse Into(source)” on page 173.
Right(string, n, <filler>)
Right({list}, n, <filler>)

**Description**
Returns a truncated or padded version of the original quoted string or list. The result contains the right n characters or list items, padded with any optional filler on the left if the length of string is less than n.

**Shift**
See “Shift(source, <n>)” on page 173.

**Shift Into**
See “Shift Into(source, <n>)” on page 173.

**Starts With(string, substring)**

**Description**
Determines whether the quoted substring appears at the start of the quoted string.

**Returns**
1 if string starts with substring, otherwise 0.

**Arguments**
string A quoted string or a reference to one. Can also be a list.
substring A quoted string or a reference to one. Can also be a list.

**Equivalent Expression**
Left(string, Length("substring")) = = "substring"

**Substitute**

**Substitute Into**
See “Substitute Into(string, substring, replacementString, ...)” on page 174.

**Substr(string, start, length)**

**Description**
Extracts the characters that are the portion of the first argument beginning at the position given by the second argument and ending based on the number of characters specified in the third argument. The first argument can be a character column or value, or an
expression evaluating to same. The starting argument and the length argument can be
numbers or expressions that evaluate to numbers.

**Example**

This example extracts the first name:

```
Substr( "Katie Layman", 1, 5 );
```

The function starts at position 1, reads through position 5, and ignores the remaining
characters, which yields “Katie.”

---

**Text Score**

(expression column, text-to-number, <weighting>, <{support vectors}>, <text explorer setup>)

**Description**

Used to create scoring formulas in Text Explorer. Not supported for use with the Stem for
Combining option.

**Returns**

Returns a vector of scores.

**Required Arguments**

- **text column** The data table column.
- **text-to-number** An associative array that maps lowercase words to numbers.

**Optional Arguments**

- **weighting** The quoted "Count", "Binary", "Ternary", "LogCount", "LCA", or an array
  of inverse document frequency weights for TFLogIDF. "Count" is the default value.
  The default value is "Count".
- **support vectors** A list of vectors that are used in the text scoring. The number and
  length of the vectors depends on the weighting argument.
- **text explorer setup** An expression that contains a block of Text Explorer setup
  information.

---

**Titlecase**

(string)

**Description**

Converts the quoted string to title case; each word in the string has an initial uppercase
character and subsequent lowercase characters.

**Returns**

A quoted string.

**Argument**

- **string** A quoted string.

**Example**

The following function capitalizes the name:

```
Titlecase( "veronica layman ")
```
Trim(string,<"Left"|"Right"|"Both">)

Trim Whitespace(string,<"Left"|"Right"|"Both">)

Description
Removes leading and trailing whitespace from the specified string.

Returns
A quoted string.

Required Argument
string A quoted string.

Optional Argument
"Left"|"Right"|"Both" A quoted string that specifies whether whitespace is removed from the left, the right, or both ends of the string. If omitted, whitespace is removed from both ends.

Example
For example, the following command returns "John":
Trim( " John ", Both )
"John"

Uppercase(string)

Description
Converts any lowercase character found in the quoted string to the equivalent uppercase character.

Word(n|[first last], string, <delimiter>, <Unmatched(result string)>)

Description
Returns the n \text{th} item of the string, where words are substrings separated by any number of any characters in the delimiter argument.

Required Arguments
n The position of the word being extracted.
[first last] A matrix that defines the beginning and end word range to return.
string The quoted string that is evaluated.

Optional Arguments
delimiter The character used as a boundary. If delimiter is absent, an ASCII space is used. If delimiter is the empty quoted string, each character is treated as a separate word.
Unmatched(result string) The quoted string to print if no match is found.
Examples

This example returns the last name:

```javascript
Word( 2, "Katie Layman" );
''Layman''
```

See Also

See “Item(n![first last], string, <delimiter>, <Unmatched(result string)>, <Include Boundary Delimiters(Boolean)>)” on page 35 for examples of how Word() differs from Item().

---

Words

See “Words(string, <delimiter>)” on page 175.

---

 XPath Query(xml, xpath_expression)

Description

Runs an XPath expression on an XML document.

Returns

A list.

Required Arguments

xml A valid XML document.

xpath_expression A quoted XPath 1.0 expression.

Example

Suppose that you created a report of test results in JMP and exported important details to an XML document. The test results are enclosed in <result> tags.

The following example stores the XML document in a variable. The XPath Query expression parses the XML to find the text nodes inside the <result> tags. The results are returned in a list.

```javascript
rpt = "[<?xml version=1.0" encoding=\"utf-8"?><JMP><report><title>Production Report</title><result>November 21st: Pass</result><result>November 22nd: Fail</result><note>Tests ran at 3:00 a.m.</note></report></JMP> ]";
results = XPath Query( rpt, "//result/text()" );
{"November 21st: Pass", "November 22nd: Fail"}
```
Character Pattern Functions

Pat Abort()

**Description**
Constructs a quoted pattern that immediately stops the pattern match. The matcher does not back up and retry any alternatives. Conditional assignments are *not* made. Immediate assignments that were already made are kept.

**Returns**
0 when a match is stopped.

**Argument**
none

Pat Altern(*pattern1*, <*pattern2*, ...>)

**Description**
Constructs a quoted pattern that matches any one of the pattern arguments.

**Returns**
A quoted pattern.

**Argument**
One or more patterns.

Pat Any(*string*)

**Description**
Constructs a quoted pattern that matches a single character in the argument.

**Returns**
A quoted pattern.

**Argument**
*pattern* A quoted string.

Pat Arb()

**Description**
Constructs a quoted pattern that matches an arbitrary quoted string. It initially matches the null quoted string. It then matches one additional character each time the pattern matcher backs into it.

**Returns**
A quoted pattern.
Argument
none

Example

p = "the beginning" + Pat Arb() >? stuffInTheMiddle + "the end";
Pат Match( "in the beginning of the story, and not near the end, there are	hree bears", p );
Show( stuffInTheMiddle );
stuffInTheMiddle = " of the story, and not near "

---

Pat Arb No(pattern)

Description
Constructs a quoted pattern that matches zero or more copies of pattern.

Returns
A quoted pattern.

Argument
pattern A quoted pattern to match against.

Example

adjectives = "large" | "medium" | "small" | "warm" | "cold" | "hot" | "sweet";
rc = Пат Match( "I would like a medium hot, sweet tea please",
   Pat Arbno( adjectives | Пат Any("", "") ) >> adj +
   ("tea" | "coffee" | "milk") );
Show( rc, adj );
rc = 1;
adj = " medium hot, sweet ";

---

Pat At(varName)

Description
Constructs a quoted pattern that matches the null quoted string and stores the current
position in the source string into the specified JSL variable (varName). The assignment is
immediate, and the variable can be used with expr() to affect the remainder of the match.

Returns
A quoted pattern.

Argument
varName The name of a variable to store the result in.

Example

p = ":" + Pat At( listStart ) + Expr(
   If( listStart == 1,
      Pat Immediate( Пат Len( 3 ), early ),
Pат Immediate( Пат Len( 2 ), late )
   )
);

early = "";
late = "";
Pat Match( "\:123456789", p );
Show( early, late );
early = "";
late = "";
Pat Match( "   \:123456789", p );
Show( early, late );

First this is produced:

---

early = "123"
late = ""
---

and later this:

---

early = ""
late = "12"
---

**Pat Break(string)**

**Description**

Constructs a quoted pattern that matches zero or more characters that are not in its argument; it stops or breaks on a character in its argument. It fails if a character in its argument is not found (in particular, it fails to match if it finds the end of the quoted source string without finding a break character).

**Returns**

A quoted pattern.

**Argument**

*string* A quoted string.

**Pat Concat(pattern1, pattern2 <pattern3, ...>)**

*Pattern1 + Pattern2 + ...*

**Description**

Constructs a quoted pattern that matches each pattern argument in turn.

**Returns**

A quoted pattern.

**Argument**

Two or more quoted patterns.
Pat Conditional (pattern, varName)

Description
Saves the result of the quoted pattern match, if it succeeds, to a variable named as the second argument (varName) after the match is finished.

Returns
A quoted pattern.

Arguments
- pattern: A quoted pattern to match against.
- varName: The name of a variable to store the result in.

Example
```
type = "undefined";
rc = Pat Match("green apples",
  Pat Conditional("red" | "green", type) + " apples"
);
Show(rc, type);
rc = 1;
type = "green";
```

Pat Fail()

Description
Constructs a quoted pattern that fails whenever the matcher attempts to move forward through it. The matcher backs up and tries different alternatives. If and when there are no alternatives left, the match fails and Pat Match returns 0.

Returns
0 when a match fails.

Argument
none

Pat Fence()

Description
Constructs a pattern that succeeds and matches the quoted null string when the matcher moves forward through it, but fails when the matcher tries to back up through it. It is a one-way trap door that can be used to optimize some matches.

Returns
1 when the match succeeds, 0 otherwise.

Argument
none
Pat Immediate(pattern, varName)

Description
Saves the result of the pattern match to a variable named as the second argument (varName) immediately.

Returns
A quoted pattern.

Arguments
pattern A quoted pattern to match against.
varName The name of a variable to store the result in.

Example
    type = "undefined";
    rc = Pat Match(
        "green apples",
        ("red" | "green") >> type + " pears"
    );
    Show( rc, type );
    rc = 0
    type = "green"
    Even though the match failed, the immediate assignment was made.

Pat Len(int)

Description
Constructs a quoted pattern that matches \( n \) characters.

Returns
A quoted pattern.

Argument
int An integer that specifies the number of characters.

Pat Look Ahead(pattern, Boolean)

Description
A zero-width pattern match after the current position.

Arguments
pattern The quoted pattern.
Boolean 0 (the default) indicates a match. 1 indicates a negative match or non-match.

Pat Look Behind(pattern, Boolean)

Description
A zero-width quoted pattern match before the current position.
Arguments

pattern  The quoted pattern.

Boolean  0 (the default) indicates a match. 1 indicates a negative match or non-match.

Pat Match(source text, pattern, <replacement string>, <"NULL">, <"ANCHOR">, <"MATCHCASE">, <"FULLSCAN">)

Description

Pat Match executes the quoted pattern against the source text. The pattern must be constructed first, either inline or by assigning it to a JSL variable elsewhere.

Returns

1 if the pattern is found, 0 otherwise.

Required Arguments

source text  A quoted string or quoted string variable that contains the text to be searched.

pattern  A quoted pattern or pattern variable that contains the text to be searched for.

Optional Arguments

replacement string  A quoted string that defines text to replace the pattern in the source text.

"NULL"  A placeholder for the third argument if ANCHOR, MATCHCASE, or FULLSCAN are necessary and there is no replacement text.

"ANCHOR"  Starts the pattern match at the beginning of the quoted string. The following match fails because the pattern, "cream", is not found at the beginning of the string:

Pat Match( "coffee with cream and sugar", "cream", NULL, ANCHOR );

"MATCHCASE"  Optional command to consider capitalization in the match. By default, Pat Match() is case insensitive.

"FULLSCAN"  Optional command to force Pat Match to try all alternatives, which uses more memory as the match expands. By default, Pat Match() does not use FULLSCAN, and makes some assumptions that allow the recursion to stop and the match to succeed.

Pat Not Any(string)

Description

Constructs a pattern that matches a single character that is not in the argument.

Returns

A quoted pattern.

Argument

string  A quoted string.
Pat Pos(int)

Description
Constructs patterns that match the quoted null string if the current position is \textit{int} from the left end of the string, and fail otherwise.

Returns
A quoted pattern.

Argument
\textit{int} An integer that specifies the position in a quoted string.

Pat R Pos(int)

Description
Constructs patterns that match the quoted null string if the current position is \textit{int} from the right end of the string, and fails otherwise.

Returns
A quoted pattern.

Argument
\textit{int} An integer that specifies the position in a quoted string.

Pat R Tab(int)

Description
Constructs a quoted pattern that matches up to position \textit{n} from the end of the quoted string. It can match 0 or more characters. It fails if it would have to move backwards or beyond the end of the string.

Returns
A quoted pattern.

Argument
\textit{int} An integer that specifies a position in a quoted string.

Pat Regex(string)

Description
Constructs a quoted pattern that matches the regular expression in the quoted \textit{string} argument.

Returns
A quoted pattern.

Argument
\textit{string} A quoted string.
Pat Rem()

Description
Constructs a quoted pattern that matches the remainder of the quoted string. It is equivalent to Pat R Tab(0).

Returns
A quoted pattern.

Argument
none

Pat Repeat(pattern, minimum, maximum, <"GREEDY" | "RELUCTANT">)

Description
Matches the quoted pattern between minimum and maximum times.

Returns
A quoted pattern.

Required Arguments
pattern A pattern to match against.
minimum An integer that must be smaller than maximum.
maximum An integer that must be greater than minimum.

Optional Argument
"GREEDY" | "RELUCTANT" If GREEDY is specified, it tries the maximum first and works back to the minimum. If RELUCTANT is specified, it tries the minimum first and works up to the maximum.

Notes
- Pat Arbno(p) is the same as Pat Repeat(p, 0, infinity, RELUCTANT)
- Pat Repeat(p) is the same as Pat Repeat(p, 1, infinity, GREEDY)
- Pat Repeat(p, n) is the same as Pat Repeat(p, n, infinity, GREEDY)
- Pat Repeat(p, n, m) is the same as Pat Repeat(p, n, m, GREEDY)

Pat Span(string)

Description
Constructs a pattern that matches one or more (not zero) occurrences of characters in its argument. It is greedy; it always matches the longest possible quoted string. It fails rather than matching zero characters.

Returns
A quoted pattern.
Argument

*string* A quoted string.

---

**Pat String**(*string*)

**Description**

Constructs a pattern that matches its quoted *string* argument.

**Returns**

A quoted pattern.

**Argument**

*string* A quoted string.

---

**Pat Succeed()**

**Description**

Constructs a pattern that always succeeds, even when the matcher backs into it. It matches the quoted null string.

**Returns**

1 when the match succeeds.

**Argument**

none

---

**Pat Tab**(*int*)

**Description**

Constructs a pattern that matches forward to position *int* in the quoted source string. It can match 0 or more characters. It fails if it would have to move backwards or beyond the end of the string.

**Returns**

A pattern.

**Argument**

*int* An integer that specifies a position in a quoted string.

---

**Pat Test**(*expr*)

**Description**

Constructs a pattern that succeeds and matches the quoted null string if *expr* is not zero and fails otherwise.

**Returns**

A quoted pattern.
Argument

`expr` An expression.

Notes

Usually the argument is wrapped with `expr()` because the test needs to be made on the current value of variables set by `Pat Immediate`, `Pat Conditional`, and `Pat At`. Without `expr`, the test is based on values that were known when the pattern was constructed, which means the test always succeeds or always fails at pattern execution time, which is probably not what you want.

Example

```julia
nCats = 0;
whichCat = 3;
string = "catch a catnapping cat in a catsup factory";
rc = Pat Match(
    string,
    "cat" + Pat Test(
        Expr(
            nCats = nCats + 1;
            nCats == whichCat;
        )
    ),
    "dog"
);
Show( rc, string, nCats );
rc = 1
string = "catch a catnapping dog in a catsup factory"
nCats = 3
```

### Regex Match(`source`, `pattern`, `<replacement string>`|`"MATCHCASE"`, `<NULL>`)

**Description**

Executes the pattern match in quoted `pattern` against the quoted `source` string.

**Returns**

A pattern.

**Required Arguments**

- `source` A quoted string.
- `pattern` A quoted pattern.

**Optional Arguments**

- `replacement string` The quoted string that specifies the text to replace the source with.
  - `"MATCHCASE"` The search is case insensitive unless you specify `MATCHCASE`.
  - `"NULL"` Indicates that the expression contains `MATCHCASE` but you don’t want to specify a replacement.
Examples

Regex Match(
  "person=Fred id=77 friend= favorite=tea", // source
  "(\w+)=(\S*) (\w+)=(\S*) (\w+)=(\S*) (\w+)=(\S*)" // pattern
);
  
  {"person=Fred id=77 friend= favorite=tea", "person", "Fred", "id", "77", "friend", "", "favorite", "tea"}

// case-insensitive, no replacement
Regex Match("beliEve", "([aeiou])(.*?)(\1)" );
  
  {"eliE", "e", "li", "E"}

// case-sensitive, no replacement
Regex Match("beliEve", "([aeiou])(.*?)(\1)", NULL, MATCHCASE );

  
  {"eliEve", "e", "liEv", "e"}

---

Comment Functions

// comment

Description

Comments to end of line.

Notes

Everything after the // is ignored when running the script.

/*. comment */

Description

A comment that can appear in the middle of a line of script.

Notes

Anything between the beginning tag /* and the end tag */ is ignored when running the script. This comment style can be used almost anywhere, even inside lists of arguments. If you place a comment inside a double-quoted string, the comment is treated merely as part of the string and not a comment. You cannot place comments in the middle of operators.

Examples

+/*comment*/=

://comment*/name

are invalid and produce errors. The first comment interrupts += and the second interrupts :name.

sums = {{a+b /*comment*/), /*comment*/ (c^2)}

is valid JSL; the comments are both ignored.
//!

**Description**

If placed on the first line of a script, this comment line causes the script to be run when opened in JMP without opening into the script editor window.

**Notes**

You can override this comment when opening the file. Select File > Open. Hold the Ctrl key while you select the JSL file and click Open. Or right-click the file in the Home Window Recent Files list and select Edit Script. The script opens into a script window instead of being executed.

/!*debug step*/
/!*debug run*/

**Description**

If placed on the first line of a script, the script is opened in the debugger when it is run.

**Notes**

All letters must be lowercase. There must be one space between debug and step or run, and there must be no other spaces present. Only one of these lines can be used, and it must be the first line of the script; a first line that is blank followed by this comment negates the debug command.

---

**Comparison Functions**

The comparison operators (\(<\), \(\leq\), \(>\), \(\geq\)) work for numbers, quoted strings, and matrices. For matrices, they produce a matrix of results. If you compare mixed arguments, such as strings with numbers or matrices, the result is a missing value. Comparisons involving lists are not allowed and also return missing values.

The equality operators (\(==\) and \(!=\)) work for numbers, quoted strings, matrices, and lists. For matrices, they produce a matrix of results; for lists, they produce a single result. If you test equality of mixed results (for example, strings with numbers or matrices) the result is 0 or unequal.

Range check operators let you check whether something falls between two specified values:

```julia
a = 1;
Show( 1 <= a < 3 );
b = 2;
Show( 2 < b <= 3 );
1 <= a < 3 = 1;
2 < b <= 3 = 0;
```
Expressions with comparison operators are evaluated all at once, not in sequence

All the comparison operators are eliding operators. That means JMP treats arguments joined by comparison operators as one big clause, as opposed to the way most expressions are evaluated one operator at a time. Evaluating as a single clause produces different results than the more usual method of evaluating in pieces. For example, the following two statements are different:

\[
12 < a < 13; \\
(12 < a) < 13;
\]

The first statement checks whether \(a\) is between 12 and 13, because all three arguments and both operators are read and evaluated together. The second statement uses parentheses to regroup the operations explicitly to evaluate from left to right, which would be the normal way to evaluate most expressions. Thus it first checks whether 12 is less than \(a\), returning 1 if true or 0 if false. Then it checks whether the result is less than 13, which is always true because 0 and 1 are both less than 13.

All the comparison operators are elided when they are used in matched pairs or in the unmatched pairs \(<...<= and <=...<. What this means is that if you want a comparison statement to be evaluated one comparison operator at a time, you should use parentheses ( ) to control the order of operations explicitly.

---

**Equal** \((a, b, \ldots)\)

\(a==b==\ldots\)

**Description**

Compares all the listed values and tests if they are all equal to each other.

**Returns**

1 (true) if all arguments evaluate to the same value.

0 (false) otherwise.

**Arguments**

Two or more variables, references, matrices, or numbers.

**Notes**

If more than two arguments are specified, a 1 is returned only if all arguments are exactly the same. This is typically used in conditional statements and to control loops.

The comparison is case-sensitive for quoted string comparisons.

---

**Greater** \((a, b, \ldots)\)

\(a>b>\ldots\)

**Description**

Compares all the list values and tests if, in each pair, the left value is greater than the right.
Returns
1 (true) if a evaluates strictly greater than b (and b evaluates strictly greater than c, and so on).
0 (false) otherwise.

Arguments
Two or more variables, references, matrices, or numbers.

Notes
If more than two arguments are specified, a 1 is returned only if each argument is greater than the one that follows it. This is typically used in conditional statements and to control loops.

Greater, Less, Greater Or Equal, and Less Or Equal can also be strung together (as in 0 < x <= 5). If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.
Less(a, b, ...)

a<b<...  

Description  
Compares all the list values and tests if, in each pair, the left value is less than the right.

Returns  
1 (true) if a evaluates strictly less than b (and b evaluates strictly less than c, and so on).
0 (false) otherwise.

Arguments  
Two or more variables, references, matrices, or numbers.

Notes  
If more than two arguments are specified, a 1 is returned only if each argument is less than
the one that follows it. This is typically used in conditional statements and to control
loops.

Greater, Less, Greater Or Equal, and Less Or Equal can also be strung together (as in
0 < x <= 5). If you do not group with parentheses, JMP evaluates each pair left to right.
You can also use parentheses to explicitly tell JMP how to evaluate the expression.

Less Less Equal(a, b, c, ...)

a<b<=c<=...  

Description  
Range check, exclusive below and inclusive above.

Returns  
1 (true) if b is greater than a and less than or equal to c.
0 (false) otherwise.

Arguments  
a, b, c  Variables, references, matrices, or numbers.

Notes  
Returns 1 when two conditions are met: the first argument is less than the second
argument, and each remaining argument is less than or equal to its argument on the right.
This is typically used in conditional statements and to control loops.

Less or Equal(a, b, ...)

a<=b<=...  

Description  
Compares all the list values and tests if, in each pair, the left value is less than or equal to
the right.
JSL Functions
Chapter 2
Comparison Functions

Returns
1 (true) if \( a \) evaluates strictly less than or equal to \( b \) (and \( b \) evaluates strictly less than or equal to \( c \), and so on).
0 (false) otherwise.

Arguments
Two or more variables, references, matrices, or numbers.

Notes
If more than two arguments are specified, a 1 is returned only if each argument is less than or equal to the one that follows it. This is typically used in conditional statements and to control loops.

Greater, Less, Greater Or Equal, and Less Or Equal can also be strung together (as in \( 0 < x <= 5 \)). If you do not group with parentheses, JMP evaluates each pair left to right. You can also use parentheses to explicitly tell JMP how to evaluate the expression.

Less Equal Less\((a, b, c, \ldots)\)
\( a<=b<c<\ldots \)

Description
A range check, inclusive below and exclusive above.

Returns
1 (true) if \( b \) is greater than or equal to \( a \) and less than \( c \).
0 (false) otherwise.

Arguments
\( a, b, c \) Variables, references, matrices, or numbers.

Notes
Returns 1 when two conditions are met: the first argument is less than or equal to the second argument, and each remaining argument is less than its argument on the right. This is typically used in conditional statements and to control loops.

Not Equal\((a, b)\)
\( a!=b \)

Description
Compares \( a \) and \( b \) and tests if they are equal.

Returns
0 (false) if \( a \) and \( b \) evaluate to the same value.
1 (true) otherwise.
Argument
   $a$, $b$ Any variable or number.

Notes
   Mostly used for conditional statements and loop control.

---

### Conditional and Logical Functions

**And**($a$, $b$)

$a$ & $b$

**Description**
   The logical And.

**Returns**
   1 (true) if both $a$ and $b$ are true.
   0 (false) if either $a$ or $b$ is false or if both $a$ and $b$ are false.
   Missing if either $a$ or $b$ is a missing value or if both $a$ and $b$ are missing values.

**Arguments**
   Two or more variables or expressions.

**Notes**
   More than two arguments can be strung together. $a$ & $b$ returns 1 (true) only if all arguments evaluate to true.

**AndMZ**($a$, $b$)

$a$ :& $b$

**Description**
   Returns the logical AND of all arguments. Missing values are treated as zeroes.

**Returns**
   1 (true) if both $a$ and $b$ are true.
   0 (false) if either $a$ or $b$ is false or if both $a$ and $b$ are false.
   0 (false) if either $a$ or $b$ is a missing value or if both $a$ and $b$ are missing values.

**Arguments**
   Two or more variables or expressions.

**Notes**
   More than two arguments can be strung together. $a$ :& $b$ returns 1 (true) only if all arguments evaluate to true.
Break()

**Description**
Stops execution of a loop completely and continues to the statement following the loop.

**Notes**
Break() works with For and While loops and also with For Each Row.

Choose(expr, r1, r2, r3, ..., resultElse)

**Description**
Evaluates expr. If the value of expr is 1, r1 is returned; if 2, the value of r2 is returned, and so on. If no matches are found, the last argument (resultElse) is returned.

**Returns**
The value whose index in the list of arguments matches expr, or the value of the last argument.

**Arguments**
- expr An expression or a value.
- r1, r2, r3, ... An expression or a value.
- resultElse The argument that is returned when no matches are found.

Continue()

**Description**
Ends the current iteration of a loop and begins the loop at the next iteration.

**Notes**
Continue() works with For and While loops, and also with For Each Row.

Filter Each(names, container, locals, body)

**Description**
Iterates over a container, which can be a list, an associative array, or a matrix, and returns a subset of the values in the container based on the evaluation of a Boolean expression at each iteration. The value, key, or element, as well as the index number, are all available at each iteration.

- For associative array containers, the key and value can be accessed using a two-item list.
- For matrix containers, a linear index is provided by default, but a two-item list can be used to access the row and column indices.
These symbols are provided within the body of the loop only. A list of local variables can also be provided. If local variables are defined, they are initialized after the first iteration symbols are set.

**Returns**

A subset from the original container. The return object has the same type as the original container.

**Arguments**

- **names** Specification of loop control variable names, specified as a list. The form of the list is determined by the type of container. All of the names are optional, so you need to specify them only if you need to refer to them in the `locals` or `body` arguments. If you do not specify any names, the first argument should be an empty list, which can be specified as `{}` or `List()`.

  - For a list container, the names list contains a name for each value in the list and a name for the index of each value in the list.
  - For an associative array container, the names list contains a two-item list of names and a name for the index of each item in the associative array.
  - For a matrix container, the names list contains a name for each element in the matrix and a second argument for the index of each element in the matrix. The second argument can be specified as a single name or as a two-item list of names that represent symbols for the row and column indices.

  - When specifying multiple containers using the `Across()` keyword, the names list contains a list of names that refer to values in each container. The number of names in the first item in the names list must match the number of containers specified in the `Across()` keyword.

- **container** A list, associative array, or a matrix. The container can be defined in the argument or it can be a reference to a previously defined object.

  - This argument can also use the `Across()` keyword, which enables you to use the function across multiple containers. The multiple containers can be specified as separate arguments or as items in a list. The `Across()` keyword has an optional `Count()` argument that enables you to specify how containers of different sizes are handled. The available `Count()` options are: "Shortest", "Longest", "Enforce Equal", and N, where N is a number. If you specify a number, the function iterates through all containers exactly N times; note that the function loops back to the start of containers that have fewer than N items.

- **locals** A list of variables that are local to the function. This is equivalent to other Local variable initializations in JSL. The initialization of the local variables occurs after the first loop control variables have been set, but the local variables do not get initialized again after that.

- **body** Any number of valid JSL expressions, glued together if there are more than one. The result of the JSL expressions should be a Boolean value. If the result of the expression is true, the container value at the current iteration is included in the result; otherwise, the
container value at the current iteration is not included in the result. You can use the Continue() function as an equivalent way to return false and skip to the next iteration. You can also use Break() function to stop iteration through the loop and proceed to the next expression that follows the loop. See Break and Continue.

Example
values = Filter Each( {x}, {10, 20, 30}, x > 15 );
Show( values );
values = {20, 30};

For(init, while, increment, body)

Description
Repeats the statement(s) in the body as long as the while condition is true. init and increment control iterations.

Returns
Null.

Arguments
init Initialization of loop control counter.
while Condition for loop to continue or end. As long as the conditional statement while is true, the loop is iterated one more time. As soon as while is false, the loop is exited.
increment Increments (or decrements) the loop counter after while is evaluated every time the loop is executed.
body Any number of valid JSL expressions, glued together if there are more than one.

Example
mysum = 0; myprod = 1;
For( i = 1, i <= 10, i++, mysum += i; myprod *= i; );
Show( mysum, myprod );
    mysum = 55;
    myprod = 3628800;

For Each(names, container, locals, body)

Description
Iterates over a container, which can be a list, an associative array, or a matrix, and provides the value, key, or element at each iteration. The index number is also available at each iteration. For associative array containers, the key and value can be accessed using a two-item list. For matrix containers, a linear index is provided by default, but a two-item list can be used to access the row and column indices. These symbols are provided within the body of the loop only. A list of local variables can also be provided. If local variables are defined, they are initialized after the first iteration symbols are set.
Arguments

names Specification of loop control variable names, specified as a list. The form of the list is determined by the type of container. All of the names are optional, so you need to specify them only if you need to refer to them in the locals or body arguments. If you do not specify any names, the first argument should be an empty list, which can be specified as {} or List().

For a list container, the names list contains a name for each value in the list and a name for the index of each value in the list.

For an associative array container, the names list contains a two-item list of names and a name for the index of each item in the associative array.

For a matrix container, the names list contains a name for each element in the matrix and a second argument for the index of each element in the matrix. The second argument can be specified as a single name or as a two-item list of names that represent symbols for the row and column indices.

When specifying multiple containers using the Across() keyword, the names list contains a list of names that refer to values in each container. The number of names in the first item in the names list must match the number of containers specified in the Across() keyword.

container A list, associative array, or a matrix. The container can be defined in the argument or it can be a reference to a previously defined object.

This argument can also use the Across() keyword, which enables you to use the function across multiple containers. The multiple containers can be specified as separate arguments or as items in a list. The Across() keyword has an optional Count() argument that enables you to specify how containers of different sizes are handled. The available Count() options are: "Shortest", "Longest", "Enforce Equal", and N, where N is a number. If you specify a number, the function iterates through all containers exactly N times; note that the function loops back to the start of containers that have fewer than N items.

locals A list of variables that are local to the function. This is equivalent to other Local variable initializations in JSL. The initialization of the local variables occurs after the first loop control variables have been set, but the local variables do not get initialized again after that.

body Any number of valid JSL expressions, glued together if there are more than one. You can use the Continue() function to skip to the next iteration. You can also use Break() function to stop iteration through the loop and proceed to the next expression that follows the loop. See Break and Continue.

Example

For Each( {value, index}, {10, 20, 30}, Show( value, index ) );
value = 10;
index = 1;
value = 20;
index = 2;
value = 30;
index = 3;

For Each Row(<dt>, script)

Description
Repeats the script on each row of the data table.

Returns
Null.

Required Argument
script  Any valid JSL expressions.

Optional Argument
dt  Positional argument that is a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.

Example
The following example creates data table references and then iterates over each row in Big Class.jmp. If the value of age in a row is greater than 15, the age is printed to the log.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
For Each Row( dt, If( :age > 15, Show( :age ) ) );

If(condition1, result1, <condition2, result2>, ..., <elseResult>)

Description
Evaluates the first of each pair of arguments and returns the evaluation of the result expression associated with the first condition argument that evaluates to a nonzero result. The condition arguments are evaluated in order. If all of the condition arguments evaluate to zero, the optional elseResult is evaluated and the result is returned. If no elseResult is specified, and none of the conditions are true, a missing value is returned. If all of the condition arguments evaluate to missing, a missing value is returned.

IfMax(expr1, result1, expr2, result2, ... <all missing results>)

Description
Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the maximum of the expressions. If more than one expression is the maximum, the first maximum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.

Returns
The result expression associated with the maximum of the expressions
**IfMin(\text{expr1}, \text{result1}, \text{expr2}, \text{result2}, \ldots <\text{all missing results}>)**

**Description**
Evaluates the first of each pair of arguments and returns the evaluation of the result expression (the second of each pair) associated with the minimum of the expressions. If more than one expression is the minimum, the first minimum is returned. If all expressions are missing and a final result is not specified, missing is returned. If all expressions are missing and a final result is specified, that final result is returned. The test expressions must evaluate to numeric values, but the result expressions can be anything.

**Returns**
The result expression associated with the minimum of the expressions

**IfMZ(\text{condition1}, \text{result1}, <\text{condition2}, \text{result2}>, \ldots, <\text{elseResult}>)**

**Description**
Evaluates the first of each pair of arguments and returns the evaluation of the result expression associated with the \text{condition1} argument that evaluates to a nonzero result. The \text{condition} arguments are evaluated in order. If all of the \text{condition} arguments evaluate to zero or missing, the optional \text{elseResult} is evaluated and the result is returned. If no \text{elseResult} is specified, and none of the conditions are true, a missing value is returned.

**Notes**
The test arguments are evaluated in order until the first nonzero result. If all test results return zero or missing, the \text{elseExpr} argument is evaluated.

IfMZ() is equivalent to If() where missing values for evaluated \text{condition} arguments are treated as zero.

**Interpolate(\text{x|xmatrix|xlist, } \text{x1, y1, x2, y2, ...})**

**Interpolate(\text{x|xmatrix|xlist, xmatrix, ymatrix})**

**Interpolate({\text{x, y}}, \text{xvector, yvector, zmatrix})**

**Description**
Performs linear interpolation for continuous data. There are many ways to specify the function.

In the simplest cases where the first argument is a single numeric value, the \text{y} value corresponding to a given \text{x} value between two sets of points or by matrices \text{xmatrix} and \text{ymatrix}. The \text{x} values, (\text{x1, x2, ...}) or \text{xmatrix}, must be in ascending order.

If the first argument is a matrix or list of numeric values, the resulting matrix or list is a set of interpolated values.
You can perform *bilinear interpolation* using the four-argument case. Here, the first argument is a list of two points, the second and third arguments are vectors that define the grid of x and y values, and the fourth argument is a matrix of data points. The function then finds the interpolated \( z \) value within the appropriate quadrant of the \( z \text{matrix} \).

**Returns**

The interpolated value or values. In the three-argument cases, the return object type matches the type of the first argument. In the four-argument case, the return object is a number.

---

**Is Associative Array** *(name)*

**Description**

Returns 1 if the evaluated argument is an associative array, or 0 otherwise.

---

**Is Empty** *(global)*

**Is Empty** *(dt)*

**Is Empty** *(col)*

**Description**

Returns 1 if the \( global \) variable, data table, or data column is undefined or holds the \( \text{Empty}() \) value, or 0 otherwise.

---

**Is Expr**(x)

**Description**

Returns 1 if the evaluated argument is an expression, or 0 otherwise.

---

**Is List**

See “Is List(x)” on page 170.

---

**Is Name**(x)

**Description**

Returns 1 if the evaluated argument is a name, or 0 otherwise.

---

**Is Namespace**(namespace)

**Description**

Returns 1 if the namespace argument is a namespace; returns 0 otherwise.
Is Number(x)

**Description**

Returns 1 if the evaluated argument is a number or missing numeric value, or 0 otherwise.

---

Is Scriptable(x)

**Description**

Returns 1 if the evaluated argument is a scriptable object, or 0 otherwise.

---

Is String(x)

**Description**

Returns 1 if the evaluated argument is a quoted string, or 0 otherwise.

---

Match(x, value1, result1, value2, result2, ..., resultElse)

**Description**

If a is equal to value1, then result1 is returned. If a is equal to value2, result2 is returned, and so on.

**Notes**

The Match() function explicitly checks to see if the compare expression x is missing and if the value of value1 is missing, then it returns the value of result1; otherwise it continues to compare the expression x to each valueN value in each valueN/resultN pair, ignoring any missing values. If the expression x is equal to any of the valueN value, then the corresponding resultN value is returned. If no matching valueN value is found, then the resultElse value is returned.

---

MatchMZ(x, value1, expr1, value2, expr2, ..., exprElse)

**Description**

Evaluates and returns the exprN argument that equals x or evaluates and returns the exprElse argument if no value equals x.

**Notes**

The MatchMZ() function works the same as the Match() function except that missing values are treated as 0.

---

Not(a)

!a

**Description**

The logical Not.
Returns
0 (false) if $a > 0$.
1 (true) if $a \leq 0$.
Missing value if $a$ is missing.

Argument
$\ a $ Any variable or number. The variable must have a numeric or matrix value.

Notes
Mostly used for conditional statements and loop control.

Description
The logical Or.

Returns
1 (true) if either of or both $a$ and $b$ are true.
0 (false) otherwise.
Missing if either are missing.

Arguments
$a, b$ Any variable or number.

Notes
Mostly used for conditional statements and loop control.

Description
Returns the logical OR of all arguments with missing values treated as zeroes: 1 if any arguments are nonzero and 0 otherwise.

Returns
1 (true) if either of or both $a$ and $b$ are true.
0 (false) otherwise.

Arguments
$a, b$ Any variable or number.

Notes
- Mostly used for conditional statements and loop control.
– `Or()` returns missing if any evaluated argument is missing. `OrMz()` returns 0 if any evaluated argument is missing.

**Return(<expr1>, <expr2>, ..., <exprN>)**

**Description**

Returns an expression value from a user-defined function.

**Example**

This example returns the evaluation of both expressions in the `Return()` function as a list. The `Return()` function can have more than one argument. If only one is present, then the value of the expression is returned. If more than one is present, then the values of all the expressions is returned in a list.

```javascript
f = Function( {a, b},
    Return( a - b, a + b )
);
{lo, hi} = f( 10, 1 );
Show( lo, hi );
Show( f( 7, 15 ) );
lo = 9;
hi = 11;
f(7, 15) = {-8, 22};
```

**Notes**

`Return()` not enclosed by a function, method, or recursive function call causes an error.

**Step(x0, x1, y1, x2, y2, ...)**

**Step(x0, [x1, x2, ...], [y1, y2, ...])**

**Description**

Returns the `y` argument corresponding to the largest `x` argument that is less than or equal to `x0`. The `x` points must be specified in ascending order.

**Stop()**

**Description**

Immediately stops a script that is running.

**Transform Each(names, container, <Output(type)>, <locals>, body)**

**Description**

Iterates over a container, which can be a list, an associative array, or a matrix, and updates each of the values in the container based on the evaluation of a JSL expression at each iteration. The value, key, or element, as well as the index number, are all available at each iteration. For associative array containers, the key and value can be accessed using a
two-item list. For matrix containers, a linear index is provided by default, but a two-item list can be used to access the row and column indices. These symbols are provided within the body of the loop only. A list of local variables can also be provided. If local variables are defined, they are initialized after the first iteration symbols are set.

Returns
An updated version of the original container. The return object has the same type as the original container, unless the `Output()` keyword is used to designate a different type for the returned container.

Arguments

`names` Specification of loop control variable names, specified as a list. The form of the list is determined by the type of container. All of the names are optional, so you need to specify them only if you need to refer to them in the `locals` or `body` arguments. If you do not specify any names, the first argument should be an empty list, which can be specified as `{}` or `List()`.

For a `list` container, the names list contains a name for each value in the list and a name for the index of each value in the list.

For an `associative array` container, the names list contains a two-item list of names and a name for the index of each item in the associative array.

For a `matrix` container, the names list contains a name for each element in the matrix and a second argument for the index of each element in the matrix. The second argument can be specified as a single name or as a two-item list of names that represent symbols for the row and column indices.

When specifying multiple containers using the `Across()` keyword, the names list contains a list of names that refer to values in each container. The number of names in the first item in the names list must match the number of containers specified in the `Across()` keyword.

`container` A list, associative array, or a matrix. The container can be defined in the argument or it can be a reference to a previously defined object.

This argument can also use the `Across()` keyword, which enables you to use the function across multiple containers. The multiple containers can be specified as separate arguments or as items in a list. The `Across()` keyword has an optional `Count()` argument that enables you to specify how containers of different sizes are handled. The available `Count()` options are: "Shortest", "Longest", "Enforce Equal", and N, where N is a number. If you specify a number, the function iterates through all containers exactly N times; note that the function loops back to the start of containers that have fewer than N items.

`Output(type)` Specifies a type for the output. This can be "List", "Matrix", or "Associative Array". By default, the output type matches the type of the input container.

`locals` A list of variables that are local to the function. This is equivalent to other Local variable initializations in JSL. The initialization of the local variables occurs after the
first loop control variables have been set, but the local variables do not get initialized again after that.

**body** Any number of valid JSL expressions, glued together if there are more than one. The result of the JSL expressions at each iteration is used in the output container. You can use the `Continue()` function to return no value for an iteration and skip to the next iteration. You can also use `Break()` function to stop iteration through the loop and proceed to the next expression that follows the loop. See [Break and Continue](#).

**Example**

```javascript
values = Transform Each( {x}, {10, 20}, x + 10 );
Show( values );
values = {20, 30};
```

---

**While**

- **Description**
  Repeatedly tests the `expr` condition and executes the `body` until the `expr` condition is no longer true.

---

**Zero Or Missing**

- **Description**
  Returns 1 if `expr` yields a missing value or zero, 0 otherwise.

---

### Constant Functions

JMP provides functions for two useful constant functions.

**Note:** These functions do not take an argument, but the parentheses are required.

---

**e()**

- **Description**
  Returns the constant \( e \), which is 2.7182818284590451...

---

**Pi()**

- **Description**
  Returns the constant \( \pi \), which is 3.1415926535897931...
Date and Time Functions

Datet ime values are handled internally as numbers of seconds since midnight, January 1, 1904.

The expression \( x = 01 \text{Jan} 1904 \) sets \( x \) to zero, since the indicated date is the base date or “zero date” in JMP. If you examine the values of dates, they should be appropriately large numbers (for example, 5\text{oct}1998 is 2990390400).

---

**Abbrev Date**(*date*)

**Description**
Converts the provided *date* to a quoted string.

**Returns**
A quoted string representation of the date.

**Argument**
*date* Can be the number of seconds since the base date (midnight, January 1, 1904), or any date-time operator.

**Example**
Abbrev Date( 29\text{Feb}2004 );
02/29/2004

---

**As Date**(*x*)

**Description**
Formats the number or expression *x* so that it shows as a date or duration when displayed in a text window. Values that represent one year or more are returned as dates. Values that represent less than a year are returned as durations.

**Returns**
A date that is calculated from the number or expression provided.

**Argument**
*x* Number or expression.

---

**Date Difference**(*datetime1, datetime2, interval name, <alignment>*)

**Description**
Returns the difference in intervals of two date-time values.

**Returns**
A number.

**Required Arguments**
datetime1, datetime2 Datetime values.
interval name A quoted string that contains a date-time interval, such as "month", "day", or "hour".

Optional Arguments
alignment A quoted string:
– "Start" includes full or partial intervals.
– "Actual" counts only whole intervals.
– "Fractional" returns fractional differences using averages for "year", "quarter", and "month" intervals.

Date DMY(day, month, year)

Description
Constructs a date value from the arguments.

Returns
The specified date, expressed as the number of seconds since midnight, 1 January 1904.

Arguments
day The numeric day of month, 1-31. Note that there is no error-checking, so you can enter February 31.
month The numeric month, 1-12.
year The year.

Date Increment.datetime, interval name, <increment>, <alignment>)

Description
Adds 1 or more intervals to a starting datetime value.

Returns
Returns the new datetime value.

Required Arguments
datetime The starting datetime value.
interval name A quoted string that contains the name of a datetime interval. "year", "quarter", "month", "week", "day", "hour", "minute", and "second" are supported.

Optional Arguments
increment A number that specifies the number of intervals. The default value is 1.
alignment A quoted string that contains a keyword:
– "Start" truncates the date to the nearest interval prior to adding the increment. For example, it removes the time and outputs the date. "start" is the default value.
– "Actual" retains the full input datetime value.
"Fractional" allows fractional incremental values using averages for the duration of "Year", "Quarter", and "Month" intervals.

**Date MDY(month, day, year)**

**Description**

Constructs a date value from the arguments.

**Returns**

The specified date, expressed as the number of seconds since midnight, 1 January 1904.

**Arguments**

- **month** The numeric month, 1-12.
- **day** The numeric day of month, 1-31. Note that there is no error-checking, so you can enter February 31.
- **year** The year.

**Day(datetime)**

**Description**

Determines the day of the month supplied by the datetime argument.

**Returns**

Returns an integer representation for the day of the month of the date supplied.

**Arguments**

- **datetime** The number of seconds since midnight, 1 January 1904. This can also be an expression.

**Example**

```
d1 = Date DMY( 12, 2, 2003 );
3127852800

Day( 3127852800 );
12
Day( d1 );
12
```

**Day Of Week(datetime)**

**Description**

Determines the day of the week supplied by the datetime argument.

**Returns**

Returns an integer representation for the day of the week of the date supplied. Weeks are Sunday–Saturday.
Arguments
datetime  The number of seconds since midnight, 1 January 1904. This can also be an expression.

Day Of Year(datetime)

Description
Determines the day of the year supplied by the datetime argument.

Returns
Returns an integer representation for the day of the year of the date supplied.

Arguments
datetime  The number of seconds since midnight, 1 January 1904. This can also be an expression.

Format(x, formatString, width|<width, decimal places>, <"Use Thousands Separator">)
Format(x, "Best", <width>, <"Use Thousands Separator">)
Format(x, ("Fixed Dec"|"Percent"), width|<width, decimal places>, <"Use Thousands Separator">)
Format(x, "Pvalue", <width>)
Format(x, ("Scientific"|"Engineering"|"Engineering SI"), <width>|<width, decimal places>)
Format(x,"Precision", width|<width, decimal places>, <"Use Thousands Separator">, <"Keep Trailing Zeroes">, <"Keep All Whole Digits">)
Format(x, "Currency", <currency code>, <width>|<width, decimal places>, <"Use Thousands Separator">, < <<Use Locale(Boolean) >)
Format(x, datetime, <width>)
Format(x, ("Latitude DDD"|"Latitude DDM"|"Latitude DMS"|"Longitude DDD"|"Longitude DDM"|"Longitude DDM"), width|<width, decimal places>, ("PUN"|"DIR"|"PUNDIR")
Format(x, "Custom", Formula(), <width>)

Description
Converts the value x into the quoted format that you specify in the subsequent arguments.

Returns
Returns the text that corresponds to the number in the specified format.
Arguments
See Using JMP for more information about the arguments. The arguments are also shown in a data table column’s Column Info window.

Examples
Format( x, "Fixed Dec", 10, 2, "Use Thousands Separator");
Format( x, "Currency", "EUR", 20, <<Use Locale(0)); // ignores computer locale
Format( x, "m/d/y", 10 );
Format( x, "Precision", 10, 2, "Keep trailing zeroes", "Keep All Whole Digits" );
Format( x, "Latitude DDD", "PUNDIR"); // "PUN" for punctuation, "DIR" for direction, PUNDIR for both
Format( x, "Custom", Formula( Abs( value ) ), 15 );

Notes
- You must always precede the number of decimal places with the width.
- If the date format is unknown, an error is written to the log.

Format Date(x, datatime, <width>)

Description
Converts the value of x into the quoted datatime that you specify in the second argument. Format choices are those shown in the data table Column Info window.

Returns
Returns the number in the specified format.

Arguments
See Using JMP for more information about the arguments.

Example
Format Date( Today(), "yyyQq" );
"04/03/2020"

Hour(datatime, <"12"|"24">

Description
Determines the hour supplied by the datatime argument.

Returns
Returns an integer representation for the hour part of the date-time value supplied.

Arguments
datatime The number of seconds since midnight, 1 January 1904. This can also be an expression.
"12"|"24" Changes the mode to 12 hours (with am and pm). The default is 24-hour mode.
HP Time()

**Description**
Returns a high precision time value (in microseconds). This function is only useful relative to another HP Time() value. The time value represents the number of microseconds since the start of the JMP session.

**Notes**
For less precise time values use Tick Seconds().

In Days(n)

**Description**
Returns the number of seconds per n days. Divide by this function to express seconds as days.

Informat(string, format)

Parse Date(string, format)

**Description**
Parses a quoted string of a given quoted format and returns a date/time value. The value is expressed as if surrounded by the As Date() function, returning the date in "ddMon yyyy" format.

**Example**
Informat( "07152000", "MMDDYYYY" );
15Jul2000

**Notes**
- To see the format options, open the Column Info window on a data table column, select a date/time value for the format, and view the Input Format list.
- If the date format is unknown, an error is written to the log.

**See Also**
"As Date(x)" on page 72

In Hours(n)

**Description**
Returns the number of seconds per n hours. Divide by this function to express seconds as hours.
In Minutes(n)

Description
Returns the number of seconds per \( n \) minutes. Divide by this function to express seconds as minutes.

In Weeks(n)

Description
Returns the number of seconds per \( n \) weeks. Divide by this function to express seconds as weeks.

In Years(n)

Description
Returns the number of seconds per \( n \) years. Divide by this function to express seconds as years.

ISO Year(datetime)

Description
Returns the ISO year of the \( \text{datetime} \) supplied. ISO years correspond to ISO weeks; they begin on the Monday of the first week that contains at least four days.

Long Date(date)

Description
Returns a locale-specific quoted string representation for the \( \text{date} \) supplied, formatted like "Sunday, February 29, 2004" or "Wednesday, November 9, 2011".

MDYHMS(date)

Description
Returns a quoted string representation for the \( \text{date} \) supplied, formatted like "2/29/04 00:02:20".

Minute(datetime)

Description
Determines the minute supplied by the \( \text{datetime} \) argument, 0-59.

Returns
Returns an integer representation for the minute part of the date-time value supplied.
Month\( (date) \)

**Description**

Returns an integer representation for the month of the \( date \) that is supplied.

Nth Day of Week in the Month\( (datetime) \)

**Description**

Determines the day of the week of the \( datetime \) argument and how many instances of that day of the week have occurred in the month of the \( datetime \) argument.

**Returns**

Returns an integer that represents the number of instances of the day of the week of the \( datetime \) argument that have occurred in the month.

Parse Date()

See “Informat\( (string, format) \)” on page 77.

Quarter\( (datetime) \)

**Description**

Returns the annual quarter of a \( datetime \) value as an integer 1-4.

Second\( (datetime) \)

**Description**

Determines the second supplied by the \( datetime \) argument.

**Returns**

Returns an integer representation for the second part of the date-time value supplied.

**Argument**

\( datetime \) Number of seconds since midnight, 1 January 1904. This can also be an expression.

Short Date\( (date) \)

**Description**

Returns a quoted string representation for the \( date \) supplied in the format MM/DD/YYYY.

Tick Seconds()

**Description**

Measures the time taken for a script to run, measured down to the 60th of a second.
Notes
For higher time value resolution (for example, microseconds) use the HP Time() function.

---

**Time Of Day**

**Description**
Returns an integer representation for the time of day of the *datetime* supplied.

---

**Today()**

**Description**
Returns the current date and time expressed as the number of seconds since midnight, 1 January 1904. No arguments are available, but the parentheses are still necessary.

---

**Week Of Year**

**Description**
Returns the week of the year that contains a date-time value. Three rules determine when the first week of the year begins.

- With rule 1 (the default), weeks start on Sunday, with the first Sunday of the year being week 2. Week 1 is a partial week or empty.
- With rule 2, the first Sunday begins with week 1, with previous days being week 0.
- With rule 3, the ISO-8601 week number is returned. Weeks start on Monday. Week 1 is the first week of the year with four days in that year. It is possible for the first or last three days of the year to belong to the neighboring year’s week number.

---

**Year**

**Description**
Returns an integer representation for the year of *date*.

---

**Discrete Probability Functions**

**Beta Binomial Distribution**

**Description**
Returns the cumulative distribution function (cdf) of the beta binomial distribution. This is the probability that a beta binomially distributed random variable is less than or equal to *k*. The cdf is calculated as the summation of the beta binomial pmf for values of X from 0 to *k*. 
Arguments

- **k** The count of interest. *k* must be an integer.
- **p** The probability of success for each trial, which must be between 0 and 1.
- **n** The number of trials, which must be greater than 1.
- **delta** The overdispersion parameter, which must be between Maximum\[-p/(n-p-1), -(1-p)/(n+2+p)\] and 1. When the overdispersion parameter is zero, the distribution reduces to Binomial\((n, p)\).

**Beta Binomial Probability\((k, p, n, delta)\)**

**Description**

Returns the probability mass function (pmf) of the beta binomial distribution. This is the probability that a beta binomially distributed random variable is equal to *k*. The pmf is parameterized as follows:

\[
P(X = k; p, n, \delta) = \binom{n}{k} \frac{\Gamma\left(\frac{1}{\delta} - 1\right) \Gamma\left[k + p\left(\frac{1}{\delta} - 1\right)\right] \Gamma\left[n - k + (1 - p)\left(\frac{1}{\delta} - 1\right)\right]}{\Gamma[p\left(\frac{1}{\delta} - 1\right)] \Gamma[(1 - p)\left(\frac{1}{\delta} - 1\right)] \Gamma(n + \frac{1}{\delta} - 1)}
\]

Arguments

- **k** The count of interest. *k* must be an integer.
- **p** The probability of success for each trial, which must be between 0 and 1.
- **n** The number of trials, which must be greater than 1.
- **delta** The overdispersion parameter \(\delta\), which must be between Maximum\[-p/(n-p-1), -(1-p)/(n+2+p)\] and 1. When the overdispersion parameter is zero, the distribution reduces to Binomial\((n, p)\).

Notes

The beta binomial distribution results from assuming that \(X|\pi\) follows a Binomial\((n, \pi)\) distribution and \(\pi\) follows a Beta\((p(1-\delta)/\delta, (1-p)(1-\delta)/\delta)\) distribution. It is useful when the data are a combination of several Binomial distributions that each have different probabilities of success.

**Beta Binomial Quantile\((p, n, delta, cumprob)\)**

**Description**

Returns the smallest integer quantile for which the cumulative probability of the Beta Binomial\((p, n, delta)\) distribution is larger than or equal to `cumprob`.

Arguments

- **p** The probability of success for each trial. *p* must be between 0 and 1.
- **n** The number of trials, which must be greater than 1.
delta  The overdispersion parameter \( \delta \), which must be between \( \text{Maximum}[-p/(n-p-1), -(1-p)/(n-2+p)] \) and 1. When the overdispersion parameter is zero, the distribution reduces to Binomial\((n, p)\).

cumprob  The cumulative probability of the quantile desired. \( \text{cumprob} \) must be between 0 and 1.

---

**Binomial Distribution\((p, n, k)\)**

**Description**

Returns the cumulative distribution function (cdf) of the binomial distribution. This is the probability that a binomially distributed random variable is less than or equal to \( k \). The cdf is calculated as the summation of the binomial pmf for values of \( X \) from 0 to \( k \).

**Arguments**

- \( p \)  The probability of success for each trial. \( p \) must be between 0 and 1.
- \( n \)  The number of trials.
- \( k \)  The number of successes, which must be less than or equal to \( n \).

**Binomial Probability\((p, n, k)\)**

**Description**

Returns the probability mass function (pmf) of the binomial distribution. This is the probability that a binomially distributed variable is equal to \( k \). The pmf is parameterized as follows:

\[
P(X = k; p, n) = \binom{n}{k} p^k (1 - p)^{n-k}
\]

**Arguments**

- \( p \)  The probability of success for each trial. \( p \) must be between 0 and 1.
- \( n \)  The number of trials.
- \( k \)  The number of successes, which must be less than or equal to \( n \).

**Binomial Quantile\((p, n, \text{cumprob})\)**

**Description**

Returns the smallest integer quantile for which the cumulative probability of the Binomial\((p, n)\) distribution is larger than or equal to \( \text{cumprob} \).

**Arguments**

- \( p \)  The probability of success for each trial. \( p \) must be between 0 and 1.
- \( n \)  The number of trials.
- \( \text{cumprob} \)  The cumulative probability of the quantile desired. \( \text{cumprob} \) must be between 0 and 1.
Gamma Poisson Distribution\((k, \lambda, \sigma)\)

**Description**

Returns the cumulative distribution function (cdf) of the gamma-Poisson distribution. This is the probability that a gamma-Poisson distributed random variable is less than or equal to \(k\). The cdf is calculated as the summation of the gamma-Poisson pmf for values of \(X\) from 0 to \(k\).

**Arguments**

- \(k\) The count of interest. \(k\) must be an integer.
- \(\lambda\) The shape parameter \(\lambda\), which must be greater than 0. This is the mean of the distribution.
- \(\sigma\) The overdispersion parameter \(\sigma\), which must be greater than or equal to 1. When the overdispersion parameter is 1, the distribution reduces to a Poisson(\(\lambda\)) distribution.

**Gamma Poisson Probability\((k, \lambda, \sigma)\)**

**Description**

Returns the probability mass function (pmf) of the gamma-Poisson distribution. This is the probability that a gamma-Poisson distributed random variable is equal to \(k\). The pmf is parameterized as follows:

\[
P(X = k; \lambda, \sigma) = \frac{\Gamma\left(k + \frac{\lambda}{\sigma - 1}\right)}{\Gamma(k + 1) \Gamma\left(\frac{\lambda}{\sigma - 1}\right)} \left(\frac{\lambda}{\sigma - 1}\right)^k \left(\frac{1}{\sigma}\right)\]

where \(\Gamma(\cdot)\) is the Gamma function.

**Arguments**

- \(k\) The count of interest. \(k\) must be an integer.
- \(\lambda\) The shape parameter \(\lambda\), which must be greater than 0. This is the mean of the distribution.
- \(\sigma\) The overdispersion parameter \(\sigma\), which must be greater than or equal to 1. When the overdispersion parameter is 1, the distribution reduces to a Poisson(\(\lambda\)) distribution.

**Notes**

The gamma Poisson distribution results from assuming that \(X|\mu\) follows a Poisson(\(\mu\)) distribution and \(\mu\) follows a Gamma\((\lambda/(\sigma-1),\sigma-1)\) distribution. It is useful when the data are a combination of several Poisson(\(\mu\)) distributions that each have different values of \(\mu\).
Gamma Poisson Quantile($\lambda$, $\sigma$, $c$)

Description
Returns the smallest integer quantile for which the cumulative probability of the Gamma
Poisson($\lambda$, $\sigma$) distribution is larger than or equal to $c$.

Arguments
$\lambda$ The shape parameter $\lambda$, which must be greater than 0. This is the mean of the
distribution.
$\sigma$ The overdispersion parameter $\sigma$, which must be greater than or equal to 1. When
the overdispersion parameter is 1, the distribution reduces to a Poisson($\lambda$) distribution.
c The cumulative probability of the quantile desired. $c$ must be between 0
and 1.

Hypergeometric Distribution($N$, $K$, $n$, $x$, $r$)

Description
Returns the cumulative distribution function (cdf) of the hypergeometric distribution.
This is the probability that a hypergeometrically distributed random variable is less than
or equal to $x$. The cdf is calculated as the summation of the hypergeometric pmf for values
of $X$ from 0 to $x$.

Required Arguments
$N$ The population size.
$K$ The number of items in the category of interest.
$n$ The sample size.
x The count of interest, which must be less than or equal to $n$ and $K$.

Optional Argument
$r$ The odds ratio.

Hypergeometric Probability($N$, $k$, $n$, $x$, $r$)

Description
Returns the probability mass function (pmf) of the hypergeometric distribution. This is the
probability that a hypergeometrically distributed random variable is equal to $x$. The pmf is
parameterized as follows:

$$P(X = x; N, n, k) = \frac{{k \choose x} \frac{N - k}{n - x}}{N \choose n}, n - x \leq N - k$$

Required Arguments
$N$ The population size.
$k$ The number of items in the category of interest.
Chapter 2
JSL Functions

JSL Syntax Reference

Discrete Probability Functions

n The sample size.
x The count of interest, which must be less than or equal to n and k.

Optional Argument
r The odds ratio.

Neg Binomial Distribution(p, n, k)

Description
Returns the cumulative distribution function (cdf) of the negative binomial distribution. This is the probability that a negative binomially distributed random variable is less than or equal to k. The cdf is calculated as the summation of the negative binomial pmf for values of X from 0 to k.

Arguments
p The probability of success for each trial. p must be between 0 and 1.
n The number of successes.
k The number of failures before the n\textsuperscript{th} success.

Neg Binomial Probability(p, n, k)

Description
Returns the probability mass function (pmf) of the negative binomial distribution. This is the probability that a negative binomially distributed random variable is equal to k. The pmf is parameterized as follows:

\[ P(X = k; p, n) = \binom{n + k - 1}{k} p^n (1 - p)^k \]

Arguments
p The probability of success for each trial. p must be between 0 and 1.
n The number of successes.
k The number of failures before the n\textsuperscript{th} success.

Notes
The return value of the pmf is the probability of observing the n\textsuperscript{th} success after k failures have occurred.

Poisson Distribution(lambda, k)

Description
Returns the cumulative distribution function (cdf) of the Poisson distribution. This is the probability that a Poisson distributed random variable with mean lambda is less than or equal to k. The cdf is calculated as the summation of the Poisson pmf for values of X from 0 to k.
Arguments

- \( k \) The number of events in a given time interval. \( k \) must be an integer.
- \( \lambda \) The shape parameter \( \lambda \), which must be greater than 0. This is the mean of the distribution.

Poisson Probability\( (\lambda, k) \)

Description

Returns the probability mass function (pmf) of the Poisson distribution. This is the probability that a Poisson distributed random variable with mean \( \lambda \) is equal to \( k \).

The pmf is parameterized as follows:

\[
P(X = k; \lambda) = \frac{e^{-\lambda} \lambda^k}{k!}
\]

Arguments

- \( k \) The number of events in a given time interval. \( k \) must be an integer.
- \( \lambda \) The shape parameter \( \lambda \), which must be greater than 0. This is the mean of the distribution.

Poisson Quantile\( (\lambda, \text{cumprob}) \)

Description

Returns the smallest integer quantile for which the cumulative probability of the Poisson\( (\lambda) \) distribution is larger than or equal to \( \text{cumprob} \).

Arguments

- \( \lambda \) The shape parameter \( \lambda \), which must be greater than 0. This is the mean of the distribution.
- \( \text{cumprob} \) The cumulative probability of the quantile desired. \( \text{cumprob} \) must be between 0 and 1.

Display Functions

Alpha Shape\( (\text{Triangulation}()) \)

Description

Returns the alpha shape for the given triangulation.
Border Box(<Left(pix)>, <Right(pix)>, <Top(pix)>, <Bottom(pix)>, <Sides(Boolean)>, db)

Description
Constructs a bordered display box that contains another display box. Optional arguments (Left, Right, Top, Bottom) add space between the border box and what it contains. The other optional argument (Sides) draws borders around the border box on any single side or combination of sides; draws the border in black or the highlight color; makes the background transparent or white or erases the background of a display box that contains it.

Returns
The display box.

Required Argument
<db> A display box object (for example, a text box or another border box).

Optional Arguments
Left(pix) An integer that measures pixels.
Right(pix) An integer that measures pixels.
Top(pix) An integer that measures pixels.
Bottom(pix) An integer that measures pixels.
Sides(pix) An integer that maps to settings for the display box.

Notes
The formula for deriving the integer for Sides is: 1*top + 2*left + 4*bottom + 8*right + 16*highlightcolor + 32*whitebackground + 64*erase. Thus, if you want to just draw a black border on the top and bottom, 1+4 = 5. If you want that same box with a white background, 5+32 = 37.

Box Plot Seg(<data>, <frequency>, <weight>, <Vertical(Boolean)>)

Description
Returns a display seg that represents a box plot based on the passed x and y values.

Returns
The display box (a box plot).

Optional Arguments
<data> The data values within the box plot.
<frequency> The frequency values within the box plot.
<weight> The weights for observations on continuous Ys.
<Vertical(Boolean)> A vertical (1) or horizontal (0) box plot.

Example
win = New Window( "Box Plot Seg Example",
Graph Box(
Frame Size( 40, 180 ),
Y Scale( 0, 100 ),
Box Plot Seg(
    [20, 30, 40], // data
    [1, 1, 3], // frequencies
    [1, 1, 1], // weights
    1 // vertical
)
);

Busy Light(< <<Automatic(Boolean)>, <Size(x, y)>, < <<Disable>)

**Description**

Creates a rotating image to indicate a busy process.

**Returns**

A rotating image.

**Optional Argument and Messages**

<<Automatic(Boolean) Rotates the image.
Size(x, y) Specifies the size of the image in pixels.
<<Disable Hides the image.

**Example**

```javascript
win = New Window( "Example",
    blb = Busy Light( <<Automatic( 1 ), Size( 50, 50 ) ) );
```

Button Box(title, script, < <<Set Icon(path)>), < <<Set Icon Location(left|right)>

**Description**

Constructs a button with the text *title* that executes *script* when clicked.

**Returns**

The display box (button box).

**Required Arguments**

- *title* A quoted string or a string variable.
- *script* A quoted string or a reference to a string that specifies a valid JSL script.

**Optional Messages**

<<Set Icon("path") Displays the image in the quoted pathname on the button. Most common graphic formats are supported, such as GIF, JPG, PNG, BMP, TIF. Since the title argument is optional, you can create a button with only a text title, with only an icon, or with both a text title and an icon. In the last case, the icon is placed next to the text title.
<<Set Icon Location("left"|"right") Allows the position of the icon on a button to be either left or right of the text.

Example
The following example shows a simple button box. When the user clicks the button box, "Pressed" is printed to the log.

```javascript
win = New Window( "Simple Example",
ex = Button Box( "Press me" )
);
ex << Set Script( Print( "Pressed" ) );
```

Notes
Line-break characters are ignored in button boxes.

Calendar Box(title, <<Date>, <<Min Date>, <<Max Date>, <<Show Time>)

Description
Constructs a pop-up calendar with selectable days and time.

Returns
The display box (calendar box).

Required Argument
title A quoted string or a string variable.

Optional Messages
<<Date The currently selected date.
<<Min Date The earliest date that can be selected.
<<Max Date The latest date that can be selected.
<<Show Time The time that can be specified.

Example
The following example creates a calendar with October 5, 1989 initially selected. The minimum date and maximum date are specified, so the user can select only dates in that range.

```javascript
New Window( "Calendar Box Example", cal = Calendar Box() );
date = Date MDY (10, 5, 1989);
cal << Date( date );
cal << Show Time( 0 ); // omit the time

/* earliest date that can be selected is 60 days before 10/5/1989
"start" truncates the value so the time is not included */
cal << Min Date( Date Increment(date, "Day", -60, "start" ) );

// latest date that can be selected is 60 days after 10/5/1989
cal << Max Date( Date Increment(date, "Day", 60, "start" ) );
```
cal << Set Function( Function( {this}, Print( Abbrev Date(this << Get Date()) ) ) ); // print the abbreviated date to the log

Cell Plot(Y(column(s)), <X(column)>)

Description
Displays each value in a cell graph.

Check Box({list}, <script>, < <<Get(n)>, < <<Set(n, Boolean)>, < <<Get Selected>, < <<Enable Item(n, Boolean)>, < <<Item Enabled(check box item)>)

Description
Constructs a display box to show one or more check boxes.

Returns
The display box (Check Box).

Required Argument
list A list of quoted strings or a reference to a list of strings.

Optional Argument
script An optional JSL script.

Optional Messages
<<Get(n) Returns 1 if the check box item specified by n is selected, or 0 otherwise.
<<Set(n, Boolean) Sets the check box item specified by n as either selected (1) or cleared (0).
<<Get Selected Returns a list of quoted strings that contain the names of the check box items that are selected.
<<Enable Item(n, Boolean) Sets the check box item specified by n as either enabled (1) or disabled (0). The state of a disabled check box cannot be changed.
<<Item Enabled(check box item) Returns 0 or 1 depending on whether the specific check box item is enabled.

Example
Create three check boxes labeled “one”, “two”, and “three”. The first check box is selected.
New Window( "Example", Check Box( {"one", "two", "three"}, <<Set( 1, 1 ) ) );

Col Box(title, display boxes)

Description
Returns a column box made up of the specified display boxes.

Arguments
title The quoted title of the column.
display boxes Display boxes that hold content within the column box.
Example

```julia
win = New Window( "Example",
exx = 1;
exy = 4;
exz = 8;
Table Box(
    String Col Box( "strings", {"x", "y", "z"} ),
    Col Box(
        "boxes",
        Slider Box( 0, 10, exx, Show( exx ) ),
        Slider Box( 0, 10, exy, Show( exy ) ),
        Slider Box( 0, 10, exz, Show( exz ) )
    )
);
```

**Description**

Constructs a display box to show a list box that allows selection of data table columns.

**Returns**

The display box (Col List Box).

**Optional Arguments**

- **Data Table** *(name)* The quoted name of the data table.
- "All" | "Character" | "Numeric" Adds all columns of the current data table into the list. Omitting "All" results in an empty col list box with the “optional” label. To display “optional character", specify "Character". To display “optional numeric", specify "Numeric".
- **width** *(pixels)* Sets the width of the list box to pixels. pixels is a number that measures pixels.
- "Grouped" Displays grouped columns in the box.
- **MaxSelected** *(n)* Sets whether only one item can be selected. For n>1, n is ignored.
- **nLines** *(n)* Sets the length of the list box to n number of lines. n is an integer.
- **script** A script.
- **MaxItems** *(n)* A number that allows only n columns to be added to the list.
- **MinItems** *(n)* A number that only requires at least n columns for the list. If n=2, the top two slots in the col list box an initial display of “required numeric” (or whatever you set the data type to be).
On Change(expr) Evaluates the expression when the selection in the list changes. Dragging between two column list boxes that have this argument results in both expressions being evaluated. The expression for the target being dragged is evaluated first, then the expression for the source is evaluated.

Optional Messages
<<Set Tips({Tip text 1, Tip text 2, ...}) Quoted strings that set tool tips for items in the list box. A quoted null string or an empty list results in no tips. A list shorter that the list of items in the list box will use the last tip text for the remaining items in the list and the list box.
<<Set Tip(Tip text) A quoted string that overrides any tool tips set using Set Tips() function. If there is a tip set for the box, you cannot set tips for each individual item.
Using Set Tip() with no arguments clears the list box tip and allows the individual item tool tips to be displayed.

Notes
– The MaxSelected(n) argument only affects whether one or more than one item can be selected. It does not enforce a limit greater than 1.
– Specialty modeling types can be used only in a role (determined by the platform) that explicitly accepts columns of the same type.

Col Span Box(title, display box args)

Description
Creates spanned columns headers inside a table box. The top column header spans two child column headers.

Returns
The display box (a Col Span Box).

Arguments

  title The title that appears in the box.
  display box args Display boxes.

Example
win = New Window( "Col Span Box",
  <<Modal,
    Table Box( 
      Col Span Box( "Confidence Limits",
        neb = Number Col Edit Box( "Upper limits", [0, 0] ),
        Number Col Edit Box( "Lower limits", [0, 0] )
      )
    ) 
  );
Combo Box({items <(tip string)>, ...}, <script>)

**Description**
Constructs a display box to show a drop-down list.

**Returns**
The display box (Combo Box).

**Arguments**
- **items** The items that the user can select.
- **tip string** A quoted string that specifies tooltip text.
- **script** An optional JSL script.

Context Box(display box, ...)

**Description**
Defines a scoped evaluation context. Each Context Box is executed independently of each other.

**Returns**
A display box.

**Arguments**
Any number of display boxes.

Contour Seg(Triangulation, [levels], <zColor([colors]|{colors}, <"Cycle Colors"|"Interpolate Colors">
   >), <"Fill"|"Fill Between"|"Fill Below"|"Fill Above">, <Transparency([]|t)>)

**Description**
Returns a display seg that represents contours of a Triangulation.

**Required Arguments**
- **Triangulation** The columns to include in the Triangulation.
- **[levels]** A matrix of values that control the contour levels that are drawn.

**Optional Arguments**
- **zColor([colors]|{colors}** Colors for each level, specified as a list or matrix.
- **"Cycle Colors"|"Interpolate Colors** Cycle Colors" alternates the colors (for example, red, green, red, green). With Interpolate Colors, the first contour is red, and the last is green. The contours between smoothly blend the colors.
- **"Fill Below"|"Fill Between"|"Fill Above"|"Fill"** "Fill Below" fills the region below the lines. "Fill Between" fills only the middle region. "Fill Above" fills the region above the lines. "Fill" works like "Fill Above", but the default is to display lines if no Fill options are specified.
- **Transparency([]|t)** The transparency specified as a number or matrix.
Example

dt = Open( "$SAMPLE_DATA/Cities.jmp" );
tri = Triangulation( X( :X, :Y ), Y( :POP ) );
{xx, yy} = tri << Get Points();
win = New Window( "Contour Seg Example",
    g = Graph Box(
        X Scale( Min( xx ) - .1, Max( xx ) + .1 ),
        Y Scale( Min( yy ) - .1, Max( yy ) + .1 ),
        Contour Seg(
            tri,
            [0, 400, 1000, 2000, 9000],
            zColor( 5 + [64 32 0 16 48] ),
            Transparency( [1, 1, 1, 1, 1] )
        )
    )
);

Notes

The triangulation is computed using the Xs, and the Y is a continuous variable defined at each position. The [levels] in this case defines values of POP that are drawn as lines, one line per level. If any Fill argument is specified, then the filled regions are [level1, level2], [level2, level3], ..., [level-n].

Current Journal()

Description

Gets the display box at the top of the current (topmost) journal.

Returns

Returns a reference to the display box at the top of the current journal.

Current Report()

Description

Gets the display box at the top of the current (topmost) report window.

Returns

Returns a reference to the display box at the top of the current report window.

Current Window()

Description

Returns a reference to the current window.
Data Filter Context Box(display box)

Description
Returns a display box that defines the extent of the local data filters that a display tree contains. Data filters and Data Filter Context Boxes can be arranged in a hierarchy and shared among platforms or boxes that the Data Filter Context Boxes contain.

Data Filter Source Box(display box)

Description
Defines which graph is the “source” of the selection filter. Selected rows in reports that are within the Data Filter Source box are included for analysis in the other reports that are within a common Data Filter Context Box.

Data Table Box(data table)

Description
Returns a table box that represents the specified data table.

Example
```jsl
dt = Open("$SAMPLE_DATA/Big Class.jmp");
win = New Window("Example", Data Table Box(dt));
```

Data Table Col Box(column)

Description
Returns a column box that corresponds to the specified data table column.

Example
```jsl
dt = Open("$SAMPLE_DATA/Big Class.jmp");
win = New Window("Example",
   Table Box(Data Table Col Box(:name), Data Table Col Box(:height))
);
```

Dialog(contents)

Description
Dialog is deprecated. Use New Window() with the Modal argument instead.

Excerpt Box(report, subscripts)

Description
Returns a display box containing the excerpt designated by the report held at number report and the list of display subscripts subscripts. The subscripts reflect the current state of the report, after previous excerpts have been removed.
Expr As Picture(Expr(...), <Width(pixels)>)

**Description**
Converts expr() to a picture as it would appear in the Formula Editor.

**Returns**
Reference to the picture.

**Required Argument**
Expr(...) Place any valid JSL expression that can be displayed as a picture inside expr().

**Optional Argument**
Width(pixels) Sets the width of the box to pix. pix is a number that measures pixels.

Filter Col Selector(<Data Table(name)>, <Width(pixels)>, <nLines(n)>, <script>, <OnChange(expr)>>)

**Description**
Returns a display box that contains a list of items. Control allows column filtering.

Get Project(title|index|display box|window)

**Description**
Returns a single project.

**Examples**
The following examples show how to get the window title of various projects.

Get Project( 1 ) << Get Window Title;
// first open project
Get Project( "My Project" ) << Get Window Title;
// first project named “My Project”
Get Project( display box ) << Get Window Title;
// parent project of the specified display box

Get Project List()

**Description**
Returns a list of all open projects.

**Example**
Get Project List() << Get Window Title;
// list of the titles of all open projects
Get Window(<Project(title|index|display box|window)>, <Type(string)>, title|index|display box)

Description

Returns a reference to a specific open window by title, index, or display box. When run in a project, Get Window() returns windows from the current project.

Optional Arguments

Project Specifies the title (a quoted string), index, display box, or window from another project.

Type(string) To limit the search to particular types of windows, use the Type() argument and one of these quoted strings: "Data Tables", "Journals", "Reports", or "Dialogs".

Examples

The following examples show how to get the window title of various windows.

Get Window( 1 ) << Get Window Title;
// first window in the current project

Get Window( "Big Class" ) << Get Window Title;
// Big Class window in the current project

Get Window( ob ) << Get Window Title;
// parent window of specified display box in the current project

Get Window( Project(), 1 ) << Get Window Title;
// first window, no project (global scope)

Get Window( Project( myProject ), "Big Class" << Get Window Title;
// Big Class window in the specified project

Get Window List(<Project(title|index|display box|window)>,><Type(string)>)

Description

Returns a list of currently open windows. By default, Get Window List() returns references to open windows in the current project. You can return an open window list from something other than the current project by using the Project() argument. To limit the search to particular types of windows, use the Type() argument and one of these quoted strings: "Data Tables", "Journals", "Reports", or "Dialogs".

Optional Arguments

Project Specifies the title, index, display box, or window from another project.

Type To limit the search to particular types of windows, use the Type() argument and one of these quoted strings: "Data Tables", "Journals", "Reports", or "Dialogs".

Examples

Get Window List() << Get Window Title;
// list of open windows in the current project
Get Window List( Type( "Reports" ) ) << Get Window Title;
// list of the titles of open reports in the current project
Get Window List( Project( 0 ), Type( "Reports" ) ); // positional arguments
// list of the titles of open reports outside of a project
Get Window List( 2 );
// second window list

Global Box( global )

Description
Constructs a box for editing global value directly.

Graph()

See “Graph Box(properties, script)” on page 98.

Graph 3D Box(properties)

Description
Constructs a display box with 3-D content.

Returns
The display box.

Arguments
properties Properties can include: Frame Size(x, y), Xname("title"), Yname("title"), Zname("title").

Notes
This display box constructor is experimental.

Graph Box(properties, script)
Graph(properties, script)

Description
Constructs a graph with axes.

Returns
The display box (Graph Box).

Arguments
properties Named property arguments: Title("title"), XScale(low, high), YScale(low, high), FrameSize(h, v), XName("x"), YName("y"), SuppressAxes.

script Any script to be run on the graph box.
H Center Box(<child box>)

Returns a display box that contains the optional child display box argument. The box is centered in the horizontal space defined by the maximum size of that child display box and all of the other siblings of the center box.

H List Box(<Align("center" | "bottom"), display box, ...)

Description

Creates a display box that contains other display boxes and displays them horizontally.

Arguments

Align("center" | "bottom") Specify center or bottom alignment of the contents in the list box. The contents are bottom aligned by default.

display box Any number of display box arguments can be contained in the list box.

H Scroll Box(<Size(h), display box>)

Description

Returns a display box that positions a larger child box using a horizontal scroll bar.

Arguments

Size(h) The horizontal length of the scroll bar.

Notes

The flexible argument is deprecated. Use Set Stretch instead. See “V Scroll Box(<Size(v), display box)” on page 118 for an example.

H Sheet Box(<Hold(report), display boxes>)

Description

Returns a display box that arranges the display boxes provided by the arguments in a horizontal layout. The <<Hold() message tells the sheet to own the report(s) that is excerpted.

H Splitter Box(<Size(h, v), display box, ...)

Description

Returns a display box that arranges the display boxes provided by the arguments in a horizontal layout (or panel). The splitter enables the user to interactively resize the panel.

Required Argument

display box Any number of display box arguments can be contained in the splitter box.
Optional Argument

Size(h, v) Specifies the size of the splitter box in pixels. This size is for the outer splitter box. Inner display boxes are proportionately sized according to the width and height of the outer splitter box.

Optional Messages

<<Size(n) Specifies the proportions of the last panel. <<Size(.25) resizes the last panel to 25% the splitter box height (or width, for vertical splitter boxes).

<<Set Sizes({n, n}) Specifies the proportions of each panel.

db<<Set Sizes({.75, .25}) sizes the first panel to 75% and the second panel to 25% of the splitter box height (or width, for vertical splitter boxes).

<<Close Panel(n, <Boolean>) Closes the panel that you specify. <<Close Panel(2) closes the second panel. With three or more panels, you must include the second Boolean value. That value indicates which panel expands to fill the space left by the closed panel.

- <<Close Panel(2,0) closes the second panel; the following sibling takes the extra space.
- <<Close Panel(2,1) closes the second panel; the preceding sibling takes the extra space.

<<Open Panel(n, <Boolean>) Opens the panel that you specify. With three or more panels, you must include the second Boolean value. Works similar to <<Close Panel described above. The panels are initially opened. You use <<Open Panel only after using <<Close Panel.

<<Get Sizes() Returns the proportions of each panel as a list.

Hier Box(text, Hier Box(...), ...)

Description

Constructs a node of a tree (similar to Diagram output) containing text. Hier Box can contain additional Hier Boxes, allowing you to create a tree. The text can be a quoted string or a Text Edit Box.

Hist Seg([data], [<freq column>], [<weight column>], <Vertical(Boolean)>, <Row States()>)

Description

Returns a histogram seg.

Required Argument

data The data in matrix format.

Optional Arguments

t Relative Argument

data The data in matrix format.

weight column The weight column in matrix format.
Vertical(Boolean) Displays the histogram vertically by default (or if set to 1). Display the histogram horizontally by setting the value to 0.

Row States Specifies a data table reference or row states.

Icon Box(name)

Description
Constructs a display box containing an icon, where the argument is a name such as Popup, Locked, Labeled, Sub, Excluded, Hidden, Continuous, Nominal, or Ordinal. The argument can also be a path to an image.

Argument
name
A quoted string that is the name of a JMP icon or the path to an icon.

Example
Icon Box("Nominal") constructs a display box that contains the Nominal icon.
Icon Box("$SAMPLE_IMAGES/pi.gif") inserts the pi.gif sample image.

Notes
– Some icons are used on both Windows and macOS. Other icons are platform specific.

If Box(Boolean, display boxes)

Description
Constructs a display box whose contents are conditionally displayed.

Arguments
Boolean 1 displays the display boxes inside the If Box. 0 does not display them.
display boxes Any display box tree.

If Seg(<State(Boolean)>)

Description
Returns a display seg that shows or hides display seg children.

Arguments
State(Boolean) Determines whether the display seg children are shown (1) or hidden (0).

Example
lines = [30 20 80 70, 10 90 90 10, 40 20 60 30];
win = New Window( "Lines Seg Example",
g = Graph Box( If Seg( true, <<Append( Lines Seg( lines ) ) ) ) )
Journal Box(string)

Description
Constructs a display box that displays the quoted string. We recommend that you do not generate the journal text by hand.

Line Seg(x, y, <Row States(dt|dt, [rows]|dt, {[rows], ...}|{row states})>, <Sizes(s)>)

Description
Creates a display seg of connected line segments for the given x and y values. The optional third argument enables row state assignments from either a data table or independently.

Lines Seg([x1 y1 x2 y2, ...])

Description
Returns a display seg with a sequence of line segments for the given x and y values.

Lineup Box(<nCol(n)>, <Spacing(pixels, <vspace>), display boxes, ...>)

Description
Constructs a display box to show an alignment of boxes in n columns.

ListBox({item, ...}, <Width(pixels)>, <maxSelected(n)>, <nLines(n)>, <script>)

Description
Creates a display box to show a list box of selection items (quoted strings). The argument can be a list of two-item lists containing the item name and a quoted string that specifies the modeling type or sorting order. Item names are case sensitive by default. The icon appears next to the corresponding item in the list box.

Marker Seg(x, y, <Row States(dt|dt, [rows]|dt, {[rows], ...}|{row states})>, <Sizes(s)>)

Description
Creates a display seg with markers for all of the x and y values. The optional third argument enables row state assignments from either a data table or independently.
Matrix Box(x)

Matrix Box(matrix, < <<Column Names(c0l1, c0l2, ...), < <<Row Names(r0w1, row2, ...)>>)

Description
Displays the matrix given in the usual array form. Column and row names are quoted strings.

Mouse Box(display box arguments)

Description
Returns a box that can make JSL callbacks for dragging and dropping, marking, or clicking and tracking mouse actions.

Arguments
display box arguments Specifies the object that the user interacts with, such as a Text Box or Button Box. See the Scripting Index in the Help menu.

Move to Project(<Source(project)|Destination(project)>, <Windows({list of windows to move})>)

Description
Moves one or more windows into a project or out of a project, or between projects.

Arguments
Source(project) The project containing the windows that you want to move.
Destination(project) The project to which you want to move the windows.
Windows({list of windows to move}) A list of windows to move to the project. If omitted, all windows will be moved. Note that the data table and all of its dependent reports will be moved. However, you need to specify only the data table name or report name in the windows argument to move it.

Example
```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
report = dt << Run Script( "Bivariate" );
project = New Project();
// move the report and data table to a new project
Move to Project( Destination( project ), Windows( {report} ) );
```
New Image()
New Image(width, height)
New Image(filepath)
New Image(Open(url))
New Image(picture)
New Image(matrix)
New Image(rgb|r|rgba, {matrix, ...})

Description
Creates a new image which can then be edited using JSL. Valid formats are png, bmp, jpeg, jpg, tiff, tif, and gif.

Returns
An image.

Arguments
All argument sets are optional, but all arguments within each set are required.
width, height  Sets the width and height of the image in pixels.
filepath  The quoted filepath to an image.
Open(url)  Opens the image at the specified URL path.
picture  A JSL picture object.
matrix  The image as a matrix of JSL color pixels.
rgb|r|rgba, {matrix, ...}  Specifies the channels ("rgb", "r", or "rgba") and
provides a matrix of values (0.0-1.0) for each channel. Examples:
New Image("r", [r matrix] );
New Image("rgb", [[r matrix], [g matrix], [b matrix]] );
New Image("rgba", [[r matrix], [g matrix], [b matrix], [a matrix]] );

New Project(arguments)

Description
Creates a project using the specified script.

Arguments
<<Add Bookmarks({<File(path)>, <Folder(path, Expanded(Boolean))>,
<Group(name, <Expanded(Boolean)>, {contents}>})  Creates bookmarks for
frequently used files in the project. The argument is a list of bookmark items, each of
which is specified using File(), Folder(), or Group(). Group() accepts File(),
Folder(), and Group() as children.
<<Reset Layout  Sets the project to use the default layout.
<<Run Script  Specifies the data tables and reports that appear in the project.
<<Save(<path>) Saves the project. Include a quoted path and file name to save the project to a specific location. Save As is an alias.

<<Set Bookmarks({<File(path)>, <Folder(path, Expanded(Boolean))>, <Group(name, <Expanded(Boolean)>, {contents})>}) Sets the bookmarks for the project. The argument is a list of bookmark items, each of which is specified using File(), Folder(), or Group(). Group() accepts File(), Folder(), and Group() as children.

<<Set Layout Sets the window layout of the project.

<<Show Bookmarks Shows or hides the bookmarks.

<<Show Log Shows or hides the log.

<<Show Window List Shows or hides the Window List.

Example

The following example creates a project from BigClass.jmp and two reports.

```julia
project = New Project();
project << Run Script(
    dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
    dt << Run Script( "Bivariate" );
    dt << Run Script( "Distribution" );
);
```

New Window(title, <arguments>, display box)

Description

Makes a new window with the required quoted title and a display box tree.

Optional Arguments

<<Script(<script>) Creates a new script window. The optional quoted string script is placed inside the script window.

<<Journal Creates an empty journal.

<<Size Window(x, y) Creates a new window of the specified height and width.

<<Modal Makes the new window a modal window, which prevents any other actions in JMP until the window is closed. If you do not include an OK or Cancel button, one is added automatically for you. **Note:** If used, this argument must be the second argument, directly after the window title. Available modal window arguments are:

- <<On Open(expr) runs expr when the window is created.

**Note:** In data tables, On Open (or OnOpen) scripts that execute other programs are never run. Set the Evaluate OnOpen Scripts preference to control when the script is run.

- <<On Close(expr) runs expr when the window is closed. Returns 0 if the window fails to close.
– `<On Validate(expr)` runs `expr` when the `OK` button is pressed. If it returns True, the window is closed otherwise the window remains open.

– `<Return Result` changes the window’s return value when it closes to match that of the deprecated `Dialog()` function.

**Show Toolbars(Boolean)** Shows or hides the toolbar. The default value is 1. (Windows only.)

**Show Menu(Boolean)** Shows or hides the menu bar. The default value is 1. (Windows only.)

**Suppress AutoHide(Boolean)** Suppresses or uses the auto-hide feature for menus and toolbars. The default value is 1. (Windows only).

**Notes**

`Dialog()` is deprecated. Use `New Window()` with the `Modal` argument instead.

---

**Number Col Box(title, numbers)**

**Description**

Creates a column named `title` (a quoted string) with numeric entries given in list or matrix form.

**Number Col Edit Box(title, {numbers}([[numbers]])

**Description**

Creates a column named `title` (a quoted string) with numeric entries given in list or matrix form. The numbers can be edited.

**Number Edit Box(initial value, <width>)**

**Description**

Creates an editable number box that initially contains the `initial value` argument.

**Returns**

The display box object.

**Argument**

`initial value` Any number to use as the initial value. If you use a date or time format, a date and time selector window is created.

`<width>` Sets the width of the box in characters.

**Outline Box(title, display box, ...)**

**Description**

Creates a new outline named `title` (a quoted string) containing the listed display boxes.
Page Break Box()

**Description**
Creates a display box that forces a page break when the window is printed.

Panel Box(title, display box)

**Description**
Creates a display box labeled with the quoted string *title* that contains the listed display boxes.

Picture Box(Open(picture), format)

**Description**
Creates a display box that contains a graphics picture object.

**Returns**
A reference to the display box.

**Argument**
- **Open(picture)**: Opens the directory that contains the picture.
- **format**: Specifies the graphic file format. Specifying the format opens the picture in JMP. If you omit this argument, the picture opens in the default graphics program. Valid formats are the quoted strings "png", "bmp", "jpeg", "jpg", "tiff", "tif", and "gif".

**Example**
```javascript
New Window( "Example",
  Picture Box( Open( "$SAMPLE_IMAGES/pi.gif", gif ) ) );
```

Platform(data table, script)

**Description**
Evaluates the specified script in the context of the specified data table.

**Returns**
The resulting display box for embedding in a display tree.

**Example**
```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
win = New Window( "Platform example",
  H List Box(
    Platform( dt,
      Bubble Plot(
        X( :weight ),
        Y( :height ),
```
Sizes( :age ),
Title Position( 0, 0 )
)
),
Platform(
  dt,
  Bubble Plot(
    X( :weight ),
    Y( :age ),
    Sizes( :height ),
    Title Position( 0, 0 )
  )
)
);

Plot Col Box(title, numbers)

**Description**

Returns a display box labeled with the quoted string `title` to graph the `numbers`. The numbers can be either a list or a matrix.

Poly Seg(x values, y values)

**Description**

Returns a display seg that represents a polygon with vertices based on the `x values` and `y values`.

**Example**

```javascript
x = [10, 50, 90];
y = [10, 90, 10];
win = New Window( "Poly Seg Example", 
g = Graph Box( Poly Seg( x, y ) ) );
frame = g[FrameBox( 1 )];
seg = (frame << Find Seg( "Poly Seg" ));
```

Popup Box({command1, script1, command2, script2, ...})

**Description**

Creates a red triangle menu. The single argument is an expression yielding a list of an even number of items alternating between the quoted command string and the expression that you want evaluated when the command is selected. If the command is an empty string, a separator line is inserted.
Notes
Pressing ALT and right-clicking the red triangle menu opens a window with check boxes for the commands.

Radio Box({item, ...}, <script>)

Description
Constructs a display box to show a set of radio buttons. The items are quoted strings. The optional script is run every time a radio button is selected.

Range Slider Box(minValue, maxValue, lowVariable, highVariable, script)

Description
Range Slider Box() returns a display box that shows a range slider control that ranges from minValue to maxValue. As the two sliders’ positions change, their values are placed into lowVariable and highVariable, and the script is run.

Returns
The display box (Range Slider Box).

Arguments
minValue, maxValue Numbers that set the minimum and maximum value the slider represents.
lowVariable The variable whose value is set and changed by the lower slider.
highVariable The variable whose value is set and changed by the upper slider.
script Any valid JSL commands that are run as the slider is moved.

Report(obj)

Description
Returns the display tree of a platform obj. This can also be sent as a message to a platform: obj<<Report.

Scene Box(x size, y size)

Description
Creates an x-sized by y-sized scene box for 3-D graphics.

Scene Display List

Description
Returns a display list for 3-D graphics.

Example
ex = Scene Display List();
ex << Color( .9, .9, .9 );
ex << Text( center, middle, .3, "Hello World" );
exScene = Scene Box( 600, 600 );
exScene << Background Color( 0 );
exScene << Show Arcball( always );
New Window( "See HelloWorld.jsl in sample scripts", exScene );
exScene << Perspective( 45, .2, 20 );
exScene << Translate( 0.0, 0.0, -4.5 );
exScene << Arcball( ex, 1.5 );
exScene << Update;

---

**Script Box**(<script>, <language>, <width>, <height>)

**Description**

Constructs an editable box that contains the quoted string `script`. The editable box is a script window and can both be edited and run as JSL.

**Optional Arguments**

- `script` A quoted string that appears in the script box.
- `width` An integer that sets the width of the script box.
- `height` An integer that sets the height of the script box.

**Example**

```plaintext
// JSON
New Window( "JSON",
  Script Box(
    "{"a":1,"b":"test"}",
    "JSON"
  )
);
```

---

**Scroll Box**(<Size(h,v>), display box, ...)

**Description**

Creates a display box that positions a larger child box using scroll bars.

**Returns**

A reference to the scroll box object.

**Required Argument**

- `display box` Any number of display box arguments can be contained in the scroll box.

**Optional Argument**

- `Size(h,v)` The `h` and `v` arguments specify the size of the box in pixels.
Notes

You can send a scroll box object a message to set the background color:

```
<<Set Background Color( {R, G, B} | <color> )
```

The `Flexible` argument is deprecated. Use the `Set Stretch` message instead. See “V Scroll Box(<Size(v)>, display box)” on page 118 for an example.

You can set the Boolean flags for horizontal (h) and vertical (v) scrolling to enable (1) or disable (0) the scroll bars. If scrolling is disabled in a given direction, the Scroll Box will behave as a regular container in that direction.

```
<<Set Scrollers (h, v)
```

To return the flags for scrolling, use the following message:

```
<<Get Scrollers
```

To set the horizontal (h) and vertical (v) positions (in pixels) for the scrollbars on the scrollbar:

```
<<Set Scroll Position (h,v)
```

To return the flags for scroll position, use the following message:

```
<<Get Scroll Position
```

To return the maximum positions for horizontal and vertical scrolling, use the following message:

```
<<Get Scroll Extents
```

Example

The following example shows a window containing a scroll box with the specified settings.

```
win = New Window( "Example",
    sb = Scroll Box(
        Size( 150, 75 ),
        List Box(
            {"First Item", "Second Item",
             "Third Item", "Fourth Item",
             "Fifth Item"},
            width( 200 ),
            max selected( 2 ),
            nLines( 6 )
        )
    )
);
win << Set Window Size( 300, 200 );
sb << Set Scrollers( 1, 1 ); // enable both scroll bars
sb << Set Scroll Position( 0, 20 ); /* position the scrollers on
the scroll bar */
```
Shape Seg( {Path(path), ...}, <Row States(dt|dt,[rows]|dt,{{rows}, ...}|{row states})>)

Description
Returns a display seg with a collection of shapes.

Required Argument
Path Specifies the path with an N\times3 matrix or with a text representation. A path matrix has three columns for x, y, and flags for each point in the path. The flag values are 0 for control, 1 for move, 2 for a line segment, 3 for a cubic Bézier segment, and are negative if the point also closes the path. Path text supports SVG syntax.

Optional Arguments
Row States Specifies a data table reference and optionally rows or the actual row state.

Example
win = New Window( "Shape Seg Example",
  Graph Box(
    Shape Seg(
      {Path( [10 10 1, 10 70 0, 70 70 0, 70 10 -3] ),
        Path( "M20,20 C20,60 60,60 60,20 Z" )},
        Row States( {Selected State( 1 ), Color State( "red" )} )
    )
  )
);
variable The variable whose value is set and changed by the slider box.

script Valid JSL commands that are run as the slider box is moved.

Optional Arguments
Set Width(n) Specifies the width of the slider box in pixels.
Rescale Slider(minValue, maxValue) Resets the maximum and minimum values for the slider box.

Notes
You can send Set Width and Rescale Slider as messages to a slider object. For example:
```
ex = .6;
New Window( "Example", mybox = Slider Box( 0, 1, ex, Show( ex ) ) );
mybox << Set Width( 200 ) << Rescale Slider( 0, 5 );
```

Spacer Box(<Size(h, v)>, <Color(color)>)

Description
Creates a display box that can be used to maintain space between other display boxes, or to fill a cell in a LineUp Box.

Returns
A reference to the display box.

Optional Arguments
Size(h, v) The h and v arguments specify the size of the box in pixels.
Color(color) Sets the color of the box to the JSL color argument.

Spin Box(script)

Description
Returns a display box that shows a button with up and down controls.

Argument
script Invoked with an argument that indicates the direction of the arrow clicked. Negative is down, and positive is up. A value of 1 indicates a single click, while larger values indicate a repeating action.

Example
```
win = New Window( "Example",
  Lineup Box(
    2,
    nb = Number Edit Box( 3 ),
    sb = Spin Box( Function( {value}, nb << Increment( value ) ) )
  )
);
nb << Set Increment( 1 );
```
**Splitter Box(<Size(x, y)>, display box, ...)**

**Description**

Returns a display box that can organize other display boxes horizontally or vertically with interactive control of sizes. Child sizes are specified as a proportion of the width or height of the splitter box. The optional *Size* argument is used only for the top-most splitter box. Lower level display boxes are sized like any other child box.

Use `H Splitter Box()` or `V Splitter Box()`.

**String Col Box(title, {string, ...})**

**Description**

Creates a column in the data table containing the quoted *string* items. The column is named after the quoted *title*.

**String Col Edit Box(title, {string, ...})**

**Description**

Creates a column in the data table containing the quoted *string* items. The string boxes are editable. The column is named after the quoted *title*.

**Notes**

To retrieve the data, use the following message:

```plaintext
data = obj << Get;
```

**Tab Box(Tab Page Box(Title(page title 1), <options>, contents of page 1), Tab Page Box(Title(page title 2), <options>, contents of page 2), ...);**

**Description**

(Previously called `Tab List Box`.) Creates a tabbed window pane. The arguments are an even number of items alternating between the name of a tab page and the contents of the tab page. The page titles must be quoted.

**Arguments**

- `Tab Page Box` Returns a display box that can be used in a tab box or as a stand-alone container with a title.
  - `Title(page title #)` specifies the title of page 1.
  - Options include `<<Closeable(Boolean)` (specifies whether the box can be closed), `<<Tip(string)` (a quoted string that specifies a tooltip), and `<<Icon(string)` (a quoted string that specifies the icon).
  - `contents of page #` is a quoted string that specifies the text on the tab.

**Example**

```plaintext
New Window("Example",
```
Tab Box(
    t1 = Tab Page Box( Title( "alpha" ), Panel Box( "panel", Text Box( "text" ) ) ),
    t2 = Tab Page Box( Title( "beta" ), Popup Box( {"x", ex = 1, "y", ex = 2} ) )
);

Notes
Certain messages that you can send to Tab Page Box have been renamed:
– Set Title is called Title.
– Set Tip is called Tip.
– Set Icon is called Icon.
– Set Closeable is called Closeable.

Tab List Box(title, tabExpr1, ...)
See “Tab Box(Tab Page Box(Title(page title 1), <options>, contents of page 1), Tab Page Box(Title(page title 2), <options>, contents of page 2), ...);” on page 114.

Tab Page Box(Title(string), <options>, contents)
Description
Returns a display box that can be used in a tab box or as a stand-alone container with a title.
Required Argument
Title A quoted string that specifies the title on the tab.
Optional Messages
<<Tip(string) A quoted string that specifies a tooltip.
<<Closeable(Boolean) Specifies whether the page can be closed.
<<Icon(string) A quoted string that specifies the icon.
<<Set Font(font name, <size>, "bold"|"italic"|"underline"|strikeout>, <angle> Specifies the font properties.
<<Set Font Name("font name") Specifies the name of the font.
<<Set Font Scale(f) Specifies the scale factor for the font. The scale factor is applied to the size that is determined by the base font and point size.
<<Set Font Size(n) Specifies the font size in pixels.
<<Set Font Style("plain"|"bold") Specifies the font style.
Notes
Certain messages that you can send to Tab Page Box have been renamed:
– Set Title is called Title.
– Set Tip is called Tip.
– Set Icon is called Icon.
– Set Closeable is called Closeable.

Table Box(display box, ...)

Description
Creates a report table with the display boxes listed as columns.

Text Box(text, <arguments>)

Description
Constructs a box that contains the quoted string text.

Arguments
<<Justify Text(position) Justifies the text left, center, or right as specified in quotes.
<<Set Wrap(pixels) Sets the point at which text wraps.

Text Edit Box(text, <arguments>)

Description
Constructs an editable box that contains the quoted string text.

Arguments
<<Password Style(Boolean) Displays asterisks in the box rather than the password.
<<Set Script Runs the specified script after the text is edited.
<<Set Width(pixels) Sets the point at which text wraps.

This Project()

Description
Gets the current project when a JSL script is run from that project.

Example
The following example gets the window title of the current project.

```julia
global project = New Project();
project << Save( "$DOCUMENTS/Test Project.jmpprj" );
project << Run Script(  
   New Window("Project Title",  
      Text Box(This Project() << Get Window Title())  
   );
);
```
Tree Box(<{rootnodes}>, <Size(width, height)>, <MultiSelect(Boolean)>)

Description
Constructs a box to show a hierarchical tree composed of tree nodes.

Arguments
{rootnodes} Specifies the names for the root nodes created by Tree Node() which the box contains.
Size(width, height) Specifies the width and height (in pixels) of the box.
MultiSelect(Boolean) Indicates that more than one item in the tree can be selected.

Tree Node(<data>)

Description
Creates a node for display in a Tree Box display. Tree Node is used for both parent and child nodes.

Notes
If you send a root node that contains one or more nodes with the Set Node Select Script defining a collapse message, then macOS runs the script twice. Windows doesn’t run the script. This behavior on macOS doesn’t just affect increments. Any script runs twice. It will print to the log twice, create a column twice, try to delete something twice, and so on.

Triangulation(<dt>, X(col1, col1), <Y(col)>)

Description
Returns an object containing the Delaunay triangulation of the given point set. The optional Y will be averaged for duplicate points, and all points in the output will be unique.

Examples
tri = Triangulation(
    X( [0 0 1 1], [0 1 0 1] ),
    Y( [0 1 2 3] )
);
dt = Open( "$SAMPLE_DATA/Cities.jmp" );
tri = Triangulation( X( :X, :Y ), Y( :POP ) );

V Center Box(display box...)

Returns a display box that contains the child display box argument. The box is centered in the vertical space defined by the maximum size of that child display box and all of the other siblings of the center box.
V List Box(<Align("Center"|"Right">, display box, ...

**Description**
Creates a display box that contains other display boxes and displays them vertically.

**Arguments**
- **Align**  Specify right or center alignment of the contents in the list box. The contents are center aligned by default.
- **display box** Any number of display box arguments can be contained in the list box.

V Scroll Box(<Size(v), display box)>)

**Description**
Returns a display box that places a scroll bar on the bottom and right if the contents are bigger than the size of the scroll box.

**Arguments**
- **Size(v)** The vertical length of the scroll bar.
- **display box** Any number of display box arguments can be contained in the scroll box.

**Example**
```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
New Window( "stretchable",
  H Splitter Box(
    Size( 400, 200 ),
    Scroll Box(
      Size( 200, 200 ),
      dt <<Run Script( "Distribution" ),
      <<Set Stretch( "Window", "Window" )
    ),
    Scroll Box(
      Size( 200, 200 ),
      dt <<Run Script( "Bivariate" ),
      <<Set Stretch( "Window", "Window" )
    ),
    <<Set Stretch( "window", "Window" )
  );
```

**Notes**
The flexible argument is deprecated. Use Set Stretch instead.
**V Sheet Box(<<Hold(report), display box, ...)**

**Description**
Returns a display box that arranges the display boxes provided by the arguments in a vertical layout. The <<Hold() message tells the sheet to own the report(s) that is excerpted.

**V Splitter Box(<Size(h,v)>, display box..., <arguments>)**

**Description**
Returns a display box that arranges the display boxes provided by the arguments in a vertical layout (or panel). The splitter enables the user to interactively resize the panel.

**Arguments**
- **Size(v)** The vertical length of the scroll bar.
- **display box** Any number of display box arguments can be contained in the splitter box.

**Optional Arguments**
For more information about the optional arguments, see “H Splitter Box(<Size(h, v), display box, ...)” on page 99.

**Web Browser Box(url)**

**Description**
Creates a display box that contains a web page. Available only on Windows in Internet Explorer.

**Returns**
A reference to the web browser box object.

**Argument**
- **url** A quoted string containing the URL to the web page to display.

**Example**
The following example creates a splitter box with the web browser box on the left and the bubble plot on the right.
```julia
dt = Open( "$SAMPLE_DATA/PopAgeGroup.jmp" );
New Window( "Example",
    H Splitter Box(
        Size( 800, 300 ),
        wb = Web Browser Box( "http://www.jmp.com" ),
        dt << Run Script( "Bubble Plot Region" )
    )
);
wb << Set Stretch( "Window", "Window" ); // auto stretch horizontally and vertically
wb << Set Max Size( 10000, 10000 ); // maximum size in pixels
```
Notes

The `<a href>` target "_blank" opens the web page in a new Internet Explorer window. The `<a href>` target "_new" opens the web page in the active Internet Explorer tab.

---

Window(<string|int>)

Returns

Either a list of references to all open windows, or a reference to an explicitly named window.

Arguments

`string` A quoted string containing the name of a specific open window.

`int` The number of a specific open window.

Notes

If no argument is provided, a list of all open windows is returned. If the argument (either a window name or number) does not exist, an empty list is returned.

---

Wrap List Box(<display box>, ...)

Description

Creates a list box that contains other display boxes and displays them horizontally, but wraps them when printing.

Arguments

`display box` Any number of display box arguments can be contained in the list box.

---

Expression Functions

Arg(expr, i)

Arg Expr(expr, i)

Description

Finds the argument numbered by `i` within the given expression.

Returns

The `i`th argument within the expression `expr`.

`Empty()` if that argument does not exist or is not specified.

Arguments

`expr` An expression.

`i` An integer that indicates which argument to return.
Notes
Arg Expr() is deprecated. Use Arg() instead.

Eval Expr(expr)
Description
Evaluates any expressions within expr, but leaves the outer expression unevaluated.
Returns
An expression with all the expressions inside expr evaluated.
Argument
expr A valid expression.

Expr(expr, i)
Description
Returns the argument unevaluated (expression-quoting).
Returns
The argument, unevaluated.
Empty() if that argument does not exist or is not specified.
Argument
expr An expression.
i An integer that indicates which argument to return.

Extract Expr(expr, pattern)
Description
Find expr matching pattern.
Returns
A pattern that matches the specified pattern.
Arguments
expr An expression.
pattern Any pattern.

Head(exprArg)

Head Expr(exprArg)
Description
Returns the head of the evaluated expression, without its arguments.
Notes
Head Expr() is deprecated. Use Head() instead.
Head Name(expr)
Head Name Expr(expr)

**Description**
Returns the head of the evaluated expression as a quoted string.

**Notes**
Head Name Expr() is deprecated. Use Head Name() instead.

N Arg(exprArg)

**Description**
Returns the number of arguments of the evaluated expression head.

N Arg Expr(exprArg)

**Description**
Returns the number of arguments of the expression head.

**Notes**
N Arg Expr() is deprecated. Use N Arg() instead.

Name Expr(x)

**Description**
Returns the unevaluated expression of x rather than the evaluation of x.

### File Functions

Close(<dt|query>, <noSave|Save(path)>)

**Description**
Closes a data table, query, or JSON file. If no arguments are specified, the current file is closed. If the file has been changed, it is automatically saved. All dependent windows are also closed (for example, report windows that are based on the data table).

**Returns**
Void.

**Arguments**
- **dt** An optional reference to a data table, query, or JSON file.
- **nosave|Save(path)** An optional switch to either save the file to the specified quoted path before closing or to close the file without saving it.
Chapter 2
JSL Functions

JSL Syntax Reference File Functions

Close All(<Project(title|index|display box|window)>, type, "Invisible"|"Private">, <NoSave|Save>)

Description
Closes all open resources of type.

Required Argument
- **type** A named argument that defines the type of resources that you want to close. The allowable types are: Data Tables, Reports, and Journals.

Optional Argument
- **Project(title|index|display box|window)** Closes the specified project window.
- "Invisible" Closes all invisible data tables.
- "Private" Closes all private data tables.
- NoSave or Save Saves the specified types of windows before closing or to close without saving.

Close Database Connection(db connection handle)

Description
Closes a database connection returned from Create Database Connection.

Close Log(Boolean)

Description
Closes the log window.

Convert File Path(path, "Absolute"|"Relative">, "POSIX"|"Windows">, Base(path)>)

Description
Converts a file path according to the arguments.

Returns
The converted path.

Required Argument
- **path** A quoted pathname that can be either Windows or POSIX.

Optional Arguments
- "Absolute"|"Relative" Specifies whether the returned pathname is in absolute or relative terms. The default value is Absolute.
- "POSIX"|"Windows" Specifies whether the returned pathname is in Windows or POSIX style. The default is POSIX.
- **Base(path)** Specifies the quoted base pathname, useful if Relative is specified. The default is the default directory. See “Set Default Directory(path)” on page 142.
Search  Searches through the specified directories for the specified string. In the example below, JMP searches $SAMPLE_DATA/ and $SAMPLE_DATA/Time Series/ for Air.jmp. If Air.jmp is in both directories, the first instance is returned. Without the search option, Convert File Path() uses the default directory instead.

Example

```javascript
Set File Search Path(  
  {Convert File Path( "$SAMPLE_DATA/" ),  
    Convert File Path( "$SAMPLE_DATA/Time Series/" )}  
);

Convert File Path( "Air.jmp", Search );

Get File Search Path() = {"/C:/Program Files/SAS/JMPPRO/16/Samples/Data/",  
"/C:/Program Files/SAS/JMPPRO/16/Samples/Data/Time Series/"};

Convert File Path("Air.jmp", search) = "/C:/Program  
Files/SAS/JMPPRO/16/Samples/Data/Time Series/Air.jmp";
```

Copy Directory(from path, to path, <Recursive(Boolean)>)

Description

Copies files from one directory to another, optionally copying subdirectories. The directory name is created in the to path and should not be part of the to path argument.

Returns

Returns 1 if the directory is copied; otherwise, returns 0.

Required Arguments

- **from path**: Specifies the directory containing the files to copy to the new directory. *from path* is a quoted string.
- **to path**: Specifies the path where the new directory should be created and to which the files are copied. *to path* is a quoted string.

Optional Argument

- **Recursive(Boolean)>**: Specifies whether to copy the from path subdirectory structure to the to path.

Notes

Copy Directory(from path, to path, Boolean) is deprecated.

Copy File(from path, to path)

Description

Copies one file to a new file using the same or a different name.

Returns

Returns 1 if the file is copied; otherwise, returns 0.
Create Database Connection(\texttt{dataSourceName}|"Connect Dialog",<DriverPrompt(\texttt{Boolean})>);

\textbf{Description}

Creates a connection to the specified database or prompts the user to provide database log in information.

\textbf{Returns}

A handle to the database connection.

\textbf{Required Argument}

\texttt{dataSourceName}  
The quoted server connection string that contains information such as the data source name and user name.

\textbf{Optional Arguments}

"Connect Dialog"  
Opens the Select Data Source window, from which the user selects the database.

Driver Prompt(\texttt{Boolean})  
Enables the ODBC driver to prompt for the connection information if necessary.

\textbf{Examples}

Specify the data source name, user name, and password:
Create Database Connection( "dsn=Books;UID=johnsmith;password=Christmas" );

Request that the ODBC driver prompt the user to enter connection information, because the quoted connection string does not specify the password:
Create Database Connection( "dsn=Books;UID=johnsmith", Driver Prompt( 1 ) );

Enable the user to select the data source, specify "Connect Dialog":
Create Database Connection( "Connect Dialog" );

Create Directory(\texttt{path})

\textbf{Description}

Creates a new directory at the specified path location.

\textbf{Returns}

Returns 1 if the directory is created; otherwise, returns 0.

\textbf{Arguments}

\texttt{path}  
Specifies the quoted path where the new directory should be located.
Creation Date(path)

Description
Returns the creation date for the specified file or directory.

Returns
Creation date.

Arguments
path Specifies the quoted directory or path and file name for the query.

Delete Directory(path, <Allow Undo(Boolean)>)

Description
Deletes the specified directory and its contents and any subdirectories.

Returns
Returns 1 if the directory is deleted; otherwise, returns 0.

Arguments
path Specifies the path and directory for deletion.
Allow Undo(Boolean) Allows undo operations, for example, moving to the Recycle Bin or Trash Can.

Delete File(path, <Allow Undo(Boolean)>)

Description
Deletes the specified file.

Returns
Returns 1 if the file is deleted; otherwise, returns 0.

Required Argument
path Specifies the quoted path and file name for deletion.

Optional Argument
Allow Undo(Boolean) Allows undo operations, for example, moving to the Recycle Bin or Trash Can.

Directory Exists(path)

Description
Verifies the specified directory exists.

Returns
Returns 1 if the directory exists; otherwise returns 0.

Arguments
path Specifies the quoted path and directory for verification.
File Exists(path)

Description
Verifies the specified file name exists at the specified path.

Returns
Returns 1 if the file exists; otherwise returns 0.

Arguments
path Specifies the quoted path and file name for verification.

FileSize(path)

Description
Determines the size of the file within the specified path.

Arguments
path Specifies the quoted path and file name.

Example
FileSize("$SAMPLE_DATA/Big Class.jmp");
13142

Files In Directory(path, <Recursive(Boolean)>)

Description
Returns a list of filenames in the path given.

Returns
List of filenames. If Recursive(Boolean) is not specified, directory names are included in the list.

Required Argument
path A valid quoted pathname.

Optional Argument
Recursive(Boolean) A keyword that causes all folders in the path (and all folders that they contain, and so on) to be searched for files.

Notes
Files In Directory(path, "Recursive"|Boolean) is deprecated.

Find All(<Project(title|index|display box|window>>, type, <"Invisible"|"Private">)

Description
Finds all open files of the specified type.
Required Argument

type  A named argument that defines the type of resources that you want to close. The allowable types are: Data Tables, Reports, and Journals.

Optional Argument

Project(title|index|display box|window) Closes the specified project window.
"Invisible" Closes all invisible data tables.
"Private" Closes all private data tables.

Example

The following example finds all open data tables:

```javascript
exdt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
exdt2 = Open( "$SAMPLE_DATA/Animals.jmp" );
windows = Find All( Data Tables );
For( i = 1, i <= N Items( windows ), i++,
    Write( Char( windows[i] << Get Window Title ) || "\N" )
);
Big Class
Animals
```

Get Default Directory()

Description

Retrieves the user's default directory. This path is used for subsequent relative paths.

If the default directory was set using Set Default Directory(), JMP returns the specified path as long as Get Default Directory() and Set Default Directory() are in the same script.

See “Set Default Directory(path)” on page 142.

Returns

The absolute pathname as a quoted string.

Arguments

none

Notes

Get Default Directory() also gets the path of an active saved scripting window.

Get Excel Worksheets(absolute path)

Description

Retrieves a list of worksheets that are in the specified Microsoft Excel workbook. If no worksheets are found, an empty list is returned. The path is a quoted string.

Notes

The function supports .xlsx and Excel 1997 or later workbooks.
Get File Search Path()

**Description**
Retrieves the current list of directories to search for opening files.

This list is configured using the `Set File Search Path()` function. See “Set File Search Path(path|list of paths)” on page 143.

**Returns**
A list of pathnames as quoted strings.

Get Path Variable(name)

**Description**
Retrieves the value of name, a path variable.

**Returns**
The absolute pathname as a quoted string.

**Argument**
name A quoted string that contains a path variable. (Examples: SAMPLE_DATA and SAMPLE_SCRIPTS)

Google Sheet Export(dt, email, spreadsheet URL|spreadsheet ID|new spreadsheet name, sheet name)

**Description**
Exports a data table to a Google sheet.

**Returns**
“1” if the export is successful.

**Arguments**
dt The data table.

email The quoted Google email address. @gmail.com is unnecessary.

spreadsheet URL|ID The quoted spreadsheet’s URL or ID (the string that precedes “spreadsheets/d/”).

new spreadsheet name The quoted name of the new spreadsheet that you are creating.

sheet name The quoted name of the sheet (or tab) within the spreadsheet.

**Notes**
– JMP features such as formulas and List Check column properties are not supported in Google Sheets.
– If the spreadsheet is empty, look in the JMP log for error messages. On Windows, select View > Log. On macOS, select Window > Log.
Google Sheet Import(email, spreadsheet URL, <sheet name>{sheet name, sheet name}, Google Sheet Settings>)

Description
Imports sheets from a Google Sheet.

Returns
A data table (or the first data table imported if several sheets are imported at once).

Required Arguments
- email: The quoted Google email address. @gmail.com is unnecessary.
- spreadsheet URL|ID: The quoted spreadsheet’s URL or ID (which precedes “spreadsheets/d/”).

Optional Arguments
- sheet name: The quoted name of the sheet or sheets that you want to import.
- Google Sheet Settings: The settings that describe how the data is imported.

See Also
See Using JMP for details about security, country restrictions, and more.

Is Directory(path)

Description
Returns 1 if the quoted path argument is a directory and 0 otherwise.

Is Directory Writable(path)

Description
Returns 1 if the directory specified in the quoted path is writable and 0 otherwise.

Is File(path)

Description
Returns 1 if the quoted path is a file and 0 otherwise.

Is File Writable(path)

Description
Returns 1 if the file specified in the quoted path is writable and 0 otherwise.
JSON To Data Table(`JSON string`, (<Private(Boolean)>|<Invisible(Boolean)>), <Guess(Stack(Boolean)|"Tall"|"Wide"|"Huge"|"Pandas")>)

**Description**
Converts a quoted JSON string to a data table.

**Returns**
A data table reference. The parsing of an empty value, "" string, missing value, or any other invalid value returns an empty data table.

**Required Argument**
`JSON string` The quoted JSON string.

**Optional Arguments**
- **Private(Boolean)** Hides the data table completely. Specify this argument if the user doesn’t need to interact with the data table.
- **Invisible(Boolean)** Hides the data table from view but shows it in the JMP Home Window.
- **Guess(Stack(Boolean)|"Tall"|"Wide"|"Huge"|"Pandas")** Stack applies to nodes that repeat within a parent node that is creating rows. By default, extra values are stored in a single table cell separated by commas. If the value is 1, repeating values are stacked in extra rows. Be careful stacking data. It can cause non-obvious data errors.
  - "Tall" imports the data in a tall data table. Select this option when the JSON file contains many rows. This option is the default setting.
  - "Wide" imports the data in a wide data table. Select this option when the JSON file contains many columns.
  - "Huge" imports the data in a tall and wide data table.
  - "Pandas" imports data in the pandas format.

**Example**
```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt = JSON to Data Table(
   "[ { \"name\": \"KATIE\", \"age\": 12, \"sex\": \"F\", \"height\": 59, \"weight\": 95 }, { \"name\": \"LOUISE\", \"age\": 12, \"sex\": \"F\", \"height\": 61, \"weight\": 123 }, { \"name\": \"JANE\", \"age\": 12, \"sex\": \"F\", \"height\": 55, \"weight\": 74 } ]"
);
```

**Notes**
Stacking the data can cause non-obvious data errors. Values that are supposed to be in the same row might not be. Here’s an example of stacking data:
```javascript
d = "\n{   "toys": [
```
The first toy should be red and have 2 wheels. The second toy should be large and have 4 wheels.

**JSON To List** *(JSON string)*

**Description**
Converts quoted JSON string to a JSL list that represents the structure specified by the JSON data. The parsing of an empty value, "" string, missing value, or any other invalid value returns {}.

**Example**
```
JSON To List( "[ { \"name\": \"KATIE\", \"age\": 12, \"sex\": \"F\", \"height\": 59, \"weight\": 95 }, { \"name\": \"LOUISE\", \"age\": 12, \"sex\": \"F\", \"height\": 61, \"weight\": 123 }, { \"name\": \"JANE\", \"age\": 12, \"sex\": \"F\", \"height\": 55, \"weight\": 74 } ]" );
```

**Show( 1 );**

---

**JSON Literal** *(JSON string)*

**Description**
Returns a valid JSON Boolean or null constant based on the specification of the parameter. The parsing of an empty value, "" string, missing value, or any other invalid value returns Empty().

---

Figure 2.1  Example of Stacking Data that Shows Errors
Last Modification Date(path)

Description
Returns the last modification date of the path.

Returns
Last modification date.

Arguments
path The quoted directory or file name.

Load Text File(path, <Charset(character set),
Force("Throw"|"Alert"|"Silent")>, <Line Separator(character)>,
"XMLParse"|"SASODSXML"|"JSON"|<BLOB(<arguments>)>)

Description
Reads the text file at path into a JSL variable.

Returns
A quoted string.

Required Argument
path A quoted pathname that points to a text file. The path can be a URL.

Optional Arguments
Charset("character set") Specifies the character set. Valid character sets are "Best
Guess", "utf-8", "utf-16", "us-ascii", "windows-1252", "x-max-roman",
"x-mac-japanese", "shift-jis", "euc-jp", "utf-16be", and "gb2312".
Force("Throw"|"Alert"|"Silent") Specifies what happens if the character set cannot
be detected.
Line Separator(character) Specifies the quoted end-of-line character. For example,
"\n" specifies a line feed character. "\t" specifies a tab.
"XMLParse" Converts an XML file into JSL.
"SASODSXML" Parses the text file as SAS ODS default XML.
"JSON" Converts JSON into an expression tree.
BLOB(<arguments>) Returns data from the file as a blob rather than a quoted string. The
following optional arguments are for reading parts of the file:
- ReadOffsetFromBegin(n) specifies the zero-based offset to begin reading from the
  beginning of the file.
- ReadOffsetFromEnd(n) specifies the zero-based offset to begin reading from the end of
  the file.
- ReadLength(n) specifies the number of bytes to read from the file, either from the
  beginning of the file or from one of the offset values.
– Base64Compressed(Boolean) specifies how the blob is converted to a printable representation. 0, the default and recommended setting, uses JMP’s ASCII-HEX representation. 1 means the blob is compressed and converted to base 64 when printed.

Move Directory(from path, to path)

Description
Moves a directory and its contents (including subdirectories) from the quoted path to another quoted path.

Returns
Returns 1 if the directory is moved; otherwise returns 0.

Arguments
from path Specifies the path and directory for relocation.
to path Specifies the destination path and directory.

Move File(from path, to path)

Description
Moves a file from the quoted path to another quoted path with the same or different file name.

Returns
Returns 1 if the file is moved. Otherwise, it returns 0.

Arguments
from path Specifies the quoted path and file name for relocation.
to path Specifies the quoted destination path and file name.

Notes
On Windows, when you move a file to a folder that does not exist, Windows creates the folder and returns 1. On macOS, the folder is not created, and an error is returned.

Open(path, arguments)

Description
Opens the data table or other JMP file or object created from a file named by the path. If no path is specified, the Open window appears. Also opens JSON and HDF5 files. See the examples in the JMP Scripting Index in the Help menu for more information about which arguments apply to specific file types.

Required Argument
path The quoted path to the file that you want to open.
Optional Arguments

Add to Recent Files (Boolean) Determines whether the file is added to the Recent Files list in the Home Window.

Charset (character set) The available character set options for importing text files are "Best Guess", "utf-8", "utf-16", "us-ascii", "windows-1252", "x-max-roman", "x-mac-japanese", "shift-jis", "euc-jp", "utf-16be", and "gb2312".

Column Names Start (n) | Column Names are on Line (n) Specifies the line number that column names start in the imported text file. If the text file uses returns between cells, column names could be on multiple lines.

Columns (column=colType(colWidth),...) Specifies the columns by name in the text file to import into a data table where:
- column: Specifies the column name used in the imported text file.
- colType("Character"|"Numeric"): Specifies whether the specified column contains character or numeric data.
- colWidth(n): Specifies the integer width of the specified column.

Columns (<arguments>) For ESRI shapefiles (.shp), this argument and its settings indicate the following:
- Shape=numeric(n): Specifies the column number in the imported ESRI shapefile that contains the shape number.
- Part=numeric(n): Specifies the column number in the imported ESRI shapefile that contains the part number.
- X=numeric(n): Specifies the column number in the imported ESRI shapefile that contains the decimal degree for the longitude (range of ±180°).
- Y=numeric(n): Specifies the column number in the imported ESRI shapefile that contains the decimal degree for the latitude (range of ±90°).

"Column Names Only" Returns a list of column names.

Compress Allow List Check (Boolean) Specifies that JMP can compress data table created from the imported text file.

Compress Character Columns (Boolean) Specifies that JMP should compress data table columns that contain character data from the imported text file.

Compress Numeric Columns (Boolean) Specifies that JMP should compress data table columns that contain numeric data from the imported text file.

Concatenate Worksheets (Boolean) Specifies that JMP should combine the imported Excel worksheets into one data table.

Create Concatenation Column (Boolean) Specifies that JMP should combine columns from an imported Excel file into one column.

Data Starts (n) | Data Starts on Line (n) Specifies the line number where data starts in the imported text file.
Debug JSL(Boolean) Opens the specified JSL script in the Debugger instead of opening it.

End Of Field("Tab"|"Space"|"Comma"|"Semicolon"|"Other"|"None") Specifies the quoted character used to delimit the end of a field in the imported text file. To specify multiple characters, separate each character designation by a comma. If you use "Other", designate the delimiter with EOF Other() argument.

End Of Line("CRLF"|"CR"|"LF"|"Semicolon"|"Other") Specifies the quoted character used to delimit the end of a line in the imported text file. To specify multiple characters, separate each character designation by a comma. If you use "Other", designate the delimiter with EOL Other() argument.

EOF Other(char) If the imported text file uses an end-of-field character other than the one specified by End of Field(), this argument specifies the character used.

EOL Other(char) If the imported text file uses an end of line character other than the one specified by End of Line(), this argument specifies the character used.

"Excel Wizard" Opens Microsoft Excel worksheets in the Excel Import Wizard. If you omit this argument, the worksheets open directly as a data table.

File Type(type) An optional quoted string that specifies the type of file that you are opening (for example, "text", "journal", "sas", "script", "png", and "jmp"). This can be useful if your file does not have a file extension, the file extension of the file does not match the contents of the file, or you want to import a JSL BLOB. If you do not specify this string, the file opens in the default program for the file extension.

Note: The path argument should be used for a zip archive. The extension (.zip) is not required. See “Zip Archives” on page 514 in the “JSL Messages” chapter for the messages that you can send to a zip archive. The basic functionality is to get a list of files in the zip archive, to read a file in the zip archive into either a quoted string or a blob, and to write files into the zip archive. Note that reading a zip archive temporarily puts the contents into memory. Reading very large zip archives can cause errors.

"Force Refresh" Closes the specified JMP (.jrn, .jsl, .jrp, or . jmpappsource) file without saving and tries to reopen the file from disk. This argument deletes any changes made since the last time the file was opened.

HTML Table(n, <ColumnNames(n)>, <DataStarts(n)>) To import a table from an HTML web page, use the URL as the filepath. The optional n argument specifies which table number, n, on the web page to open. If you omit the value, only the first table on the page is imported. The optional ColumnNames(n) specifies the row that contains column names. The optional DataStarts(n) specifies the row on which the data begins.
Chapter 2
JSL Functions

**Tip:** If the table you are importing contains images, they are first imported as text. To load the images in your JMP data table, run the automatically generated table script named Load Pictures. A new expression column containing the images is created. See *Using JMP* for more information about expression columns.

**Ignore Columns**

Specifies the quoted column names in the JMP data table or other JMP file that should not be included in the data table.

"Invisible" Opens the file as invisible. This quoted keyword applies to these files: data table, JMP file, external, text, Excel, SAS, ESRI shapefile, and HTML. The data table appears only in the JMP Home Window and the Window menu.

**Labels**

Specifies the imported text file contains labels or column headers as the first line in the file. The default value is True.

**Lines to Read**

Specifies the number of lines in the text file to import. JMP starts counting lines after column names are read.

**Number of Columns**

Specifies the number of columns contained in the imported text file.

**Run JSL**

Runs the specified JSL file instead of opening it. Include a Boolean argument or an expression that contains a Boolean value. If the script begins with //!, which automatically runs the script, include the Boolean value (0) to open the script instead.

**Password**

Specifies the quoted password for a password-protected SAS file to avoid entering it manually. The password is not encrypted. (Password-protected Microsoft Excel files cannot be imported.)

"PDF Wizard" Opens a PDF file in the PDF Import Wizard, where you can control how data is imported.

"Private" Opens the table as invisible and without showing it in the JMP Home Window or Window menu. For example, you might create a private data table to hold temporary data that the user does not need to see. This quoted keyword applies to the following files: data table, JMP file, external, text, Excel, SAS, ESRI shapefile, or HTML. Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

**Quarantine Action**

Specifies whether scripts run when you open downloaded data tables. Also provides an option to display a window that prompts users to examine or open the data table. If they click Examine, the scripts are disabled.

**Scan Whole File**

Specifies how long JMP scans the text file to determine data types for the columns. This is a Boolean value. The default value is true; the entire file is scanned until the data type is determined. To import large files, consider setting the value to false, which scans the file for five seconds.

**Select Columns**

Specifies the quoted column names in the JMP data table or other JMP file that should be included in the data table.
"Strip Quotes" | Strip Enclosing Quotes(\textit{Boolean}) If the fields in the text file are quoted, setting this to \texttt{True} removes the quotes, and setting it to \texttt{False} does not remove the quotes. The default value is \texttt{True}.

\textbf{Table Contains Column Headers(\textit{Boolean})} Indicates the imported text file contains labels or column headers as the first line in the file. The default value is \texttt{True}.

"Text Wizard" Opens the text file in the text import window, where you can select import options. Otherwise, the Text Data Files options in the JMP preferences apply, and the text file is automatically imported as a data table.

\textbf{Treat Empty Columns as Numeric(\textit{Boolean})} Specifies that JMP should import text file columns of missing data as numeric rather than character. Possible missing value indicators are a period, a Unicode dot, NaN, or a blank quoted string. The default value is \texttt{False}.

\textbf{Use Apostrophe as Quotation Mark(\textit{Boolean})} Declares apostrophes as quotation marks in importing text files. This option is not recommended unless your data comes from a nonstandard source that places apostrophes around data fields rather than quotation marks. The default value is \texttt{False}.

\textbf{Use Labels for Var Names(\textit{Boolean})} For SAS data sets, this option specifies to use SAS labels as JMP columns names. The default value is \texttt{False}.

\textbf{Use for All Sheets(\textit{Boolean})} Indicates that JMP should use the \texttt{Worksheets} settings for all worksheets in the Excel file to be opened as a data table.

\textbf{Worksheet Settings(\textit{Boolean}, \textit{<options>})} specifies options for importing an Excel file into a JMP data table. Available options are:

- \textbf{Has Column Headers(\textit{Boolean})} specifies that the Excel file has column headers in the first row.
- \textbf{Number of Rows in Headers(\textit{n})} specifies the number of rows in the Excel file used as column headers.
- \textbf{Headers Start on Row(\textit{n})} specifies the row number in the Excel file where the column headers begin. Default is row 1.
- \textbf{Data Starts on Row(\textit{n})} specifies the row number in the Excel file where the data begins.
- \textbf{Data Starts on Column(\textit{n})} specifies the column number in the Excel file where the data begins.
- \textbf{Data Ends on Row(\textit{n})} specifies the row number in the Excel file where data ends.
- \textbf{Data Ends on Column(\textit{n})} specifies the column number in the Excel file where the data ends.
- \textbf{Replicated Spanned Rows(\textit{Boolean})} specifies that the Excel file contains spanned columns should be imported into JMP as spanned columns.
- \textbf{Suppress Hidden Rows(\textit{Boolean})} indicates that JMP should not import rows hidden in the Excel file.
– **Suppress Hidden Columns** (*Boolean*) indicates that JMP should not import columns hidden in the Excel file.

– **Treat as Hierarchy** (*Boolean*) indicates that JMP should treat multiple column headers (merged cells) as hierarchies when importing an Excel file. If True, the Excel file opens with the merged columns stacked (Tables > Stacked).

**Worksheets**("Sheet Name"|{"Sheet Name", "Sheet Name",...}|n) Opens the specified Excel file worksheet by name, all worksheets in a list of names, or the indexed number of the worksheet. If the worksheets are not specified, all worksheets in the spreadsheet open as separate data tables.

**Note:** You can import .xls worksheets from a web site by specifying worksheets arguments. .xlsx worksheets cannot be imported from a web site using `Open()`.

"XML Wizard" Opens XML files in the XML Import Wizard. If you omit this argument, the XML file opens as a data table.

**Year Rule | Two Digit Year Rule**

Indicates the year format used in the imported text file. For example, if the earliest date is 1979, use "1970-2069".

**Description**
Opens the database indicated by `dataSourceName` (or opened by the user) with the `SELECT`, `SQLFILE`, or `tableName` arguments.

**Returns**
A data table named `outputTableName`.

**Required Argument**
`dataSourceName` | "Connect Dialog" `dataSourceName` specifies the name of the data source. "Connect Dialog" shows a window from which the user selects the data source.

**Optional Arguments**
"Invisible" Creates an invisible data table that hides the table from view but lists it in the JMP Home Window and Window menu.

"Private" Hides the data table completely. Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

`outputTableName` The name of the data table in JMP.

**Example**
```
Open Database(
  "DSN=dBASE Files;DBQ=C:/Program Files/SAS/JMPPRO/16/Samples/Import Data/;",
```
 Parse JSON(JSON string)

Description

Converts JSON string into an associative array or list based on the structure of the JSON data. Convert the result to a list if the parsed JSON object contains more than one member. The parsing of an empty value, "" quoted string, missing value, or any other invalid value returns Empty().

Example

The following example converts JSON into a list:

```julia
j = Parse JSON(
    "[ { "name": "KATIE", "age": 12, "sex": "F", "height": 59, "weight": 95 }, { "name": "LOUISE", "age": 12, "sex": "F", "height": 61, "weight": 123 }, { "name": "JANE", "age": 12, "sex": "F", "height": 55, "weight": 74 } ]"
);
Show(j);
```

Pick Directory(<"Prompt">, <path>, <Show Files(Boolean)>)

Description

Prompts the user for a directory, returning the directory path as a quoted string.

Returns

The path for the directory that the user selects.

Optional Arguments

"Prompt" The quoted string appears at the top of the Browse window (Windows) or the Finder window (macOS).

path The quoted string specifies the initial directory that appears in the Pick Directory window.

Show Files(Boolean) 1 shows files in the Pick Directory window. 0 hide the files. The default is 0.
Pick File(<"Prompt">, <initial directory>, <{filter list}>, <first filter>, <Save Flag(Boolean)>, <default file>), <"Multiple">)

Description
Prompts the user to select one or more files in the Open window.

Returns
The path of the file that the user selects.

Optional Arguments
"Prompt" A quoted string. If provided, that string appears at the top of the Open window.
initial directory A quoted string that is a valid filepath to a folder. If provided, it specifies where the Open window begins. If not provided, or if it’s an empty string, the JMP Default Directory is used.
filter list A list of quoted strings that define the filetypes to show in the Open window. See the following example for syntax.
first filter An integer that specifies which of the filters in the filter list to use initially. If you use an integer that is too large or small for the list (for example, 4 for a list of 3), the first filter in the list is used.
Save Flag(Boolean) A Boolean that specifies whether the Open window or Save window is used. 0 lets the user select a file to open in JMP. 1 lets the user save a new, empty file of the selected type in the selected folder. The default value is 0.
default file The quoted name of the file that appears in the window by default.
"Multiple" The quoted name that lets the user select multiple files if the Save Flag value is 0.

Notes
Although all arguments are optional, they are also positional. For example, you cannot specify a filter list without also specifying the caption and the initial directory.
The buffer size in the computer’s physical memory affects the number of files the user can open.

Example
The following script assigns Select JMP File as the window title; shows the JMP Samples/Data directory; shows JMP Files and All Files in the File name list and selects JMP Files; displays the Open window; and shows the sample data file name Hollywood Movies.jmp.

Pick File(
"Select JMP File",
"$SAMPLE_DATA",
{"JMP Files|jmp;jsl;jrn", "All Files|*"},
1,
0,
"Hollywood Movies.jmp"
JSL Functions
Chapter 2
File Functions

});

Rename Directory(old path name, new directory name)

Description
Renames a directory without moving or copying it.

Returns
Returns 1 if the directory is renamed; otherwise, returns 0.

Arguments
old path name A quoted string that specifies the path and old directory name.
new directory name A quoted string that specifies the new directory name.

Notes
When you specify the new directory Name, include only the directory name, not the entire path.

Rename File(old path name, new file name)

Description
Renames a file without moving or copying it.

Returns
Returns 1 if the file is renamed; otherwise, returns 0.

Arguments
old path name Specifies the path and old file name.
new file name Specifies the new file name.

Notes
When you specify the new name, include only the file name, not the entire path.

Save Text File(path, text|BLOB, <Mode("Replace"|"Append")>)

Description
Returns the path name of the created file. text is quoted string.

Set Default Directory(path)

Description
Sets the default directory, which is used for resolving relative paths.

See Also
“Get Default Directory()” on page 128
Set File Search Path(path|{list of paths})

Description
Sets the current list of directories to search for opening files. Using {"."} as the path configures JMP to use the current directory.

Example
Set File Search Path( {"C:/JMP/13/source", "C:/Program Files/SAS/JMPPRO/16/Samples"} );

See Also
“Get File Search Path()” on page 129.

Set Path Variable(name, <path>)

Description
Sets the path stored in the variable.

Required Argument
name The quoted name of the variable.

Optional Argument
path The path.

TripleS Import(path, <arguments>)

Description
Imports the specified Triple-S Survey (SSS) file. The SSS format consists of a pair of files: .xml or .sss, and a .csv, .dat, or .asc file. Both sets of files must have the same root name and be in the same folder.

Required Argument
path A quoted string that contains the full path to the .xml or .sss file.

Optional Arguments
"Invisible" A quoted keyword that hides the table from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call Close(dt), where dt is the data table reference returned by TripleS Import.

Use Labels for Imported Column Names(Boolean) Converts the label names to column headings. The default value is 1.

Example
dt = TripleS Import( "C:/Data/airlines.sss", "Invisible", Use Labels for Imported Column Names( 0 ) );
Financial Functions

Double Declining Balance\((cost, \textit{salvage}, \textit{life}, \textit{period}, <\textit{factor}>)\)

**Description**
Returns the depreciation of an asset for a specified period of time. The function uses the double-declining balance method or some other depreciation factor.

**Required Arguments**
- \textit{cost} The initial cost.
- \textit{salvage} The value at the end of the depreciation.
- \textit{life} The number of periods in the depreciation cycle.
- \textit{period} The length of the period, in the same units as \textit{life}.

**Optional Argument**
- \textit{factor} The rate at which the balance declines. The default value is 2.

**Notes**
This function is equivalent to the Excel function DDB.

Future Value\((rate, \textit{nper}, \textit{pmt}, <\textit{pv}>, <\textit{Type}(\text{Boolean})>)\)

**Description**
Returns the future value of an investment that is based on periodic, constant payments and a constant interest rate.

**Required Arguments**
- \textit{rate} The interest rate.
- \textit{nper} The number of periods.
- \textit{pmt} The constant payment.

**Optional Arguments**
- \textit{pv} The present value. The default value is 0.
- \textit{Type}(\text{Boolean}) 0 specifies end-of-period payments. 1 specifies beginning-of-period payments. The default value is 0.

**Notes**
This function is equivalent to the Excel function FV.

Interest Payment\((rate, \textit{per}, \textit{nper}, \textit{pv}, <\textit{fv}>, <\textit{Type}(\text{Boolean})>)\)

**Description**
Returns the interest payment for a given period for an investment that is based on periodic, constant payments and a constant interest rate.
Required Arguments
rate The interest rate.
per The period for which you want the interest.
nper The total number of periods.
pv The present value.

Optional Arguments
fv The future value. The default value is 0.
Type(Boolean) 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Notes
This function is equivalent to the Excel function IPMT.

Interest Rate(nper, pmt, pv, <fv>, <Type(Boolean)>, <guess>)

Description
Returns the interest rate per period of an annuity.

Required Arguments
nper The total number of periods.
pmt The constant payment.
pv The present value.

Optional Arguments
fv The future value. The default value is 0.
Type(Boolean) 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.
guess Your estimate of the rate The default value is 0.1 (10%).

Notes
This function is equivalent to the Excel function RATE.

Internal Rate of Return(values, <guess>)
Internal Rate of Return(guess, value1, value2, ...)

Description
Returns the internal rate of return for a series of cash flows in the values argument.

Arguments
values A one-dimensional matrix of values. If the second form of the function is used, list each value separately.
guess What you think is near the result. The default value is 0.1 (10%). This argument is required if you specify values. It is required if you specify individual values.
Notes

This function is equivalent to the Excel function IRR.

Modified Internal Rate of Return(values, finance rate, reinvest rate)
Modified Internal Rate of Return(finance rate, reinvest rate, value1, value2, ...)

Description

Returns the modified internal rate of return for a series of periodic cash flows. The cost of investment and the interest received on reinvested cash is included.

Arguments

values A one-dimensional matrix of values. If the second form of the function is used, list each value separately.
finance rate The interest rate that you pay on the money in the cash flows.
reinvest rate The interest rate that you receive on the cash flows when you reinvest them.

Notes

This function is equivalent to the Excel function MIRR.

Net Present Value(rate, values)
Net Present Value(rate, value1, value2, ...)

Description

Returns the net present value of an investment by using a discount rate and a series of future payments (negative values) and income (positive values).

Arguments

rate The discount rate.
values A one-dimensional matrix of values. If the second form of the function is used, list each value separately.

Notes

This function is equivalent to the Excel function NPV.

Number of Periods(rate, pmt, pv, <fv>, <type(0|1)>)

Description

Returns the number of periods for an investment that is based on periodic, constant payments and a constant interest rate.

Required Arguments

rate The interest rate.
pmt The constant payment.
pv The present value.

Optional Arguments

fv The future value. The default value is 0.

type(0/1) 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Notes

This function is equivalent to the Excel function NPER.

Payment(rate, nper, pv, <fv>, <type(0/1)>)

Description

Returns the payment for a loan that is based on constant payments and a constant interest rate.

Required Arguments

rate The interest rate.

nper The total number of periods.

pv The present value.

Optional Arguments

fv The future value. The default value is 0.

type(0/1) 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Notes

This function is equivalent to the Excel function PMT.

Present Value(rate, nper, pmt, <fv>, <type(0/1)>)

Description

Returns the present value of an investment.

Arguments

rate The interest rate per period.

nper The total number of periods.

pmt The constant payment.

fv The future value. The default value is 0.

type(0/1) 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Notes

This function is equivalent to the Excel function PV.
Principal Payment(rate, per, nper, pv, <fv>, <type(0/1)>)

Description
Returns the payment on the principal for a given period for an investment that is based on periodic, constant payments and a constant interest rate.

Required Arguments
rate  The interest rate per period.
per   The period for which you want the interest.
nper  The total number of periods.
pv    The present value.

Optional Arguments
fv    The future value. The default value is 0.
type(0/1)  An optional switch. 0 specifies end-of-period payments, and 1 specifies beginning-of-period payments. The default value is 0.

Notes
This function is equivalent to the Excel function PPMT.

Straight Line Depreciation(cost, salvage, life)

Description
Returns the straight-line depreciation of an asset for one period.

Arguments
cost  The initial cost of the asset.
salvage The value at the end of the depreciation.
life  The number of periods in the depreciation cycle.

Notes
This function is equivalent to the Excel function SLN.

Sum Of Years Digits Depreciation(cost, salvage, life, per)

Description
Returns the sum-of-years’ digits depreciation of an asset for a specified period.

Arguments
cost  The initial cost of the asset.
salvage The value at the end of the depreciation.
life  The number of periods in the depreciation cycle.
per   The length of the period, in the same units as life.

Notes
This function is equivalent to the Excel function SYD.
Add Color Theme({name, <flags>, {color}, <{position}>})

**Description**

Creates a custom color theme that you can apply to components such as markers, data table rows, and treemaps. Add the color theme to the JMP Preferences by including `Add Color Theme(...)` inside `Preferences()`.

**Returns**

Null.

**Required Arguments**

- **name**  The quoted name of the color theme.
- **color** Lists of RGB values. These values define the blocks in categorical color themes and the gradients in continuous color themes. Each list of RGB values corresponds to a slider in the preferences Color Themes window.
- **position** An optional list of numbers between 0 and 1 with one position per color. Each position corresponds to a slider in the preferences Color Themes window. If you omit the position, the sliders are evenly spaced.

**Optional Argument**

- **flags** A flag for the Continuous or Categorical color theme list and category of color.

  - Continuous, <Continuous>, Sequential
  - Continuous, <Continuous>, Diverging
  - Continuous, <Continuous>, Chromatic
  - Categorical, <Continuous>, Sequential
  - Categorical, <Continuous>, Diverging
  - Categorical, Qualitative
  - Categorical, <Continuous>, Chromatic

  With the default JMP color themes, Sequential colors transition from left to right or right to left. Diverging colors are lighter in the middle. Chromatic colors consist of blocks or gradients of bright color. All categories except for Qualitative can be both continuous and categorical.

  If you omit the flag, the color is shown in the Continuous, Sequential and Categorical, Sequential categories.

**Examples**

The following example creates a continuous color theme named Blue to Purple. The color is in the Diverging category. RGB values are defined in the four lists.

```javascript
Add Color Theme(
    "Blue to Purple", "Continuous", "Diverging",
    {{0, 0, 255}, {57, 108, 244}, "white", {128, 0, 100}}
);
```
Notes
Any style except for Qualitative can be Continuous and Categorical at the same time. For example, the Cool to Warm Diverging theme is in the Continuous and Categorical theme lists. In JMP, select Preferences > Graphs to see examples.
To delete a color theme, use Remove Color Theme().

See Also
“Remove Color Theme(name|{name, <flags>, {color, ...}, <|position, ...>|}>)” on page 165

Arc(x1, y1, x2, y2, startangle, endangle)

Description
Inscribes an arc in the rectangle described by the arguments.

Returns
Null.

Arguments
x1, y1 The point at the top left of the rectangle
x2, y2 The point at the bottom right of the rectangle
startangle, endangle The starting and ending angle in degrees, where 0 degrees is 12 o’clock and the arc or slice is drawn clockwise from startangle to endangle.

Arrow(<pixellength>, {x1, y1}, {x2, y2})

Description
Draws an arrow from the first point to the second point. The optional first argument specifies the length of the arrow’s head lines (in pixels).

Returns
Null.

Required Arguments
{x1, y1}, {x2, y2} Two lists of two numbers that each specify a point in the graph.

Optional Argument
pixellength The length of the arrowhead in pixels.

Notes
The two points can also be enclosed in square brackets: Arrow(<pixellength>, [x1, x2], [y1, y2]).

Back Color(name)

Description
Sets the color used for filling the graph’s background.
Chapter 2 JSL Functions

JSL Syntax Reference Graphics Functions

**Char To Path**(path)

**Description**
Converts a path specification from a quoted string to a matrix.

**Returns**
A matrix.

**Arguments**
path A quoted string that contains the path specification.

**Circle**({x, y}, radius|PixelRadius(n), <...>, <"Fill">)

**Description**
Draws a circle centered at {x, y} with the specified radius.

**Returns**
Null.

**Required Arguments**
{x, y} A number that describes a point in the graph
radius The length of the circle’s radius in relation to the vertical axis. If the vertical axis is resized, the circle is also resized.
PixelRadius(n) The length of the circle’s radius in pixels. If the vertical axis is resized, the circle is not resized.

**Optional Argument**
"Fill" A positional argument indicating that all circles defined in the function are filled with the current fill color. If "Fill" is omitted, the circle is empty.

**Notes**
The center point and the radius can be placed in any order. You can also add additional center point and radius arguments and draw more than one circle in one statement. One point and several radii results in a bull’s-eye. Adding another point still draws all previous circles, and then adds an additional circle with the last radius specified. This means that this code:
Graph Box(circle({20, 30}, 5, {50, 50}, 15))
results in three circles, not two. First, a circle with radius 5 is drawn at 20, 30. Second, a circle with radius 5 is drawn at 50, 50. Third, a circle with radius 15 is drawn at 50, 50.
**Color To HLS(color)**

**Description**
Converts the `color` argument (including any JMP color) to a list of HLS values.

**Returns**
A list of the hue, lightness, and saturation components of `color`. The values range between 0 and 1.

**Argument**

`color` A number from the JMP color index.

**Example**
The output from `ColorToHLS()` can either be assigned to a single list variable or to a list of three scalar variables:

```jscript
hls = Color To HLS( 8 );
{h, l, s} = Color To HLS( 8 );
Show( hls, h, l, s );
    hls = {0.778005464480874, 0.509803921568627, 0.976};
    h = 0.778005464480874;
    l = 0.509803921568627;
    s = 0.976;
```

---

**Color To RGB(color)**

**Description**
Converts the `color` argument (including any JMP color) to a list of RGB values.

**Returns**
A list of the red, green, and blue components of `color`. The values range between 0 and 1.

**Argument**

`color` A number from the JMP color index.

**Example**
The output from `ColorToRGB()` can either be assigned to a single list variable or to a list of three scalar variables:

```jscript
rgb = Color To RGB( 8 );
{r, g, b} = Color To RGB( 8 );
Show( rgb, r, g, b );
    rgb = {0.670588235294118, 0.0313725490196078, 0.988235294117647};
    r = 0.670588235294118;
    g = 0.0313725490196078;
    b = 0.988235294117647;
```

---

**Contour(xVector, yVector, zGridMatrix, zContour, <messages>)**

**Description**
Draws contours given a grid of values.
Returns
None.

Required Arguments

- **xVector** The \( n \) values that describe \( z\text{GridMatrix} \).
- **yVector** The \( m \) values that describe \( z\text{GridMatrix} \).
- **zGridMatrix** An \( n \times m \) matrix of values on some surface.
- **zContour** The values for the contour lines.

Optional Messages

- **<<zColor(color, option)** The colors to use for the contour lines.
- **"Fill"|"Fill Between"|"Fill Below"|"Fill Above"** Specifies where the contour fill appears.
- **<<Transparency(vector)** Specifies the transparency level of the fill in a vector.

Contour Function(\( z\text{Expr}, x\text{Name}, y\text{Name}, (z|z\text{Matrix}), < <<x\text{Grid}(\text{min}, \text{max}, \text{incr})), < <<y\text{Grid}(\text{min}, \text{max}, \text{incr})), < <<z\text{Color}(\text{color}, \text{option})), < <<z\text{Labeled}>, < <<"Filled">, < <<"FillBetween">, < <<"Ternary">, < <<Transparency(number|matrix))

Description

Draws sets of contour lines of the expression, a function of the two symbols. The \( z \) argument can be a single value or an index or matrix of values.

Returns
None.

Arguments

- **zExpr** Any expression (for example, \( \text{Sine}(y)+\text{Cosine}(x) \)).
- **xName, yName** The values to use in the expression.
- **z|zMatrix** A \( z \)-value or a matrix of \( z \)-values.

Optional Messages

- **<<xGrid, <<yGrid** Defines a box, beyond which the contour lines are not drawn.
- **<<zColor** Defines the color in which to draw the contour lines. The argument can be either a scalar or a matrix but must evaluate to numeric.
- **<<zLabeled** Labels the contours.
- **"Filled"** Fills the contour levels using the current fill color.
- **"FillBetween"** Fills only between adjacent contours using the current fill color. For \( nz \) contours specified, this option fills \( nz-1 \) regions for the intervals between the \( nz \) values. Using this option is recommended over using the \( <<\text{Filled} \) option.
- **"Ternary"** Clips lines to be within the ternary coordinate system inside ternary plots.
- **<<Transparency(number|matrix)** Sets the transparency level of the fill. A vector of numbers between 0 and 1 are sequenced through and cycled for the \( z \) contours. This option should be used only in conjunction with the \( <<\text{FillBetween} \) option.
Drag Line(xMatrix, yMatrix, <dragScript>, <mouseUpScript>)

Description
Draws line segments between draggable vertices at the coordinates given by the matrix arguments.

Returns
None.

Required Arguments
- xMatrix A matrix of x-coordinates.
- yMatrix A matrix of y-coordinates.

Optional Arguments
- dragScript Any valid JSL script. The script is run at drag.
- mouseUpScript Any valid JSL script. The script is run at mouseup.

Drag Marker(xMatrix, yMatrix, <dragScript>, <mouseUpScript>)

Description
Draws draggable markers at the coordinates given by the matrix arguments.

Returns
None.

Arguments
- xMatrix A matrix of x-coordinates.
- yMatrix A matrix of y-coordinates.
- dragScript Any valid JSL script. The script is run at drag.
- mouseUpScript Any valid JSL script. The script is run at mouseup.

Drag Polygon(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

Description
Draws a filled polygon with draggable vertices at the coordinates given by the matrix arguments.

Returns
None.

Required Arguments
- xMatrix A matrix of x-coordinates.
- yMatrix A matrix of y-coordinates.

Optional Arguments
- dragScript Any valid JSL script. The script is run at drag.
- mouseUpScript Any valid JSL script. The script is run at mouseup.
Drag Rect(xMatrix, yMatrix, <dragScript>, <mouseupScript>)

**Description**
Draws a filled rectangle with draggable vertices at the first two coordinates given by the matrix arguments.

**Returns**
None.

**Required Arguments**
- `xMatrix` A matrix of two x-coordinates.
- `yMatrix` A matrix of two y-coordinates.

**Optional Arguments**
- `dragScript` Any valid JSL script. The script is run at drag.
- `mouseupScript` Any valid JSL script. The script is run at mouseup.

**Notes**
`xMatrix` and `yMatrix` should each contain exactly two values. The resulting coordinate pairs should follow the rules for drawing a `Rect()`. The first point (given by the first value in `xMatrix` and the first value in `yMatrix`) must describe the top, left point in the rectangle. The second point (given by the second value in `xMatrix` and the second value in `yMatrix`) must describe the bottom, right point in the rectangle.

Drag Text(xMatrix, yMatrix, string, <dragScript>, <mouseupScript>)

**Description**
Draws the `string` (or all the items if a list is specified) at the coordinates given by the matrix arguments.

**Returns**
None.

**Arguments**
- `xMatrix` A matrix of x-coordinates.
- `yMatrix` A matrix of y-coordinates.
- `string` A quoted string to be drawn in the graph.
- `dragScript` Any valid JSL script. The script is run at drag.
- `mouseupScript` Any valid JSL script. The script is run at mouseup.

Fill Color(name|color|rgbList)

**Description**
Sets the color used for filling solid areas.

**Returns**
None.
Fill Pattern(name|mask|image)

Description
Sets the pattern for filled areas.

Arguments
name|mask|image The quoted color name, matrix of values between 0 and 1, or image path.

Get Color Theme Detail(name)

Description
Returns a script for the specified color theme.

Example
The following example returns the script for the JMP default color theme:

Get Color Theme Details( "JMP Default" );

{"JMP Default", 9221, {{213, 72, 87}, {57, 177, 67}, {64, 111, 223}...}}

Get Color Theme Names(<kind>)

Description
Returns a list of all color theme names or color themes of the specified kind. The kinds include "Continuous", "Categorical", "Sequential", "Diverging", "Qualitative", or "Chromatic".

Example
The following example returns all color themes:

Get Color Theme Names();

{"Green to Black to Red", "Green to White to Red", "White to Black"...} 

The following example returns the diverging color themes:

Get Color Theme Names( "diverging" );

{"Green to Black to Red", "Green to White to Red", "Blue to Gray to Red"...}

Gradient Function(zExpr, xName, yName, [zLow, zHigh], zColor([colorLow, colorHigh]), <<<xGrid(min, max, incr)>, <<<yGrid(min, max, incr)> < <<Transparency(alpha|vector))

Description
Fills a set of rectangles on a grid according to a color determined by the expression value as it crosses a range corresponding to a range of colors.
Required Arguments

- \textit{zExpr}: Any expression (for example, \texttt{Sine(y)+Cosine(x)}).
- \textit{xName, yName}: The values to use in the expression.
- \textit{zLow, zHigh}: A matrix of low and high values (2 to 10).
- \textit{zColor([colorLow, colorHigh])}: The two colors that are blended together (4 is green, 6 is orange).

Optional Messages

- \texttt{<<xGrid, <<yGrid}: Specifies a box, beyond which the gradients are not drawn.
- \texttt{<<zColor}: The color in which to draw the contour lines. The argument can be either a scalar or a matrix but must evaluate to numeric.
- \texttt{<<Transparency(number|matrix)}: The transparency level of the fill. A vector of numbers between 0 and 1 are sequenced through and cycled for the z contours.

Example

\begin{verbatim}
Gradient Function(Log(a * a + b * b),
a, b, [2 10],
zColor([4, 6]));
\end{verbatim}

- \texttt{H Line(x1, x2, y)}
- \texttt{H Line(y)}

\textbf{Description}

- Draws a horizontal line at \textit{y} across the graph. If you specify start and end points on the \textit{x}-axis (\textit{x1} and \textit{x2}), the line is drawn horizontally at \textit{y} from \textit{x1} to \textit{x2}. You can also draw multiple lines by using a matrix of values in the \textit{y} argument.

- \texttt{H Size()}

\textbf{Description}

- Returns the horizontal size of the graphics frame in pixels.

- \texttt{Handle(xPos, yPos, dragScript, mouseUpScript)}

\textbf{Description}

- Places draggable marker at coordinates given by \textit{xPos, yPos}. The first script is executed at drag and the second at mouseup.

- \texttt{Heat Color(x, <<<<theme>>)}
- \texttt{Heat Color(x)}

\textbf{Description}

- Returns the JMP color that corresponds to \textit{n} in the color "\textit{theme}".
Returns
An integer that is a JMP color.

Required Argument
\( x \) A value between 0 and 1.

Optional Message
\( \text{theme} \) A quoted color theme that is supported by Cell Plot. The default value is "Blue to Gray to Red".

HLS Color(\( h, l, s \))
HLS Color({\( h, l, s \)})

Description
Converts hue, lightness, and saturation values into a JMP color number.

Returns
An integer that is a JMP color number.

Arguments
Hue, lightness, and saturation, or a list containing the three HLS values. All values should be between 0 and 1.

In Path(x, y, (pathMatrix|pathText))

Description
Determines if the point described by \( x \) and \( y \) falls in \( path \).

Returns
True (1) if the point \((x, y)\) is in the given path, False(0) otherwise.

Arguments
\( x \) and \( y \) The coordinates of a point.

\( \text{pathMatrix|pathText} \) Either a matrix or a quoted string describing a path.

In Polygon(x, y, xMatrix, yMatrix)
In Polygon(x, y, xyPolygon)

Description
Returns 1 or 0, indicating whether the point \((x, y)\) is inside the polygon that is defined by the \( x\text{Matrix} \) and \( y\text{Matrix} \) vector arguments.

\( x\text{Matrix}, y\text{Matrix} \) can also be combined into a two-column matrix \((\text{xyPolygon})\), allowing you to use three arguments instead of four. Also, \( x \) and \( y \) can be conformable vectors, and then a vector of 0s and 1s are returned based on whether each \((x, y)\) pair is inside the polygon.
Level Color(i)
Level Color(i, n)
Level Color(i, n, <theme>)
Level Color(i, <theme>)

**Description**
Assigns a JMP color to categorical data in a graphic.

**Returns**
An integer that is a JMP color.

**Required Arguments**
- i An integer that is greater than or equal to 1 and less than or equal to the number of categories specified by n.
- n The number of categories.

**Optional Argument**
- theme A quoted color theme from the Value Color list of the Column Properties window. If not specified, the JMP Default color theme is applied.

**Notes**
When the second argument is a quoted character string and not n, then the second argument determines the color theme.

Line({x1, y1}, {x2, y2}, ...), <<ValueSpace(Boolean)
Line([[x1, x2, ...], [y1, y2, ...]], <<ValueSpace(Boolean))

**Description**
Draws a line between points.

**Arguments**
- {x1, y1}, {x2, y2}|[x1, x2, ...], [y1, y2, ...] Can be any number of lists of two points, separated by commas or a matrix of x values and a matrix of y values.

**<<ValueSpace(Boolean)** Draws lines that follow the projection when the line represents a movement of the underlying data, such as a bubble trail in a bubble plot. The Boolean value can be a constant or an expression.

Line Style(name|number)

**Description**
Sets the line style used to draw the graph.

**Argument**
- n Can be either a quoted style name or the style’s number:
  - 0 or "Solid"
1 or "Dotted"
2 or "Dashed"
3 or "DashDot"
4 or "DashDotDot"

Marker(<rowState>, {x1, y1}, {x2, y2}, ...)
Marker(<rowState>, [x1, x2, ...], [y1, y2, ...])

Description
Draws one or more markers at the points described either by lists or matrices. The optional rowState argument sets the type of marker.

Marker Size(n)
Description
Sets the size used for markers.

Mousetrap(dragScript, mouseUpscript)
Description
Captures click coordinates to update graph properties. The first script is executed at drag and the second script at mouseup.

New Heat Image(matrix, <colorTheme>)
Description
Creates a heat map image based on a matrix and color theme or gradient.

Arguments
matrix A matrix of values. The function creates a heat map that has the same dimensions as the input matrix.

colorTheme A color theme or set of gradient properties that define the mapping of values to colors. The example below shows the use of a custom gradient.

Example
width = 256;
height = 256;
wstride = 16;
hstride = 16;
b = J(hstride, wstride, Random Normal() );
a = Transform Each( {z, {row, col}},
J( height, width, 0 ),
b[Floor( (row - 1) / hstride ) + 1,
Floor( (col - 1) / wstride ) + 1]
E1 = New Heat Image(a, gradient(
    {Color Theme( "Blue To Gray To Orange" ),
    Scale Type( "Standard Deviation" ),
    Show Missing Color( "On" ),
    Reverse Gradient( 1 )}
));
New Window( "test", Lineup Box( E1 ));

Normal Contour(prob, meanMatrix, stdMatrix, corrMatrix, <colorsMatrix>, <fill=x>)

Description
Draws normal probability contours for \( k \) populations and two variables.

Required Arguments
- prob: A scalar or matrix of probabilities.
- meanMatrix: A matrix of means of size \( k \) by 2.
- stdMatrix: A matrix of standard deviations of size \( k \) by 2.
- corrMatrix: A matrix of correlations of size \( k \) by 1.

Optional Arguments
- colorsMatrix: Specifies the color(s) for the \( k \) contour(s). The colors must be specified as JSL colors (either JSL color integer values or return values of JSL Color functions such as RGB Color or HLS Color).
- fill=x: Specifies the amount of transparency for the contour fill color.

Oval(x1, y1, x2, y2, <Fill(Boolean)>)

Description
Draws an oval inside the rectangle whose diagonal has the coordinates \((x1, y1)\) and \((x2, y2)\). \texttt{Fill} is Boolean. If \texttt{Fill} is 0, the oval is empty. If \texttt{Fill} is nonzero, the oval is filled with the current fill color. The default value for \texttt{Fill} is 0.

Path((pathMatrix|pathText), <Fill(Boolean)>)

Description
Draws a stroke along the given path. If a fill is specified, the interior of the path is filled with the current fill color.
Required Arguments

- `pathMatrix` An N×3 matrix. If you don’t specify the path matrix, specify the path text.
- `pathText` A quoted string that contains SVG code.

Optional Arguments

- `Fill(Boolean)` Specifies whether a line is drawn (0) or the path is filled (1). The default value is 0.

Notes

A path matrix has three columns, for x and y, and a flag. The flag value for each point can be 0 for control, 1 for move, 2 for line segment, 3 for cubic Bézier segment, and any negative value to close the path.

---

Path To Char(`path`)

**Description**

Converts a path specification from a matrix to a quoted string.

**Returns**

A quoted string.

**Argument**

- `path` An N×3 path matrix.

**Notes**

A path matrix has three columns, for x and y, and a flag. The flag value for each point can be 0 for control, 1 for move, 2 for line segment, 3 for cubic Bézier segment, and any negative value to close the path.

---

Pen Color(`n`)

**Description**

Sets the color used for the pen.

---

Pen Size(`n`)

**Description**

Sets the thickness of the pen in pixels.

---

Pick Color(`<window title>`, `<name|index|RGBlist>`)  

**Description**

Creates a color picker, which enables the user to select a color to apply to graphs. The operating system color picker lets users select a predefined color or create their own color. You can also specify a default color in your script. If you omit the default color, Black is selected.
Returns
The color that the user selected in the operating system's color picker.

Arguments
- window title: The quoted title of the color picker window.
- name: The name of the default JMP color.
- index: The number of the default JMP color.
- RGBlist: The RGB values of the default color.

Pie(left, top, right, bottom, startAngle, endAngle)

Description
Draws a filled pie slice. The two points describe a rectangle, within which is a virtual oval. Only the slice described by the start and end angles is drawn.

Pixel Line To(h, v)

Description
Draws a one-pixel-wide line from the current pixel location to the location given in pixel coordinates. Set the current pixel location using the Pixel Origin() and Pixel Move To() functions.

Pixel Move To(h, v)

Description
Moves the current pixel location to a new location given in pixel coordinates.

Pixel Origin(x, y)

Description
Sets the origin, in graph coordinates, for subsequent Pixel Line To() or Pixel Move To() functions.

Polygon({x1, y1}, {x2, y2}, ...)
Polygon(xMatrix, yMatrix)

Description
Draws a filled polygon defined by the listed points.
Polygon Area({x1, y1}, {x2, y2}, ...)

Polygon Area(xMatrix, yMatrix)

Description
Calculates the area of the specified polygon.

Examples
area = Polygon Area( {0, 0}, {0, 10}, {10, 10}, {10, 0} );
area = Polygon Area( [10 20 30], [10 30 20] );

Polygon Centroid({x1, y1}, {x2, y2}, ...)

Polygon Centroid(xMatrix, yMatrix)

Description
Calculates the centroid of the specified polygon.

Examples
{cx, cy} = Polygon Centroid( {0, 0}, {0, 10}, {10, 10}, {10, 0} );
centroid = Polygon Centroid( [10 20 30], [10 30 20] );

Pixel Path(h, v, (path matrix|path text), <fill=Boolean>, <scale=n>, <orient={n, n}>)

Description
Draws a stroke along the given pixel-based path if the fill is 0, or paints the interior of the path if the fill is not 0.

Required Arguments
h, v Specifies the horizontal and vertical position.
path matrix Contains three columns for h, v, and flags for each point in the path. The flag values are 0 for control, 1 for move, 2 for line segment, 3 for cubic Bézier segment, and are negative if the point also closes the path. Each flag (one for each point) can be 0, 1, 2 or 3, (or negative, if it closes the shape).
If you don’t specify the path matrix, specify the path text.
path text Supports SVG syntax. The path is scaled (scale) and translated about its origin according to the optional parameters (fill and orient), with the orientation specified in the axis space.

Optional Arguments
fill(Boolean) 0 fills the shape. 1 draws an empty shape.
orient Rotates the object. For example, an orientation of {Sqrt( 2 ), Sqrt( 2 )} draws the shape on a 45-degree angle.
scale Sizes the object. For example, a scale of 1.0 draws the shape as it is defined; a scale of 2.0 draws it twice as big; and a scale of 0.5 draws it half as big.
Pixel Text(<properties>, \{h, v\}, text, ...)  

**Description**  
Moves to the \{h, v\} pixel position and draws text that the quoted `text` argument specifies.

**Required Arguments**  
- `h` The horizontal pixel position.  
- `v` The vertical pixel position.  
- `text` The quoted string to display at the start and end of the pixels.

**Optional Arguments**  
- `center justified` Center justifies the text.  
- `right justified` Right justifies the text.  
- `erased` Omits pixels from the edges of the rectangle of text. The text is drawn over the graph content in the background color, erasing the graph within the rectangle to make the text more readable.  
- `boxed` Displays a box around the text.  
- `counterclockwise` Rotates the text counterclockwise.  
- `clockwise` Rotates the text clockwise.

---

Rect(`left`, `top`, `right`, `bottom`, \<Fill(Boolean)\>)  
Rect(`\{left, top\}`, `{right, bottom}`, \<Fill(Boolean)\>)  

**Description**  
Draws a rectangle whose diagonal has the coordinates (`left`, `top`) and (`right`, `bottom`). \`Fill\` is Boolean. If \`Fill\` is 0, the rectangle is empty. If \`Fill\` is nonzero, the rectangle is filled with the current fill color. The default value for \`Fill\` is 0.

---

Remove Color Theme(`name`\{|\`name`, `<flags>`, `{color, ...}`, `{position, ...}`\}|)`  

**Description**  
Removes a custom color theme from the global list, either by name or by the full color theme object.

**Required Arguments**  
- `name` The quoted name of the color theme.  
- `color` The RGB values for the color.

**Optional Arguments**  
- `flags` A number that represents metadata such as whether the theme is continuous or categorical. Run `Get Color Theme Details("name")` on the color theme and use the flag that is returned.  
- `position` A number between 0 and 1. There is one number per color that indicates where on the gradient that color is, where 0 is the beginning and 1 is the end.
Example

```plaintext
Remove Color Theme( {"Yellow Blue", 0, {{255, 255, 0}, {0, 0, 255}}, {0.0, 1.0}} );
```

---

**RGB Color(r, g, b)**

**Description**

Converts red, green, and blue values into a JMP color number.

**Returns**

An integer that is a JMP color number.

**Arguments**

Red, green, and blue, or a list containing the three RGB values. All values should be between 0 and 1.

---

**Text(<properties>, ({x, y}|{left, bottom, right, top}), text)**

**Description**

Draws the quoted string `text` at the given point, either the x and y axes or the left, bottom, right, and top axes.

Properties can be any of several named arguments: Center Justified, Right Justified, Erased, Boxed, Counterclockwise, Position, and named arguments. The position, named arguments, and quoted strings can be added in any order. The position and named arguments apply to all the strings.

---

**Text Color(n)**

**Description**

Sets the color for text strings.

---

**Text Font(fontName, <size>, <bold italic underline strikeout>, <angle>)**

**Description**

Sets the font for text strings. Use without arguments to get the current font properties. Angle is in degrees clockwise.

Quote the font properties. To apply multiple properties, specify them together, as in "bold italic".

---

**Text Size(n)**

**Description**

Sets the font size in points for text strings.
Transparency($alpha$)

**Description**
Sets the transparency of the current drawing, with $alpha$ between 0 and 1 where 0 is clear (no drawing) and 1 is completely opaque (the default).

**Notes**
Not all operating systems support transparency.

V Line($x$, <$y_1$, $y_2$>)

**Description**
Draws a vertical line at $x$ across the graph. If you specify start and end points on the $y$-axis ($y_1$ and $y_2$), the line is drawn vertically at $x$ from $y_1$ to $y_2$. You can also draw multiple lines by using a matrix of values in the $x$ argument.

V Size()

**Description**
Returns the vertical size of the graphics frame in pixels

X Function($zExpr$, $yName$, <$Min(min)$, $Max(max)$, $Fill(Boolean)$, $Inc(upper bound)$)

**Description**
Draws a plot of the function as the $yName$ is varied over the $y$-axis of the graph.

X Origin()

**Description**
Returns the $x$-value for the left edge of the graphics frame.

X Range()

**Description**
Returns the distance from the left to right edge of the display box. For example, $X\ Origin() + X\ Range()$ is the right edge.

X Scale($xMin$, $xMax$)

**Description**
Sets the range for the horizontal scale. The default value for $xMin$ is 0. The default value for $xMax$ is 100.
XY Function\((x(t), y(t), t, \text{Min}(min), \text{Max}(max), (\text{Inc}(bound) | \text{Steps}(min)))\)

**Description**

Combines an expression of \(x(t)\) and \(y(t)\) to draw an x-y curve for the specified range of parameter \(t\). Each time \(t\) it is varied between Min and Max, the \(x\) and \(y\) expressions are evaluated using the current value of \(t\).

**Note:** Either \(\text{Inc()}\) or \(\text{Steps()}\) is needed if the default granularity misses details.

Y Function\((y\text{Expr}, x\text{Name}, <\text{Min}(min), \text{Max}(max), \text{Fill}(\text{Boolean}), \text{Inc}(bound)>)\)

**Description**

Draws a plot of the function as the symbol is varied over the \(x\)-axis of the graph.

Y Origin()

**Description**

Returns the \(y\)-value for the bottom edge of the graphics frame.

Y Range()

**Description**

Returns the distance from the bottom to top edges of a display box. For example, \(Y\ Origin() + Y\ Range()\) is the top edge.

Y Scale\((y\text{Min}, y\text{Max})\)

**Description**

Sets the range for the vertical scale. If you do not specify a scale, it defaults to 0, 100.

**HTTP Functions**

Decode 64 Blob\((string)\)

**Description**

Decodes the quoted string using Base-64 encoding.

Encode 64 Blob\((string)\)

**Description**

Encodes the quoted string using Base-64 encoding.
List Functions

As List(matrix)

Description
Converts a matrix into a list. Multi-column matrices are converted to a list of row lists.

Returns
A list.

Argument
matrix Any matrix.

Concat Items({string1, string2, ...}, <delimiter>)

Description
Converts a list of quoted string expressions into one string, with each item separated by a delimiter. The delimiter is a blank if unspecified.

Returns
The concatenated quoted string.

Arguments
string Any quoted string.
delimiter An optional quoted string that is placed between each item. The delimiter can be more than one character long.

Example
str1 = "one";
str2 = "two";
str3 = "three";
comb = Concat Items({str1, str2, str3});
"one two three"
comb = Concat Items({str1, str2, str3}, " : ");
"one : two : three"
del = ";";
comb = Concat Items({str1, str2, str3}, del);
"one,two,three"

Eval List({list})

Description
Evaluates expressions inside list.

Returns
A list of the evaluated expressions.
Arguments
list A list of valid JSL expressions.

Insert(source, item, <position>)

Insert(source, key, value)

Description
Inserts a new item into the source at the given position. If position is not given, item is added to the end.

For an associative array: Adds the key into the source associative array and assigns value to it. If the key exists in source already, its value is overwritten with the new value.

Required Arguments
source A quoted string, list, vector, expression, or associative array.
item|key Any value to be placed within source. For an associative array, key might or might not be present in source.
value A value to assign to the key.

Optional Arguments
position Optional numeric value that specifies the position in source to place the item into.

Insert Into(source, item, <position>)

Insert Into(source, key, value)

Description
Inserts a new item into the source at the given position in place. The source must be an L-value.

Arguments
source A variable that contains a quoted string, list, vector, display box, expression, or associative array.
item|key Any value to be placed within source. For an associative array, key might be present in source.
position Optional numeric value that specifies the position in source to place the item into.
value A value to assign to the key.

Is List(x)

Description
Returns 1 if the evaluated argument is a list, or 0 otherwise.
Items(string, <delimiter>, <Include Boundary Delimiters(Boolean)>)

Description
Returns a list of (possibly empty) quoted sub-strings separated by exactly one of any of the characters specified in the delimiter argument.

Arguments
- string: The quoted string that is evaluated.
- Delimiter (Optional): The character used as a boundary. If delimiter is absent, an ASCII space is used. If delimiter is the empty quoted string, each character is treated as a separate word.
- Include Boundary Delimiters(Boolean) (Optional): Returns the empty strings between the boundary and the delimiter.

Example
Items( "http://www.jmp.com", ":/." );
{"http", "", "", "www", "jmp", "com"}

Items(",toy", ",");
{"toy"}

Items(",toy", ",", Include Boundary Delimiters( 1 ));
{"", "toy", ""}

/* There is no text between the boundary (the beginning of the quoted string) and the comma delimiter, so you get an empty string. The same principle applies to the delimiter at the end of the string. */

List(a, b, c, ...)
\{a, b, c, ...\}

Description
Constructs a list from a set of items.

N Items(source)

Description
Determines the number of elements in the source specified.

Returns
For a list or display box, the number of items in the list or display box is returned. For an associative array, the number of keys is returned. For a matrix, the number of elements in the matrix is returned. For a namespace, the number of functions and variables in the namespace is returned. For a class object, the number of methods, functions, and variables is returned.

Arguments
- source: A list, associative array, matrix, display box, or namespace.
Remove(source, position, <n>)
Remove(source, {items})
Remove(source, key)

**Description**

Deletes the \(n\) item(s), starting from the indicated \(position\). If \(n\) is omitted, the item at \(position\) is deleted. If \(position\) and \(n\) are omitted, the item at the end is removed. For an associative array: Deletes the \(key\) and its value.

**Returns**

A copy of the \(source\) with the items deleted.

**Arguments**

- **source** A quoted string, list, vector, expression, or associative array.
- **position** or **key** An integer (or list of integers) that points to a specific item (or items) in the list or expression.
- **n** (Optional) An integer that specifies how many items to remove.

---

Remove From(source, position, <n>)
Remove From(source, key)

**Description**

Deletes the \(n\) item(s) in place, starting from the indicated \(position\). If \(n\) is omitted, the item at \(position\) is deleted. If \(position\) and \(n\) are omitted, the item at the end is removed. For an associative array: Deletes the \(key\) and its value. The \(source\) must be an L-value.

**Returns**

The original \(source\) with the items deleted.

**Arguments**

- **source** A quoted string, list, vector, expression, display box, or associative array.
- **position** or **key** An integer (or list of integers) that points to a specific item (or items) in the list or expression.
- **n** (Optional) An integer that specifies how many items to remove.

---

Reverse(source)

**Description**

Reverse order of elements or terms in the \(source\).

**Argument**

- **source** A quoted string, list, matrix, or expression.
Reverse Into(source)

Description
Reverses the order of elements or terms in `source` in place.

Argument
source A quoted string, list, matrix, display box, or expression.

Shift(source, <n>)

Description
Shifts an item or `n` items from the front to the back of the `source`.

Arguments
source A quoted string, list, matrix, or expression.
`n` (Optional) An integer that specifies the number of items to shift. Positive values shift items from the beginning of the `source` to the end. Negative values shift items from the end of the `source` to the beginning. The default value is 1.

Shift Into(source, <n>)

Description
Shifts items in place.

Arguments
source A quoted string, list, matrix, display box, or expression.
`n` (Optional) An integer that specifies the number of items to shift. Positive values shift items from the beginning of the `source` to the end. Negative values shift items from the end of the `source` to the beginning. The default value is 1.

Sort List({list}|expr)

Description
Sort the elements or terms of `list` or `expr`.

Sort List Into({list}|expr)

Description
Sort the elements or terms of `list` or `expr` in place.
Substitute(string, "substring", "replacementString", ...)
Substitute({list}, listItem, replacementItem, ...)
Substitute(Expr(sourceExpr), Expr(findExpr), Expr(replacementExpr), ...)

Description
This is a search and replace function. It searches for a specific portion (second argument) of the source (first argument), and replaces it (third argument).

If a quoted string, finds all matches to substring in the source string, and replaces them with the replacementString.

If a list, finds all matches to listItem in the source list, and replaces them with the replacementItem.

If an expression, finds all matches to the findExpr in the sourceExpr, and replaces them with the replacementExpr. Note that all expressions must be enclosed within an Expr() function.

Arguments
string, list, sourceExpr A quoted string, list, matrix, or expression in which to perform the substitution.
substring, listItem, findExpr A quoted string, list item, or expression to be found in the source string, list, or expression.
replacementString, replacementItem, replacementExpr A quoted string, list item, or expression to replace the found string, list item, or expression.

Substitute Into(string, substring, replacementString, ...)
Substitute Into(list, listItem, replacementItem, ...)
Substitute Into(Expr(sourceExpr), Expr(findExpr), Expr(replacementExpr), ...)

Description
This is a search and replace function, identical to Substitute() except in place. It searches for a specific portion (second argument) of the source (first argument), and replaces it (third argument). The first argument must be an L-value.

If a quoted string, finds all matches to substring in the source string, and replaces them with the replacementString.

If a list, finds all matches to listItem in the source list, and replaces them with the replacementItem.

If an expression, finds all matches to the findExpr in the sourceExpr, and replaces them with the replacementExpr. Note that all expressions must be enclosed within an Expr() function.
**Arguments**

- **string**, **list**, **sourceExpr** A quoted string, list, matrix, or expression in which to perform the substitution.
- **substring**, **listItem**, **findExpr** A quoted string, list item, or expression to be found in the source string, list, or expression.
- **replacementString**, **replacementItem**, **replacementExpr** A quoted string, list item, or expression to replace the found string, list item, or expression.

**Words(string, <delimiter>)**

**Description**

Extracts the words from the quoted `string` according to the delimiters given. The default delimiter is ASCII whitespace. If you include a second argument, any and all characters in that argument are considered delimiters. If `delim` is an empty string, each character is treated as a separate word.

**Examples**

```plaintext
Words( "the quick brown fox" );
{"the","quick","brown","fox"}
Words( "Doe, Jane P."",".");
{"Doe","Jane","P"}
```

## MATLAB Integration Functions

JMP provides the following interfaces to access MATLAB. The basic execution model is to first initialize the MATLAB connection, perform the required MATLAB operations, and then terminate the MATLAB connection. In most cases, these functions return 0 if the MATLAB operation was successful or an error code if it was not. If the MATLAB operation is not successful, a message is written to the Log window. The single exception to this is MATLAB `Get()` , which returns a value.

## MATLAB JSL Function Interfaces

**MATLAB Connect( <named arguments> )**

**Description**

Initializes the MATLAB integration interfaces and returns an active MATLAB integration interface connection as a scriptable object.

**Returns**

MATLAB scriptable object.
Named Arguments
  Echo(Boolean) Sends the MATLAB source lines to the JMP log. The default value is true.

MATLAB Control( <named arguments> )

Description
  Sends control operations to signal MATLAB with external events such as source line echoing.

Returns
  None.

Arguments
  None.

Named Arguments
  Echo(Boolean) Global. Echo MATLAB source lines to the JMP log.
  Visible(Boolean) Global. Determine whether to show or hide the active MATLAB workspace.

MATLAB Execute( { list of inputs }, { list of outputs }, mCode, <named arguments> )

Description
  Submits the MATLAB code to the active global MATLAB connection given a list of inputs. Upon completion, retrieves a list of outputs.

Returns
  0 if successful, otherwise nonzero.

Arguments
  { list of inputs } Positional, name list. List of JMP variable names to send to MATLAB as inputs.
  { list of outputs } Positional, name list. List of JMP variable names to retrieve from MATLAB as outputs.
  mCode Positional, quoted string. The MATLAB code to submit.

Named Arguments
  Expand(Boolean) Perform an Eval Insert on the MATLAB code prior to submission.
  Echo(Boolean) Echo MATLAB source lines to the JMP log. Default is true.

Example
  The following example sends the JMP variables x and y to MATLAB, executes the MATLAB statement $z = x \times y$, and then gets the MATLAB variable z and returns it to JMP.
  ```
  MATLAB Init();
  x = [1 2 3];
  ```
y = [4 5 6];
MATLAB Execute( {x, y}, {z}, "z = x * y;" );
Show( z );

MATLAB Get( name )

Description
Gets named variable from MATLAB to JMP.

Returns
Value of named variable.

Arguments
name Positional. The name of a JMP variable to be sent to MATLAB.

Example
Suppose that a matrix named qbx and a structure named df are present in your MATLAB connection.
// get the MATLAB variable qbx and placed it into a JMP variable qbx
qbx = MATLAB Get( qbx );

/* get the MATLAB variable df and placed it into a JMP data table referenced by df */
df = MATLAB Get( df );

Table 2.1 shows what JMP data types can be exchanged with MATLAB using the MATLAB Get( ) function. Getting lists from MATLAB recursively examines each element of the list and sends each base MATLAB data type. Nested lists are supported.

<table>

<td>Numeric Matrix</td>
</tr>
</tbody>
</table>
MATLAB Get Graphics( format )

Description
Get the last graphic object written to the MATLAB graph display window in a specific
graphic format. The graphic object can be returned in several graphic formats.

Returns
JMP Picture object.

Argument
format Positional. The format the MATLAB graph display window contents are to be
converted to. Valid formats are png, bmp, jpeg, jpg, tiff, tif, and gif.

MATLAB Get Version

Description
Returns the version number of MATLAB being used with the JMP MATLAB interfaces.

MATLAB Init( <named arguments> )

Description
Initializes the MATLAB integration interfaces.

Returns
Return code.

Named Arguments
Echo(Boolean) Sends MATLAB source lines to the JMP log. This option is global. The
default value is true.

MATLAB Is Connected()

Description
Determines whether a MATLAB connection is active.

Returns
1 if connected, otherwise 0.

</tbody>
</table>
MATLAB JMP Name To MATLAB Name( name )

Description
Maps a JMP variable name to its corresponding MATLAB variable name using MATLAB variable name naming rules.

Returns
A quoted string, mapped MATLAB variable name.

Argument
name Positional. The name of a JMP variable to be sent to MATLAB.

MATLAB Send( name, <named arguments> )

Description
Sends the named variable from JMP to MATLAB.

Returns
0 if successful, otherwise nonzero.

Arguments
name Positional. The name of a JMP variable to be sent to MATLAB.

Named Arguments
The following optional arguments apply to data tables only:
Selected(Boolean) Send selected rows from the referenced data table to MATLAB.
Excluded(Boolean) Send only excluded rows from the referenced data table to MATLAB.
Labeled(Boolean) Send only labeled rows from the referenced data table to MATLAB.
Hidden(Boolean) Send only hidden rows from the referenced data table to MATLAB.
Colored(Boolean) Send only colored rows from the referenced data table to MATLAB.
Markered(Boolean) Send only markered rows from the referenced data table to MATLAB.
Row States(Boolean, <named arguments>) Send row states from referenced data table to MATLAB by adding an additional data column named “RowState”. Create multiple selections by adding together individual settings. The row state consists of individual settings with the following values:
- Selected = 1
- Excluded = 2
- Labeled = 4
- Hidden = 8
- Colored = 16
- Markered = 32
The following optional, named Row States arguments are supported:

- **Colors(Boolean)** Send row colors. Adds additional data column named “RowStateColor”.
- **Markers(Boolean)** Send row markers. Adds additional data column named “RowStateMarker”.

**Example**

```julia
// create a matrix, assign it to X, and send the matrix to MATLAB
X = [1 2 3];
ml = MATLAB Send( X );

/* open a data table, assign a reference to it to dt, and send the data table along with its current row states to MATLAB */
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
ml = MATLAB Send( dt, Row States( 1 ) );
```

Table 2.2 shows what JMP data types can be exchanged with MATLAB using the `MATLAB Send()` function. Sending lists to MATLAB recursively examines each element of the list and sends each base JMP data type. Nested lists are supported.

<table>
<thead>
<tr>

<td>Numeric</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
</tr>
<tr>
<td>Double Matrix</td>
<td>Matrix</td>
</tr>
<tr>
<td>Structure</td>
<td>Data Table</td>
</tr>
</tbody>
</table>

**Example**

```julia
MATLAB Init();
X = 1;
MATLAB Send( X );
S = "Report Title";
MATLAB Send( S );
M = [1 2 3, 4 5 6, 7 8 9];
MATLAB Send( M );
MATLAB Submit("X
S
M
" );
MATLAB Term();
```
MATLAB Send File(filename, <MATLAB Name(name)>)

Description
Sends a data file to MATLAB.

Arguments
filename Specifies a quoted string that identifies the pathname to the file to be sent to MATLAB.
MATLAB Name Enables you to change the name of the file sent to MATLAB.

MATLAB Submit File( 'pathname', <named arguments> )

Description
Submits statements to MATLAB using a file pointed to by pathname.

Returns
0 if successful, otherwise nonzero.

Arguments
Pathname Positional, quoted string. Pathname to file containing MATLAB source lines to be executed.

Named Arguments
Expand(Boolean) Perform an Eval Insert on the MATLAB code prior to submission.
Echo(Boolean) Echo MATLAB source lines to the JMP log. Default is true.

MATLAB Submit( mCode, <named arguments> )

Description
Submits the MATLAB code to the active global MATLAB connection.

Returns
0 if successful, otherwise nonzero.

Arguments
mCode Positional, quoted string. The MATLAB code to submit.

Named Arguments
Expand(Boolean) Perform an Eval Insert on the MATLAB code prior to submission.
Echo(Boolean) Echo MATLAB source lines to the JMP log. Default is true.

Example
The following example creates two vectors of random points and plots them as x and y variables.
MATLAB Init();
mC = MATLAB Submit("[/
x = rand(5);
fprintf("%f/n", x);
\begin{verbatim}
y = rand(5);
fprintf('%f/n', x);
z = plot(x, y);
\end{verbatim}

\textbf{MATLAB \texttt{Term}();}

\textbf{Description}
Terminates the currently active MATLAB integration interface.

\textbf{Returns}
1 if an active MATLAB connection exists, otherwise returns 0.

\textbf{Arguments}
None.

\section*{Matrix Functions}

\textbf{\texttt{All}(A, \ldots)}

\textbf{Returns}
1 if all matrix arguments are nonzero; 0 otherwise.

\textbf{\texttt{Any}(A, \ldots)}

\textbf{Returns}
1 if one or more elements of one or more matrices are nonzero; 0 otherwise.

\textbf{\texttt{B Spline Coef}(x, \text{Internal Knot Grid}, <degree=3>, <Knot End Points=min(x)||max(x)>>)}

\textbf{Description}
Finds the matrix of B-spline coefficients for the data in the \texttt{x} argument.

\textbf{Returns}
The matrix of B-spline basis coefficients. This matrix can be used as a design matrix in a linear model. The first column of the matrix contains an intercept term.

\textbf{Arguments}
\begin{itemize}
\item \texttt{x} A row or column vector that contains the data.
\item \texttt{Internal Knot Grid} Either a single number that designates the number of desired knot points based on percentiles of \texttt{x} or a vector of values that designate the internal knot points. The number of internal knots must be greater than zero and less than or equal to the number of unique elements in \texttt{x} minus two.
\end{itemize}
**degree**  A number that indicates the degree of the B-splines. Defaults to 3.

**Knot End Points**  A 2x1 matrix that designates the lower and upper knot points. If this argument is not specified, the default lower and upper knot points are the minimum and maximum values of \( x \), respectively.

**Notes**
This function is used in column formulas created by the Functional Data Explorer platform.

---

**CDF(Y)**

**Description**
Returns values of the empirical cumulative probability distribution function for \( Y \), which can be a vector or a list. Cumulative probability is the proportion of data values less than or equal to the value of \( \text{QuantVec} \).

**Syntax**
\[
\{\text{QuantVec, CumProbVec}\} = \text{CDF} (\text{YVec})
\]

---

**Chol Update(L, V, C)**

**Description**
If \( L \) is the Cholesky root of an \( n \times n \) matrix \( A \), then after calling \( \text{cholUpdate} \) \( L \) is replaced with the Cholesky root of \( A + V^\ast C^\ast V' \) where \( C \) is an \( m \times m \) symmetric matrix and \( V \) is an \( n \times m \) matrix.

---

**Cholesky(A)**

**Description**
Finds the lower Cholesky root (\( L \)) of a positive semi-definite matrix, \( L^\ast L' = A \).

**Returns**
\( L \) (the Cholesky root).

**Arguments**
\( A \)  a symmetric matrix.

---

**Correlation(matrix, "Pairwise", "Shrink", "Freq(vector)", "Weight(vector)")**

**Description**
Calculates the correlation matrix of the data in the \( \text{matrix} \) argument.

**Returns**
The correlation matrix for the specified matrix.
**Argument**

matrix  A matrix that contains the data. If the data has $m$ rows and $n$ columns, the result is an $m$-by-$m$ matrix.

"Pairwise"  Uses the pairwise method for missing values rather than the row-wise method.

"Shrink"  Performs the Schafer-Strimmer shrinkage estimate.

<<Freq(vector)  A vector that specifies frequencies for the rows of the matrix argument.

<<Weight(vector)  A vector that specifies weights for the rows of the matrix argument.

**Notes**

By default, rows are discarded if they contain missing values. If the "Pairwise" option is specified, all pairs of nonmissing values are used in the correlation matrix calculation.

This function uses multithreading if available, so it is recommended for large problems with many rows.

When a column is constant, the correlations for it are 0, and the diagonal element is also 0.

### Covariance(matrix, <<"Pairwise">, <<"Shrink">, <<Freq(vector)>, <<Weight(vector)>)

**Description**

Calculates the covariance matrix of the data in the `matrix` argument.

**Returns**

The covariance matrix for the specified matrix.

**Argument**

matrix  A matrix that contains the data. If the data has $m$ rows and $n$ columns, the result is an $m$-by-$n$ matrix.

"Pairwise"  Uses the pairwise method for missing values rather than the row-wise method.

"Shrink"  Performs the Schafer-Strimmer shrinkage estimate.

<<Freq(vector)  A vector that specifies frequencies for the rows of the matrix argument.

<<Weight(vector)  A vector that specifies weights for the rows of the matrix argument.

**Notes**

By default, rows are discarded if they contain missing values. If the "Pairwise" option is specified, all pairs of nonmissing values are used in the covariance matrix calculation.

This function uses multithreading if available, so it is recommended for large problems with many rows.
Design(vector, < levelsList | <<levels, <<ElseMissing >)

Description
Creates a design matrix that contains a column of 1s and 0s for each unique value of a vector of values.

Returns
A design matrix with a column of 1s and 0s for each unique value of the argument or a list that contains the design matrix and a list of levels.

Argument
vector A vector.
levelsList An optional list or matrix argument that specifies the levels in the returned matrix.
<<levels An optional argument that changes the return value to a list that contains the design matrix and a list of the levels.
<<ElseMissing An optional argument that changes the handling of values in the vector argument that do not appear in the levelsList argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

Notes
Missing values in the levelsList argument are not ignored. For example:

Show( Design( ., [. 0 1] ),
Design( 0, [. 0 1] ),
Design( 1, [. 0 1] ),
Design( [0 0 1 . 1], [. 0 1] ),
Design( {0, 0, 1, ., 1}, [. 0 1] ));
Design(. [, . 0 1]) = [1 0 0];
Design(0, [, . 0 1]) = [0 1 0];
Design(1, [, . 0 1]) = [0 0 1];
Design([0 0 1 . 1], [, . 0 1]) =
[ 0 1 0,
 0 1 0,
 0 0 1,
 1 0 0,
 0 0 1];
Design({0, 0, 1, ., 1}, [, . 0 1]) =
[ 0 1 0,
 0 1 0,
 0 0 1,
 1 0 0,
 0 0 1];
Design Last(vector, < levelsList, <<ElseMissing >)

**Description**

Creates a design matrix that contains a column of 1s and 0s for all but the last of the unique values of the argument. The last level is coded as a row of 0s.

**Returns**

A full-rank design matrix or a list that contains the design matrix and a list of levels.

**Arguments**

- `vector` A vector.
- `levelsList` An optional list or matrix argument that specifies the levels in the returned matrix. If this argument is specified, the last level in this list or matrix is treated as the last level in the design matrix. Otherwise, the last level is defined as the largest value in the `vector` argument.
- `<<ElseMissing` An optional argument that changes the handling of values in the `vector` argument that do not appear in the `levelsList` argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

Design Nom(vector, < levelsList | <<levels, <<ElseMissing >)

Design F(vector, < levelsList | <<levels, <<ElseMissing >)

**Description**

Creates a design matrix that contains a column of 1s and 0s for all but the last of the unique values of the argument. The last level is coded as a row of -1s.

**Returns**

A full-rank design matrix or a list that contains the design matrix and a list of levels.

**Argument**

- `vector` A vector.
- `levelsList` An optional list or matrix argument that specifies the levels in the returned matrix. If this argument is specified, the last level in this list or matrix is treated as the last level in the design matrix. Otherwise, the last level is defined as the largest value in the `vector` argument.
- `<<levels` An optional argument that changes the return value to a list that contains the design matrix and a list of levels.
- `<<ElseMissing` An optional argument that changes the handling of values in the `vector` argument that do not appear in the `levelsList` argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

**Notes**

Missing values in the `levelsList` argument are not ignored. For example:
Design Ord(vector, < levelsList | <<levels, <<ElseMissing >)

Description

Creates a design matrix that contains a column for all but the last of the unique values of the argument. The first level is coded as a row of 0s. Each subsequent (nth) level in the levelsList argument is coded as a row of (n-1) 1s and the rest 0s.

Returns

A full-rank design matrix or a list that contains the design matrix and a list of levels.

Argument

- `vector` A vector.
- `levelsList` An optional list or matrix argument that specifies the levels in the returned matrix.
- `<<levels` An optional argument that changes the return value to a list that contains the design matrix and a list of levels.
- `<<ElseMissing` An optional argument that changes the handling of values in the vector argument that do not appear in the levelsList argument. If this argument is specified, missing values are placed in the design matrix. Otherwise, 0s are placed in the design matrix.

Notes

Missing values in the levelsList argument are not ignored. For example:

Show( Design Ord( ., [. 0 1] ),
Design Ord( 0, [. 0 1] ),
Design Ord( 1, [. 0 1] ),
Design Ord( [0 0 1 . 1], [. 0 1] ),
Design Ord( {0, 0, 1, ., 1}, [. 0 1] ) );

Design Ord(.[, [. 0 1]]) = [1 0];
Design Ord(0[, [. 0 1]]) = [0 1];
Design Ord(1[, [. 0 1]]) = [-1 -1];
Design Ord([0 0 1 . 1], [. 0 1]) = [0 1, 0 1, -1 -1, 1 0, -1 -1];
Design Ord({0, 0, 1, ., 1}, [. 0 1]) = [0 1, 0 1, -1 -1, 1 0, -1 -1];
Det(A)

**Description**
Determinant of a square matrix.

**Returns**
The determinant.

**Argument**
A  A square matrix.

Diag(A, <B>)

**Description**
Creates a diagonal matrix from a square matrix or a vector. If two matrices are provided, concatenates the matrices diagonally.

**Returns**
The matrix.

**Argument**
A  a matrix or a vector.

Direct Product(A, B)

**Description**
Direct (Kronecker) product of square matrices or scalars A[i,j]*B.

**Returns**
The product.

**Arguments**
A, B  Square matrices or scalars.

Distance(x1, x2, <scales>, <powers>)

**Description**
Produces a matrix of distances between rows of x1 and rows of x2.

**Returns**
A matrix.

**Arguments**
x1, x2  Two matrices.
scales  Optional argument to customize the scaling of the matrix.
powers  Optional argument to customize the powers of the matrix.
E Div(A, B)
A:/B

Returns
A matrix that contains the element-by-element division of two matrices.

Arguments
A, B Two matrices. Both matrix elements must have the same dimensions.

E Max(A, B)

Returns
A matrix that contains the element-by-element maximum values of two or more matrices or scalar arguments.

Arguments
A, B Two or more matrices or scalars. All matrix elements must have the same dimensions.

E Min(A, B)

Returns
A matrix that contains the element-by-element minimum values of two or more matrices or scalar arguments.

Arguments
A, B Two or more matrices or scalars. All matrix elements must have the same dimensions.

E Mult(A, B)
A:*B

Description
Element-by-element multiplication of two matrices.

Returns
A matrix that contains the element-by-element multiplication of two or more matrices or scalar arguments.

Arguments
A, B Two or more matrices or scalars. All matrix elements must have the same dimensions.
Eigen(A)

Description
Eigenvalue decomposition.

Returns
A list \{M, E\} such that \( E \times \text{Diag}(M) \times E = A' \).

Argument
A  A symmetric matrix.

Estimate Bartlett Factor Score(dataRow, ManMeans, LatMeans, S, A)

Description
Estimates factor scores from a structural equation model (SEM) using Bartlett’s method.

Returns
A row vector of estimated factor scores based on the structural equation model.

Arguments
dataRow  A row vector of data values.
ManMeans A vector of model-implied manifest variable means.
LatMeans A vector of model-implied latent variable means.
S  The symmetric S matrix from a structural equation model.
A  The rectangular A matrix from a structural equation model.

Estimate Factor Score(dataRow, Covariance, ManMeans, LatMeans)

Description
Estimates factor scores from a structural equation model (SEM).

Returns
A row vector of estimated factor scores based on the structural equation model.

Arguments
dataRow  A row vector of data values.
Covariance A model-implied variance-covariance matrix.
ManMeans A vector of model-implied manifest variable means.
LatMeans A vector of model-implied latent variable means.

Note
This function is used in the Save Factor Scores option in an Structural Equation Model report.
Fourier Basis Coef(x, Number Pairs, <Period=max(x)-min(x)+1>)

**Description**
Finds the matrix of Fourier basis coefficients for the data in the \( x \) argument.

**Returns**
The matrix of Fourier basis coefficients. This can be used as a design matrix in a linear model. The first column of the matrix contains an intercept term. The remaining columns contain pairs of basis coefficients, where pair \( i \) is defined as the \( \sin() \) and \( \cos() \) of \( i \times \left( \frac{2 \times \pi}{\text{Period}} \right) \times x \).

**Arguments**
- \( x \) A row or column vector that contains the data.
- Number Pairs The number of \( \sin() \) and \( \cos() \) pairs for the Fourier basis.
- Period The period for trigonometric functions that make up the Fourier basis.

**Notes**
This function is used in column formulas created by the Functional Data Explorer platform.

---

G Inverse(A)

**Description**
Generalized (Moore-Penrose) matrix inverse.

---

H Direct Product(A, B)

**Description**
Horizontal direct product of two square matrices of the same dimension or scalars.

---

Hough Line Transform(matrix, <NAngle(number)>, <NRadius(number)>)

**Description**
Takes a matrix of intensities and transforms it in a way that is useful for finding streaks in the matrix. Produces a matrix containing the Hough Line Transform with angles as columns and radiuses as rows.

**Argument**
- matrix A matrix that can be derived from the intensities of an image, but is more likely from a semiconductor wafer that may have defects across in a streak due to planarization machines.
- NAngle(number) Enter the number of the angle to obtain a different sized transform. The default is 180 degrees.
- NRadius(number) Enter the number of the radius to obtain a different sized transform. The default is \( \sqrt{\text{NRow} \times \text{nRow} + \text{nCol} \times \text{Col}} \).
Identity(n)

**Description**

Creates an \( n \)-by-\( n \) identity matrix with ones on the diagonal and zeros elsewhere.

**Returns**

The matrix.

**Argument**

\( n \) An integer.

Index(i, j, <increment>)

i::j

**Description**

Creates a column matrix whose values range from \( i \) to \( j \).

**Returns**

The matrix.

**Arguments**

\( i, j \) Integers that define the range: \( i \) is the beginning of the range, \( j \) is the end.

\( \text{increment} \) Optional argument to change the default increment, which is +1.

Inv()

See “Inverse(A)” on page 192.

Inv Update(A, X, 1|-1)

**Description**

Efficiently update an \( X'X \) matrix.

**Arguments**

\( A \) The matrix to be updated.
\( X \) One or more rows to be added to or deleted from the matrix \( A \).

1|-1 The third argument controls whether the row or rows defined in the second argument, \( X \), are added to or deleted from the matrix \( A \). 1 means to add the row or rows and -1 means to delete the row or rows.

Inverse(A)

Inv(A)

**Description**

Returns the matrix inverse. The matrix must be square non-singular.
Is Matrix(x)

**Description**
Returns 1 if the evaluated argument is a matrix, or 0 otherwise.

\[ J(nrows, <ncols>, <value>) \]

**Description**
Creates a matrix of identical values.

**Returns**
The matrix.

**Arguments**
- `nrows` Number of rows in matrix. If `ncols` is not specified, `nrows` is also used as `ncols`.
- `ncols` Number of columns in matrix.
- `value` The value used to populate the matrix. If `value` is not specified, 1 is used.

KDTable(matrix)

**Description**
Returns a table to efficiently look up near neighbors.

**Returns**
A KDTable object.

**Argument**
- `matrix` A matrix of k-dimensional points. The number of dimensions or points is not limited. Each column in the matrix represents a dimension to the data, and each row represents a data point.

**Messages**
- **<<Distance between rows(row1, row2)** Returns the distance between two the two specified rows in the KDTable. The distance applies to removed and inserted rows as well.
- **<<K nearest rows(stop, <position>)** Returns a matrix. Position is a point that is described as a row vector for the coordinate of a row, or as the number of a row. If `position` is not specified, returns the \( n \) nearest rows and distances to all rows. If `position` is specified, returns the \( n \) nearest rows and distances to either a point or a row. **Stop** is either \( n \) or {\( n, limit \)}. The limit parameter limits the number of rows that will be found. It can be specified one of two ways: a number, like 5, means return the 5 nearest rows. A list, like \{5,10\}, means return up to 5 nearest rows, stopping when the distance of 10 is exceeded. In the second case, the last row may have a distance greater than 10. Since the command continues until it finds the closest row beyond the stop radius, this point is also returned. This can be especially useful if there are no rows within the radius.
<<Remove rows(number | vector) Remove either the row specified by number or the rows specified by vector. Returns the number of rows that were removed. Rows that were already removed are ignored.

<<Insert rows(number | vector) Re-insert either the row specified by number or the rows specified by vector. Returns the number of rows that were inserted. Rows that were already inserted are ignored.

Notes
When rows are removed or inserted, the row indices do not change. You can remove and re-insert only rows that are in the KDTable object. If you need different rows, construct a new KDTable.

Least Squares Solve(y, X, < <<noIntercept, <<weights(OptionalWeightVector), <<method("Sweep" | "GInv")>)

Description
Computes least squares regression estimates for the assumed model y = X * beta + error.

Returns
A list that contains the matrix Beta=Inverse(X'X)X'y and the estimated variance matrix of Beta.

Optional Named Arguments
<<noIntercept Specifies a no-intercept model.
<<weights(optional weight vector) Specifies a vector of weights to perform weighted least squares.
<<method("Sweep" | "GInv") Specifies the method for solving the normal equations. The default Sweep method is more computationally efficient, but you can also specify the generalized inverse ("GInv") method, which is more numerically stable.

Linear Regression(y, X, < <<noIntercept, <<printToLog, <<weight(OptionalWeightVector), <<freq(OptionalFreqVector)>)

Description
Fits a linear regression for the assumed model y = X * beta + error.

Returns
A list that contains a vector of the estimates, a vector of the standard error, and a list of diagnostics. The list of diagnostics contains vectors of the t statistics and p-values for the estimates, as well as the R-Square and adjusted R-Square values for the regression fit.

Optional Named Arguments
<<noIntercept Excludes the intercept.
<<printToLog Prints a summary of the fit to the log.
<<weight(vector) Specifies a vector of weights to perform weighted least squares.
<<freq(vector) Specifies a vector of frequencies for each row of y and X.
Example

\[
\begin{align*}
\text{n} &= 10; \\
x &= J( n, 1, \text{Random Normal}() ); \\
y &= 1 + x \ast 3 + J( n, 1, \text{Random Normal}() ); \\
\{\text{Estimates, Std_Error, Diagnostics}\} &= \text{Linear Regression}( y, x, <<\text{printToLog} ); \\
\text{As Table}( y \| x ); \\
\text{Bivariate}( Y( :\text{Col1} ), X( :\text{Col2} ), \text{Fit Line}( 1 ) );
\end{align*}
\]

---

**Loc(A)**

**Loc(A, item)**

**Description**

Returns a matrix of subscript positions where \( A \) is nonzero and nonmissing. For the two-argument function, Loc returns a matrix of positions where \( \text{item} \) is found within \( A \). If the first argument is a list, the second argument is required.

**Argument**

- \( A \) a matrix or a list
- \( \text{item} \) the item to be found within the matrix or list \( A \)

---

**Loc Max(A)**

**Description**

Returns the position of the maximum element in a matrix.

**Returns**

An integer that is the specified position.

**Argument**

- \( A \) a matrix

---

**Loc Min(A)**

**Description**

Returns the position of the minimum element in a matrix.

**Returns**

An integer that is the specified position.

**Argument**

- \( A \) a matrix

---

**Loc NonMissing(matrix, ..., \{list\}, ...)**

**Description**

Returns indices of nonmissing rows in matrices or lists. In lists, the function can also return indices of nonempty characters.
Loc Sorted(A, B)

Description
Returns a column vector of subscript positions where the values of A have values less than or equal to the values in B based on a binary search. A must be a matrix sorted in ascending order without missing values.

Returns
The new matrix, which has the same dimensions as B. If a value in B is less than the first value in A, the returned subscript position for that value is 1.

Argument
A, B matrices

Examples
Matrix({{x11, ..., x1m}, {x21, ..., 2m}, {...}, {xn1, ..., xnm}})
Matrix({x1, ..., xn})
Matrix(n, m)
Matrix Mult(A, B)
\[ C = A \times B, \ldots \]

**Description**
Matrix multiplication.

**Arguments**
A, B, ... Two or more matrices, which must be conformable (all matrices after the first one listed must have the same number of rows as the number of columns in the first matrix).

**Notes**
Matrix Mult() allows only two arguments, while using the * operator enables you to multiply several matrices.

Matrix Rank(A)

**Description**
Returns the rank of the matrix A.

Mode({list} or matrix)

**Description**
Selects the most frequent item from a numeric or character list or a numeric matrix. In the event of a tie, the lower value is selected. If multiple arguments are specified, a combination of numeric values and quoted character strings is acceptable.

**Arguments**
Specify either a list or a matrix.

Multivariate Normal Impute(yVec, meanYvec, symCovMat, colMin, colMax)

**Description**
Imputes missing values in yVec based on the mean and covariance.

**Arguments**
yVec The vector of responses.
meanYvec The vector of response means.
symCovMat A symmetric matrix containing the response covariances. If the covariance matrix is not specified, then JMP imputes with means.
colMin A vector of column minimums. Provides lower bounds for the imputations.
colMax A vector of column maximums. Provides upper bounds for the imputations.
NChooseK Matrix(n, k)

Description
Returns a matrix of $n$ things taken $k$ at a time ($n$ select $k$).

N Col(x)
N Cols(x)

Description
Returns the number of columns in either a data table or a matrix.

Argument
x Can be a data table or a matrix.

Ortho(A, <Centered(0)>, <Scaled(1)>)

Description
Orthonormalizes the columns of matrix $A$ using the Gram Schmidt method. <Centered(0)> makes the columns to sum to zero. <Scaled(1)> makes them unit length.

Ortho Poly(vector, order)

Description
Returns orthogonal polynomials for a vector of indices representing spacings up to the order given.

P Spline Coef(x, Internal Knot Grid, <degree=3>)

Description
Finds the matrix of penalized basis spline (P-spline) coefficients for the data in the $x$ argument.

Returns
The matrix of P-spline basis coefficients, which is the truncated power basis of the specified degree. The truncated power basis of degree $p$ with knots $k_1$ through $k_K$ is defined as follows:

$$1, x, x^2, ..., x^p, (x - k_1)_+^p, ..., (x - k_K)_+^p$$

where $(x - k_1)_+$ is the positive part of $(x - k_1)$ and is set to zero for negative values of $(x - k_1)$.

Arguments
$x$ A row or column vector that contains the data.
Internal Knot Grid Either a single number that designates the number of desired knot points based on percentiles of \( x \) or a vector of values that designate the internal knot points.

degree A number that indicates the degree of the P-splines. Defaults to 3.

Notes
This function is used in column formulas created by the Functional Data Explorer platform.

Parallel Assign({thread_local_var = global_var, ...}, matrix[a, b] = expression using a and b)

Description
Uses multiple threads to assign values to the matrix. Enables you to take advantage of multiple cores on a computer. The function has two arguments.

- The first argument is a list of assignment statements that copies global variables into each thread’s local variable list.
- The second argument is an assignment expression with a left-hand-side that is a matrix with one or two prototype indexes and a right hand side that can be any JSL expression using those indexes and the local variables from the list (and in JMP global: variables).

Example
The following example provides read access to the global namespace.

\[
a = 42;
n = [1 2 3, 4 5 6, 7 8 9];
Show( Parallel Assign( {}, x[i, j] = global:a ) );
Show( x );
Parallel Assign({}, x[i,j] = global:a) = 1;
x = 
[ 42 42 42, 42 42 42, 42 42 42 ];
\]

Print Matrix(M, <named arguments>)

Description
Returns a quoted string that contains a well-formatted matrix. You can use the function, for example, to print the matrix to the log.

Argument
M A matrix.

Optional Named Arguments

\(<\text{ignore locale(Boolean)}\> \text{ Set to false (0) to use the decimal separator for your locale. Set to true (1) to always use a period (.) as a separator. The default value is false (0).}\)
<<decimal digits(n) An integer that specifies the number of digits after the decimal separator to print.
<<style("style name") Use one of three available styles: Parseable is a reformatted JSL matrix expression. Latex is formatted for LaTex. If you specify Other, you must define the following three arguments.
<<separate("character") Define the separator for concatenated entries.
<<line begin("character") Define the beginning line character.
<<line end("character") Define the ending line character.

---

QR(A)

Description
Returns the QR decomposition of A. Typical usage is \{Q, R\} = QR(A).

---

Rank Index(vector)

Rank(vector)

Description
Returns a vector of indices that, used as a subscript to the original vector, sorts the vector by rank. Excludes missing values. Lists of numbers or quoted strings are supported in addition to matrices.

---

Ranking(vector)

Description
Returns a vector of ranks of the values of vector, low to high as 1 to n, ties arbitrary. Lists of numbers or quoted strings are supported in addition to matrices.

---

Ranking Tie(vector)

Description
Returns a vector of ranks of the values of vector, but ranks for ties are averaged. Lists of numbers or quoted strings are supported in addition to matrices.

---

Scoring Impute(rowWithMissing, VMat, colMeanVec, colStdDevVec)

Description
Provides streaming functionality for the Automated Data Imputation (ADI) algorithm.

Returns
Returns the row vector with the missing values imputed using the standard least squares estimation.
Arguments
rowwithMissing A row vector that contains missing values.
VMat A loading matrix that is produced by the ADI algorithm.
colMeanVec A vector of the column means ignoring missing cells.
colStdDevVec A vector of the column standard deviations ignoring missing cells.

Shape(A, nrow, <ncol>, <<bycol>)

Description
Reshapes the matrix A across rows to the specified dimensions. Each value from the matrix A is placed into the reshaped matrix. By default, the values are placed row-by-row.

Returns
The reshaped matrix.

Arguments
A A matrix.
nrow The number of rows that the new matrix should have.
ncol (Optional) The number of columns the new matrix should have.
<<bycol> (Optional) Specifies that the values be placed into the reshaped matrix column-by-column, instead of row-by-row.

Notes
If ncol is not specified, the number of columns is whatever is necessary to fit all of the original values of the matrix into the reshaped matrix.
If a missing value is specified for nrow, the number of rows is whatever is necessary to fit all of the original values of the matrix into the reshaped matrix.
If the new matrix is smaller than the original matrix, the extra values are discarded.
If the new matrix is larger than the original matrix, the values are repeated to fill the new matrix.

Examples
a = Matrix({ {1, 2, 3}, {4, 5, 6}, {7, 8, 9} });
[ 1 2 3,
  4 5 6,
  7 8 9]

Shape(a, 2);
[ 1 2 3 4 5,
  6 7 8 9 1]

Shape(a, 2, 2);
[ 1 2,
  3 4]

Shape(a, 4, 4);
Shape(a, 4, 4, <<bycol>);

```
[ 1 2 3 4,
  5 6 7 8,
  9 1 2 3,
  4 5 6 7]
```

Solve(A, b)

Description

Solves a linear system. In other words, \( x = \text{inverse}(A) \times b \).

Sort Ascending(source)

Description

Returns a copy of a list or matrix \( source \) with the items in ascending order.

Sort Descending(source)

Description

Returns a copy of a list or matrix \( source \) with the items in descending order.

Sparse SVD(X, <nSingularValues=min(nRow, nCol)>,<tolerance=1e-10>)

Description

Computes the singular value decomposition of matrix X using the implicitly restarted, partially reorthogonalized Lanczos method for sparse matrices.

Returns

Returns a list (U, M, V) such that \( U \times \text{diag}(M) \times V \) is equal to x.

Spline Coef(x, y, lambda)

Description

Returns a five column matrix of the form knots | a | b | c | d where knots is the unique values in x.

x is a vector of regressor variables, y is the vector of response variables, and lambda is the smoothing argument. Larger values for lambda result in smoother splines.
Spline Eval(x, coef)

**Description**
Evaluates the spline predictions using the `coef` matrix in the same form as returned by `SplineCoef()`, in other words, `knots||a||b||c||d`. The `x` argument can be a scalar or a matrix of values to predict. The number of columns of `coef` can be any number greater than 1 and each is used for the next higher power. The powers of `x` are centered at the knot values. For example, the calculation for `coef` of `knots||a||b||c||d` is `j` is such that `knots[j]` is the largest knot smaller than `x`.

\[ xx = x - knots[j] \]

is the centered `x` value:

\[ \text{result} = a[j] + xx * (b[j] + xx * (c[j] + xx * d[j])) \]

The following line is equivalent:

\[ \text{result} = a[j] + b[j] * xx + c[j] * xx^2 + d[j] * xx^3 \]

Spline Smooth(x, y, lambda)

**Description**
Returns the smoothed predicted values from a spline fit.

`x` is a vector of regressor variables, `y` is the vector of response variables, and `lambda` is the smoothing argument. Larger values for `lambda` result in smoother splines.

SVD(A)

**Description**
Singular value decomposition.

Sweep(A, <indices>)

**Description**
Sweeps, or inverts a matrix a partition at a time.

Trace(A)

**Description**
The trace, or the sum of the diagonal elements of a square matrix.

Transpose(A)

**Description**
Transposes the rows and columns of the matrix `A`.

**Returns**
The transposed matrix.
Arguments
A A matrix.

Equivalent Expression
A'

V Concat(A, B, ...)

Description
Vertical concatenation of two or more matrices.

Returns
The new matrix.

Arguments
Two or more matrices.

V Concat To(A, B, ...)

Description
Vertical concatenation in place. This is an assignment operator.

Returns
The new matrix.

Arguments
Two or more matrices.

V Max(matrix)

Description
Returns a row vector containing the maximum of each column of matrix.

V Mean(matrix)

Description
Returns a row vector containing the mean of each column of matrix.

V Median(matrix)

Description
Returns a row vector containing the median of each column of matrix.

V Min(matrix)

Description
Returns a row vector containing the minimum of each column of matrix.
V Quantile(matrix, p)

Description
Returns a row vector containing the $p^{th}$ quantile of each column of matrix.

V Standardize(matrix)

Description
Returns a matrix column-standardized to mean = 0 and standard deviation = 1.

V Std(matrix)

Description
Returns a row vector containing the standard deviations of each column of matrix.

V Sum(matrix)

Description
Returns a row vector containing the sum of each column of matrix.

Varimax(matrix, <norm=1>)

Description
Performs a varimax rotation.

Returns
A list that contains the rotated matrix and the orthogonal rotation matrix.

Arguments
matrix A matrix to be rotated.

norm Specify 1 to perform a normalized rotation, and specify 0 to perform a non-normalized rotation. The default value is 1.

Vec Diag(A)

Description
Creates a vector from the diagonals of a square matrix A.

Returns
The new matrix.

Arguments
A A square matrix.

Notes
Using a matrix that is not square results in an error.
Vec Quadratic(symmetric matrix, rectangular matrix)

Description
Constructs an \( n \)-by-\( m \) matrix. Used in calculation of hat values.

Returns
The new matrix.

Arguments
Two matrices. The first must be symmetric.

Equivalent Expression
Vec Diag(X*Sym*X')

VPTree(matrix)

Description
Returns a table that is used for efficiently looking up nearest neighbors. The vantage-point tree algorithm is particularly useful for wide data problems.

Returns
A VPTree object.

Argument
matrix A matrix of \( k \)-dimensional points. The number of dimensions or points is not limited. Each column in the matrix represents a dimension to the data, and each row represents a data point.

Numeric Functions

Abs(n)

Description
Calculates the absolute value of \( n \).

Returns
Returns a positive number of the same magnitude as the value of \( n \).

Argument
n Any number.

Ceiling(n)

Description
If \( n \) is not an integer, rounds \( n \) to the next highest integer.
Returns
Returns the smallest integer greater than or equal to $n$.

Argument
n Any number.

Derivative(expr, {name, ...}, ...)

Description
Calculates the derivative of the $expr$ expression with respect to $name$.

Returns
Returns the derivative.

Arguments
expr Any expression. Indirect arguments (for example, Name Expr, Expr, Eval) are supported.
name Can be a single variable or a list of variables.

Notes
Adding an additional variable (Derivative(expr, name, name2)) takes the second derivative.

Floor(n)

Description
If $n$ is not an integer, rounds $n$ to the next lowest integer.

Returns
Returns the largest integer less than or equal to $n$.

Argument
n Any number.

Examples
Floor( 2.7 );
2
Floor( -.5 );
-1

Integrate(expr, varname, lowLimit, upLimit, <<Tolerance(1e-10), <<StoreInfo({list}), <<StartingValue(val))

Description
Integrates an expression with respect to a scalar value, using the adaptive quadrature method from Gander and Gautschi (2000).

Arguments
expr an expression that defines the integrand.
varname the name of the variable of integration. If this variable contains a value, that value specifies a starting value that is used as a typical value to improve the accuracy of the integral.

lowLimit specifies the lower limit of integration. To specify negative infinity as the lower limit of integration, set this to missing.

upLimit specifies the upper limit of integration. To specify positive infinity as the upper limit of integration, set this to missing.

StoreInfo saves diagnostics of the numerical integration routine to the argument of StoreInfo().

StartingValue specifies a starting value that is used as a typical value to improve the accuracy of the integral.

Invert Expr(expr, name)

Description
Attempts to unfold expr around name.

Mod()

See “Modulo(number, divisor)” on page 208

Modulo(number, divisor)

Mod(number, divisor)

Description
Returns the remainder when number is divided by divisor.

Examples
Modulo(6, 5);
1

Normal Integrate(muVector, sigmaMatrix, expr, x, nStrata, nSim)

Description
Returns the result of radial-spherical integration for smooth functions of multivariate, normally distributed variables.

Arguments
muVector A vector.
sigmaMatrix A matrix.
expr An expression in terms of the variable x.
x The variable used in the expression expr.
nStrata Number of strata.
Chapter 2
JSL Functions

JSL Syntax Reference Numeric Functions

nSim  Number of simulations.

Num Deriv(f(x,...), <parnum=1>)

Description
Returns the numerical derivative of the \( f( x, ... ) \) function with respect to one of its arguments. You can specify that argument as the second argument in the \textit{Num Deriv} function. If no second argument is specified, the derivative is taken with respect to the function's first argument. The derivative is evaluated using numeric values specified in the \( f( x, ... ) \) function expression.

Notes
The \textit{Num Deriv()} function might appear not to produce the correct results as seen here:

\begin{verbatim}
x = 3;
n = Num Deriv( 3 * x ^ 2 );
// 9.00000000001455
\end{verbatim}

The preceding usage is not correct. The function was designed to be used in the Nonlinear platform to differentiate functions for which it does not know the analytic derivatives. The proper usage takes the following form:

\begin{verbatim}
x = 3;
f = Function( \{x\}, 3 * x ^ 2 );
n = Num Deriv( f( x ), 1 );
// 18.000029999854
\end{verbatim}

Num Deriv2(f(x,...))

Description
Returns the numerical second derivative of the \( f( x, ... ) \) function with respect to \( x \). The derivative is evaluated using numeric values specified in the \( f( x, ... ) \) function expression.

Round(n, places)

Description
Rounds \( n \) to number of decimal \textit{places} given.

Simplify Expr(expr(expression))
Simplify Expr(nameExpr(global))

Description
Algebraically simplifies an expression
Optimization Functions

Constrained Maximize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description
Finds the values for the x arguments, specified as a list, that maximize the expr expression with optional linear constraints. You must either specify lower and upper bounds in parentheses for each argument or with the optional Set Variable Limit() message. The x arguments can be scalar values or vectors.

In the following messages, A is a matrix of coefficients. \( x = [x_1, x_2, ...] \) is the vector of arguments. b is a vector that forms the right side of the expression.

Messages
<<Less than EQ({A, b}) Sets the constraint to less than or equal to the specified values \( (A^*x \leq b) \).
<<Greater Than EQ({A, b}) Sets the constraint to greater than or equal to the specified values \( (A^*x \geq b) \).
<<Equal To({A, b}) Sets the constraint as equal to the specified values \( (A^*x = b) \).
<<Starting Values([x1Start, x2Start, ...]) Specifies a starting point.
<<Max Iter(int) An integer that specifies the maximum number of iterations to be performed.
<<Tolerance(p) \( p \) sets the tolerance for the convergence criterion. The default tolerance is \( 10^{-5} \).
<<Show Details("true") Returns a list with the final values for (objective value, number of iterations, gradient, and Hessian). Shows the step-by-step results of the optimizer in the log.
<<SetVariableLimit({low,high}) Specifies vectors for the lower and upper limits for the optimization variables.

Constrained Minimize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description
Finds the values for the x arguments, specified as a list, that minimize the expr expression with optional linear constraints. You must either specify lower and upper bounds in parentheses for each argument or with the optional Set Variable Limit() message. The x arguments can be scalar values or vectors.

In the following messages, A is a matrix of coefficients. \( x = [x_1, x_2, ...] \) is the vector of arguments. b is a vector that forms the right side of the expression.

Messages
<<Less than EQ({A, b}) Sets the constraint to less than or equal to the specified values \( (A^*x \leq b) \).
<<Greater Than \( EQ\{A, b\} \)\) Sets the constraint to greater than or equal to the specified values \( (A^*x \geq b) \).

<<Equal To\{A, b\}\) Sets the constraint as equal to the specified values \( (A^*x = b) \).

<<Starting Values([x1Start, x2Start, ...])\) Specifies a starting point.

<<Max Iter(int)\) An integer that specifies the maximum number of iterations to be performed.

<<Tolerance(p)\) \( p \) sets the tolerance for the convergence criterion. The default tolerance is \( 10^{-5} \).

<<Show Details("true")\) Returns a list with the final values for (objective value, number of iterations, gradient, and Hessian). Shows the step-by-step results of the optimizer in the log.

<<SetVariableLimit({low, high})\) Specifies vectors for the lower and upper limits for the optimization variables.

---

**Desirability(yVector, desireVector, y)**

**Description**

Fits a function to go through the three points, suitable for defining the desirability of a set of response variables \( (y)'s \). \( yVector \) and \( desireVector \) are matrices with three values, corresponding to the three points defining the desirability function. The actual function depends on whether the desire values are in the shape of a larger-is-better, smaller-is-better, target, or antitarget.

**Returns**

The desirability function.

**Arguments**

\( yVector \) Three input values.

\( desireVector \) the corresponding three desirability values.

\( y \) the value of which to calculate the desirability.

---

**LPSolve(A, b, c, L, U, neq, nle, nge, <slackVars(Boolean)>)**

**Description**

Returns a list containing the decision variables (and slack variables if applicable) in the first list item and the optimal objective function value (if one exists) in the second list item.

**Arguments**

\( A \) A matrix of constraint coefficients.

\( b \) A matrix that is a column of right hand side values of the constraints.

\( c \) A vector of cost coefficients of the objective function.

\( L, U \) Matrices of lower and upper bounds for the variables.

\( neq \) The number of equality constraints.
nle  The number of less than or equal inequalities.
nge  The number of greater than or equal inequalities.
slackVars(Boolean) (Optional) Determines whether the slack variables are returned in addition to the decision variables. The default value is 0.

Notes
The constraints must be listed as equalities first, less than or equal inequalities next, and greater than or equal inequalities last.

Maximize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

Description
Finds the values for the \( x \) arguments, specified as a list, that maximize the expression \( expr \). You can specify lower and upper bounds in parentheses for each argument. Additional arguments for the function enable you to set the maximum number of iterations, tolerance for convergence, and view more details about the optimization. The Newton-Raphson method is used when an analytical derivative is found for the Hessian. Otherwise, the Symmetric-Rank One method (SR1), a quasi-Newton method, is used.

Messages
<<Max Iter(int) An integer that specifies the maximum number of iterations to be performed. The default maximum number of iterations is 250.
<<Tolerance(p) \( p \) sets the tolerance for the convergence criterion. The default tolerance is \( 10^{-8} \).
<<Details("both" | "displaySteps" | "returnDetails") Specifies what output is returned. If "displaySteps" is specified, step-by-step results of the optimization appear in the Log window. If "returnDetails" is specified, the function returns a list that contains the final values for the objective value, number of iterations, gradient, and Hessian. Specify "both" to get the return value and the results in the Log.
<<Gradient(exprList) Specifies a list of expressions that define the analytical gradient that is used for the optimization. Each expression in the list represents a derivative of the expression \( expr \).
<<Hessian(exprList) Specifies a list of expressions that define the analytical Hessian that is used for the optimization. Each expression in the list represents the upper triangular portion of the Hessian matrix in row-major order.
<<Method(NR | SR1) Specifies either the Newton-Raphson (NR) method or the Symmetric-Rank One (SR1) method for the optimization method.
<<UseNumericDeriv("true") Specifies that the optimization use a numeric approximation.
Minimize(expr, {x1(low1, up1), x2(low2, up2), ...}, messages)

**Description**

Finds the values for the x arguments, specified as a list, that minimize the expression `expr`. You can specify lower and upper bounds in parentheses for each argument. Additional arguments for the function enable you to set the maximum number of iterations, tolerance for convergence, and view more details about the optimization. The Newton-Raphson method is used when an analytical derivative is found for the Hessian. Otherwise, the Symmetric-Rank One method (SR1), a quasi-Newton method, is used.

**Messages**

- `<Max Iter(int)` An integer that specifies the maximum number of iterations to be performed. The default maximum number of iterations is 250.
- `<Tolerance(p)` `p` sets the tolerance for the convergence criterion. The default tolerance is $10^{-8}$.
- `<Details("both" | "displaySteps" | "returnDetails")` Specifies what output is returned. If "displaySteps" is specified, step-by-step results of the optimization appear in the Log window. If "returnDetails" is specified, the function returns a list that contains the final values for the objective value, number of iterations, gradient, and Hessian. Specify "both" to get the return value and the results in the Log.
- `<Gradient(exprList)` Specifies a list of expressions that define the analytical gradient that is used for the optimization. Each expression in the list represents a derivative of the expression `expr`.
- `<Hessian(exprList)` Specifies a list of expressions that define the analytical Hessian that is used for the optimization. Each expression in the list represents the upper triangular portion of the Hessian matrix in row-major order.
- `<Method(NR | SR1)` Specifies either the Newton-Raphson (NR) method or the Symmetric-Rank One (SR1) method for the optimization method.
- `<UseNumericDeriv("true")` Specifies that the optimization use a numeric approximation.

---

**Probability Functions**

**Beta Density**($x, \alpha, \beta, <\theta=0>, <\sigma=1>$)

**Description**

Returns the probability density function (pdf) evaluated at $x$ of the beta distribution. The pdf is parameterized as follows:

$$f(x) = \frac{1}{B(\alpha, \beta)\sigma^\alpha + \beta - 1}(x - \theta)^{\alpha - 1}(\theta + \sigma - x)^{\beta - 1}$$
where \( B(\cdot) \) is the Beta function.

**Arguments**
- \( x \): A quantile at which the pdf is evaluated. \( x \) must be between \( \theta \) and \( \theta + \sigma \).
- \( \alpha, \beta \): Shape parameters \( \alpha \) and \( \beta \), which must both be greater than 0.
- \( \theta \): Optional threshold parameter. The default is 0.
- \( \sigma \): Optional scale parameter, which must be greater than 0. The default is 1.

**Notes**
The beta distribution is useful for modeling the probabilistic behavior of random variables that are constrained to fall in the interval \([0, 1]\), such as proportions.

**Beta Distribution**

\[
\text{Beta Distribution}(x, \alpha, \beta, <\theta=0>, <\sigma=1>)
\]

**Description**
Returns the cumulative distribution function (cdf) evaluated at \( x \) of the beta distribution. The cdf uses the same parameterization as the `Beta Density()` function.

**Arguments**
- \( x \): A quantile at which the cdf is evaluated. \( x \) must be between \( \theta \) and \( \theta + \sigma \).
- \( \alpha, \beta \): Shape parameters \( \alpha \) and \( \beta \), which must both be greater than 0.
- \( \theta \): Optional threshold parameter. The default is 0.
- \( \sigma \): Optional scale parameter, which must be greater than 0. The default is 1.

**Beta Quantile**

\[
\text{Beta Quantile}(p, \alpha, \beta, <\theta=0>, <\sigma=1>)
\]

**Description**
Returns the \( p \)th quantile from a beta distribution with shape arguments \( \alpha \) and \( \beta \). The quantile function does not have a closed form equation.

**Arguments**
- \( p \): The probability of the quantile desired. \( p \) must be between 0 and 1.
- \( \alpha, \beta \): Shape parameters \( \alpha \) and \( \beta \), which must both be greater than 0.
- \( \theta \): Optional threshold parameter. The default is 0.
- \( \sigma \): Optional scale parameter, which must be greater than 0. The default is 1.

**Cauchy Density**

\[
\text{Cauchy Density}(q, <\text{center}=0>, <\text{scale}=1>)
\]

**Description**
Returns the probability density function (pdf) evaluated at \( q \) of a Cauchy distribution. The pdf is parameterized as follows:

\[
f(q) = \frac{1}{\pi \sigma} \frac{1}{1 + \left(\frac{q - \mu}{\sigma}\right)^2}
\]
### Arguments

- **q** A quantile at which the pdf is evaluated.
- **center** Optional location parameter \( \mu \). The default is 0.
- **scale** Optional scale parameter, \( \sigma \), which must be greater than 0. The default is 1.

### Cauchy Distribution(q, <center=0>, <scale=1>)

#### Description

Returns the cumulative distribution function (cdf) probability that a Cauchy distributed random variable is less than \( q \). The cdf is parameterized as follows:

\[
F(q) = \frac{1}{2} + \frac{1}{\pi} \arctan \left( \frac{x - \mu}{\sigma} \right)
\]

### Arguments

- **q** A quantile at which the cdf is evaluated.
- **center** Optional location parameter \( \mu \). The default is 0.
- **scale** Optional scale parameter, \( \sigma \), which must be greater than 0. The default is 1.

### Cauchy Quantile(p, <center=0>, <scale=1>)

#### Description

Returns the \( p \)th quantile from a Cauchy distribution. The \( p \)th quantile is the value for which the probability is \( p \) that a random value would be less than or equal to \( p \). The quantile function is parameterized as follows:

\[
F^{-1}(p) = \sigma \tan \left( \pi \left( p + \frac{1}{2} \right) \right) + \mu
\]

### Arguments

- **p** The probability of the quantile desired. \( p \) must be between 0 and 1.
- **center** Optional location parameter \( \mu \). The default is 0.
- **scale** Optional scale parameter \( \sigma \), which must be greater than 0. The default is 1.

### ChiSquare Density(q, df, <nc=0>)

#### Description

Returns the probability density function (pdf) evaluated at \( q \) of the chi-square distribution. The pdf is parameterized as follows:

\[
f(q) = \exp \left( -\frac{\lambda}{2} \right) \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} \frac{\lambda}{2r} f_{n+2r}(q)
\]
where $f_{n+2r}(q)$ is the density of a central chi-square distribution with $n+2r$ degrees of freedom.

**Arguments**

- `q` A quantile at which the pdf is evaluated. `q` must be greater than or equal to 0.
- `df` The degrees of freedom $n$, which must be greater than 0.
- `nc` Optional noncentrality parameter $\lambda$, which must be nonnegative. The default is 0.

**ChiSquare Distribution**($q$, `df`, `<nc=0>`)  
**Description**  
Returns cumulative distribution function at quantile $x$ for chi-square with $df$ degrees of freedom centered at $nc$. The cdf is parameterized as follows:

$$F(q) = \exp(-\lambda/2) \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} F_{n+2r}(q),$$

where $F_{n+2r}(q)$ is the cumulative distribution of a central chi-square distribution with $n+2r$ degrees of freedom.

**Arguments**

- `q` A quantile at which the cdf is evaluated. `q` must be greater than or equal to 0.
- `df` The degrees of freedom $n$, must be greater than 0.
- `nc` The optional noncentrality parameter $\lambda$, must be nonnegative. The default is 0.

**ChiSquare Log CDistribution**($x$, `df`, `<nc=0>`)  
**Description**  
Returns the log of $(1 - value)$, where value is the cumulative distribution function evaluated at $x$ of the chi-square distribution with $df$ degrees of freedom and noncentrality parameter $nc$.

**ChiSquare Log Density**($x$, `df`, `<nc=0>`)  
**Description**  
Returns the log of the value of the probability density function evaluated at $x$ of the chi-square distribution with $df$ degrees of freedom and noncentrality parameter $nc$.

**ChiSquare Log Distribution**($x$, `df`, `<nc=0>`)  
**Description**  
Returns the log of the value of the cumulative distribution function evaluated at quantile $x$ of the chi-square distribution with $df$ degrees of freedom and noncentrality parameter $nc$. 

ChiSquare Noncentrality(x, df, prob)

Description
Returns the chi-square distribution noncentrality parameter \( nc \) that satisfies the following:
\[
prob = \text{ChiSquare Distribution}(x, df, nc)
\]

Arguments
- \( x \) A quantile at which the cdf is evaluated.
- \( df \) The degrees of freedom \( n \), which must be greater than 0.
- \( prob \) The probability of the quantile desired; \( prob \) must be between 0 and 1.

ChiSquare Quantile(p, df, <nc=0>)

Description
Returns the \( p \text{th} \) quantile from a chi-square distribution with \( df \) degrees of freedom, centered at \( nc \). The quantile function does not have a closed form equation.

Arguments
- \( p \) The probability of the quantile desired. \( p \) must be between 0 and 1.
- \( df \) The degrees of freedom \( n \), which must be greater than 0.
- \( nc \) Optional noncentrality parameter \( \lambda \), which must be nonnegative. The default is 0.

Dunnett P Value(q, nTrt, dfe, <lambdaVec=.>)

Description
Returns the \( p \)-value from Dunnett’s multiple comparisons test.

Arguments
- \( q \) A number that is the test statistic.
- \( nTrt \) The number of treatments being compared to the control treatment.
- \( dfe \) The error degrees of freedom.
- \( lambdaVec \) A vector of parameters. If \( lambdaVec \) is missing (.), each of the parameters is set to \( 1/Sqrt(2) \).

Dunnett Quantile(1-alpha, nTrt, dfe, <lambdaVec=.>)

Description
Returns the quantile used in Dunnett’s multiple comparisons test.

Arguments
- \( 1-alpha \) A number that is the confidence level.
- \( nTrt \) The number of treatments being compared to the control treatment.
- \( dfe \) The error degrees of freedom.
lambdaVec  A vector of parameters. If lambdaVec is missing (.), each of the parameters is set to 1/Sqrt(2).

Exp Density(x, <theta=1>)

Description
Returns the probability density function (pdf) evaluated at x of the exponential distribution. The pdf is parameterized as follows:

\[ f(x) = \frac{1}{\theta} \exp(-x/\theta) \]

Arguments
- x  A quantile at which the pdf is evaluated. x must be greater than or equal to 0.
- theta  Optional scale parameter \( \theta \), which must be greater than 0. The default is 1.

Exp Distribution(x, <theta=1>)

Description
Returns the cumulative distribution function (cdf) evaluated at x of the exponential distribution. The cdf is parameterized as follows:

\[ F(x) = 1 - \exp(-x/\theta) \]

Arguments
- x  A quantile at which the cdf is evaluated. x must be greater than or equal to 0.
- theta  Optional scale parameter \( \theta \), which must be greater than 0. The default is 1.

Exp Quantile(p, <theta=1>)

Description
Returns the \( p \)th quantile from an exponential distribution with scale parameter \( \theta \). The quantile function is parameterized as follows:

\[ F^{-1}(p) = -\theta \log(1 - p) \]

Arguments
- p  The probability of the quantile desired. p must be between 0 and 1.
- theta  Optional scale parameter \( \theta \), which must be greater than 0. The default is 1.

F Density(x, dfnum, dfden, <nc=0>)

Description
Returns the probability density function (pdf) evaluated at x for the F distribution with numerator and denominator degrees of freedom dfnum and dfden, with optional noncentrality parameter nc.
where \( B(\cdot) \) is the Beta function.

**Arguments**
- \( x \) A quantile at which the pdf is evaluated. \( x \) must be greater than 0.
- \( \text{dfnum} \) The degrees of freedom, \( v_1 \), of the chi-square distribution in the numerator of the \( F \)-distribution. \( \text{dfnum} \) must be greater than 0.
- \( \text{dfden} \) The degrees of freedom, \( v_2 \), of the chi-square distribution in the denominator of the \( F \)-distribution. \( \text{dfden} \) must be greater than 0.
- \( nc \) Optional noncentrality parameter \( \lambda \), which must be nonnegative. The default is 0.

**F Distribution**(\( x, \text{dfnum}, \text{dfden}, <nc=0> \))

**Description**
Returns the cumulative distribution function (cdf) evaluated at \( x \) for the F distribution with numerator and denominator degrees of freedom \( \text{dfnum} \) and \( \text{dfden} \) and noncentrality parameter \( nc \).

**F Log CDistribution**(\( x, \text{dfnum}, \text{dfden}, <nc=0> \))

**Description**
Returns the log of \((1 - \text{value})\), where \text{value} is the cumulative distribution function evaluated at \( x \) of the F distribution with numerator and denominator degrees of freedom \( \text{dfnum} \) and \( \text{dfden} \), with optional noncentrality parameter \( nc \).

**F Log Density**(\( x, \text{dfnum}, \text{dfden}, <nc=0> \))

**Description**
Returns the log of the value of the probability density function (pdf) evaluated at \( x \) for the F distribution with numerator and denominator degrees of freedom \( \text{dfnum} \) and \( \text{dfden} \), with optional noncentrality parameter \( nc \).

**F Log Distribution**(\( x, \text{dfnum}, \text{dfden}, <nc=0> \))

**Description**
Returns the log of the value of the cumulative distribution function (cdf) evaluated at \( x \) for the F distribution with numerator and denominator degrees of freedom \( \text{dfnum} \) and \( \text{dfden} \) and noncentrality parameter \( nc \).
F Noncentrality(x, dfnum, dfden, prob)

Description
Returns the F distribution noncentrality parameter \( nc \) that satisfies the following:

\[
prob = F \text{ Distribution}(x, \ dfnum, \ dfden, \ nc)
\]

See Also
“F Distribution(x, dfnum, dfden, \(<nc=0>\))” on page 219

F Power(alpha, dfh, dfm, d, n)

Description
Returns the power from a given situation involving an F test or a t test.

Arguments
alpha  The significance level of the test. \( alpha \) must be between 0 and 1.
dfh    The hypothesis degrees of freedom. \( dfh \) must be greater than 0.
dfm    The degrees of freedom in the whole model. \( dfm \) must be greater than 0.
d The squared effect size, defined as \( \Delta^2/\sigma^2 \). In this equation, \( \sigma^2 \) is the error variance and \( \Delta^2 \) is defined as follows:

\[
\Delta^2 = (\bar{x} - \mu)^2 \text{ for a one-sample t test}
\]

\[
\Delta^2 = \frac{(\bar{x}_1 - \bar{x}_2)^2}{4} \text{ for a two-sample t test}
\]

\[
\Delta^2 = \frac{\sum_{i=1}^{k} (\bar{x}_i - \bar{x})^2}{k} \text{ for a k-sample F test}
\]
n The total number of observations. \( n \) must be greater than \( dfm \).

F Quantile(x, dfnum, dfden, \(<nc=0>\))

Description
Returns the \( \rho \text{th} \) quantile from the F distribution with numerator and denominator degrees of freedom \( dfnum \) and \( dfden \) and noncentrality parameter \( nc \).

F Sample Size(alpha, dfh, dfm, d, power)

Description
Returns the sample size from a given situation involving an F test or a t test.

Arguments
alpha  The significance level of the test. \( alpha \) must be between 0 and 1.
dfh    The hypothesis degrees of freedom. \( dfh \) must be greater than 0.
dfm  The degrees of freedom in the whole model. dfm must be greater than 0.

d  The squared effect size, defined as $\Delta^2/\sigma^2$. In this equation, $\sigma^2$ is the error variance and $\Delta^2$ is
defined as follows:

$$\Delta^2 = (\bar{x} - \mu)^2$$ for a one-sample $t$ test

$$\Delta^2 = \frac{(\bar{x}_1 - \bar{x}_2)^2}{4}$$ for a two-sample $t$ test

$$\Delta^2 = \frac{\sum_{i=1}^{k} (\bar{x}_i - \bar{x})^2}{k}$$ for a $k$-sample $F$ test

power  The desired power for the test.

**Frechet Density**($x$, mu, sigma)

**Description**

Returns the probability density function (pdf) evaluated at $x$ of the Fréchet distribution. The pdf is parameterized as follows:

$$f(x) = \exp\left[-\exp\left(-\frac{\log(x) - \mu}{\sigma}\right)\right] \exp\left(-\frac{\log(x) - \mu}{\sigma}\right) \frac{1}{x\sigma}$$

**Arguments**

$x$  A quantile at which the pdf is evaluated. $x$ must be greater than 0.

mu  The location parameter $\mu$.

sigma  The scale parameter $\sigma$, which must be greater than 0.

**Frechet Distribution**($x$, mu, sigma)

**Description**

Returns the cumulative distribution function (cdf) evaluated at $x$ of the Fréchet distribution. The cdf is parameterized as follows:

$$F(x) = \exp\left[-\exp\left(-\frac{\log(x) - \mu}{\sigma}\right)\right]$$

**Arguments**

$x$  A quantile at which the cdf is evaluated. $x$ must be greater than 0.

mu  The location parameter $\mu$.

sigma  The scale parameter $\sigma$, which must be greater than 0.
Frechet Quantile(p, mu, sigma)

Description

Returns the $p^{th}$ quantile from a Fréchet distribution with location $mu$ and scale $sigma$. The quantile function is parameterized as follows:

$$F^{-1}(p) = \exp[-\sigma \log{-\log(p)} + \mu]$$

Arguments

- $p$ The probability of the quantile desired. $p$ must be between 0 and 1.
- $mu$ The location parameter $\mu$.
- $sigma$ The scale parameter $\sigma$, which must be greater than 0.

Gamma Density(x, <alpha=1>, <scale=1>, <threshold=0>)

Description

Returns the probability density function (pdf) evaluated at $x$ of the Gamma distribution. The pdf is parameterized as follows:

$$f(x) = \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - \theta)^{\alpha - 1} \exp(-(x - \theta)/\beta)$$

Arguments

- $x$ A quantile at which the pdf is evaluated. $x$ must be greater than $\theta$.
- $alpha$ Optional shape parameter $\alpha$, which must be greater than 0. The default is 1.
- $scale$ Optional scale parameter $\beta$, which must be greater than 0. The default is 1.
- $threshold$ Optional threshold parameter $\theta$. The default is 0.

Gamma Distribution(x, <alpha=1>, <scale=1>, <threshold=0>)

IGamma(x, <alpha=1, scale=1, threshold=0>)

Description

Returns the cumulative distribution function (cdf) evaluated at quantile $x$ for the gamma distribution with parameters $alpha$, $scale$, and $threshold$.

Gamma Log CDistribution(x, <alpha=1>, <scale=1>, <threshold=0>)

Description

Same as $\log(1 - \text{Gamma Distribution}(x, alpha))$ except that it has a much greater range.
\textbf{Gamma Log Density}(x, <alpha=1>, <scale=1>, <threshold=0>)

\textbf{Description}

Same as Log(Gamma Density(x, alpha)) except that it has a much greater range.

\textbf{Gamma Log Distribution}(x, <alpha=1>, <scale=1>, <threshold=0>)

\textbf{Description}

Same as Log(Gamma Distribution(x, alpha)) except that it has a much greater range.

\textbf{Gamma Quantile}(p, <alpha=1>, <scale=1>, threshold>)

\textbf{Description}

Returns the \( p \)th quantile from the gamma distribution with the \textit{alpha}, \textit{scale}, and \textit{threshold} parameters given.

\textbf{GenGamma Density}(x, mu, sigma, lambda)

\textbf{Description}

Returns the probability density function (pdf) evaluated at \( x \) of an extended generalized gamma probability distribution. The pdf is parameterized as follows:

\[
f(x) = \begin{cases} 
\frac{|\lambda|}{x^\sigma} \phi_{\text{log}}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda \neq 0 \\
\frac{1}{x^\sigma} \phi_{\text{nor}}(\omega) & \text{if } \lambda = 0
\end{cases}
\]

where \( \omega = [\log(x) - \mu]/\sigma \). Note that the following is the pdf for the standardized log-gamma variable with shape parameter \( \kappa > 0 \):

\[
\phi_{\text{log}}(z; \kappa) = \frac{1}{\Gamma(\kappa)} \exp[\kappa z - \exp(z)]
\]

Note that \( \phi_{\text{nor}}(\cdot) \) is the standard normal pdf.

\textbf{Arguments}

- \( x \) A quantile at which the pdf is evaluated. \( x \) must be greater than 0.
- \( mu \) The location parameter \( \mu \).
- \( sigma \) The scale parameter \( \sigma \), which must be greater than 0.
- \( lambda \) A shape parameter \( \lambda \).
GenGamma Distribution(x, mu, sigma, lambda)

Description

Returns the cumulative distribution function (cdf) of the extended generalized gamma distribution. The cdf is parameterized as follows:

\[
F(x) = \begin{cases} 
    \Phi_{lg}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda > 0 \\
    \Phi_{nor}(\omega) & \text{if } \lambda = 0 \\
    1 - \Phi_{lg}[\lambda \omega + \log(\lambda^{-2}); \lambda^{-2}] & \text{if } \lambda < 0 
\end{cases}
\]

where \( \omega = (\log(x) - \mu)/\sigma \). Note that the following is the cdf for the standardized log-gamma variable with shape parameter \( \kappa > 0 \):

\[
\Phi_{lg}(z; \kappa) = \Gamma_I[\exp(z); \kappa]
\]

where \( \Gamma_I[\cdot] \) denotes the incomplete gamma function. Note that \( \Phi_{nor}(\cdot) \) is the standard normal cdf.

Arguments

- x  A quantile at which the cdf is evaluated. x must be greater than 0.
- mu The location parameter \( \mu \).
- sigma The scale parameter \( \sigma \), which must be greater than 0.
- lambda A shape parameter \( \lambda \).

GenGamma Quantile(p, mu, sigma, lambda)

Description

Returns the \( p^{th} \) quantile from an extended generalized gamma distribution with parameters \( \mu, \sigma, \) and \( \lambda \). The quantile function does not have a closed form equation.

Arguments

- p The probability of the quantile desired. p must be between 0 and 1.
- mu The location parameter \( \mu \).
- sigma The scale parameter \( \sigma \), which must be greater than 0.
- lambda A shape parameter \( \lambda \).

GLog Density(x, mu, sigma, lambda)

Description

Returns the probability density function (pdf) evaluated at \( x \) of a generalized logarithmic distribution. The pdf is parameterized as follows:
\[
f(x) = \frac{1}{\sigma} \left[ \log \left( \frac{x + \sqrt{x^2 + \lambda^2}}{2} \right) - \mu \right] \frac{x + \sqrt{x^2 + \lambda^2}}{\sigma(x^2 + \lambda^2 + x\sqrt{x^2 + \lambda^2})}
\]

where \( \phi(\cdot) \) is the standard normal pdf.

**Arguments**
- \( x \) A quantile at which the pdf is evaluated.
- \( \mu \) The location parameter \( \mu \).
- \( \sigma \) The scale parameter \( \sigma \), which must be greater than 0.
- \( \lambda \) A shape parameter \( \lambda \), which must be greater than 0.

**Notes**
When the shape parameter is equal to zero, the distribution reduces to a Lognormal(\( \mu, \sigma \)).

---

**GLog Distribution(\( x, \mu, \sigma, \lambda \))**

**Description**
Returns the probability that a generalized logarithmically distribution random variable is less than \( x \). The cdf is parameterized as follows:

\[
F(x) = \Phi \left\{ \frac{1}{\sigma} \left[ \log \left( \frac{x + \sqrt{x^2 + \lambda^2}}{2} \right) - \mu \right] \right\}
\]

where \( \Phi(\cdot) \) is the standard normal cdf.

**Arguments**
- \( x \) A quantile at which the cdf is evaluated.
- \( \mu \) The location parameter \( \mu \).
- \( \sigma \) The scale parameter \( \sigma \), which must be greater than 0.
- \( \lambda \) A shape parameter \( \lambda \), which must be greater than 0.

**GLog Quantile(\( p, \mu, \sigma, \lambda \))**

**Description**
Returns the \( p^{th} \) quantile from a generalized logarithmic distribution.

---

**IGamma()**

See “Gamma Distribution(\( x, \alpha=1, \sigma=1, \text{threshold}=0 \))” on page 222.
Johnson Sb Density(q, gamma, delta, theta, sigma)

Description
Returns the probability density function (pdf) evaluated at q of a Johnson Sb distribution. The pdf is parameterized as follows:

\[
f(q) = \Phi \left[ \gamma + \delta \ln \left( \frac{q - \theta}{\sigma - (q - \theta)} \right) \right] \left( \frac{\delta \sigma}{(q - \theta)(\sigma - (q - \theta))} \right)
\]

where \(\Phi(\cdot)\) is the standard normal pdf.

Arguments
- q A quantile at which the pdf is evaluated. q must be in the interval theta to theta + sigma.
- gamma Shape parameter \(\gamma\).
- delta Shape parameter \(\delta\), which must be greater than 0.
- theta Location parameter \(\theta\).
- sigma Scale parameter \(\sigma\), which must be greater than 0.

Johnson Sb Distribution(q, gamma, delta, theta, sigma)

Description
Returns the cumulative distribution function (cdf) evaluated at q of a Johnson Sb distribution. The cdf is parameterized as follows:

\[
F(q) = \Phi \left[ \gamma + \delta \ln \left( \frac{q - \theta}{\sigma - (q - \theta)} \right) \right]
\]

where \(\Phi(\cdot)\) is the standard normal cdf.

Arguments
- q A quantile at which the cdf is evaluated. q must be in the interval theta to theta + sigma.
- gamma Shape parameter \(\gamma\).
- delta Shape parameter \(\delta\), which must be greater than 0.
- theta Location parameter \(\theta\).
- sigma Scale parameter \(\sigma\), which must be greater than 0.

Johnson Sb Quantile(p, gamma, delta, theta, sigma)

Description
Returns the \(p^{th}\) quantile from a Johnson Sb distribution.

Arguments
- p The probability of the quantile desired. p must be between 0 and 1.
- gamma Shape parameter \(\gamma\).
Joseph Sl Density \( (x, \gamma, \delta, \theta, \sigma) \)

**Description**

Returns the probability density function (pdf) evaluated at \( x \) of a Johnson Sl distribution. The pdf is parameterized as follows:

\[
f(x) = \frac{\delta}{|x - \theta|} \phi\left[\gamma + \delta \ln\left(\frac{x - \theta}{\sigma}\right)\right]
\]

where \( \phi(\cdot) \) is the standard normal pdf.

**Arguments**

- \( x \) A quantile at which the pdf is evaluated. \( x \) must be greater than \( \theta \) if \( \sigma = 1 \) and less than \( \theta \) if \( \sigma = -1 \).
- \( \gamma \) Shape parameter \( \gamma \).
- \( \delta \) Shape parameter \( \delta \), which must be greater than 0.
- \( \theta \) Location parameter \( \theta \).
- \( \sigma \) Scale parameter \( \sigma \) that indicates if the distribution is skewed positively or negatively. \( \sigma \) must be equal to either \( +1 \) (skewed positively) or \( -1 \) (skewed negatively).

Johnson Sl Distribution \( (q, \gamma, \delta, \theta, \sigma) \)

**Description**

Returns the cumulative distribution function (cdf) evaluated at \( q \) of a Johnson Sl distribution.

\[
F(x) = \begin{cases} 
\Phi\left[\gamma + \delta \ln\left(\frac{x - \theta}{\sigma}\right)\right], & \sigma = 1 \\
1 - \Phi\left[\gamma + \delta \ln\left(\frac{x - \theta}{\sigma}\right)\right], & \sigma = -1 
\end{cases}
\]

where \( \Phi(\cdot) \) is the standard normal cdf.

**Arguments**

- \( q \) A quantile at which the cdf is evaluated. \( q \) must be greater than \( \theta \) if \( \sigma = 1 \) and less than \( \theta \) if \( \sigma = -1 \).
- \( \gamma \) Shape parameter \( \gamma \).
- \( \delta \) Shape parameter \( \delta \), which must be greater than 0.
- \( \theta \) Location parameter \( \theta \).
**Johnson Sl Quantile**

**Description**

Returns the \( p \)th quantile from a Johnson Sl distribution.

**Arguments**

- **\( p \)**: The probability of the quantile desired. \( p \) must be between 0 and 1.
- **gamma**: Shape parameter \( \gamma \).
- **delta**: Shape parameter \( \delta \), which must be greater than 0.
- **theta**: Location parameter \( \theta \).
- **sigma**: Parameter \( \sigma \) that defines if the distribution is skewed positively or negatively. Sigma must be equal to either +1 (skewed positively) or -1 (skewed negatively).

**Johnson Su Density**

**Description**

Returns the probability density function (pdf) evaluated at \( x \) of a Johnson Su distribution. The pdf is parameterized as follows:

\[
f(x) = \frac{\delta}{\sigma} \left[ 1 + \left( \frac{x - \theta}{\sigma} \right)^2 \right]^{-1/2} \Phi \left[ \gamma + \delta \sinh^{-1} \left( \frac{x - \theta}{\sigma} \right) \right]
\]

where \( \Phi(\cdot) \) is the standard normal pdf.

**Arguments**

- **x**: A quantile at which the pdf is evaluated.
- **gamma**: Shape parameter \( \gamma \).
- **delta**: Shape parameter \( \delta \), which must be greater than 0.
- **theta**: Location parameter \( \theta \).
- **sigma**: Scale parameter \( \sigma \), which must be greater than 0.

**Johnson Su Distribution**

**Description**

Returns the cumulative distribution function (cdf) evaluated at \( q \) of a Johnson Su distribution. The cdf is parameterized as follows:

\[
F(x) = \Phi \left[ \gamma + \delta \sinh^{-1} \left( \frac{x - \theta}{\sigma} \right) \right]
\]

where \( \Phi(\cdot) \) is the standard normal cdf.
Arguments

q A quantile at which the cdf is evaluated.
gamma Shape parameter $\gamma$.
delta Shape parameter $\delta$, which must be greater than 0.
theta Location parameter $\theta$.
sigma Scale parameter $\sigma$, which must be greater than 0.

Johnson Su Quantile($p$, gamma, delta, theta, sigma)

Description

Returns the $p^{\text{th}}$ quantile from a Johnson Su distribution.

Arguments

$p$ The probability of the quantile desired. $p$ must be between 0 and 1.
gamma Shape parameter $\gamma$.
delta Shape parameter $\delta$, which must be greater than 0.
theta Location parameter $\theta$.
sigma Scale parameter $\sigma$, which must be greater than 0.

LEV Density($x$, mu, sigma)

Description

Returns the probability density function (pdf) evaluated at $x$ of the largest extreme value distribution with location $\mu$ and scale $\sigma$. The pdf is parameterized as follows:

\[
f(x) = \frac{1}{\sigma} \exp \left[ -\frac{x-\mu}{\sigma} - \exp \left( -\frac{x-\mu}{\sigma} \right) \right]
\]

Arguments

$x$ A quantile at which the pdf is evaluated.
mu The location parameter $\mu$.
sigma The scale parameter $\sigma$, which must be greater than 0.

LEV Distribution($x$, mu, sigma)

Description

Returns the cumulative distribution function (cdf) evaluated at $x$ of the largest extreme value distribution with location $\mu$ and scale $\sigma$. The cdf is parameterized as follows:

\[
F(x) = \exp \left[ -\exp \left( -\frac{x-\mu}{\sigma} \right) \right]
\]

Arguments

$x$ A quantile at which the cdf is evaluated. $x$ must be greater than $\sigma$. 
mu The location parameter $\mu$.

sigma The scale parameter $\sigma$, which must be greater than 0.

**LEV Quantile(p, mu, sigma)**

**Description**

Returns the $p^{th}$ quantile from a largest extreme value distribution with location $mu$ and scale $sigma$. The quantile function is parameterized as follows:

$$ F^{-1}(p) = -\sigma \log(-\log(p)) + \mu $$

**Arguments**

- $p$ The probability of the quantile desired. $p$ must be between 0 and 1.
- $mu$ The location parameter $\mu$.
- $sigma$ The scale parameter $\sigma$, which must be greater than 0.

**LogGenGamma Density(x, mu, sigma, lambda)**

**Description**

Returns the probability density function (pdf) evaluated at $x$ of a log generalized gamma probability distribution with parameters $mu$, $sigma$, and $lambda$. The pdf is parameterized as follows:

$$ f(x) = \begin{cases} 
\frac{[\lambda]}{\sigma} \phi_{lg}[\lambda \omega + \log(\lambda^{-2});\lambda^{-2}] & \text{if } \lambda \neq 0 \\
\frac{1}{\sigma} \phi_{nor}(\omega) & \text{if } \lambda = 0 
\end{cases} $$

where $\omega = [x - \mu]/\sigma$. Note that the following is the pdf for the log-gamma variable with shape parameter $\kappa > 0$:

$$ \phi_{lg}(z;\kappa) = \frac{1}{\Gamma(\kappa)} \exp[\kappa z - \exp(z)] $$

Note that $\phi_{nor}(\cdot)$ is the standard normal pdf.

**Arguments**

- $x$ A quantile at which the pdf is evaluated.
- $mu$ The location parameter $\mu$.
- $sigma$ The scale parameter $\sigma$, which must be greater than 0.
- $lambda$ A shape parameter $\lambda$. 
LogGenGamma Distribution(x, mu, sigma, lambda)

Description
Returns the cumulative distribution function (cdf) evaluated at x of the log generalized gamma distributed random variable (with parameters \(\mu\), \(\sigma\), and \(\lambda\)). The cdf is parameterized as follows:

\[
F(x) = \begin{cases} 
  \Phi_{lg}[\lambda \omega + \log(\lambda^{-2});\lambda^{-2}] & \text{if } \lambda > 0 \\
  \Phi_{nor}(\omega) & \text{if } \lambda = 0 \\
  1 - \Phi_{lg}[\lambda \omega + \log(\lambda^{-2});\lambda^{-2}] & \text{if } \lambda < 0 
\end{cases}
\]

where \(\omega = [x - \mu]/\sigma\). Note that the following is the cdf for the log-gamma variable with shape parameter \(\kappa > 0\):

\[
\Phi_{lg}(z;\kappa) = \Gamma_{I}[\exp(z);\kappa]
\]

where \(\Gamma_{I}[\cdot]\) denotes the incomplete gamma function. Note that \(\Phi_{nor}(\cdot)\) is the standard normal cdf.

Arguments
- x A quantile at which the cdf is evaluated.
- mu The location parameter \(\mu\).
- sigma The scale parameter \(\sigma\), which must be greater than 0.
- lambda A shape parameter \(\lambda\).

LogGenGamma Quantile(p, mu, sigma, lambda)

Description
Returns the \(p^{th}\) quantile from a log generalized gamma distribution.

Arguments
- p The probability of the quantile desired. \(p\) must be between 0 and 1.
- mu The location parameter \(\mu\).
- sigma The scale parameter \(\sigma\), which must be greater than 0.
- lambda A shape parameter \(\lambda\).

Logistic Density(x, mu, sigma)

Description
Returns the probability density function (pdf) evaluated at \(x\) of a logistic distribution with location \(mu\) and scale \(sigma\). The pdf is parameterized as follows:
JSL Functions

Chapter 2
Probability Functions

Arguments

\[ x \] A quantile at which the pdf is evaluated.
\[ \mu \] The location parameter \( \mu \).
\[ \sigma \] The scale parameter \( \sigma \), which must be greater than 0.

Logistic Distribution \((x, \mu, \sigma)\)

Description

Returns the cumulative distribution function (cdf) evaluated at \( x \) of the logistic distribution with location \( \mu \) and scale \( \sigma \). The cdf is parameterized as follows:

\[
F(x) = \frac{1}{1 + \exp\left(-\frac{x - \mu}{\sigma}\right)}
\]

Arguments

\[ x \] A quantile at which the cdf is evaluated. \( x \) must be greater than \( \sigma \).
\[ \mu \] The location parameter \( \mu \).
\[ \sigma \] The scale parameter \( \sigma \), which must be greater than 0.

Logistic Quantile \((p, \mu, \sigma)\)

Description

Returns the \( p^{th} \) quantile from a logistic distribution with location \( \mu \) and scale \( \sigma \). The quantile function is parameterized as follows:

\[
F^{-1}(p) = -\sigma \log\left(\frac{1}{p} - 1\right) + \mu
\]

Arguments

\[ p \] The probability of the quantile desired. \( p \) must be between 0 and 1.
\[ \mu \] The location parameter \( \mu \).
\[ \sigma \] The scale parameter \( \sigma \), which must be greater than 0.

Loglogistic Density \((x, \mu, \sigma)\)

Description

Returns the probability density function (pdf) evaluated at \( x \) of a loglogistic distribution with location \( \mu \) and scale \( \sigma \). The pdf is parameterized as follows:

\[
f(x) = \frac{\exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma \left[1 + \exp\left(-\frac{x - \mu}{\sigma}\right)\right]^2}
\]
**Lognormal Density Function**

\[ f(x) = \frac{1}{x\sigma} \frac{\exp\left(\frac{\log(x) - \mu}{\sigma}\right)}{1 + \exp\left(\frac{\log(x) - \mu}{\sigma}\right)}^2 \]

**Arguments**
- \( x \): A quantile at which the pdf is evaluated.
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.

**Loglogistic Distribution**

\[ F(x) = \frac{1}{1 + \exp\left(\frac{\log(x) - \mu}{\sigma}\right)} \]

**Arguments**
- \( x \): A quantile at which the cdf is evaluated.
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.

**Loglogistic Quantile Function**

\[ F^{-1}(p) = \exp\left[ -\sigma \log\left(\frac{1}{p} - 1\right) + \mu \right] \]

**Arguments**
- \( p \): The probability of the quantile desired. \( p \) must be between 0 and 1.
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.
The function \( f(x) = \frac{1}{x} \phi \left[ \frac{\log(x) - \mu}{\sigma} \right] \)

where \( \phi(\cdot) \) is the standard normal pdf.

**Arguments**
- **x** A quantile at which the pdf is evaluated. \( x \) must be greater than or equal to 0.
- **mu** The location parameter \( \mu \).
- **sigma** The scale parameter \( \sigma \), which must be greater than 0.

---

### Lognormal Distribution (x, mu, sigma)

**Description**
Returns the cumulative distribution function (cdf) evaluated at \( x \) of a lognormal distribution with location \( \mu \) and scale \( \sigma \). The cdf is parameterized as follows:

\[
F(x) = \Phi \left[ \frac{\log(x) - \mu}{\sigma} \right]
\]

where \( \Phi(\cdot) \) is the standard normal cdf.

**Arguments**
- **x** A quantile at which the pdf is evaluated. \( x \) must be greater than or equal to 0.
- **mu** The location parameter \( \mu \).
- **sigma** The scale parameter \( \sigma \), which must be greater than 0.

---

### Lognormal Quantile (x, mu, sigma)

**Description**
Returns the \( p^{th} \) quantile of a lognormal distribution with location \( \mu \) and scale \( \sigma \).

---

### Normal Biv Distribution (x, y, r, <mu1>, <s1>, <mu2>, <s2>)

**Description**
Computes the probability that an observation \((X, Y)\) is less than or equal to \((x, y)\) with correlation coefficient \( r \) where \( X \) is individually normally distributed with mean \( \mu_1 \) and standard deviation \( s_1 \) and \( Y \) is individually normally distributed with mean \( \mu_2 \) and standard deviation \( s_2 \). If \( \mu_1, s_1, \mu_2, \text{ and } s_2 \) are not given, the function assumes the standard normal bivariate distribution with \( \mu_1=0, s_1=1, \mu_2=0, \text{ and } s_2=1 \).

---

### Normal Density (x, <mean=0>, <stddev=1>)

**Description**
Returns the probability density function (pdf) evaluated at \( x \) for the normal distribution with \( \text{mean} \) and \( \text{stddev} \). The pdf is parameterized as follows:
Chapter 2  JSL Functions  235
JSL Syntax Reference Probability Functions

Normal Distribution(x, <mean=0>, <stddev=1>)

Description
Returns the cumulative distribution function (cdf) evaluated at \( x \) for the normal distribution with \( \text{mean} \) and \( \text{stddev} \). The cdf is parameterized as follows:

\[
F(x) = \Phi\left(\frac{x - \mu}{\sigma}\right)
\]

Note that \( \Phi(\cdot) \) is the standard normal cdf, defined as follows:

\[
\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp\left(-\frac{t^2}{2}\right) dt
\]

Arguments
- \( x \) A quantile at which the pdf is evaluated.
- \( \mu \) Optional location parameter \( \mu \). The default is 0.
- \( \sigma \) Optional scale parameter \( \sigma \), which must be greater than 0. The default is 1.

Normal Log CDistribution(x, <mean=0>, <std dev=1>)

Description
Returns \( 1 - \log \) (value) of the distribution function at quantile \( x \) for the normal distribution.

Normal Log Density(x, <mean=0>, <stddev=1>)

Description
Returns the log of the value of the density function at quantile \( x \) for the normal distribution with \( \text{mean} \) and \( \text{stddev} \). The default \( \text{mean} \) is 0. The default \( \text{stddev} \) is 1.
Normal Log Distribution(x, <mean=0>, <std dev=1>)

**Description**
Returns the log of the value of the distribution function at quantile x for the normal distribution.

Normal Mixture Density(q, mean, stdev, probability)

**Description**
Returns the density at q of a normal mixture distribution with group means mean, group standard deviations stdev, and group probabilities probability. The mean, stdev, and probability arguments are all vectors of the same size.

Normal Mixture Distribution(q, mean, stdev, probability)

**Description**
Returns the probability that a normal mixture distributed variable with group means mean, group standard deviations stdev, and group probabilities probability is less than q. The mean, stdev, and probability arguments are all vectors of the same size.

Normal Mixture Quantile(p, mean, stdev, probability)

**Description**
Returns the p\(^{th}\) quantile, the values for which the probability is p that a random value would be lower. The mean, stdev, and probability arguments are all vectors of the same size.

Normal Quantile(p, <mean=0>, <stddev=1>)

Probit(p, <mean=0>, <stddev=1>)

**Description**
Returns the p\(^{th}\) quantile from the normal distribution with mean and stddev. The default mean is 0. the default stddev is 1.

Probit()

See “Normal Quantile(p, <mean=0>, <stddev=1>)” on page 236.

SEV Density(x, mu, sigma)

**Description**
Returns the probability density function (pdf) evaluated at x of the smallest extreme distribution with location mu and scale sigma. The pdf is parameterized as follows:
\( f(x) = \frac{1}{\sigma} \exp \left[ \frac{x - \mu}{\sigma} - \exp \left( \frac{x - \mu}{\sigma} \right) \right] \)

**Arguments**
- \( x \): A quantile at which the pdf is evaluated.
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.

**SEV Distribution(\( x, \mu, \sigma \))**

**Description**
Returns the cumulative distribution function (cdf) evaluated at \( x \) of the smallest extreme distribution with location \( \mu \) and scale \( \sigma \). The cdf is parameterized as follows:

\[ F(x) = 1 - \exp \left[ -\exp \left( \frac{x - \mu}{\sigma} \right) \right] \]

**Arguments**
- \( x \): A quantile at which the cdf is evaluated. \( x \) must be greater than \( \sigma \).
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.

**SEV Quantile(\( p, \mu, \sigma \))**

**Description**
Returns the \( p \)th quantile of the smallest extreme distribution with location \( \mu \) and scale \( \sigma \). The quantile function is parameterized as follows:

\[ F^{-1}(p) = \sigma \log[-\log(1-p)] + \mu \]

**Arguments**
- \( p \): The probability of the quantile desired. \( p \) must be between 0 and 1.
- \( \mu \): The location parameter \( \mu \).
- \( \sigma \): The scale parameter \( \sigma \), which must be greater than 0.

**SHASH Density(\( x, \gamma, \delta, \theta, \sigma \))**

**Description**
Returns the probability density function (pdf) evaluated at \( x \) of a sinh-arcsinh (SHASH) distribution. The pdf is parameterized as follows:

\[ f(x) = \frac{\delta \cosh(w)}{\sqrt{\sigma^2 + (x - \theta)^2}} \phi[\sinh(w)] \]

where
\( \phi(\cdot) \) is the standard normal pdf

\[ w = \gamma + \delta \sinh^{-1}\left( \frac{x - \theta}{\sigma} \right) \]

**Arguments**

- \( x \) A quantile at which the pdf is evaluated.
- \( \text{gamma} \) The shape parameter \( \gamma \).
- \( \text{delta} \) The shape parameter \( \delta \), which must be greater than 0.
- \( \text{theta} \) The location parameter \( \theta \).
- \( \text{sigma} \) The scale parameter \( \sigma \), which must be greater than 0.

**SHASH Distribution\((x, \text{gamma}, \text{delta}, \text{theta}, \text{sigma})\)**

**Description**

Returns the cumulative distribution function (cdf) evaluated at \( x \) of the sinh-arcsinh (SHASH) distribution. The cdf is parameterized as follows:

\[ F(x) = \Phi\left[ \sinh\left( \gamma + \delta \sinh^{-1}\left( \frac{x - \theta}{\sigma} \right) \right) \right] \]

where \( \Phi(\cdot) \) is the standard normal cdf.

**Arguments**

- \( x \) A quantile at which the cdf is evaluated.
- \( \text{gamma} \) The shape parameter \( \gamma \).
- \( \text{delta} \) The shape parameter \( \delta \), which must be greater than 0.
- \( \text{theta} \) The location parameter \( \theta \).
- \( \text{sigma} \) The scale parameter \( \sigma \), which must be greater than 0.

**SHASH Quantile\((p, \text{gamma}, \text{delta}, \text{theta}, \text{sigma})\)**

**Description**

Returns the \( p \)th quantile from a sinh-arcsinh (SHASH) distribution (with parameters \text{gamma}, \text{delta}, \text{theta}, \text{and} \text{sigma}).

**Arguments**

- \( p \) The probability of the quantile desired. \( p \) must be between 0 and 1.
- \( \text{gamma} \) The shape parameter \( \gamma \).
- \( \text{delta} \) The shape parameter \( \delta \), which must be greater than 0.
- \( \text{theta} \) The location parameter \( \theta \).
- \( \text{sigma} \) The scale parameter \( \sigma \), which must be greater than 0.
Students t Density()

See “t Density(x, df, <nc=0>)” on page 239.

Students t Distribution()

See “t Distribution(q, df, <nc=0>)” on page 239.

Students t Quantile()

See “t Quantile(p, df, <nc=0>)” on page 240.

t Density(x, df, <nc=0>)

Students t Density(x, df, <nc=0>)

Description

Returns the probability density function (pdf) evaluated at \( x \) of the Student’s \( t \) distribution with degrees of freedom \( df \). The pdf is parameterized as follows:

\[
f(x) = \frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{\pi v}} \left[1 + \frac{x^2}{v}\right]^{-\frac{v+1}{2}}
\]

Arguments

- \( x \) A quantile at which the pdf is evaluated.
- \( df \) The degrees of freedom \( v \), which must be greater than or equal to 1.
- \( nc \) The optional noncentrality parameter \( \lambda \), which must be nonnegative. The default is 0.

t Distribution(q, df, <nc=0>)

Students t Distribution(q, df, <nc=0>)

Description

Returns the probability that a Student’s \( t \) distributed random variable is less than \( q \). \( nc \) defaults to 0.

t Log CDistribution(x, df, <nc=0>)

Description

Returns 1 - log (value) of the normal distribution function at quantile \( x \) for the \( t \) distribution.
\texttt{t Log Density}(x, \text{df}, <\text{nc}=0>)

\textbf{Description}

Returns the log of the value of the density function at quantile \textit{x} for the \textit{t} distribution.

\texttt{t Log Distribution}(x, \text{df}, <\text{nc}=0>)

\textbf{Description}

Returns the log of the value of the distribution function at quantile \textit{x} for the \textit{t} distribution.

\texttt{t Noncentrality}(x, \text{df}, \text{prob})

\textbf{Description}

Returns the \textit{t} distribution noncentrality parameter \textit{nc} that satisfies the following:

\begin{equation*}
\text{prob} = \text{T Distribution}(x, \text{df}, \text{nc})
\end{equation*}

\texttt{t Quantile}(p, \text{df}, <\text{nc}=0>)

\texttt{Students t Quantile}(p, \text{df}, <\text{nc}=0>)

\textbf{Description}

Returns the \textit{p}th quantile from the Student’s \textit{t} distribution with degrees of freedom \textit{df}. \textit{nc} defaults to 0.

\texttt{Tukey HSD P Value}(q, n, dfe)

\textbf{Description}

Returns the \textit{p}-value from Tukey’s HSD multiple comparisons test.

\textbf{Arguments}

- \textit{q} The test statistic. The test statistic that is specified is Tukey’s adjusted critical value, which is the quantile of Tukey’s studentized range distribution divided by the square root of 2.
- \textit{n} The number of groups in the study.
- \textit{dfe} The error degrees of freedom, based on the total study sample.

\texttt{Tukey HSD Quantile}(\text{1-alpha}, n, dfe)

\textbf{Description}

Returns the quantile used in Tukey’s HSD multiple comparisons test. The quantile that is returned is Tukey’s adjusted critical value, which is the quantile of Tukey’s studentized range distribution divided by the square root of 2.

\textbf{Arguments}

- \text{1-alpha} The confidence level.
The number of groups in the study.
dfe The error degrees of freedom, based on the total study sample.

Weibull Density(x, shape, <scale=1>, <threshold=0>)

Description
Returns the probability density function (pdf) evaluated at \( x \) of the Weibull distribution. The pdf is parameterized as follows:

\[
  f(x) = \frac{\beta}{\alpha} \left(\frac{x-\theta}{\alpha}\right)^{\beta-1} \exp\left[-\left(\frac{x-\theta}{\alpha}\right)^{\beta}\right]
\]

Arguments
- \( x \) A quantile the pdf is evaluated at. \( x \) must be greater than \( \text{threshold} \).
- shape Shape parameter \( \beta \), which must be greater than 0.
- scale Optional scale parameter \( \alpha \), which must be greater than 0. The default is 1.
- threshold Optional threshold parameter \( \theta \). The default is 0.

Weibull Distribution(x, shape, <scale=1>, <threshold=0>)

Description
Returns the cumulative distribution function (cdf) at \( x \) of the Weibull distribution. The cdf is parameterized as follows:

\[
  F(x) = 1 - \exp\left[-\left(\frac{x-\theta}{\alpha}\right)^{\beta}\right]
\]

Arguments
- \( x \) A quantile at which the pdf is evaluated. \( x \) must be greater than \( \text{threshold} \).
- shape Shape parameter \( \beta \), which must be greater than 0.
- scale Optional scale parameter \( \alpha \), which must be greater than 0. The default is 1.
- threshold Optional threshold parameter \( \theta \). The default is 0.

Weibull Quantile(p, shape, <scale=1>, <threshold=0>)

Description
Returns the \( p \)th quantile from the Weibull distribution with the parameters given. The quantile function is calculated as follows:

\[
  F^{-1}(p) = \alpha\left[\ln(1-p)\right]^{\beta} + \theta
\]

Arguments
- \( p \) The probability of the quantile desired. \( p \) must be between 0 and 1.
- shape Shape parameter \( \beta \), which must be greater than 0.
scale  Optional scale parameter $\alpha$, which must be greater than 0. The default is 1.
threshold Optional threshold parameter $\theta$. The default is 0.

### Programming Functions

#### As Boolean(x)

**Description**
Evaluates a JSL expression and returns a JSL Boolean value for use with JSON data.

**Example**
```latex
x = 45;
b = \text{As Boolean}( x > 2 );
Show( b );
\quad b = \text{true};
```

#### As Column(name)

**As Column(dt, name)**

**:name**

**dt:name**

**Description**
This scoping operator forces *name* to be evaluated as a data table column in the current
data table (or the table given by the optional data table reference argument, *dt*) rather than
as a global variable.

**Arguments**
- *name*  Variable name.
- *dt*  The data table reference

**Notes**
*:name* refers to a column name in the current data table. You can also specify which data
table to refer to by use *dt:*name.

#### As Constant(expr)

**Description**
Evaluates an expression once to create a value that does not change after it is computed.

**Returns**
The result of the evaluation.
Argument

\[
\text{expr} \quad \text{Any JSL expression.}
\]

Notes
A few platforms that can save prediction columns to a data table use As Constant(). The function is wrapped around the part of the formula that is constant across all rows. The argument is evaluated for the first row and then the result is used without re-evaluation for subsequent rows.

As Global(name)
::name

Description
This scoping operator forces name to be evaluated as a global variable rather than as a data table column.

Arguments
name Variable name.

As List(matrix)

See “As List(matrix)” on page 169.

As Name(string)

Description
Evaluates argument as a quoted string and changes it into a name.

Returns
A name.

As Namespace(name)

Description
Accesses the specified namespace. An error is thrown if no such namespace exists.

Returns
The namespace.

Arguments
name Unquoted name of a defined namespace.
As Scoped(namespace, variable)

namespace:variable

**Description**
Accesses the specified `variable` within the specified `namespace`.

**Returns**
The value of the variable, or an error the scoped variable is not found.

**Arguments**
- `namespace` The name of a defined namespace.
- `variable` A variable defined within `namespace`.

Associative Array({key, value}, ...)

Associative Array(keys, values)

**Description**
Creates an associative array (also known as a dictionary or hash map).

**Returns**
An associative array object.

**Arguments**
Either list of key-value pairs; or a list, matrix, or data table column that contains keys followed by a list, matrix, or data table column, respectively, that contains the corresponding values.

Class Exists(class)

**Description**
Returns a value indicating whether a class definition represented by the class reference is a defined class.

**Returns**
0 or 1.

**Argument**
- `class` A quoted string representation of the name of a defined class or reference to an instantiated class object.

Clear Globals(<name>, <name>, ...)

**Description**
Clears the values for all global symbols. Symbols in any scope other than global are not affected. If one or more names are specified, only those global symbols are cleared.
Returns
Null.

Optional Arguments
name Any global variable name(s).

See Also
“Clear Symbols(<name>, <name>, ...)” on page 245

Clear Log()

Description
Empties the log.

Clear Symbols(<name>, <name>, ...)

Description
Clear the values for all symbols in any and all scopes. If one or more names are specified, only those symbols are cleared.

Returns
Null.

Optional Arguments
name Any global variable name(s).

See Also
“Clear Globals(<name>, <name>, ...)” on page 244

Close Log()

Description
Closes the log.

Define Class("class name", <Base Class( "base class name", <"base class name", ...> ),>, <Show( All(Boolean) ) | Show( <Members(Boolean),> <Methods(Boolean),> <Functions(Boolean)> ),>, <Assignment Statements>)

Description
Defines a new class object.

Example
Define Class("aa",
_init_ = Method( {} ); x = 1; m1 = Method( {a, b}, a * b )
);
Delete Classes(<Force(Boolean)>, < <class>, ...>)

Description
Deletes all currently defined classes.

Optional Arguments
Force(Boolean) Deletes the class or classes even if they are in use.
class Specifies the classes to delete. You can specify more than one class. This argument can be a quoted string representation of the name of a defined class or a reference to an instantiated class object.

Delete Globals(<name>, <name>, ...) 

Description
Deletes all global symbols, except global symbols that are locked. Symbols in any scope other than global are not affected. If one or more names are specified, only those global symbols are cleared.

Optional Arguments
name Any global variable name(s).

See Also
“Delete Symbols(<name>, <name>, ...)” on page 246

Delete Namespaces(<Force(Boolean expression)>, < <namespace reference>, ...>)

Delete(<Force(Boolean expression)>, < <namespace reference>, ...>)

Description
Deletes all currently defined namespaces or one or more specific namespaces.

Optional Arguments
Force(Boolean expression) Deletes the namespace even if it’s in use.
namespace reference Specifies the namespaces to delete. You can specify more than one namespace reference.

Notes
• When you delete a namespace that contains locked namespaces, an error appears in the log. Use the Force() argument to delete the locked namespaces.
• With no arguments, Delete Namespaces() ignores locked namespaces.

Delete Symbols(<name>, <name>, ...)

Description
Deletes all symbols in any and all scopes. If one or more names are specified, only those symbols are deleted.
Optional Arguments
name Any global variable name(s).

See Also
“Delete Globals(<name>, <name>, ...)” on page 246

Eval(expr)

Description
Evaluates expr, and then evaluates the result of expr (unquoting).

Returns
The result of the evaluation.

Argument
expr Any JSL expression.

Eval Insert(string, <startDel>, <endDel>, < <<Use Locale(1) >>)

Description
Allows for multiple substitutions.

Returns
The result.

Arguments
string A quoted string with embedded expressions.
startDel Optional starting delimiter. The default value is ^.
endDel optional ending delimited. The default value is the starting delimiter.
Use Locale(1) Optional argument that preserves locale-specific numeric formatting.

Eval Insert Into(string, <startDel>, <endDel>)

Description
Allows for multiple substitutions in place. The same operation as in Eval Insert is performed, and the result is placed into the quoted string.

Returns
The result.

Arguments
string A quoted string variable that contains a string with embedded expressions.
startDel Optional starting delimiter. The default value is ^.
endDel optional ending delimited. The default value is the starting delimiter.
Eval List

See “Eval List([list])” on page 169.

Exit(<NoSave>)
Quit(<NoSave>)

Description
Exits JMP.

Returns
Void.

Arguments
NoSave  Optional, named command; exits JMP without prompting to save any open files.
This command is not case-sensitive, and spaces are optional.

First(expr, <expr>, ...)

Description
Evaluates all expressions provided as arguments.

Returns
Only the result of the first evaluated expression.

Arguments
expr  Any valid JSL expression.

Function({arguments}, <{local variables}>, <Return(<expr>)>, script)

Description
Stores the body script with arguments as local variables.

Returns
The function as defined. If the Return() argument is specified, the expression is returned.
When called later, it returns the result of the script given the specified arguments.

Arguments
{arguments}  A list of arguments to pass into the function. You can specify some
arguments as optional or required.
{local variables}  A list of variables that are local to the function. You can declare local
variables in three ways:
{var1, var2}
{var1=0, var1="a string"}
{Default Local}
The last option declares that all unscoped variables used in the function are local to the
function.
Return(expr) This optional argument returns an expression from an user defined function. If a null expression is used, a period, ",, is returned.

script Any valid JSL script.

Get Class Names(< <class>, ...>)

Description
Gets a set of names to all classes or the set of specific class references.

Arguments
class A quoted string representation of the name of a defined class or a reference to an instantiated class object.

Returns
A list of class names as determined by the arguments to the function.

Get Classes(< <class>, ...>)

Description
Gets a set of references to all classes or the set of specific class references.

Arguments
class A quoted string representation of the name of a defined class or a reference to an instantiated class object.

Returns
A list of class references as determined by the arguments to the function.

Get Environment Variable("variable")

Description
Retrieves the value of an operating system environment variable.

Returns
A quoted string that contains the value of the specified environment variable. If the specified variable is not found, an empty string is returned.

Arguments
"variable" A quoted string that contains the name of an environment variable.

Notes
On macOS, environment variable names are case-sensitive. On Windows, the names are case-insensitive.

Get Locale Setting()

Gets a local setting such as a decimal setting.
Get Log(<n>)

Description
Returns a list of lines from the log.

Returns
A list of quoted strings. Each string contains one line from the log.

Argument
n  Optional, integer. If no argument is specified, all the lines are returned. If a positive number is specified, the first $n$ lines are returned. If a negative number is specified, the last $n$ lines are returned. If $n=0$, no lines are returned (an empty list). If the log is empty, an empty list is returned.

Get Namespace Names(< <namespace reference>,...>)

Description
Returns a list of the names of all currently defined namespaces.

Example
nsaa = New Namespace("aa",
    {
        x = 1
    }
);
nsbb = New Namespace("bb",
    {
        y = 1
    }
);
lns = Get Namespace Names();
Show(lns);
nsaa << Delete;
nb = New Namespace("bb",
    {
        y = 1
    }
);
ls = Get Namespace Names();
Show(ls);
nb = New Namespace("bb",
    {
        y = 1
    }
);
Get Namespaces(< <namespace reference>,...>)

Description
Returns a list of currently defined namespaces.

Example
nsaa = New Namespace("aa",
    {
        x = 1
    }
);
 Include("pathname", <named arguments>)

Description
Opens the script file identified by the quoted string *pathname*, parses the script in it, and executes it.

Returns
Whatever the included script returns. If you use the «Parse Only» option, Include returns the contents of the script.

Named Arguments
«Parse Only» Parses the script but does not execute the script.
«New Context» Causes the included script to be run its own unique namespace. When the parent and included scripts use the global namespace, include «Names Default to Here» along with «New Context».
«Allow Include File Recursion» Lets the included script include itself.

Notes
If a trailing space is included in the path name, the space is ignored on Windows. On macOS, the script fails.

Include File List()

Description
Returns a list of files that are included at the point of execution.

Is Class(class)

Description
Returns a value that indicates whether the class reference is a class object.

Argument
A class reference to an instantiated class object.

Returns
Returns a zero or a 1.
Is Log Open()

**Description**

Returns result if log window is open.

---

Length

See “Length(string)” on page 36.

---

List

See “List(a, b, c, ...)” on page 171.

---

Local({name=value, ...}, script)

**Description**

Resolves names to local expressions.

---

Local Here(expression)

**Description**

Creates a local Here namespace block. Use this function to prevent name collisions when multiple scripts are executed from the same root namespace (for example, when a script executes two button scripts that have the same variables). The argument can be any valid JSL expression.

---

Lock Namespaces(<string>,|< {string}, ...>)

**Description**

Locks all variables or specified named variables in this namespace and prevents variables from being added, changed, or removed.

**Example**

```js
ns = New Namespace( 
    "aaa"
);
ns << Lock Namespaces;
Try( ns << Delete Namespaces, Show( exception_msg ) );
Delete Namespaces();
Try( Delete Namespaces("aaa"), Show( exception_msg ) );
```

---

LockGlobals(name1, name2, ...)

**Description**

Locks one or more global variables to prevent it or them from being changed.
Lock Symbols(<name>, <name>, ...)

**Description**
Locks the specified symbols, which prevents them from being modified or cleared. If no symbols are provided, all global symbols are locked. If no symbols are provided and the script has the *Names Default To Here* mode turned on, then all local symbols are locked.

Log Capture(expr)

**Description**
Evaluates the expr, captures the output that would normally be sent to the log, and instead returns it.

**Returns**
A quoted string that contains the log output.

**Argument**
Any valid JSL expression.

**Notes**
No output appears in the log.

Method({arg1 = val1, ...}, script)

**Description**
Creates a method within a class. Note that methods use local scoping for all variables that are not explicitly scoped, with the exception of class member variables.

**Arguments**

```plaintext
{ arg1 = val1, ... }  The set of expected arguments and optional initialization expressions to be passed to the method when called.
script     Any valid JSL script.
```

N Items

See “N Items(source)” on page 171.

Names Default To Here(Boolean)

**Description**
Determines where unresolved names are stored, either as a global or local (if *Boolean* is 0) or in the *Here* scope (if *Boolean* is 1).
Namespace(name)

Description
Returns a reference to the named namespace (name).

Argument
Name  A namespace name quoted string or a reference to a namespace.

Namespace Exists(name)

Description
Returns 1 if a namespace with the specified name exists; otherwise, returns 0.

New Namespace("name", {list of expressions})

Description
Creates a new namespace with the specified name. If a name is not provided, an anonymous name is provided.

Returns
A reference to the namespace.

Arguments
name  An optional, quoted string that contains the name of the new namespace.
{list of expressions}  An optional list of expressions within the namespace.

Open Log(<Boolean>)

Description
Opens the log. Include the Boolean argument to make the window active, even if it is already open.

New Object("class name"(constructor arguments))
New Object(class name(constructor arguments))
New Object(class reference(constructor arguments))

Description
Creates an instance object of a class.

Arguments
"class name"  Name of the class to be instantiated.
class name  Unquoted name of the class to be instantiated.
class reference  Reference to an existing class object that will be used to instantiate a new object of the same class.
constructor arguments  Set of arguments to be passed to the _init_ constructor.
Example

```javascript
Define Class(
  "complex",
  real = 0; imag = 0;
  _init_ = Method( {a, b}, real = a; imag = b; );
  Add = Method( {y}, complex( real + y:real, imag + y:imag ) );
  Sub = Method( {y}, complex( real - y:real, imag - y:imag ) );
  Mul = Method( {y},
    complex( real * y:real - imag * y:imag, imag * y:real + real * y:imag )
  );
  Div = Method( {y},
    t = complex( 0, 0 );
    mag2 = y:Magsq();
    t:real = real * y:real + imag * y:imag;
    t:imag = imag * y:real + real * y:imag;
    t:real = t:real / mag2;
    t:imag = t:imag / mag2;
    t;
  );
  Magsq = Method( {}, real * real + imag * imag );
  Mag = Method( {}, Sqrt( real * real + imag * imag ) );
  To String = Method( {}, Char( real ) || " + " || Char( imag ) || "i" )
);
cl = New Object( complex( 1, 2 ) );
```

Parameter({name=value, ...}, model expression)

**Description**
Defines formula parameters for models for the Nonlinear platform.

---

Parse(string)

**Description**
Converts a quoted character string into a JSL expression.

---

Print(expr, expr, ...)

**Description**
Prints the values of the specified expressions to the log.

---

Quit()

See “Exit(<NoSave>)” on page 248.
Recurse(function)

Description
Makes a recursive call of the defining function.

Save Log(pathname)

Description
Writes the contents of the log to the specified file location.

Send(obj, message)

obj << message

Description
Sends a message to a platform object.

Set Environment Variable( "variable", <"value">)

Description
Sets the environment variable to the value specified. If the “value” argument is missing or is an empty quoted string, then the environment variable is deleted from the JMP process environment variable table.

Show(expr, expr, ...)

Description
Prints the name and value of each expression to the log.

Show Classes(< <class>,...>)

Description
Shows the contents of user-defined classes in the log. You can specify more than one class. If you do not specify an argument, all user-defined classes are shown in the log.

Example
Define Class( "aa",
   _init_ = Method( {} ); x = 1; m1 = Method( {a, b}, a * b )
);
Define Class( "bb",
   _init_ = Method( {} ); y = 1; m2 = Method( {a, b}, a / b )
);
Show Classes();
// Class aa
_init_ = Method( {} );
m1 = Method( {a, b}, a * b );
x = 1;

// Class bb

_init_ = Method( {} );
m2 = Method( {a, b}, a / b );
y = 1;

Show Globals()

Description
Shows the values for all global symbols. Symbols in any scope other than global are not shown.

See Also
“Show Symbols()” on page 257

Show Namespaces(< <namespace reference>,...>)

Description
Shows the contents of all user-defined namespaces, both named and anonymous. You can specify zero or more namespaces.

Show Symbols()

Description
Shows the values for all symbols in any and all scopes.

See Also
“Show Globals()” on page 257

Sort List

See “Sort List(list|expr)” on page 173.

Sort List Into

See “Sort List Into(list|expr)” on page 173.

Throw("text")

Description
Returns a Throw. If you include text, throwing stores text in a global exception_msg. If text begins with “!” and is inside a Try() expression, throwing creates an error message
about where the exception was caught. “!” stops the script even if the \texttt{Throw()} is caught by the second argument of \texttt{Try()}. 

\textbf{Try(expr1, expr2)}

\textbf{Description}
Evaluates \texttt{expr1}. If the evaluation returns a \texttt{Throw}, execution stops, and nothing is returned. \texttt{expr2} is evaluated next to return the result.

\textbf{Examples}
\begin{verbatim}
Try( Sqrt( "s" ), "invalid" );
"invalid"

Try( Sqrt( "s" ), exception_msg );
{"Cannot convert argument to a number [or matrix]"(1, 2, "Sqrt", 
Sqrt/*###*/("s"))}
\end{verbatim}

\textbf{Notes}
\texttt{Expr2} can be a quoted character string or the global exception message (\texttt{exception_msg}) that contains more information about the error returned.

\textbf{Type(x)}

\textbf{Description}
Returns a quoted string that names the type of object \texttt{x} is. The list of possible types is: Unknown, List, DisplayBox, Picture, Column, TableVar, Table, Empty, Pattern, Date, Integer, Number, String, Name, Matrix, RowState, Expression, Associative Array, BLOB.

\textbf{Unlock Symbols(name1, name2, ...)}
\textbf{Unlock Globals(name1, name2, ...)}

\textbf{Description}
Unlocks the specified symbols that were locked with a \texttt{Lock Symbols()} or \texttt{Lock Globals()} command.

\textbf{Wait(n)}

\textbf{Description}
Pauses \texttt{n} seconds before continuing the script. The default setting is 3 seconds. Specifying \texttt{Wait(0)} enables one cycle of message processing. For example, you can use this function to allow a button press in the UI. The shortest duration that actually allows JMP to pause is \texttt{n = 0.01}. The longest duration you can specify without prompting a JMP dialog is \texttt{n = 60*60*4}. 
Notes
You can use Wait(n) if you want something to stay on the screen long enough to see it, if you need a platform to finish launching before scripting it, or if you need to press buttons in the UI while the script runs.

Watch(all | name1, ...)
Description
Shows variables from global, here, and local namespaces and their values in a window. If “all” is provided as the argument, all globals are placed into the window.
Notes
– New globals are not added to the window list.
– Watching associative arrays that have been modified using messages is not supported.

Wild()
Description
Only used with Extract Expr() for expression matching to denote a wildcard position that matches any expression.

Wild List()
Description
Only used with Extract Expr() for expression matching to denote a series of wildcard arguments that match any expression.

Write("text")
Description
Prints text to the log without surrounding quotation marks.

Python Integration Functions

Python Connect(<Echo(Boolean),> <Path(path),> <Use Python Version(string),> <Python System Path(list)>)
Description
Initializes the Python integration interfaces and returns an active Python integration interface connection as a scriptable object.
Returns
A Python scriptable object.

Optional Named Arguments
- **Echo(Boolean)**  Global argument. Prints the Python source lines to the JMP log. The default value is true.
- **Path**  Specifies the path to the Python DLL or shared library.
- **Use Python Version(string)**  Specifies which version of Python should be used for JMP-to-Python processing.
- **Python System Path**  Specifies a JSL list of paths that define a Python sys path set on macOS.

**Python Control(<named arguments>)**

Description
Sends control operations to signal Python with external events, such as source line echoing.

Returns
Returns 0 if the call succeeded and 1 if an error occurred.

Optional Named Arguments
- **Interactive(Boolean)**  Enables interactive mode in the Python matplotlib package. Determines whether the graphics window is released or closed when graphics rendering is complete.
- **Echo(Boolean)**  Global argument. Prints the Python source lines to the JMP log. The default value is true.

**Python Disconnect**

Description
Terminates the Python interfaces.

**Python Execute({list of inputs}, {list of outputs}, Python_Code, named_arguments)**

Description
Submits Python code to the active global Python integration interface connection given a list of inputs. On completion, returns a list of outputs.

Returns
Returns 0 if successful and 1 otherwise.

Positional Arguments
- **{list of inputs}**  A list of JMP variable names to be sent to Python as inputs.
- **{list of outputs}**  A list of JMP variable names to be retrieved from Python as outputs.
Python Code  The Python code to submit.

Named Arguments
See “Python Submit(Pytho_code, <named_arguments>)” on page 264.

Example
This example initiates the Python connection, sends a character variable, a numeric variable, and a set of matrices to Python. Python is then instructed to perform a set of matrix operations on the sent matrices. The Python Execute() function then get the set of matrices created by the matrix operations and gets the values of the character and numeric variables that was originally sent. Upon completion of the data retrieval, the Python connection is closed.

```python
Python Init();
a = "abcdef";
d = 3.141;
v = [9 8 7, 6 5 4, 3 2 1];
m = [1 2 3, 4 5 6, 7 8 9];
ml = Python Execute(
    {v, m, a, d},
    {x1, x2, y1, y2, z1, z2, a, d},
"[
import numpy as np
x1 = np.multiply(v, m) # matrix product
print('x1=', x1)
x2 = np.divide(v, m) # matrix division
print('x2=', x2)
y1 = np.dot(v, m) # dot product of v and m
print('y1=', y1)
y2 = np.dot(m, v) # dot product of m and v
print('y2=', y2)
z1 = np.inner(v, m) # inner product of v and m
print('z1=', z1)
z2 = np.inner(m, v) # inner product of m and v
print('z2=', z2)
]");
Show( v, m, ml, x1, x2, y1, y2, z1, z2, a, d );
Python Term();
x1= [[ 9.  16.  21.]
    [ 24.  25.  24.]
    [ 21.  16.  9.]]
x2= [[ 9.          4.          2.33333333]
    [ 1.5         1.          0.66666667]
    [ 0.42857143  0.25        0.11111111]]
...
Python Get(name)

**Description**

Gets a named variable from Python to JMP.

**Returns**

Returns the value of the named variable.

**Argument**

*name*  The name of the Python variable to be sent to JMP. The argument can represent any of the following Python data types: numeric, quoted string, matrix, list, or data frame.

**Example**

```jscodesrc
definition
Python Init(); // initiate the Python connection

qbx = "The right stuff";

// send the qbx variable and sample data table "Animals.jmp" to Python
Python Send( qbx );

dt = Open( "$SAMPLE_DATA/Animals.jmp" );
Python Send( dt );
Close( dt, nosave );

// get the Python variable qbx and place it into a JMP variable qbx
qbx = Python Get( qbx );

/* get the Python variable dt and place it into a JMP data table referenced by df */
df = Python Get( dt );

Python Term();

Show( qbx );
df << New Data View;
Wait( 10 );
Close( df, nosave );
Python Term();
  qbx = "The right stuff";
```

Python Get Graphics(format)

**Description**

Gets the last graphics object written to the Python graph display window in the specified graphics format. The graphics object can be returned in several different graphic formats.
Returns
Returns a JMP picture object.

Argument
format  The format that the Python graph display window contents are to be converted to. Valid formats are png, bmp, jpeg, jpg, tiff, tif, and gif.

Python Get Version

Description
Returns the version number of Python being used with the JMP Python interfaces.

Python Init(<Echo(Boolean),> <Path(path),> <Use Python Version(string),> <Python System Path({list})>

Description
Initializes the Python integration interfaces.

Returns
Returns 0 if operation is successful and 1 if not successful.

Optional Named Arguments
Echo(Boolean)  Global argument. Prints the Python source lines to the JMP log. The default value is true.
Path  Specifies the path to the Python DLL or shared library.
Use Python Version(string)  Specifies which version of Python should be used for JMP-to-Python processing.
Python System Path  Specifies a JSL list of paths that define a Python sys path set on macOS.

Python Is Connected

Description
Determines whether a Python integration interface connection is currently connected to Python.

Returns
Returns 1 if connected and 0 otherwise.

Python JMP Name to Python Name(name)

Description
Maps a JMP variable name to its corresponding Python variable name using Python variable name naming rules.
Returns
A quoted string, the mapped Python name.

Argument
name  The name of the JMP variable to be sent to Python.

Python Send(name)

Description
Sends a named variable from JMP to Python.

Returns
Returns 0 if successful.

Argument
name  The name of the JMP variable to be sent to Python.

Python Send File(filename, <, Python Name(name)>)

Description
Sends a data file to Python. The filename argument is a quoted string that specifies a pathname to the file to be sent to Python.

Python Submit(Python_Code, <named_arguments>)

Description
Submits Python code to the active global Python integration interface connection.

Returns
Returns 0 if successful and non-zero otherwise.

Named Arguments
Python_Code  The Python code to submit. Statements can be a quoted string value or a list of string values.
Expand(Boolean) (Optional) Performs an Eval Insert() on the Python code before submission.
Echo(Boolean) (Optional) Prints the Python source lines to the JMP log.

Example
Python Init(); // initiate the Python connection
commands = "
friends = ['john', 'pat', 'gary', 'michael']
print(friends)
for i, name in enumerate(friends):
    print( "iteration {iteration} is {name}".format(iteration=i, name=name))
";
Python Submit( commands );
Python Term();
['john', 'pat', 'gary', 'michael']
iteration 0 is john
iteration 1 is pat
iteration 2 is gary
iteration 3 is michael
0

Python Submit File(path)

Description
Submits statements to Python using the file specified in the path name.

Argument
path The path to the file that contains the Python source lines to be executed.

Python Term

Description
Terminates the currently active Python integration interface.

Returns
Returns 0 if successful and 1 otherwise.

R Integration Functions

R Connect( <named_arguments> )

Description
Returns the current R connection object. If there is no connection to R, it initializes the R integration interfaces and returns an active R integration interface connection as a scriptable object.

Returns
R scriptable object.

Arguments
Echo(Boolean) (Optional) Sends all source lines to the JMP log. This option is global. The default value is true.

R Control(Interrupt|Async(Boolean)|Echo(Boolean))

Description
Changes the control options for R.
R Execute( {list of inputs}, {list of outputs}, "rCode", <named_arguments> )

**Description**
Submit the specified R code to the active global R connection given a list of inputs. On completion, the outputs are returned into the specified list.

**Returns**
0 if successful; nonzero otherwise.

**Arguments**
- `{list of inputs}` A list of JMP variable names to be sent to R as inputs.
- `{list of outputs}` A list of JMP variable names to contain the outputs returned from R.
- `rCode` A quoted string that contains the R code to submit.
- `Expand(Boolean)` An optional, Boolean, named argument. Performs an Eval Insert() on the R code before submitting to R.
- `Echo(Boolean)` An optional, Boolean, named argument. Sends all source lines to the JMP log. This option is global. The default value is `true`.

**Example**
Send the JMP variables x and y to R, execute the R statement `z <- x * y`, and then get the R variable `z` and return it to JMP.

```r
x = [1 2 3];
y = [4 5 6];
rc = R Execute( {x, y}, {z}, "z <- x * y" );
```

R Get( variable_name )

**Description**
Gets the named variable from R to JMP.

**Returns**
The value of the named variable.

**Argument**
- `name` Required. The name of an R variable whose value to return to JMP.

**Example**
Assume that a matrix named `qbx` and a data frame named `df` are present in your R connection.

// get the R variable `qbx` and placed it into a JMP variable `qbx`
qbx = R Get( qbx );

// get the R variable `df` and placed it into a JMP data table referenced by `df`
df = R Get( df );
R Get Graphics( "format" )

Description
Gets the last graphics object written to the R graph display window in the specified format.

Returns
A JMP picture object.

Argument
format  Required. Specifies the graphics format to be used. Valid formats are png, bmp, jpeg, jpg, tiff, tif, and gif.

R Get Version

Description
Returns the version number of R being used with JMP R interfaces.

R Init( named_arguments )

Description
Initializes the R session.

Returns
0 if the initialization is successful; any nonzero value otherwise.

Argument
Echo(Boolean)  (Optional) Sends all source lines to the JMP log. This option is global. The default value is true.

R Is Connected()

Description
Determines whether a connection to R exists.

Returns
1 if connected; 0 otherwise.

Arguments
None.

R JMP Name to R Name( name )

Description
Maps the specified JMP variable name to the corresponding R variable name using R naming rules. Requires an active connection to R.
Argument

name  The name of a JMP variable to be sent to R.

Returns

A quoted string that contains the R name.

R Send( name, <R Name( name )> )

Description

Sends named variables from JMP to R.

Returns

0 if the send is successful; any nonzero value otherwise.

Arguments

name  required. The name of a JMP variable to be sent to R.

R Name(name)  (Optional) You can give the variable that you send to R a different name. For example

R Send(Here:x, R Name(“localx”))

For data tables only:

Selected(Boolean)  optional, named, Boolean. Send only selected rows from the referenced data table to R.

Excluded(Boolean)  optional, named, Boolean. Send only excluded rows from the referenced data table to R.

Labeled(Boolean)  optional, named, Boolean. Send only labeled rows from the referenced data table to R.

Hidden(Boolean)  optional, named, Boolean. Send only hidden rows from the referenced data table to R.

Colored(Boolean)  optional, named, Boolean. Send only colored rows from the referenced data table to R.

Markered(Boolean)  optional, named, Boolean. Send only markered rows from the referenced data table to R.

Row States(Boolean, <named arguments>)  optional, named. Includes a Boolean argument and optional named arguments. Send row state information from the referenced data table to R by adding an additional data column named “RowState”. Multiple row states are created by adding together individual settings. Here are the individual values:

– Selected = 1
– Excluded = 2
– Hidden = 4
– Labeled = 8
– Colored = 16
Here are the named arguments for the `Row States()` argument:

- **Colors** (Boolean) optional, named, Boolean. Sends row colors. Adds additional data column named “RowStateColor”.
- **Markers** (Boolean) optional, named, Boolean. Sends row markers. Adds additional data column named “RowStateMarker”.

**Examples**

Create a matrix, assign it to `X`, and send the matrix to R:

```julia
X = [1 2 3];
rc = R Send( X );
```

Open a data table, assign a reference to it (`dt`), and send the data table, along with its current row states, to R:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
rc = R Send( dt, Row States(1) );
```

**R Send File( "pathname", <R Name("name")> )**

**Description**

Sends the specified data file from JMP to R.

**Returns**

0 if the send is successful; any nonzero value otherwise.

**Arguments**

- **pathname** required. A quoted string that contains a pathname for a file.
- **R Name(name)** (Optional) You can give the data file that you send to R a different name.

**R Submit( "rCode", <named_arguments> )**

**Description**

Submits the specified R code to the active global R connection.

**Returns**

0 if successful; nonzero otherwise.

**Arguments**

- **rCode** A required, quoted string that contains the R code to submit.
- **Expand** (Boolean) An optional, Boolean, named argument. Performs an `Eval Insert()` on the R code before submitting to R.
- **Echo** (Boolean) An optional, Boolean, named argument. Sends all source lines to the JMP log. This option is global. The default value is `true`.
- **Async** (Boolean) An optional, Boolean, named argument. If set to true (1), the submit can be canceled either by pressing the ESCAPE key, or by using this message to an R connection: `rconn<<Control(Interrupt(1))`. False (0) is the default value.
Example
rc = R Submit("[x <- rnorm(5)
    print(x)
    y <- rnorm(5)
    print(y)
    z = plot(x, y)
]"");

R Submit File( "pathname" )

Description
Submits statements to R using a file pointed in the specified pathname.

Returns
0 if successful; nonzero otherwise.

Argument
Pathname A quoted string that contains the pathname to the file that contains the R code to be executed.

R Term()

Description
Terminates the currently active R integration interface.

Returns
Returns 0 if the termination is successful and -1 otherwise.

Arguments
None

Random Functions

Col Shuffle(<By var,...>)

Description
Creates a random ordering of the row numbers of the current data table when used in a column formula.

Note: This function is generally used in a column formula.

Returns
A random integer between 1 and the number of rows in the current data table.
Argument
By var (Optional) A By variable enables you to randomly order the rows within the
groups of the By variable values.

Example
dt = Open("$SAMPLE_DATA/Big Class.jmp");
dt << New Column("Shuffle", Numeric, Continuous, Set Formula(Col Shuffle()));
This example creates a column formula that shuffles the order of the row numbers (1 to 40)
each time the formula is evaluated. Each number appears only once.

Make Validation Formula(rates, <<Stratification Columns(cols), <<Grouped
Columns(cols), <<Cutpoint Column(col))

Description
Generates a validation column. This function is primarily used by the Make Validation
Column utility.

Arguments
rates Vector of three rates that specify the training, validation, and test rates,
respectively.
<<Stratification Columns Assigns one or more stratification columns.
<<Grouped Columns Assigns one or more grouping columns.
<<Cutpoint Column Assigns a numeric cutpoint column.

Random Beta(alpha, beta, <theta=0>, <sigma=1>)

Description
Returns a random number from a beta distribution with two shape parameters, alpha and
beta, and optional parameters theta and sigma.

Arguments
alpha, beta Shape parameters α and β, which must both be greater than 0.
theta Optional threshold parameter θ. The default is 0.
sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Random Beta Binomial(n, p, <delta=0>)

Description
Returns a random number from a beta binomial distribution for n trials with probability p
and overdispersion parameter delta.

Arguments
n The number of trials, which must be greater than or equal to 2. If the specified n is not
an integer, the non-integer part is truncated.
Random Binomial(n, p)

Description
Returns a random number from a binomial distribution with \( n \) trials and probability \( p \) of the event of interest occurring.

Arguments
- \( p \)  The probability of success for each trial, which must be between 0 and 1.
- \( n \)  The number of trials.

Random Category(probA, resultA, probB, resultB, <..., ...,> resultElse)

Description
Returns one of the specified result expressions at random, chosen from pairs of probability and result expressions. A random uniform number is generated and compared to the \( \text{prob} \) arguments to determine which \( \text{result} \) argument is returned.

Arguments
- \( \text{probA} \)  Numeric value between 0 and 1 that represents the probability of the corresponding result expression being returned.
- \( \text{resultA} \)  Expression that corresponds to \( \text{probA} \).
- \( \text{resultElse} \)  Expression that is returned if no previous result expression has been returned.

Random Cauchy()

Description
Returns a random number from a Cauchy distribution with a median of zero.

Random ChiSquare(df, <nc=0>)

Description
Returns a random number from a chi-square distribution with given \( df \) (degrees of freedom) and optional noncentrality parameter.

Arguments
- \( df \)  The degrees of freedom \( n \), which must be greater than 0.
- \( nc \)  Optional noncentrality parameter \( \lambda \), which must be nonnegative. The default is 0.
Random Exp()

Description
Returns a random number from an exponential distribution with scale parameter equal to 1. Equivalent to the negative log of Random Uniform.

Random F(dfnum, dfden, <noncentral=0>)

Description
Returns a random number from an F distribution with a given dfnum, dfden, and optional noncentrality parameter.

Arguments
- dfnum The degrees of freedom, $v_1$, of the chi-square distribution in the numerator of the F-distribution. dfnum must be greater than 0.
- dfden The degrees of freedom, $v_2$, of the chi-square distribution in the denominator of the F-distribution. dfden must be greater than 0.
- noncentral Optional noncentrality parameter $\lambda$, which must be nonnegative. The default is 0.

Random Frechet(<mu=0>, <sigma=1>)

Description
Returns a random number from a Fréchet distribution with the location mu and scale sigma.

Arguments
- mu Optional location parameter $\mu$. The default is 0.
- sigma Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.

Random Gamma(alpha, <scale=1>)

Description
Returns a random numbers from a gamma distribution for given alpha and optional scale.

Arguments
- alpha The shape parameter $\alpha$, which must be greater than 0.
- scale Optional scale parameter $\beta$, which must be greater than 0. The default is 1.

Random Gamma Poisson(lambda, <sigma=1>)

Description
Returns a random number from a gamma Poisson distribution with parameters lambda and sigma.
Arguments

- **lambda** The shape parameter \( \lambda \), which must be greater than 0.
- **sigma** Optional overdispersion parameter \( \sigma \), which must be greater than or equal to 1.

The default is 1. When the overdispersion parameter is 1, the distribution reduces to a Poisson(\( \lambda \)) distribution.

Random GenGamma(<mu=0>, <sigma=1>, <lambda=0>)

**Description**

Returns a random number from an extended generalized gamma distribution with parameters \( \mu \), \( \sigma \), and \( \lambda \).

**Arguments**

- **mu** Optional location parameter \( \mu \). The default is 0.
- **sigma** Optional scale parameter \( \sigma \), which must be greater than 0. The default is 1.
- **lambda** Optional shape parameter \( \lambda \). The default is 0.

Random Geometric(p)

**Description**

Returns a random number from the geometric distribution with probability \( p \) that a specific event occurs at any one trial.

Random GLog(mu, sigma, lambda)

**Description**

Returns a random number from a generalized logarithmic distribution with parameters \( \mu \), \( \sigma \), and \( \lambda \).

**Arguments**

- **mu** The location parameter \( \mu \).
- **sigma** The scale parameter \( \sigma \), which must be greater than 0.
- **lambda** A shape parameter \( \lambda \), which must be greater than 0.

Random Index(n, k)

**Description**

Returns a \( k \) by 1 matrix of random integers between 1 and \( n \) with no duplicates.

Random Integer(n)

**Description**

Returns a random integer from 1 to \( n \) or from \( k \) to \( n \).
Random Johnson Sb($\gamma$, $\delta$, $\theta$, $\sigma$)

**Description**

Returns a random number from a Johnson Sb distribution with parameters $\gamma$, $\delta$, $\theta$, and $\sigma$.

**Arguments**
- $\gamma$ Shape parameter $\gamma$.
- $\delta$ Shape parameter $\delta$, which must be greater than 0.
- $\theta$ Location parameter $\theta$.
- $\sigma$ Scale parameter $\sigma$, which must be greater than 0.

Random Johnson Sl($\gamma$, $\delta$, $\theta$, $\sigma$)

**Description**

Returns a random number from a Johnson Sl distribution with parameters $\gamma$, $\delta$, $\theta$, and optional $\sigma$.

**Arguments**
- $\gamma$ Shape parameter $\gamma$.
- $\delta$ Shape parameter $\delta$, which must be greater than 0.
- $\theta$ Location parameter $\theta$.
- $\sigma$ Optional parameter $\sigma$ that indicates if the distribution is skewed positively or negatively. $\sigma$ must be equal to either +1 (skewed positively) or -1 (skewed negatively). The default is +1.

Random Johnson Su($\gamma$, $\delta$, $\theta$, $\sigma$)

**Description**

Returns a random number from a Johnson Su distribution with parameters $\gamma$, $\delta$, $\theta$, and $\sigma$.

**Arguments**
- $\gamma$ Shape parameter $\gamma$.
- $\delta$ Shape parameter $\delta$, which must be greater than 0.
- $\theta$ Location parameter $\theta$.
- $\sigma$ Scale parameter $\sigma$, which must be greater than 0.

Random LEV(<$\mu$=0>, <$\sigma$=1>)

**Description**

Returns a random number from an LEV distribution with the location $\mu$ and scale $\sigma$.

**Arguments**
- $\mu$ Optional location parameter $\mu$. The default is 0.
JSL Functions Chapter 2
Random Functions JSL Syntax Reference

sigma Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.

Random LogGenGamma(<mu=0>, <sigma=1>, <lambda=0>)

Description
Returns a random number from a log generalized gamma distribution with parameters $\mu$, $\sigma$, and $\lambda$.

Arguments
$\mu$ Optional location parameter $\mu$. The default is 0.
$\sigma$ Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.
$\lambda$ Optional shape parameter $\lambda$. The default is 0.

Random Logistic(<mu=0>, <sigma=1>)

Description
Returns a random number from a logistic distribution with location $\mu$ and scale $\sigma$.

Arguments
$\mu$ Optional location parameter $\mu$. The default is 0.
$\sigma$ Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.

Random Loglogistic(<mu=0>, <sigma=1>)

Description
Returns a random number from a loglogistic distribution with location $\mu$ and scale $\sigma$.

Arguments
$\mu$ Optional location parameter $\mu$. The default is 0.
$\sigma$ Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.

Random Lognormal(<mu=0>, <sigma=1>)

Description
Returns a random number from a lognormal distribution with location $\mu$ and scale $\sigma$.

Arguments
$\mu$ Optional location parameter $\mu$. The default is 0.
$\sigma$ Optional scale parameter $\sigma$, which must be greater than 0. The default is 1.
Random Multivariate Normal(mean, covar, <nrows=1>)

Description
Returns a random vector from a multivariate normal distribution with mean vector mean and covariance matrix covar. To generate multiple vectors, specify an integer greater than 1 for the nrows argument. When nrows is greater than 1, the return value is a matrix. The number of columns in the random vector or matrix is equal to the number of rows in the covar argument.

Arguments
mean Mean vector for the multivariate normal distribution.
covar Covariance matrix for the multivariate normal distribution. This matrix must be a symmetric square matrix that contains the same number of columns as the mean vector.
nrows Optional argument that specifies the number of random vectors returned. The default number of rows is 1.

Random Negative Binomial(n, p)

Description
Returns a random number from a negative binomial distribution for n successes with probability of success p.

Random Normal(<mu=0>, <sigma=1>)

Description
Returns a random number from a normal distribution with mean mu and standard deviation sigma.

Arguments
mu Optional location parameter μ. The default is 0.
sigma Optional scale parameter σ, which must be greater than 0. The default is 1.

Random Normal Mixture(meanvec, sdvec, probabvec)

Description
Returns a random number from a normal mixture distribution with the specified arguments.

Arguments
meanvec A vector that contains group means.
sdvec A vector that contains the group standard deviations.
probabvec A vector that contains the group probabilities.
Random Poisson(lambda)

**Description**
Returns a random number from a Poisson distribution with shape parameter `lambda`.

**Arguments**
- `lambda` The shape parameter `λ`, which must be greater than 0.

Random Reset(seed)

**Description**
Restarts the random number sequences with `seed`.

Random Seed State(<seed state>)

**Description**
Retrieves or restores the random seed state to or from a BLOB object.

Random SEV(<mu=0>, <sigma=1>)

**Description**
Returns a random number from an SEV distribution with the specified location `mu` and scale `sigma`.

**Arguments**
- `mu` Optional location parameter `μ`. The default is 0.
- `sigma` Optional scale parameter `σ`, which must be greater than 0. The default is 1.

Random SHASH(gamma, delta, theta, sigma)

**Description**
Returns a random number from a sinh-arcsinh (SHASH) distribution with parameters `gamma`, `delta`, `theta`, and `sigma`.

**Arguments**
- `gamma` The shape parameter `γ`.
- `delta` The shape parameter `δ`, which must be greater than 0.
- `theta` The location parameter `θ`.
- `sigma` The scale parameter `σ`, which must be greater than 0.

Random Shuffle(matrix)

**Description**
Returns the matrix with the elements shuffled into a random order.
Random \( t(df, <noncentral=0>) \)

**Description**
Returns a random number from a \( t \) distribution with the specified \( df \) (degrees of freedom). The noncentrality argument may be negative or positive. The default value of \( noncentral \) is 0.

Random Triangular(min, mode, max)
Random Triangular(mode, max)
Random Triangular(mode)

**Description**
Generates a random number from a triangular distribution between 0 and 1 with the \( mode \) that you specify. The triangular distribution is typically used for populations that have a small number of data.

**Arguments**
- \( min \) Specifies the lower limit of the triangular distribution. The default value is 0.
- \( mode \) Specifies the mode of the triangular distribution.
- \( max \) Species the upper limit of the triangular distribution. The default value is 1.

**Notes**
If you specify only the mode, the minimum value is 0, and the maximum value is 1. If you specify the mode and maximum value, the minimum value is 0 by default.

Random Uniform()
Random Uniform(x)
Random Uniform(min, max)

**Description**
Generates a random number from a uniform distribution between 0 and 1. Random Uniform(x) generates a number between 0 and \( x \). Random Uniform (min, max) generates a number between \( min \) and \( max \). The result is an approximately even distribution.

Random Weibull(shape, <scale=1>)

**Description**
Returns a random number from a Weibull distribution with parameters \( shape \) and optional \( scale \).

**Arguments**
- \( shape \) Shape parameter \( \beta \), which must be greater than 0.
scale  Optional scale parameter $\alpha$, which must be greater than 0. The default is 1.

Resample Freq(<rate=1, <column>>)  

**Description**  
Generates a frequency count for sampling with replacement. If no arguments are specified, the function generates a 100% resample.

**Note:** This function is generally used in a column formula.

**Arguments**  
- **rate** (Optional) Specifies the rate of resampling. The default value is 1. A negative value specifies that fractional frequencies are allowed.
- **column** (Optional) If you specify `column`, you must also specify `rate`. The sample size is calculated by the rate multiplied by the sum of the specified column. If rate is negative, then the sample size is the negative of the rate multiplied by the sum of the specified column. If you do not specify a column, the generated frequencies sum to the number of rows.

**Example**  
To ensure that the numbers in the frequency column match each time you run the script, use `As Constant()`. `As Constant()` evaluates an expression to create a constant value that does not change after it has been computed.

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dc = dt >> New Column( "column",
   Formula( 
      As Constant( 
         Random Reset( 123 );
         0;
      ) + Resample Freq();
   )
);
dc << Eval Formula;

**Notes**  
- A typical use of this function generates a column with many 1s, some 0s, some 2s, and so forth, corresponding to which rows were randomly assigned any of $n$ randomly selected rows.
- A typical use of this with an *existing* frequency column produces a new frequency column whose values are similar to the old frequency column (have the same expected value); however, the values vary somewhat due to random selection at the rates corresponding to the old frequency column.
Row Functions

As Table(matrix, <matrix 2, ...>, < <<invisible >, < <<private >, < <Column Names({list}) >)

Description

Creates a new data tables from the matrix.

Returns

The new data table.

Argument

matrix Any matrix.

<<invisible Creates an invisible data table that hides the table from view but lists it in the JMP Home Window and Window menu.

<<private Hides the table completely. Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

<<Column Names(list) The list specified column names for the data. The argument is a list of quoted column names.

Col Stored Value(<dt>, col, <row>)

Description

Returns the data values stored in the column and disregards values assigned through column properties (such as Missing Value Codes).

Arguments

dt Optional reference to a data table. If this value is not supplied, the current data table is used.

col Name of the column.

row (Optional) Row name or number. If this value is not specified, the current row is used.

Example

Suppose that the Missing Value Codes column property is assigned to the x1 column to treat “999” as a missing value. Another column includes a formula that calculates the mean. To use the value “999” instead of a missing value to calculate the mean, use Col Stored Value() in the formula:

Mean( Col Stored Value( :x1 ), :x2, :x3 )
Column(<dt>, "name", "formatted")
Column(<dt>, n)

Description
- Gets a reference to the data table column.

Arguments
- dt  Optional reference to a data table. If this is not supplied, the current data table is used.
- name  A quoted string that is the name of the column.
- formatted  A quoted string that returns the formatted string of the cell value.
- n  The column number.

Column Name(n)

Description
- Determines the name of the column specified by number.

Returns
- The name of the n\textsuperscript{th} column as an expression (not a quoted string).

Argument
- n  The number of a column.

Count(from, to, step, times)

Description
- Used for column formulas. Creates row by row the values beginning with the from value and ending with the to value. The number of steps specifies the number of values in the list between and including the from and to values. Each value determined by the first three arguments of the count function occurs consecutively the number of times that you specify. When the to value is reached, count starts over at the from value. If the from and to arguments are data table column names, count takes the values from the first row only. Values in subsequent rows are ignored.

Returns
- The last value.

Arguments
- from  Number, column reference, or expression. Count starts counting with this value.
- to  Number, column reference, or expression. Count stops counting with this value.
- step  Number or expression. Specifies the number of steps to use to count between from and to, inclusive.
- times  Number or expression. Specifies the number of times each value is repeated before the next step.
Examples

/* the rows in the column named colname are filled with the series 0, 3, 6, 0, 
... until all rows are filled */
For Each Row(:colname[row()] = count(0, 6, 3, 1))

/* the rows in the column named colname are filled with the series 0, 0, 3, 
3, 6, 6, 0, ... until all rows are filled */
For Each Row(:colname[row()] = count(0, 6, 3, 2))

Notes
Count() is dependent on Row(), and is therefore mainly useful in column formulas.

Current Data Table(<dt>)

Description
Without an argument, gets the current (topmost) data table. With an argument, sets the 
current data table.

Returns
Reference to the current data table.

Argument
dt Optional name of or reference to a data table.

Notes
Private tables cannot be made current with Current Data Table().

Data Table(n)
Data Table("name")
Get Data Table(<project(title|index|box|window),> name|index)

Description
 Gets reference to the nth open data table or the table with the given name in a global 
variable.

Returns
Reference to the specified data table.

Argument
n Number of a data table.
name Quoted string, name of a data table.
Dif(col, n)

Description
Calculates the difference of the value of the column col in the current row and the value n rows previous to the current row.

Returns
The difference.

Arguments
- col: A column name (for example, :age).
- n: A number.

Dim(<dt|matrix>)

Description
Returns a row vector with the dimensions of the current data table, a specified data table, or a matrix. The dimensions are the number of rows and the number of columns and are listed in that order.

Arguments
- dt: A data table.
- matrix: A matrix.

Notes
If no argument is specified, the dimensions of the current data table are returned.

Get Data Table List(<Project(title|index|box|window>)

Description
Returns a list of all open data tables.

Notes
Use Project(0) to specify no project when running the expression in a project.

Lag(col, n)

Description
Returns for each row the value of the column n rows previous.

N Row(dt); NRow(matrix)
N Rows(dt); NRows(matrix)

Description
Returns the number of rows in the data table given by dt or in the matrix.
N Table()

**Description**

Returns the number of open data tables. Private tables are not included.

**New Column("name", "data type", "modeling type", Width(n), Format("format", width, precision), Formula(), Set Values, Like(column reference), actions)**

**Description**

Adds a new column named "name" after the last column in dt. Unless otherwise specified, columns are numeric, continuous, and 12 characters wide.

**Returns**

A column reference.

**Notes**

Can also be used as a message: dt<<New Column.

The Like() argument copies the data type, modeling type, format, formula, and other properties from the reference column into the new column.

**See Also**

“dt<<New Column(name, data type, modeling type, Format(format, width), Formula(), Set Values({..., ..., }), Set Property(properties))” on page 392 in the “JSL Messages” chapter

**New Table("name", visibility("invisible" | "private" | "visible"), actions)**

**Description**

Creates a new data table with the specified name.

**Arguments**

- **name** A quoted string that contains the name of the new table.
- **visibility** Optional quoted keyword. invisible hides the data table from view but lists it in the JMP Home Window and Window menu. private hides the table completely. visible shows the data table. "visible" is the default value.

**Note:** Creating a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.

- **actions** Optional argument that can define the new table.
Row()
Row() = y

Description
Returns or sets the current row number. No argument is expected.

Sequence(from, to, <step size>, <repeat times>)

Description
Produces an arithmetic sequence of numbers across the rows in a data table. The step size and repeat times arguments are optional, and the default value for both is 1.

Subscribe to Data Table List(<subscriber name|"">, <OnOpen(function)|OnClose(function)|OnRename(function)>)

Description
Subscribes to the data table list. You will be notified when a new data table has been added, closed, or renamed.

Subscript(a, b, c)
list[i]
matrix[b, c]

Description
Subscripts for lists extract the ith item from the list, or the bth row and the cth column from a matrix.

Suppress Formula Eval(Boolean)

Description
Turns off automatic calculation of formulas for all data tables.

Unsubscribe to Data Table List(<subscriber name>, <"OnOpen"|"OnClose"|"All">)

Description
Removes a subscription to the data table list that has been added through Subscribe to Data Table List().
Row State Functions

As Row State(i)

Description
Converts \( i \) into a row state value.

Returns
A row state from the \( i \) given.

Argument
\( i \) an integer

Color Of(rowstate)

Description
Returns or sets the color index.

Returns
The color index of \( \text{rowstate} \).

Argument
rowstate a row state argument

Example
Set the color of the fifth row to red.
Color Of( Rowstate( 5) ) = 3

Color State(i)

Description
Returns a row state with the color index of \( i \).

Returns
A row state.

Argument
\( i \) index for a JMP color

Combine States(rowstate, rowstate, ...)

Description
Generates a row state combination from two or more row state arguments.

Returns
A single numeric representation of the combined row states.
Arguments
   rowstate  Two or more row states.

Excluded(rowstate)

Description
   Returns or sets an excluded index.

Returns
   The excluded attribute, 0 or 1.

Argument
   rowstate  One or more row states.

Excluded State(num)

Description
   Returns a row state for exclusion from the num given.

Hidden(rowstate)

Description
   Returns or sets the hidden index.

Hidden State(num)

Description
   Returns a row state for hiding from the num given.

Hue State(num)

Description
   Returns a hue state from the num given.

Labeled(rowstate)

Description
   Returns or sets the labeled index.

Labeled State(num)

Description
   Returns a labeled state from the num given.
Marker Of(rowstate)

**Description**
Returns or sets the marker index of a row state.

Marker State(num)

**Description**
Returns a marker state from the `num` given.

Row State(<dt,> <n>)

**Description**
Returns the row state changed from the initial condition of the active row or the `n`th row.

**Arguments**
- `dt` Optional positional argument: a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.
- `n` The row number.

**Example**
The following example creates the data table references and then returns the row state of row 1 in Big Class.jmp:
```
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt2 = Open( "$SAMPLE_DATA/San Francisco Crime.jmp" );
Row State( dt1, 1 );
```

Selected(rowstate)

**Description**
Returns or sets the selected index.

Selected State(num)

**Description**
Returns a selected state from the `num` given.

Shade State(num)

**Description**
The Shade State function assigns 5 shade levels to a color or hue.
SAS Integration Functions

As C Expr(x)

**Description**
Returns a C programming language representation of the expression.

**Returns**
A quoted string.

As JavaScript Expr(x)

**Description**
Returns a JavaScript representation of the expression.

**Returns**
A quoted string.

As JSON Expr(x)

**Description**
Returns a JSON (JavaScript Object Notation) representation of the expression.

**Returns**
A quoted string.

As Python Expr(x)

**Description**
Returns a Python representation of the expression.

**Returns**
A quoted string.

As SAS Expr(x)

**Description**
Converts an expression to a version that is more suitable for SAS DATA step. The code must be wrapped in a PROC DS2 call. Use `Expr( . . . )` for literal expressions. Use `NameExpr(name)` for expressions stored in a variable. Otherwise, the expression returns the expression to convert.

**Returns**
A quoted string.
Current Metadata Connection()

Description
Returns the active SAS metadata server connection, if any, as a scriptable object.

Current SAS Connection()

Description
Gets the active global SAS server connection, if any, as a scriptable object.

Get SAS Version Preference()

Description
Returns the SAS version selected in the SAS Integration page of the Preferences as a quoted string.

JMP6 SAS Compatibility Mode(Boolean)

Description
Setting this to 1 (true) causes SAS operators to operate in a mode compatible with JMP 6 capabilities.

Meta Connect("machine", port), <"authDomain">, <"username">, <"password">, <named arguments>)
Meta Connect(<Profile("profile name")), <Password("password"), <named arguments>)
Meta Connect(<Environment("environment name")), <named arguments>)

Description
Connects to a SAS Metadata Server. If no arguments are specified, an empty connection window appears. If some arguments are specified, a window partially filled in with the argument values appears. If all arguments are specified, the connection is made and no window appears.

Returns
1 if connection is successful, 0 if not.

Arguments
machine (Optional) A quoted string that contains the DNS name of the machine.
port Required if machine is specified. A quoted string or integer that contains the port on which the metadata server listens.
authDomain (Optional) A quoted string that contains the authentication domain for the credentials supplied. Not necessary unless username and password are included.
username (Optional) A quoted string that contains the user name for the connection.
**password** (Optional) A quoted string that contains the password for the connection.

**Optional Named Arguments**

**Profile("profile_name")** A quoted string that contains the name of the metadata server connection profile from which connection information should be retrieved.

**Environment("environment_name")** A quoted string that contains the name of the WIP environment from which connection information should be retrieved.

**Password("password")** A quoted string that contains the password for the specified profile name.

**CheckPreferenceOnly(0|1)** If specified, Meta Connect returns the status of the *I want to connect to a SAS Metadata Server* option in the SAS Integration page of JMP Preferences. If that box is checked, Meta Connect returns 1; if not, 0.

**Repository(string)** Takes a quoted string that contains the name of the repository to which to connect.

**ProfileLookup(0|1)** If *machine* and *port* are specified rather than a profile name, and ProfileLookup is specified, an attempt is made to find a metadata server connection profile with a machine name and port matching those provided. If one is found, other connection information (such as authentication domain, user name, and password) is obtained from that profile.

**Prompt(Always|Never|IfNeeded)** Takes one of the keywords *Always* (always prompt before attempting to connect), *Never* (never prompt, just fail), or *IfNeeded* (the default; prompt if connection with the given arguments fails).

**SASVersion("<version number>" <,Strict>)** Attempts to change the SAS version preference to the specified value before making the metadata server connection. If the SAS version is already locked to a different version than the one specified, the SASVersion argument will fail. By default, if the SAS version cannot be set, JMP will try the metadata server connection. However, if you include *Strict* as the second argument, the inability to change the SAS version will be treated as an error, and JSL processing will stop. If you do not include *Strict*, the SAS version argument is treated as a hint and will set the version preference if it can. JMP will still try to connect if the version cannot be set. The order you put these arguments in can make a difference. The attempt to change the SAS Version is made immediately when that argument is encountered. That can affect the validity of other arguments, particularly for MetaConnect. Valid values for SASVersion are “9.3” and “9.4”. Note: Using the SASVersion argument has the same effect as changing the SAS Server Version on the SAS Integration Preferences page.

**Notes**

- If no arguments are included and if no profile is saved, the Connect to SAS Metadata Server window appears.
- If you connect to a physical workspace server, there is no metadata server involved, so metadata security is never applied. You must connect to a SAS Metadata Server and
then connect to a logical workspace server. Then metadata security is enforced on the metadata-defined libraries you access.

```javascript
Meta Create Profile("profile", <named arguments>)
```

**Description**

Creates a metadata server connection profile and adds it to the current user’s set of saved metadata server connection profiles.

**Returns**

1 if `profile` was successfully created, otherwise 0.

**Arguments**

- `profile` A quoted string that contains the name of the created profile. If a profile by the given name already exists, `MetaCreateProfile` fails unless `Replace` is specified.

**Optional Named Arguments**

- `HostName("name")` A quoted string that contains the name of the host computer running the SAS Metadata Server that this profile will connect to.
- `Port(n)` The port number (`n`) that the SAS Metadata Server is listening for connections on.
- `AuthenticationDomain("domain")` | `AuthDomain("domain")` A quoted string that sets the authentication domain to use for the connection.
- `Description("desc")` | `Desc("desc")` A quoted string that sets a description for this profile.
- `Password("password")` A quoted string that contains the password to store in this profile.
- `Replace(0|1)` If `name` matches a profile that already exists, `Replace` must be specified for the existing profile to be replaced by the one provided. The default value is False (0).
- `UserName("username")` A quoted string that contains the user name that this profile uses to connect to the SAS Metadata Server.
- `UseSingleSignOn(0|1)` If specified, this profile attempts to use Single Sign-On (currently also known as Integrated Windows Authentication) to connect to the SAS Metadata Server. This option is valid only for connecting to SAS 9.3 or higher Metadata Servers. If `UseSingleSignOn` is True (1), `UserName` and `Password` cannot be specified. The default value is False (0).

```javascript
Meta Delete Profile("name")
```

**Description**

Deletes the named metadata server connection profile from the current user’s set of saved metadata server connection profiles.

**Returns**

1 if profile was successfully deleted, otherwise 0.
Argument
  name  A quoted string that contains the name of the profile to delete.

Meta Disconnect()
Description
  Disconnect the current SAS Metadata Server connection, if any.
Returns
  Void.

Meta Get Environments()
Description
  Returns a list of the SAS Environments that are defined in the SAS Environments
  definition file, which is configured in the SAS Preferences.

Meta Get Repositories()
Description
  Gets a list of the repositories available on the current SAS Metadata Server connection.
Returns
  A list of repository names as quoted strings.

Meta Get Servers()
Description
  Get a list of the SAS Servers that are registered in the SAS Metadata Repository to which
  the session is currently connected.
Returns
  A list of server names as quoted strings.

Meta Get Stored Process("path")
Description
  Get a stored process object from the currently connected SAS Metadata Repository.
Returns
  Stored Process scriptable object.
Arguments
  path  Quoted string that is the path to the stored process in metadata, starting at the BIP
        Tree.
Meta Is Connected()

**Description**
Determines whether a current connection to a SAS Metadata Server exists.

**Returns**
1 if a connection exists; 0 otherwise.

**Arguments**
None.

Meta Set Repository("repositoryName")

**Description**
Set the SAS Metadata Repository to use for metadata searches.

**Returns**
1 if setting the repository was successful, 0 otherwise.

**Arguments**
repositoryName A quoted string that contains the name of the repository to make current.

SAS Assign Lib Refs("libref", "path", <"engine">, <"engine options">)

**Description**
Assign a SAS libref on the active global SAS server connection.

**Returns**
1 if successful, 0 otherwise.

**Arguments**
libref A quoted string that contains a library reference (8-character maximum) to assign.
path A quoted string that contains the full path on the SAS server to the library being assigned.
engine Optional, quoted string that contains the engine for the SAS server to use when accessing members of this library.
engine options Optional, quoted string that contains the options needed for the engine being used.

SAS Connect(<"machine_name">, <"port">, <named_arguments>)

**Description**
Connect to a local, remote, or logical SAS server.

**Returns**
SAS Server scriptable object.
Arguments

machine_name (Optional) A quoted string that can contain a physical machine name or
the name of a metadata-defined (logical) server. In the first case, the port must be
provided. In the second case, a port must not be provided. If neither name nor port are
included, and JMP is running on Windows, a connection to SAS on the local machine
(via COM) is attempted, and all named arguments are ignored.

port (Optional) A quoted string or integer. If name is a physical machine name, this is the
port on that machine to connect to. If name is a metadata-defined (logical) server, port
must not be included.

Optional Named Arguments

UserName("name") A quoted string that contains the user name for the connection.
Password("password") A quoted string that contains the password for the connection.
ReplaceGlobalConnection(0|1) A Boolean. The default value is True. If True, and a
successful SAS server connection is made, this connection replaces the active SAS
connection that becomes the target of other global SAS JSL function calls. If False, the
global SAS connection is not changed, and the returned SASServer scriptable object
should be used to send messages to this server connection.

ShowDialog(0|1) A Boolean. The default value is False. If True, other arguments
(except ReplaceGlobalConnection) are ignored and the SAS Server Connection
window appears. This provides the JSL programmer a way to open the SAS Connect
window.

Prompt(Always|Never|IfNeeded) A keyword. Always means always prompt before
attempting to connect. Never means never prompt even if the connection attempt fails
(just fail and send an error message to the log), and IfNeeded (the default value) means
prompt if the attempt to connect with the given arguments fails (or is not possible with
the information given).

ConnectLibraries(0|1) A Boolean. Defaults to the SAS Integration Preference setting
governing whether to automatically connect metadata-defined libraries when
connecting to a SAS server. If true, all metadata-defined libraries are connected at SAS
server connection time, which can be time-consuming. If false, metadata-defined
libraries are not connected. To connect specific libraries later, use the SAS Connect
Libref global function or Connect Libref message to a SAS server object.

SASVersion("<version number>" <,Strict>) Attempts to change the SAS version
preference to the specified value before making the metadata server connection. If the
SAS version is already locked to a different version than the one specified, the
SASVersion argument will fail. By default, if the SAS version cannot be set, the
metadata server connection will still be tried. However, if you include Strict as the
second argument, the inability to change the SAS version will be treated as an error and
JSL processing will stop. If you do not include Strict, the SAS version argument is
treated as a hint and will set the version preference if it can, but if it cannot it will still
try to connect. The order you put these arguments in can make a difference. The
attempt to
change the SAS Version is made immediately when that argument is encountered. That can affect the validity of other arguments, particularly for MetaConnect. Valid values for SASVersion are “9.3” and “9.4”. Note: Using the SASVersion argument has the same effect as changing the SAS Server Version on the SAS Integration Preferences page.

Example

// prompt for login credentials
Meta Connect( "dev.company.com", 28561 );

sas = SAS Connect( "SASApp" );

// dump some libraries and data sets to the JMP log
Show( sas << Get Librefs() );
Show( sas << Get Data Sets( "Chocolate Enterprises 2017" ));

sas << Import Data( "Chocolate Enterprises 2017", "Products" );

/* The preceding lines produce the following text in the JMP log and import the data set: */
sas << Get Data Sets("Chocolate Enterprises 2008"):{"CHOC_DATA", "CHOC_SURVEY", "CUSTOMERS", "ORDER_DETAIL", "PRODUCTS", "SALES_ANALYSIS", "SALES_SUMMARY"}

Get Librefs returns the short library names, not the longer logical names. However, you can use either one, and metadata security will still be applied for metadata-defined libraries.

SAS Connect Lib Refs(libref)

Description
Connects a SAS libref on the active SAS server connection.

Returns
1 if successful and 0 otherwise.

SAS Deassign Lib Refs(\"libref\")

Description
De-assign a SAS libref on the active global SAS server connection.

Returns
1 if successful; 0 otherwise.

Arguments
libref A quoted string that contains the library reference to de-assign.
**SAS Disconnect()**

**Description**
Disconnect the active global SAS connection, if any.

**Returns**
1 if a SAS connection exists and was successfully disconnected, 0 otherwise.

**Arguments**
None.

---

**SAS Export Data(dt, "library", "dataset", <named_arguments>)**

**Description**
Exports a JMP data table to a SAS data set in a library on the active global SAS server connection.

**Returns**
1 if the data table was exported successfully; 0 otherwise.

**Arguments**
- `dt` data table or a reference to a data table.
- "library" the library to which to export the data table.
- "dataset" the name of the new SAS data set.

**Optional Named Arguments**
- `Columns(list)|Columns(col1, col2, ...)` A list of columns or a comma-separated list of columns.
- `Password("password")` A quoted string that contains the password to serve as the READ, WRITE, and ALTER password for the exported SAS data set. If the exported data set is replacing an existing data set with an ALTER password, this password is used as the ALTER password for overwriting the data set. If `Password` is specified, values for `ReadPassword`, `WritePassword`, and `AlterPassword` are ignored.
- `ReadPassword("password")` A quoted string that contains the password to serve as the READ password for the exported SAS data set.
- `WritePassword("password")` A quoted string that contains the password to serve as the WRITE password for the exported SAS data set.
- `AlterPassword("password")` A quoted string that contains the password to serve as the ALTER password for the exported SAS data set. If the exported data set is replacing an existing data set with an ALTER password, this password is used as the ALTER password for overwriting the data set.
- `PreserveSASColumnNames(0|1)` A Boolean. If true and the JMP data table originally came from SAS, the original SAS column names are used in the exported SAS data set. The default value is False.
PreserveSASFormats(0|1) A Boolean. If true and the JMP data table originally came from SAS, the original SAS formats and informats are applied to the columns in the exported SAS data set. The default value is True.

ReplaceExisting(0|1) A Boolean. If true, an existing SAS data set with the specified name in the specified library is replaced by the exported SAS data set. If false, a data set with the specified name already exists in the specified library; the export is stopped. The default value is false.

SaveJMPMetadata(0|1) Includes SAS 9.4 Extended Attributed to store JMP metadata (such as table script and column properties). Default is 0 (disabled).

HonorExcludedRows(0|1) A Boolean. If true, any rows in the JMP data table that are marked as excluded are not exported. The default value is false.

Notes
Information about the export is sent to the log.

SAS Get Data Sets("libref")

Description
Returns a list of the data sets defined in a SAS library.

Returns
A list of quoted strings.

Arguments
libref A quoted string that contains the SAS libref or friendly library name associated with the library for which the list of defined SAS data sets is returned.

SAS Get File("source", "dest", "encoding")

Description
Get a file from the active global SAS server connection. JMP creates a FILENAME statement (with an encoding, if specified) and uses it to read the file on the SAS server.

Returns
1 if successful, 0 otherwise.

Arguments
source A quoted string that contains the full path of file on the server to be downloaded to the client machine.
dest A quoted string that contains the full path on the client machine for where to put the copy of the file downloaded from the server.
encoding A quoted string that contains the encoding used in the file (for example, "utf-8"). The server must support the specified encoding.
SAS Get File Names("fileref")

**Description**
Get a list of filenames found in the given fileref on the active global SAS server connection.

**Returns**
A list of quoted strings.

**Arguments**
- *fileref* A quoted string that contains the name of the fileref from which to retrieve filenames.

SAS Get File Names In Path("path")

**Description**
Get a list of filenames found in the given path on the active global SAS server connection.

**Returns**
A list of quoted strings.

**Arguments**
- *path* A quoted string that contains the directory path on the server from which to retrieve filenames.

SAS Get File Refs()

**Description**
Get a list of the currently defined SAS filerefs on the active global SAS server connection.

**Returns**
List of two lists. The first list is a list of quoted strings of fileref names. The second is a corresponding list of strings of physical names.

SAS Get Lib Refs(<named arguments>)

**Description**
Get a list of the currently defined SAS librefs on the current global SAS server connection.

**Returns**
A list of quoted strings.

**Named Arguments**
- **Friendly Names(0|1)** Optional, Boolean. If True, then for any libraries that have friendly names (metadata-defined libraries), the friendly name is returned rather than the 8-character libref.
### SAS Get Log()

**Description**
Retrieve the SAS Log from the active global SAS server connection.

**Returns**
A quoted string.

### SAS Get Output()

**Description**
Retrieve the listing output from the last submission of SAS code to the current global SAS server connection.

**Returns**
A quoted string.

### SAS Get Results()

**Description**
Retrieve the results of the previous SAS Submit as a scriptable object, which allows significant flexibility in what to do with the results.

**Returns**
A SAS Results Scriptable object.

### SAS Get Var Names(\textit{string}, \textit{"dataset"}, \textit{<password("password")}>)

**Description**
Retrieves the variable names contained in the specified data set on the current global SAS server connection.

**Returns**
A list of quoted strings.

**Arguments**
- \textit{string} A quoted string that contains one of the following:
  - The name of the SAS Library containing the SAS data set to be imported. In that case, the \textit{dataset} name argument is required.
  - The full member name of the SAS data set to be imported, in the form “libname.membername”.
  - The SAS Folders tree path to a logical SAS data table to be imported. This option requires a connection to a SAS 9.3 or higher Metadata Server.
- \textit{dataset} (Optional) A quoted string that contains the name of the data set from which to retrieve variable names.
password("password") (Optional) A quoted string that contains the read password for the data set. If this is not provided and the data set has a read password, the user is prompted to enter it.

SAS Import Data(string, <"dataset">, <named arguments>)

Description
Import a SAS data set from the active global SAS server connection into a JMP table.

Returns
JMP Data Table object.

Arguments

string A quoted string that contains one of the following:
- The name of the SAS Library containing the SAS data set to be imported. In that case, the "dataset" name argument is required. The name can be a friendly metadata library name or a SAS 8-character library name.
- The full member name of the SAS data set to be imported, in the form "libname.membername".
- The SAS Folders tree path to a logical SAS data table to be imported. This option requires a connection to a SAS 9.3 or higher Metadata Server.

dataset (Optional) A quoted string that contains the name of the data set.

Optional Named Arguments

Columns("list")|Columns(col1, col2, ...) A quoted string list or multiple strings that contain the names of columns to include in the import.

ConvertCustomFormats(0|1) The default value is True (1). If True and custom formats are found in the SAS data set being imported, an attempt is made to convert the SAS custom formats to JMP value labels for those columns.

Invisible(0|1) The default value is False (0). If true, the JMP data table is hidden from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call Close(dt), where dt is the data table reference returned by SASImportData.

Where("filter") A quoted string that contains the filter to use when importing data, as in Where("salary<50000").

Password("password") A quoted string that contains the read password for the data set. If this is not provided and the data set has a read password, the user is prompted to enter it.

UseLabelsForVarNames(0|1) If True, the labels from the SAS data set become the column names in the resulting JMP table. If False, the variable names from the SAS data set become the column names in the JMP table. The default value is False.
**RestoreJMPMetadata(0|1)** Includes SAS 9.4 Extended Attributes to store JMP metadata. Default is 0 (disabled).

**Sample(named arguments)** optional, named. Allows a random sample of the SAS data set to be imported into JMP. If both Where and Sample are specified, the WHERE clause is used to filter the SAS data set first, and then a random sample of the resulting rows is taken based on the arguments supplied to Sample. Note that Sample uses PROC SURVEYSELECT on the SAS server, which is available only if the SAS/STAT package is licensed and installed on that server. The documentation for PROC SURVEYSELECT might be helpful in understanding how sampling is performed. By default (if no arguments are supplied), a 5% simple random sample is taken. Here are the available arguments (all optional):

- **Simple | Unrestricted**: If Simple is specified, sampling is performed without replacement. If Unrestricted is specified, sampling is performed with replacement. These two options are mutually exclusive and only one can be specified.

- **SampleSize(int) | N(int)**: Total number of rows for the sample, or number of rows per strata level for stratified sampling

- **SampleRate(number) | Rate(number) | Percent(number)**: Specifies the sampling rate. For stratified sampling, the rate is applied to each strata level. Note that the supplied value is assumed to be a percentage, so SampleRate(3.5) means a 3.5% sampling rate.

- **Strata({col1, col2, ...}) | Strata(col1, col2, ...)**: Perform stratified random sampling using the column names supplied as Strata variables.

- **NMin(int)**: Minimum number of rows (either overall or per strata level for stratified sampling) to return. Only applies to rate-based sampling.

- **NMax(int)**: Maximum number of rows (either overall or per strata level for stratified sampling) to return. Only applies to rate-based sampling.

- **Seed(int)**: Number to use as the seed for sampling. Useful for replicating the same sample. By default, the seed is a random number based on time of day. See PROC SURVEYSELECT documentation.

- **OutputHits(0|1)**: Boolean; the default value is false. When doing Unrestricted sampling, if the same row of the input data set is selected more than once, by default that row still appears only once in the resulting JMP data table, with the NumberHits column indicating the number of times that the row was selected. Setting OutputHits to true causes an input row that is selected multiple times to appear multiple times in the resulting JMP data table.

- **SelectAll(0|1)**: Boolean, the default value is true. If SelectAll is true, PROC SURVEYSELECT selects all stratum rows whenever the stratum sample size exceeds the total number of rows in the stratum. If SelectAll is false and PROC SURVEYSELECT finds a case where the stratum sample size exceeds the total number
of rows in a given stratum, an error results and sampling fails. `SelectAll` only applies to Simple random sampling.

`SQLTableVariable(0|1)` If `True`, an SQL table variable is created in the resulting JMP table that shows the SQL that was submitted to SAS to obtain the data. If `False`, the SQL table variable is not created. The default value is `True`. If an SQL table variable is created and the data set required a read password, the password is masked.

---

**SAS Import Query**

**Description**

Execute the requested SQL query on the current global SAS server connection, importing the results into a JMP data table.

**Returns**

JMP Data Table object.

**Arguments**

- `sqlquery` A quoted string that contains the SQL query to perform and from which to import the result.

**Optional Named Arguments**

- `ConvertCustomFormats(0|1)` The default value is true. If true and custom formats are found in the SAS data set being imported, an attempt is made to convert the SAS custom formats to JMP value labels for those columns.
- `Invisible(0|1)` The default value is false. If true, the JMP data table is hidden from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call `Close(dt)`, where `dt` is the data table reference returned by `SAS Import Query`.
- `UseLabelsForVarNames(0|1)` The default value is true. If `True`, the labels from the SAS data set become the column names in the resulting JMP table. If `False`, the variable names from the SAS data set become the column names in the JMP table.
- `RestoreJMPMetadata(0|1)` Includes SAS 9.4 Extended Attributes to store JMP metadata. Default is 0 (disabled).
- `SQLTableVariable(0|1)` The default value is true. If `True`, an SQL table variable is created in the resulting JMP table that shows the SQL that was submitted to SAS to obtain the data. If `False`, the SQL table variable is not created. If an SQL table variable is created and the data set required a read password, the password is masked.

---

**SAS Is Connected**

**Description**

Discovers whether there is an active global SAS server connection.
Returns

1 if an active global SAS connection exists, 0 otherwise.

SAS Is Local Server Available()

Description

Returns True if a local SAS Server is available; otherwise, returns False.

SAS Load Text File("path")

Description

Download the file specified in path from the active global SAS server connection and retrieve its contents as a quoted string.

Returns

A quoted string.

Arguments

"path" A quoted string that contains the full path on the server of the file to download and retrieve the contents as a string.

SAS Name("name")

SAS Name({list of names})

Description

Converts JMP variable names to SAS variable names by changing special characters and blanks to underscores and various other transformations to produce a valid SAS name.

Returns

A quoted string that contains one or more valid SAS names, separated by spaces.

Argument

"name" A quoted string that represents a JMP variable name; or a list of quoted JMP variable names.

SAS Open For Var Names("path")

Description

Opens a SAS data set only to obtain the names of its variables, returning those names as a list of quoted strings.

Returns

A list of variable names in the file.

Argument

path A quoted string that is a pathname of a SAS data set.
SAS Send File("source", "dest", "encoding")

Description
Send a file from the client machine to the active global SAS server connection. JMP creates a FILENAME statement (with an encoding, if specified) and uses it to save the file on the SAS server.

Returns
1 if successful, 0 otherwise.

Arguments
source A quoted string that contains the full path of the file on the client machine to be uploaded to the server.
dest A quoted string that contains the full path on the server that receives the file uploaded from the client machine.
encoding A quoted string that contains the encoding used in the file (for example, “utf-8”). The server must support the specified encoding.

SAS Submit("sasCode", <named arguments>)

Description
Submit some SAS code to the active global SAS server connection.

Returns
1 if successful, 0 otherwise.

Arguments
sasCode A quoted string that contains the SAS code to submit.

Optional Named Arguments
Async(0|1) A Boolean. If True (1), the submit occurs asynchronously (in the background). Use the Get Submit Status() message on the SAS Server Scriptable Object to determine the status of the submit. The default value is False (0).
ConvertCustomFormats(0|1) A Boolean. When SAS data sets generated by submitted SAS code are imported into JMP after the submit completes (see Open Output Datasets), the value of ConvertCustomFormats determines whether an attempt is made to convert any custom formats found on columns in the SAS data to JMP value labels. The default value is True (1).
DeclareMacros(var1, var2, ...) JSL variable names. Provides a simple way to pass the values of JSL variables to SAS as macro variables. Each JSL variable specified should evaluate to a quoted string or numeric value. Fully qualified JSL variables names, only the variable name is sent to SAS. For example, namespace:variable_name becomes variable_name in SAS.
GetSASLog(<Boolean|OnError>, <JMPLog|Window>) A Boolean. If no arguments are supplied, the SAS Log is retrieved and displayed in the location indicated in SAS Integration Preferences. The first argument to GetSASLog can be either a Boolean value...
or the keyword OnError. If a Boolean value is supplied, true means display the SAS Log, and false means not to display it. OnError instructs JMP to only show the SAS Log if an error occurred in the submit. The second argument to GetSASLog tells JMP where to display the SAS Log. If JMPLog is specified, the SAS Log is appended to the JMP Log. If Window is specified, the SAS Log is opened in a separate window.

**GraphicsDevice(string) or GDevice(string)** A quoted string that specifies a value for the GDEVICE SAS option to be used for graphics generated by the submitted SAS code. The value must be a valid SAS graphics device. The default value is determined in Preferences.

**Interactive(0|1)** JMP includes the QUIT statement in the generated wrapper code. Interactive PROCs work even if JMP is generating the ODS wrapper. On every SUBMIT, specify the argument that is part of an interactive sequence. Otherwise, QUIT will be generated in both the prologue-generated and epilogue-generated code.

**NoOutputWindow** A Boolean. If True, the SAS Output window containing the listing output from the submission does not appear. The default value is False.

**ODS(0|1)** If true, additional SAS code is submitted causing ODS results to be generated for the submitted SAS code. The default value is determined in Preferences.

**ODSFormat(string)** A quoted string that determines the format of generated ODS results. Valid values are “HTML”, “RTF”, and “PDF”. The default value is determined in Preferences.

**ODSGraphics(0|1)** If true, ODS statistical graphics are generated for the submitted SAS code. Setting ODSGraphics to true causes ODS to also be set to true. The default value is determined in Preferences.

**ODSStyle(string)** A quoted string that specifies the ODS Style to use when generating ODS results. **String** must be a valid SAS Style. The default value is determined in Preferences.

**ODSStyleSheet(path)** A quoted string that specifies a local CSS style sheet to use when formatting generated ODS results. **Path** must be a path to a CSS file valid for the client machine (the machine running JMP). The default value is determined in Preferences.

**OnSubmitComplete(script)** A quoted string that specifies a JSL script that should be run when the submit completes. This is especially useful for asynchronous submits. If script is the name of a defined JSL function, that function is executed, with the SAS Server scriptable object passed as the first argument.

**OpenODSResults(0|1)** If true, ODS results that are generated by the submitted SAS code (due to ODS being true) are automatically opened after the submit completes. The default value is True (1).

**OpenOutputDatasets(<All|None|dataset1, dataset2, ...>)** JMP detects when submitted SAS code creates new SAS data sets. OpenOutputDatasets (which can be abbreviated OutData) determines what, if anything, is done with those data sets with the SAS Submit completes. If All is specified, all data sets generated by the SAS code are imported into JMP when the SAS Submit completes. If None is specified, none of the
generated data sets are imported. If there are specific data sets known to be generated by the submitted SAS code that you want to be imported into JMP when the SAS submit completes, you can alternatively provide their names, and only the requested data sets are imported. The default value is determined in Preferences.

Title(string) A quoted string that specifies the window title to use for the window that displays ODS output from the submit.

SAS Submit File("filename", <named arguments>)

Description
Submit a SAS code file to the active global SAS server connection.

Returns
1 if successful; 0 otherwise.

Arguments
filename A quoted string that contains the name of file containing SAS code to submit.

Named Arguments
Same as for SAS Submit.

SQL Functions

Note: Database table names that contain the characters $# -+/%&|;? are not supported.

As SQL Expr(x, <style>)

Description
Converts an expression to code that you can use in an SQL Select statement. Use Expr(...) for literal expressions. Use NameExpr(name) for expressions stored in a variable. Otherwise, the expression returns the expression to convert.

Returns
A quoted string that contains the expression converted to valid SQL syntax for use in an SQL Select statement.

New SQL Query(Connection
("ODBC:connection_string")|("SAS:connection_string"),
Select(Column("column", "t1")), From(Table("table", <Schema("schema")>,

<Alias("t1")>), <Options(JMP 12 Compatible(1)|JMP 13 Compatible(1)|Run on Open(1))>

New SQL Query(Connection("ODBC:connection_string;")|("SAS:connection_string;"), Custom("SELECT col1, col2, col3 FROM table;"), <Options(JMP 12 Compatible(1)|JMP 13 Compatible(1)|Run on Open(1))>)

Creates an SQL Query object for the specified connection, columns, data table, or for the custom SQL query.

**Returns**

A data table that contains the queried data. The data table includes the quoted SQL query string and table scripts for modifying and updating the query.

**Arguments**

- **Connection** The quoted string for an ODBC or SAS connection.
- **Select** The column that you want to select and its alias.
- **From** The table that is queried and the optional schema and column alias.
- **Custom** An SQL statement that selects columns from the specified table.
- **Version** The minimum JMP version required to open the query. If this condition is not met, a message regarding compatibility is written to the log, and the query does not open.
- **Options** Boolean. JMP 12 Compatible is included in generated scripts when you select the Query Builder preference to create a JMP 12 compatible option or select the corresponding Query Builder red triangle menu option. The option enables JMP 12 users to run a JMP 13 query that might contain compatibility issues. Include Run on Open(1) to run the query when opened rather than opening the query in edit mode.

**Example**

```julia
New SQL Query(
    Connection(
        "ODBC Connection String..."
    ),
    QueryName( "g6_Movies" ),
    Select( Column("ItemNo", "t1"), Column("LengthMins", "t1"), Column("Genre", "t1")),
    From( Table("g6_Movies", Schema("SQBTest"), Alias("t1"))),
    << Run Background( On Run Complete( dt = queryResult ) ));

Show( dt );
```

**Notes**

- Query Builder creates a symbol called queryResult in the context of an On Run Complete() script. This is a reference to the data table imported by the query. queryResult enables you to assign a global variable to the table for later use.
- New SQL Query() always closes the ODBC connection after performing the query.
• After you run `New SQL Query()`, the database connection that you make appears in the Database > Open Table window as an available connection. But the connection you see in the Database > Open Table window is due to JMP keeping track of how to connect to that database; no ODBC connection is left open.

• There is not a command to close an ODBC connection established with `New SQL Query()` because `New SQL Query()` always closes the connection after performing the query.

• After you run `New SQL Query()`, the database connection appears in the Database > Open Table window as an available connection. JMP is keeping track of how to connect to that database; the ODBC connection was not left open.

```
Query(<<dt1|Table(dt1, alias1)>, ..., <dtN, aliasN>>>, <private | invisible>, <scalar>, sqlStatement )
```

**Description**
Performs a SQL query on selected data tables.

**Returns**
The result of the query, either a data table or a single value.

**Arguments**
- `dt1, dtN` (Optional) A variable that has been assigned to the data table.
- `Table` (Optional) Passes a reference to the data table.
- `alias1, aliasN` Specifies the alias of the database table.
- `private` (Optional) Avoids showing the resulting data table. Using a private data table speeds the process of getting to the data; it does not save the computer from allocating the memory necessary to hold the data table data.
- `invisible` (Optional) Hides the resulting data table from view. The data table appears only in the JMP Home Window and the Window menu. Hidden data tables remain in memory until they are explicitly closed, reducing the amount of memory that is available to JMP. To explicitly close the hidden data table, call `Close(dt)`, where `dt` is the data table reference.
- `scalar` (Optional) Indicates that the query returns a single value.
- `sqlStatement` Required. The SQL statement, most likely a SELECT statement. The statement must be the last argument.

**Example**
The following example selects all data for students who are older than 14 years of age.

```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
result = Query( Table( dt, "t1" ), "SELECT * FROM t1 WHERE age > 14;" );
```

**See Also**
Appendix A, “SQL Functions Available for JMP Queries”
Statistical Functions

Arc Finder(X(col), Y(col), Group(lot, wafer))

Description
Finds arcs in the point data and creates a new column that identifies the arcs.

Example
```julia
dt = Open( "SAMPLE_DATA/Wafer Stacked.jmp" );
Arc Finder(
    Group( :Lot, :Wafer ),
    X( :X_Die ),
    Y( :Y_Die ),
    Min Distance( 12 ), // minimum distance among 3 points to seed an arc
    Min Radius( 15 ), // minimum radius of the acceptable arc
    Max Radius( 2000 ), // maximum radius of acceptable arc
    Max Radius Error( 2 ), // how close a point needs to be added
    Min Arc Points( 5 ), // how many points to define an arc
    Number of Searches( 500 ), // how many random probes of data
    Max Number Arcs( 3 ) // number of arcs searched for
);
dt << Color or Mark by Column( :Arc Number );
dt << Graph Builder(
    Size( 1539, 921 ),
    Variables( X( :X_Die ), Y( :Y_Die ), Wrap( :Lot_Wafer Label ), Color( :Arc Number ) ),
    Elements( Points( X, Y, Legend( 6 ) ) )
);
```

Notes
- The function is scaled for data that have a range of 30 to 50 units.
- The function is suitable only for data that are subset to the interesting defect points.
- It is not suitable when the density of points is high.

ARIMA Forecast(column, length, model, estimates, from, to)

Description
Determines the forecasted values for the specified rows of the specified column using the specified model and estimates.

Returns
A vector of forecasted values for column within the range defined by from and to.

Arguments
column A data table column.
length  Number of rows within the column to use.
model  Messages for Time Series model options.
estimates  A list of named values that matches the messages sent to ARIMA Forecast().
        If you perform an ARIMA Forecast and save the script, the estimates are part of the script.
from, to  Define the range of values. Typically, from is between 1 and to, inclusive. If from is less than or equal to 0, and if from is less than or equal to to, the results include filtered predictions.

Best Partition(xindices, yindices, <<Ordered, <<Continuous Y, <<Continuous X)

Description
    Experimental function to determine the optimal grouping.
Returns
    A list.
Arguments
    xindices, yindices  Same-dimension matrices.

Col Cumulative Sum(name, <By var, ...>)

Cumulative Sum(name)

Description
    Returns the cumulative sum for the current row. Col Cumulative Sum supports By columns, which do not need to be sorted.
Arguments
    name  A column name.
    By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Col Maximum(name, <By var, ...>)

Col Max(name)

Description
    Calculates the maximum value across all rows of the specified column. The result is internally cached to speed up multiple evaluations.
Returns
    The maximum value that appears in the column.
Arguments
    name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Mean(name, <By var, ...>)

Description
Calculates the mean across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns
The mean of the column.

Argument
name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Median(name, <By var, ...>)

Description
Calculates the median across all rows of the specified column. The ordering is cached internally to speed up multiple evaluations.

Returns
The median of the column.

Argument
name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.
Col Minimum(name, <By var, ...>)

Col Min(name)

Description
Calculates the minimum value across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns
The minimum value that appears in the column.

Argument
name A column name.

By var (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Moving Average(name, options, <By var, ...>)

Moving Average(name, options)

Description
Returns the moving average over a given interval based at the current row. Col Moving Average supports By columns.

Arguments
name A column name.

Weighting(1|0|n) Required positional argument. Determines how the values are weighted. 1 indicates uniform weighting, 0 indicates incremental weighting (a ramp or triangle). Any other number is the parameter for an exponential moving average (EWMA or EMA).

Before(1|0|n) Positional argument. Controls the size of the range (or window) by including the specified number of items before the current item in the average (in addition to the current item). The default value, -1, means all of the preceding items.

After(1|0|n) Positional argument. Controls the size of the range (or window) by including the specified number of items after the current item in the average (in addition to the current item). The default value, 0, means no following items.
Partial Window is Missing  Boolean positional argument. Controls how missing values are treated. By default, missing values are ignored. 0 computes the average of partial windows.

By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Examples

// equal weighting of a five-item lagging range
Col Moving Average( x, 1, 4 );

// ramp weighting of all preceding items
Col Moving Average( x, 0 );

// triangle weighting of a five-item centered range
Col Moving Average( x, 0, 2, 2 );

// exponential weighting of all preceding items
Col Moving Average( x, 0.25 );

Col N Missing(name, <By var, ...>)

Description
Calculates the number of missing values across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns
The number of missing values in the column.

Argument
name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Number(name, <By var, ...>)

Description
Calculates the number of nonmissing values across all rows of the specified column. The result is internally cached to speed up multiple evaluations.
Returns
The number of nonmissing values in the column.

Argument
name A column name.
By var (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Quantile(name, p, <ByVar>)

Description
Calculates the specified quantile p across all rows of the specified column. The result is internally cached to speed up multiple evaluations.

Returns
The value of the quantile.

Argument
name A column name.
p A specified quantile p between 0 and 1.
ByVar (Optional) A By group.

Example
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Col Quantile( :height, .5 );
   63
63 is the 50th percentile, or the median, of all rows in the height column.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Col Rank(column, <ByVar>, ...>, <<tie("average"|"arbitrary"|"row"|"minimum"))

Description
Ranks each row’s value, from 1 for the lowest value to the number of columns for the highest value. Ties are broken arbitrarily.
Arguments

col\(\text{umn}\)  The column to be ranked.
ByVar  (Optional) A By variable to compute statistics across groups of rows.
<\text{tie}>  Determines how the tie is broken. A tie occurs when the values being ranked are the same. For the data [33 55 77 55], 33 has rank 1 and 77 has rank 4, and the question is how to assign ranking for the 55s. average reports the average of the possible rankings, 2.5, for both 55s. arbitrary matches JMP 12 behavior by assigning the possible rankings in an unspecified order, which could be 2 and 3 or 3 and 2. row assigns the ranks in the order that they originally appear. (The first 55 would be 2 and the second 55 would be 3.) minimum gives both values the lowest possible rank, 2.

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use Col\ Stored\ Value() to base the calculation on the value stored in the column instead.

See Also

“Col\ Stored\ Value(<dt>, col, <row>)” on page 281

Col Simple Exponential Smoothing(column, alpha, <ByVar> )

Description

Returns the simple exponential smoothing prediction for the current row using smoothing weight \(\alpha\).

Arguments

col\(\text{umn}\)  The column of time series observations.
alpha  The smoothing weight.
ByVar  (Optional) A By variable to compute predictions across groups of rows. By variables do not need to be presorted.

Notes

The predicted value for row \(t\) is given by the following:

\[
\text{Predicted}[t] = \alpha \times \text{Observed}[t-1] + (1-\alpha) \times \text{Predicted}[t-1]
\]

By definition, \(\text{Predicted}[1] = \text{Observed}[1]\).

Col Standardize(name,<By\ var, ...>)

Description

Calculates the column mean divided by the standard deviation across all rows of the specified column.

Returns

The standardized mean.
Argument

name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. If a By variable is specified, the values are standardized against the mean and standard deviation of their corresponding By variable group.

Notes

Standardizing centers the variable by its sample standard deviation. Thus, the following commands are equivalent:

```
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
dt << New Column( "stdht", Formula( Col Standardize( height ) ) );
dt << New Column( "stdht2", Formula( (height - Col Mean( height )) / Col Std Dev( height ) ) );
```

Notes

If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also

“Col Stored Value(<dt>, col, <row>)” on page 281

### Col Std Dev(name,<By var, ...>)

**Description**

Calculates the standard deviation across rows in a column. The result is internally cached to speed up multiple evaluations.

**Returns**

The standard deviation.

**Argument**

name  A column name.
By var  (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

**Notes**

If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

**See Also**

“Col Stored Value(<dt>, col, <row>)” on page 281
Col Sum(name,<By var, ...>)

Description
Calculates the sum across rows in a column. Calculating all missing values (Col Sum(., .)) returns missing. The result is internally cached to speed up multiple evaluations.

Returns
The sum.

Argument
name A column name.
By var (Optional) A By variable to compute statistics across groups of rows. Use the By variable in a column formula or in a For Each Row() function.

Notes
If a data value is assigned by a column property (such as Missing Value Codes), use Col Stored Value() to base the calculation on the value stored in the column instead.

See Also
“Col Stored Value(<dt>, col, <row>)” on page 281

Fit Censored(Distribution("name"), YLow(vector) | Y(Vector), <YHigh(vector)>, <Weight(vector)>, <X(matrix)>, <Z(matrix)>, <HoldParm(vector)>, <Use random sample to compute initial values(percent)>, <Use first N observations to compute initial values(nobs)>)

Description
Fits a distribution using censored data.

Returns
A list that contains parameter estimates, the covariance matrix, the log-likelihood, the AICc, the BIC, and a convergence message. See Fitting Linear Models.

Arguments
Distribution("name") The quoted name of the distribution to fit.
YLow(vector) | Y(Vector) If you do not have censoring, then use Y and an array of your data, and do not specify YHigh. If you do have censoring, then specify YLow and YHigh as the lower and upper censoring values, respectively.

Optional Arguments
YHigh(vector) A vector that contains the upper censoring values. Specify this only if you have censoring and also specify YLow.
Weight(vector) A vector that contains the weight values.
X(matrix) The regression design matrix for location.
Z(matrix) The regression design matrix for scale.
HoldParm(vector) An array of specified parameters. The parameters should be nonmissing where they are to be held fixed, and missing where they are to be estimated. This is primarily used to test hypotheses that certain parameters are zero or some other specific value.

Use random sample to compute initial values(percent) A percent of the observations to be used in the computation of the initial values. Specify this if the data vector is large.

Use first N observations to compute initial values(nobs) A number of observations at the start of the data vector to be used in the computation of the initial values. Specify this if the data vector is large.

---

Fit Circle(Xvec, Yvec)

**Description**
Fits a circle that best goes through three or more points using a least squares approach. If only three points are specified, a direct solution can be found, and the sum of squared errors is zero.

**Returns**
A list that contains the X and Y coordinates of the center point of the circle, the length of the radius, and the sum of squared errors.

**Arguments**
- Xvec Vector of X coordinates of three or more points.
- Yvec Vector of Y coordinates of three or more points.

**Syntax**
\[
\{Xcenter, yCenter, radius, SSE\} = \text{Fit Circle}(Xvec, Yvec)
\]

---

Hier Clust(x)

**Description**
Returns the clustering history for a hierarchical clustering using Ward’s method (without standardizing data).

**Argument**
- x A data matrix.

---

IRT Ability(Q1, <Q2, Q3, ... Qn,> parmMatrix)

**Description**
Returns scores for the latent variable in an item response theory model with n binary items and a matrix of known parameters. The parameter matrix should contain as many rows as there are parameters in the model and as many columns as there are items in the analysis.
Arguments
Q1, Q2, ..., Qn A set of n binary items.
parmMatrix A matrix of parameters from an item response theory model.

KDE(vector, <named arguments>)

Description
Returns a kernel density estimator with automatic bandwidth selection.

Argument
vector A vector.

Optional Named Arguments
<<weights Must be a vector of the same length as vector, and can contain any nonnegative real numbers. Weights represents frequencies, counts, or similar concepts.
<<bandwidth(n) A nonnegative real number. Enter a value of 0 to use the bandwidth selection argument.
<<bandwidth_scale(n) A positive real number.
<<bandwidth_selection(n) n must be 0, 1, 2, or 3, corresponding to Sheather and Jones, Normal Reference, Silverman rule of thumb, or Oversmoother, respectively.
<<kernel(n) n must be 0, 1, 2, 3, or 4, corresponding to Gaussian, Epanechnikov, Biweight, Triangular, or Rectangular, respectively.

LenthPSE(x)

Description
Returns Lenth’s pseudo-standard error of the values within a vector.

Argument
x A vector.

Max() See “Maximum(var1, var2, ...)” on page 321.

Maximum(var1, var2, ...)
Max(var1, var2, ...)

Description
Returns the maximum value of the arguments or of the values within a single matrix or list argument. If multiple arguments are specified, they must be all numeric values or all quoted strings.
Mean(var1, var2, ...)  
**Description**  
Returns the arithmetic mean of the arguments or of the values within a single matrix or list argument.

Median(var1, var2, ...)  
**Description**  
Returns the median of the arguments or of the values within a single matrix or list argument.

Min()  
See “Minimum(var1, var2, ...)” on page 322.

Min(var1, var2, ...)  
**Description**  
Returns the minimum value of the arguments or of the values within a single matrix argument. If multiple arguments are specified, they must be either all numeric values or all quoted strings.

N Missing(expression)  
**Description**  
Rowwise number of missing values in variables specified.

Number(var1, var2, ...)  
**Description**  
Rowwise number of nonmissing values in variables specified.

Product(i=initialValue, limitValue, bodyExpr)  
**Description**  
Multiplies the results of bodyExpr over all i until the limitValue and returns a single product.
Quantile(p, arguments)

Description
Returns the p\textsuperscript{th} quantile of the arguments. The first argument can be a scalar or a matrix of values between 0 and 1. The remaining arguments can also be specified as values within a single matrix or list argument.

Range(var1, var2, ...)

Description
Returns the minimum and maximum values of the arguments. The result is returned as a two-element row vector that contains the minimum and the maximum.

Robust PCA(X, <Lambda(2/sqrt(max(nrow, ncol)))>, <tolerance=1e-10>, <maxit(75)>, <Center(1)>, <Scale(1)>)

Description
Performs a sequence of singular value decompositions and thresholding steps to decompose the data matrix into a low-rank matrix and a sparse matrix of residuals.

Returns
A The low-rank matrix estimation.
E The sparse matrix of residuals.
S A vector of singular values.

Arguments
X A data matrix.
Lambda Specifies a value greater than 0 that determines the sparsity of the matrix of residuals. For larger values of Lambda, the matrix of residuals is more sparse.
tolerance The convergence criterion.
maxit The maximum number of SVD iterations.
Center Centers the data prior to performing the SVD iterations.
Scale Scales the data prior to performing the SVD iterations.

Std Dev(var1, var2, ...)

Description
Rowwise standard deviation of the variables specified.

Sum(var1, var2, ...)

Description
Rowwise sum of the variables specified. Calculating all missing values (Sum(., .)) returns missing.
SSQ(x1, ...)  

**Description**  
Returns the sum of squares of all elements. Takes numbers, matrices, or lists as arguments and returns a scalar number. Skips missing values.

Summarize(<dt>, <by>, <count>, <sum>, <mean>, <min>, <max>, <stddev>, <corr>, <quantile>, <first>)  

**Description**  
Gathers summary statistics for a data table and stores them in global variables.  

**Returns**  
None.  

**Arguments**  
- `dt` Optional positional argument: a reference to a data table. If this argument is not in the form of an assignment, then it is considered a data table expression.  
- All other arguments are optional and can be included in any order. Typically, each argument is assigned to a variable so you can display or manipulate the values further.  
- `name=By(col | list | Eval)` Using a BY variable changes the output from single values for each statistic to a list of values for each group in the BY variable.

Summarize YByX(X(<x columns>, Y (<y columns>), Group(<grouping columns>), Freq(<freq column>), Weight(<weight column>))  

**Description**  
Calculates all Fit Y by X combinations on large-scale data sets.  

**Returns**  
A data table of $p$-values and LogWorth values for each Y and X combination.  

**Arguments**  
- `X(co1)` The factor columns used in the fit model.  
- `Y(co1)` The response columns used in the fit model.  
- `Group(gco1)` The group of columns used in the fit model.  
- `Freq(co1)` The frequency (for each row) column used in the fit model.  
- `Weight(co1)` The importance (or influence) column used in the fit model.  

**Notes**  
Performs the same function as the Response Screening platform.

Summation(init, limitvalue, body)  

**Description**  
Summation sums the results of the `body` statement(s) over all $i$ to return a single value.
Tolerance Limit(1-\(\alpha\), p, n)

**Description**
Constructs a \(1-\alpha\) confidence interval to contain proportion \(p\) of the means with sample size \(n\).

Transcendental Functions

**Arrhenius(n)**

**Description**
Converts the temperature \(n\) to the value of explanatory variable in Arrhenius model.

**Returns**
\[
\frac{11604.5181215503}{n+273.15}
\]

**Argument**
\(n\) Temperature in Celsius.

**Notes**
This is frequently used as a transformation.

**Arrhenius Inv(n)**

**Description**
The inverse of the Arrhenius function. Converts the value \(n\) to the temperature in Celsius.

**Returns**
\[
(11604.5181215503/n) - 273.15
\]

**Argument**
\(n\) The value of the converted explanatory variable in Arrhenius model.

**Notes**
This is frequently used as a transformation.

**Beta(a, b)**

**Description**
\[
\frac{\Gamma(a) \Gamma(b)}{\Gamma(a + b)}
\]

**Returns**
Returns the beta function.
Arguments
  a, b numbers

Cytometry Logicle(x, T, W, M, A)

Description
  Computes a cytometry logicle transformation.

See Also
  Update for the logicle data scale including operational code implementations (Moore & Parks, 2012)

Cytometry Logicle Inverse(y, T, W, M, A)

Description
  Computes the inverse cytometry logicle transformation.

See Also
  Update for the logicle data scale including operational code implementations (Moore & Parks, 2012)

Digamma(n)

Description
  The derivative of the log of the gamma function (LGamma).

Returns
  The digamma function evaluated at n.

Argument
  n  A number

Exp(a)

Description
  Raises e to the power a.

Returns
  \(e^a\).

Argument
  a  A number

Equivalent Expression
  \(e()^{\wedge}a\)
ExpM1(x)

**Description**

Returns a more accurate calculation of $\exp(x)-1$ when $x$ is very small.

Factorial(n)

**Description**

Multiplies all numbers 1 through $n$, inclusive

**Returns**

The product.

**Arguments**

$n$ Any integer

**Notes**

One and only one argument must be specified.

FFT({list}, <named arguments>)

**Description**

Conducts a Fast Fourier Transformation (FFT) on a list of matrices.

**Returns**

The function takes one matrix, or a list of matrices for complex numbers. The returned value is a list of two matrices with the same dimensions as the first argument.

**Argument**

List A list of one or two matrices. If one is provided, it is considered to be the real part. If two are provided, the first is the real part and the second is the imaginary part. Both matrices must have the same dimensions, and both must have more than one row.

**Optional Named Arguments**

- <<inverse(Boolean) If true (1), an inverse FFT is conducted.
- <<multivariate(Boolean) If true (1), a multivariate FFT is conducted. If false(0), a spatial FFT is conducted.
- <<scale(number) Multiplies the return values by the specified number.

Fit Transform To Normal(Distribution("name"), Y(vector), <Freq(vector))

**Description**

Fits a transformation to normality for a vector of data. This includes the Johnson Sl, Johnson Sb, Johnson Su, and GLog distributions.

**Returns**

A list that contains parameter estimates, the covariance matrix, the log-likelihood, AICc, a convergence message, and the transformed values. See Fitting Linear Models.
Gamma(t, <limit>)

**Description**

The gamma function of \( x \), or for each row if \( x \) is a column:

\[
\Gamma(t) = \int_0^\infty x^{t-1} e^{-x} \, dx
\]

**Returns**

The gamma.

**Arguments**

- \( t \) a number or a column
- \( \text{limit} \) optional limit. The default is infinity.

**Notes**

\( \text{Gamma}(t, \text{limit}) \) is the same integral as \( \text{Gamma}(t) \) but with the limit of integration that is defined instead of infinity.

LGamma(t)

**Description**

Returns the log gamma function for \( t \), which is the natural log of gamma.

Ln(n)

**Description**

Returns the natural logarithm (base \( e \) logarithm) of \( n \).

Log(n, <base>)

**Description**

Returns the natural logarithm (base \( e \) logarithm) of \( n \). An optional second argument lets you specify a different base. For example, \( \text{Log}(n, 3) \) for the base 3 logarithm of \( n \). The Log argument can be any numeric expression. The expression \( \text{Log}(\text{e}()) \) evaluates as 1, and \( \text{Log}(32, 2) \) is 5.

Log10(n)

**Description**

Returns the common (base 10) logarithm of \( n \).

Log1P(n)

**Description**

Same as \( \text{Log}(1 + x) \), except that it is more accurate when \( x \) is very small.
Logist(x)

**Description**
Returns 1/(1+Exp(-x)), which converts a number in the domain $-\infty\ldots+\infty$ into range 0...1. The function is useful in logistic regression.

Logist Percent(p)

**Description**
Similar to the Logist() function but with the result scaled from 0 to 100.

Logit(p)

**Description**
Returns $\log(p/(1-p))$.

Logit Percent(p)

**Description**
Similar to the Logit() function with the argument 0 to 100 rather than 0 to 1.

N Choose K(n, k)

**Description**
This function returns the number of $n$ things taken $k$ at a time (“$n$ choose $k$”) and is computed in the standard way using factorials, as $n!/(k!(n-k)!)$ . For example, NChooseK(5,2) evaluates as 10.

**Notes**
This is implemented internally in JMP using lGamma functions. The result is not always an integer.

Power(a, <b>)

**a^b**

**Description**
Raises $a$ to the power of $b$.

**Returns**
The product of $a$ multiplied by itself $b$ times.

**Arguments**
a  Can be a variable, number, or matrix.
b  (Optional) Can be a variable or a number.
Notes
For Power(), the second argument (b) is optional, and the default value is 2. Power(a) returns a^2.

Root(n, <r>)

Description
Returns the rth root of n, where r defaults to 2 for square root.

SbInv(z, gamma, delta, theta, sigma)

Description
Returns a transformation of a standard normal variable to a double bounded Johnson variable.

SbTrans(x, gamma, delta, theta, sigma)

Description
Returns a transformation of a double bounded Johnson variable to a standard normal variable.

Scheffe Cubic(x1, x2)

Description
Returns x1*x2*(x1-x2). This function supports notation for cubic mixture models.

SHASHInv(z, gamma, delta, theta, sigma)

Description
Returns a transformation of a standard normal variable to a sinh-arcsinh (SHASH) variable. The transformation is calculated as σ*sinh((arcsinh(z)-γ)/δ)+0.

SHASHTrans(x, gamma, delta, theta, sigma)

Description
Returns a transformation of a sinh-arcsinh (SHASH) variable to a standard normal variable. The transformation is calculated as sinh(γ+δ*arcsinh((x-θ)/σ)).

SlInv(z, gamma, delta, theta, sigma)

Description
Returns a transformation of a standard normal variable to a Johnson Sl variable.
SlTrans(x, gamma, delta, theta, sigma)

Description
Returns a transformation of a Johnson Sl variable to a standard normal variable.

Sqrt(n)

Description
Returns the square root of n.

Squash(expr)

Description
An efficient computation of the function 1/[1 + exp(expr)].

Squish(expr)

Description
Equivalent to Squash(-expr), or 1/(1 + e^{-expr}.

SuInv(z, gamma, delta, theta, sigma)

Description
Returns a transformation of a standard normal variable to an unbounded Johnson variable.

SuTrans(x, gamma, delta, theta, sigma)

Description
Returns a transformation of an unbounded Johnson variable to a standard normal variable.

Trigamma()

Description
Returns the trigamma function evaluated at n. The trigamma function is the derivative of the digamma function.

Trigonometric Functions

JMP’s trigonometric functions expect all angle arguments in radians.
ArcCosH(x)

Description
Inverse hyperbolic cosine.

Returns
The inverse hyperbolic cosine of \( x \).

Argument
\( x \) Any number, numeric variable, or numeric expression.

ArcCosine(x)
ArCos(x)

Description
Inverse cosine.

Returns
The inverse cosine of \( x \), an angle in radians.

Argument
\( x \) Any number, numeric variable, or numeric expression.

ArcSine(x)
ArSin(x)

Description
Inverse sine.

Returns
The inverse sine of \( x \), an angle in radians.

Argument
\( x \) Any number, numeric variable, or numeric expression.

ArcSinH(x)

Description
Inverse hyperbolic sine.

Returns
The inverse hyperbolic sine of \( x \).

Argument
\( x \) Any number, numeric variable, or numeric expression.
ArcTangent(x1, <x2=1>)
ArcTan(x1 <x2=1>)
ATan(x1 <x2=1>)

Description
Inverse tangent.

Returns
The inverse trigonometric tangent of \(x_1/x_2\), where the result is in the range \(-\pi/2, \pi/2\).

Argument
- \(x_1\) Any number, numeric variable, or numeric expression.
- \(x_2=1\) Specifies \(atan2\).

ArcTanH(x)

Description
Inverse hyperbolic tangent.

Returns
The inverse hyperbolic tangent of \(x\).

Argument
- \(x\) Any number, numeric variable, or numeric expression.

CosH(x)

Description
Hyperbolic cosine.

Returns
The hyperbolic cosine of \(x\).

Argument
- \(x\) Any number, numeric variable, or numeric expression.

Cosine(x)

Description
Cosine.

Returns
The cosine of \(x\).

Argument
- \(x\) Any number, numeric variable, or numeric expression. The angle in radians.
Sine(expr)
Sin(expr)

**Description**
Returns the sine.

SinH(expr)

**Description**
Returns the hyperbolic sine.

Tangent(expr)
Tan(expr)

**Description**
Returns the tangent of an argument given in radians.

TanH(expr)

**Description**
Returns the hyperbolic tangent of its argument.

---

**Utility Functions**

Add(a, b, ...)
a+b+...

**Description**
Adds the values of the listed arguments. No arguments are changed.

**Returns**
The sum.

**Arguments**
For Add(), a comma-separated list of variables, numbers, or matrices.
For a+b, any number of variables, numbers, or matrices.

**Notes**
- Any number of arguments is permitted. If no argument is specified, Add() returns 0.
- Add() returns missing if any arguments are missing. To ignore missing values, use Sum().
See Also

- the *Scripting Guide*
- See “Sum(var1, var2, ...)” on page 323

Beep()

**Description**

Produces an alert sound.

**Returns**

Null.

BLOB MD5(blob)

**Description**

Converts the *blob* argument into a 16-byte blob.

**Notes**

The 16-byte blob is the MD5 checksum, or the hash, of the source blob.

BLOB Peek(blob, offset, length)

**Description**

Creates a new blob from a subrange of bytes of the *blob* argument.

**Returns**

A blob object.

**Arguments**

- *blob* a binary large object.
- *offset* An integer that specifies how many bytes into the blob to begin construction. The first byte is at offset 0, the second byte at offset 1.
- *length* An integer that specifies how many bytes to copy into the new blob, starting at the offset.

Build Information()

**Description**

Returns the build date and time, whether it’s a release or debug build, and the product name in a quoted comma-delimited string.
Caption(\{h, v\}, "text", <Delayed(seconds)>, <Font(font)>, <FontSize(size)>, <TextColor("color")>, <BackColor("color")>, <Spoken(Boolean)>

**Description**

Displays a caption window at the location described by \{h, v\} that displays text. The caption can be delayed before being displayed by seconds, or can be spoken. You can also specify the font type, size, and color and background color.

**Returns**

Null.

**Arguments**

- \{h, v\} a list with two values. h is the horizontal displacement from the top left corner of the monitor in pixels. v is the vertical displacement from the top left corner in pixels.
- text A quoted string or a reference to a string that is to be displayed in the caption.
- Delayed(seconds) seconds is optional delay before displaying the caption. Setting this option causes this caption and all subsequent captions to be delayed by the specified number of seconds.
- Font(font) Specify the font type.
- Font Size(size) Specify the font size.
- Text Color("color") Specify the color of text.
- Back Color("color") Specify the background color.
- Spoken(Boolean) Causes text to be spoken as well as displayed. The current setting (on or off) remains in effect until switched by another Caption statement that includes a Spoken setting.

---

Datafeed()

See “Open Datafeed()” on page 350.

---

Debug Break()

When the JSL Debugger is open, this function stops a JSL script from executing at that point in the script. This function is useful for tracking in the debugger under user-specified conditions. If the JSL Debugger is not running, this function does not execute.

---

Decode64 BLOB(string)

**Description**

Decodes a printable quoted string of base 64 text into a blob.

**Returns**

A blob.
Arguments

string  A quoted base-64 encoded string.

Example

Decode64 BLOB( "dGhlIHF1aWNRIGyb3duIGZveA==" );
Char To BLOB( "the quick brown fox", "ascii~hex" )

Decode64 Double(string)

Description

Creates a floating point number from a quoted base-64 encoded string.

Returns

A floating point number.

Arguments

string  A quoted base-64 encoded string.

Disable JMP Live URL(url)

Description

Specifies the URLs that users cannot publish to. This preference must be added to jmpStartAdmin.jsl.

See the Common Tasks chapter in the Scripting Guide for details about the location of jmpStartAdmin.jsl.

If a URL appears in both the Disable JMP Server() and Enable JMP Server() lists, publishing to the URL is disabled.

Example

Disable JMP Live URL( "https://public.jmp.com" )

Divide(a, b)
Divide(x)

a/b

Description

Divides a by b. If only one argument is given (divide(x)), divides 1 by x.

Returns

The quotient of a/b; or the reciprocal of x (1/x) if only one argument is provided.

Arguments

a, b, x  Can be a variable, number, or matrix.

Notes

If both arguments are matrices, it does matrix division.
Empty()

Description
Does nothing. Used in the formula editor for making empty boxes.

Returns
Missing.

Arguments
None.

Enable JMP Live URL(url)

Description
Specifies the URLs that users can publish to. This preference must be added to jmpStartAdmin.jsl.

See the Common Tasks chapter in the Scripting Guide for details about the location of jmpStartAdmin.jsl.

If a URL appears in both the Enable JMP Server() and Disable JMP Server() lists, publishing to the URL is disabled.

Example
Enable JMP Live URL( "https://public.jmp.com" )

Encode64 BLOB(x)

Description
Encodes a blob into a printable quoted string of base 64 text.

Returns
A quoted base-64 encoded string.

Example
Encode64 BLOB( Char To BLOB( "the quick brown fox" ) );
"dGhlIHF1aWNrIGJyb3duIGZveA=="

Encode64 Double(n)

Description
Creates a quoted base-64 encoded string from a floating point number.

Returns
A quoted base-64 encoded string.

Arguments
n A floating point number.
Faure Quasi Random Sequence(nDim, nRow)

**Description**
Generates a sequence of spacefilling quasi random numbers using the Faure sequence.

**Get Addin("id")**

**Description**
Retrieves a registered add-in by *id*.

**Returns**
A scriptable object for the add-in. Returns empty if no add-in with the specified ID was found.

**Argument**
"id" The ID of an installed add-in.

**Get Addins()**

**Returns**
A list of all registered add-ins.

**Get Addr Info("address", <port>)**

**Description**
Converts a name to its numeric address.

**Returns**
A list of quoted strings. The first element is the command (Get Addr Info). The second is the results (for example, “ok” if the command was successful). The third is a list of strings of information. Included in that information is the address that corresponds to the name that was supplied.

**Arguments**
address A quoted string that specifies the name (for example, "www.sas.com").
port The port of the address.

**Get Clipboard()**

**Description**
Returns text from the computer’s clipboard. If the content is not text, the result is null.

**Example**

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Copy Table Script( "Distribution" );
s = Get Clipboard();
nw = New Window( "Script", Script Box( s ) );
```
Get Name Info("address", <port>)

Description
Converts a numeric address to its name.

Returns
A list of quoted strings. The first element is the command (GetNameInfo). The second is the results (for example, “ok” if the command was successful). The third is a list of strings of information. Included in that information is the port name that corresponds to the address that was supplied.

Arguments
address A quoted string that specifies the numeric address (for example, "149.173.5.120").
port The port of the address.

Get Platform Preferences(<platform <(option, ...) > ... >)
Get Platform Preference(<platform <(option, ...) > ... >)

Description
Returns the preferences for the specified platforms.

Returns
A list of platform preferences.

Argument
platform (Optional) Specifies the platform name. If not specified, all platform preferences are returned. You can specify one or more preferences for a platform.
option (Optional) Specifies the preference value. If not specified, all platform preference values are returned.

Notes
Table 2.3 describes the syntax for getting platform preferences.

Table 2.3 Get Platform Preferences() Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get Platform Preferences( )</td>
<td>Returns the current option values for all platform preferences.</td>
</tr>
<tr>
<td>Get Platform Preferences( Platform )</td>
<td>Returns the current option values for the specified platform preferences.</td>
</tr>
</tbody>
</table>
### Table 2.3 Get Platform Preferences() Syntax (Continued)

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get Platform Preferences( Platform( Option ) )</td>
<td>Returns the current option values for the specified platform.</td>
</tr>
<tr>
<td>Get Platform Preferences( &lt;&lt;Changed )</td>
<td>Returns the current option values that have changed for all platforms.</td>
</tr>
<tr>
<td>Get Platform Preferences( Platform( &lt;&lt;Changed ) )</td>
<td>Returns the current option values that have changed for all platform preferences.</td>
</tr>
<tr>
<td>Get Platform Preferences( Platform( Option ( &lt;&lt;Changed ) ) )</td>
<td>Returns the current option values that have changed for the specified platform.</td>
</tr>
</tbody>
</table>

### Examples

Suppose that the user modified several platform preferences through the JMP Platforms window or a script.

```julia
Platform Preferences(
   Distribution( Set Bin Width( 2 ), Horizontal Layout( 1 ) ),
   Model Dialog( Keep Dialog Open( 1 ) ),
   Graph Builder( Legend Position( "Bottom" ) )
);
```

To return all of the modified platform preferences, use `Get Platform Preferences( <<Changed )`:

```julia
Get Platform Preferences( <<Changed );
```

```julia
Get Platform Preferences( <<ChangedEventArgs );
   Platform Preferences(
      Distribution( Horizontal Layout( 1 ), Set Bin Width( 2, <<On ) ),
      Graph Builder( Legend Position( "Bottom", <<On ) ),
      Model Dialog( Keep dialog open( 1 ) )
   );
```

**Get Preferences(<preference_name>)**

**Get Preference(<preference_name>)**

### Description

Returns the settings for the specified preferences.

### Returns

A list of preference settings.
Argument
preference_name (Optional) If no preference is specified, all preferences are returned. Otherwise, the settings for the specified preference are returned.

Notes
The preferences for the following areas are not accessible in JSL: Text Data Files, Windows Specific, Mac OS Settings, Fonts, Communications, Script Editor, and JMP Updates. For more information about getting platform preferences, see “Get Platform Preferences(<platform <(option, ...) ... >)” on page 340.

Glue(expr1, expr2, ...)
expr1; expr2

Description
Evaluates each argument in turn.

Returns
The result of the last argument evaluated.

Arguments
One or more valid JSL expressions.

Notes
A semicolon placed between expressions is the more commonly used form for Glue().

Gzip Compress(blob)

Description
Compresses a blog of data into a gzip blob.

Example
Gzip Compress(
Char To BLOB(
   "random data does not usually compress well and may get larger"
)
);
Char To BLOB(
   "~1F~8B~08~00~00~00~00~00~00~00~00~0A~0D~CA~C1~0D~00~21~08~04~C0V~B6~B5~CDA~FC~80~5C~00c~EC^~E7~C9)~E1~106~21~A1~85~19~8DU~8Bf~07_~F8~9FZ~85~ADfx~13~CE~83~A1~0Dc~0E~CD~0B~94~16~1E~00~00~00",
   "ascii~hex"

Gzip Uncompress(blob)

Description
Uncompresses a blob of gzip data into a blob.
**Example**

```javascript
Gzip Uncompress(/*typically this data might come from Gzip Compress() but might also come from a.gz file using Load Text File() with the blob option*/
Char To BLOB(
    "~1F~8B~08~00~00~00~00~00~00~00~00~0D~CA~C1~0D~00~21~08~04~C0V~B6~B5~CDA~FA~C8~0~5C~00c~EC~E7~C9~E1~106~21~A1~85~19~8D~8B~07~F8~9F~85~ADfx~13~CE~83~A1~0Dc~0E~CD~0B~94~16~1E~00~00~00",
    "ascii~hex"
);
Char To BLOB(
    "random data does not usually compress well and may get larger",
    "ascii~hex"
);
```

---

**Host Is("argument")**

**Description**

Determines whether the host environment is the specified OS.

**Returns**

True (1) if the current host environment matches the argument, false (0) otherwise.

**Argument**

Argument Windows" or "Mac" tests for the specified operating system.

---

**Is Alt Key()**

**Description**

Returns 1 if the Alt key is being pressed, or 0 otherwise.

**Notes**

On a macOS, Is Alt Key() tests for the Option key.

---

**Is Command Key()**

**Description**

Returns 1 if the Command key is being pressed, or 0 otherwise.

---

**Is Context Key()**

**Description**

Returns 1 if the Context key is being pressed, or 0 otherwise.
Is Control Key()

Description
Returns 1 if the Control key is being pressed, or 0 otherwise.

Notes
On a macOS, Is Control Key() tests for the Command key.

Is Option Key()

Description
Returns 1 if the Option key is being pressed, or 0 otherwise.

Is Shift Key()

Description
Returns 1 if the Shift key is being pressed, or 0 otherwise.

JMP Product Name()

Description
Returns either "Standard", "Pro", or "Student", depending on which version of JMP is licensed.

JMP Version()

Description
Returns the version number of JMP that you are running.

Returns
release.revision<.fix>

Arguments
none

Load DLL("path" <,AutoDeclare(Boolean | Quiet | Verbose)>)

Load DLL("path" <, Quiet | Verbose>)

Description
 Loads the DLL in the specified path.

Arguments
path A pathname that specifies where to load the DLL.
AutoDeclare(Boolean | Quiet | Verbose) Optional argument. AutoDeclare(1) and AutoDeclare(Verbose) write verbose messages to the log. AutoDeclare(Quiet)
turns off log window messages. If you omit this option, verbose messages are written to the log.

Quiet | Verbose Optional argument. When you use Declare Function(), this option turns off log window messaging (Quiet) or turns on log window messaging (Verbose).

See Also

Once a DLL is loaded, you send the DLL object messages to interact with it. See “Dynamic Link Libraries (DLLs)” on page 457 in the “JSL Messages” chapter for more information about these messages.

Mail("address"|"addresses", "subject", "message", <"attachment filepath" | {"attachment 1 filepath", "attachment 2 filepath", ...}>)

Description

(Windows) Sends e-mail (using MAPI) to the address with the specified subject and message texts. Sends one or more attachments specified by the optional attachment argument. The attachment argument can evaluate to a quoted string or list of strings.

(macOS) Creates an e-mail in the user’s Mail application. The user must click Send in the e-mail. In Microsoft Outlook, you must manually add attachments to the e-mail.

Examples

To send an email with multiple attachments on Windows:

```javascript
Mail(
    "yourname@company.com",
    "New data and script",
    "Today's updated data table and script are attached.",
    {"$DOCUMENTS/wd.jsl", "$DOCUMENTS/survey.jmp"}
);
```

or:

```javascript
list = {"$DOCUMENTS/wd.jsl", "$DOCUMENTS/survey.jmp"};
Mail(
    "yourname@company.com",
    "New data and script",
    "Today's updated data table and script are attached.",
    list
);
```

To send an email to multiple recipients:

```javascript
Mail(
    {"hername@company.com", "hisname@company.com"},
    "Database updates",
    "Today's sales database contains the numbers from last month."
);
```
Notes

On macOS, `Mail()` works on Yosemite and later operating systems.

---

**Main Menu**(string, <string>)

**Description**

Execute the command found on JMP’s menu named by the quoted string.

**Arguments**

- **string** The internal path name as shown in the menu editor for items. For example, “NEW” is the internal name for the New subcommand in the File menu.
- **string** (Optional) The name of the window to send the command to.

**Examples**

Main Menu() accepts either a full path or a partial path. If a partial name is used, and there are other menu items with the same name, the first menu item found is executed. JMP searches the top-level menu (File, Tables, DOE, and so on) first for the partial name and then searches inside each of those menus in order.

Main Menu( "File:New:Data Table" ); // full path
Main Menu( "Data Table" ); // partial path

---

**Minus**(a)

- a

**Description**

Reverses the sign of a.

**Returns**

- a if a is positive (a=3; -a=-3; Minus(a)=-3).
- a if a is negative (a=-3; -a=3; Minus(a)=3).
- 0 if a is 0 (a=0; -a=0; Minus(a)=0).
- Missing if a is missing.

**Argument**

- a Can be variable or a number. A variable must contain a number or a matrix.

---

**Multiple File Import**(arguments)

**Description**

Imports one or more files into a data table. You can create this JSL by selecting Save Script to Script Window from the Multiple File Import window.

**Returns**

Creates a Multiple File Import Object. The object accepts messages to set a folder, filter files, and specify import options.
Arguments

<<Set Folder  Specifies the folder that contains the files you want to import.

<<Set Name Filter  (Optional) Specifies the file name or extension of the files. The name filter uses * to represent zero-or-more characters and ? to represent exactly one character. * and ? also match a period. The default setting is *.*, or all files. Because you can specify files using a semicolon-delimited list of filters, file names that include semicolons or | must be specified using ? or *.

<<Set Name Enable(Boolean)  Enables the name filter. The setting is off by default.

<<Set Size Filter  (Optional) Filters the file list by file size. Specify the sizes by kB (kilobytes, or 1000 bytes) in a list. The default values are based on the size range of the files in the file list.

<<Set Size Enable(Boolean)  (Optional) Enables the size filter. The default setting is off.

<<Set Date Filter  (Optional) Filters the file list by date and time. Specify the date and time in a list in seconds. The default values are based on the date and time range of the files in the file list.

<<Set Date Enable(Boolean)  (Optional) Enables the date filter. The default setting is off.

<<Set Add File Name Column(Boolean)  (Optional) Includes a column that contains the imported file name. The default setting is off.

<<Set Add File Size Column(Boolean)  (Optional) Includes a column that contains the size of the imported file. The default setting is off.

<<Set Add File Date(Boolean)  (Optional) Includes a column that contains the time and date stamp of the imported file. The default setting is off.

<<Set Import Mode(Row Per File|Row Per Line|CSV Data)  (Optional) Specifies the format of the file that is imported: whole file on one row, one line on one row, and CSV. CSV Data is the default setting.

<<Set Charset(Best Guess|utf-8|utf-16|us-ascii|windows-1252|x-mac-roman|x-mac-japanese|shift-jis|euc-jp|utf-16be|gb2312)  (Optional) The character set in the imported file. The character set specified in the General preferences (Open Text File Charset) is set by default.

<<Set Stack Mode(Stack Similar|TablePerFile)  (Optional) Specifies how the files are combined. Stack Similar is the default setting. (When JMP detects that the files have the same columns, the files are concatenated into a single data table.)

<<Set CSV Has Headers(Boolean)  (Optional) Specifies whether the CSV file contains a header row. The setting is on by default.

<<Set CSV Allow Numeric(Boolean)  (Optional) Sets the data type to numeric. The setting is on by default.

<<Set CSV First Header Line(n)  (Optional) Specifies the header row number. 1 is the default setting.
<<Set CSV Number of Header Lines(n) (Optional) Specifies the number of header rows. 1 is the default setting.
<<Set CSV First Data Line(n) (Optional) Specifies the first line that contains data. 2 is the default setting.
<<Set CSV EOF Comma(Boolean) (Optional) Specifies a comma delimiter. The setting is on by default.
<<Set CSV EOF Tab(Boolean) (Optional) Specifies a tab delimiter.
<<Set CSV EOF Space(Boolean) (Optional) Specifies a space delimiter.
<<Set CSV EOF Spaces(Boolean) (Optional) Specifies spaces as the delimiter.
<<Set CSV EOF Other("") (Optional) Specifies a custom delimiter.
<<Set CSV EOF CRLF(Boolean) (Optional) Specifies carriage return and line feed end-of-line characters. The setting is on by default.
<<Set CSV EOF CR(Boolean) (Optional) Specifies a carriage return end-of-line character. The setting is on by default.
<<Set CSV EOF LF(Boolean) (Optional) Specifies a line feed end-of-line character.
<<Set CSV Semicolon(Boolean) (Optional) Specifies a semicolon end-of-line character. The setting is off by default.
<<Set CSV EOL Other("") (Optional) Specifies a custom end-of-line character.
<<Set CSV Quote("") (Optional) Specifies the character used as a quote. The default setting is ", a double quotation mark.
<<Set CSV Escape("") (Optional) Specifies the escape sequence such as a backlash instead of doubling the quotation mark.

Import Data Imports the data.

Example

```
mfi = Multiple File Import(
    <<Set Folder( "$SAMPLE_IMPORT_DATA" ),
    <<Set Name Filter( "UN*.csv" ), // import files with this name
    <<Set Name Enable( 1 ) // display the file name in a column
)
<<Import Data();
```

Multiply(a, b, ...)

a*b*...

Description

Multiplies all values. No arguments are changed.

Returns

The product.

Arguments

Any number of variables, numbers, or matrices.
Notes

Any number of arguments is permitted. If no argument is specified, Multiply() returns 1.

Name(string)

Description

A name is something to call an item.

- If the name begins with an alphabetic character or underscore, and continues with alphanumeric characters, whitespace, Unicode mathematical symbols and certain punctuation (apostrophes, percentage signs, periods, backslashes, and underscores, then you can use the name directly in scripts.
- You can use names that do not follow these rules with the Name() keyword.

Examples

( "name"n) is preferred. Name( string ) is deprecated.
"my-var-name"n = "hello";
Length( "my-var-name"n )
5

New OAuth2 Token(user(yourgoogleaccount@gmail.com), client ID(string),
client secret(string), refresh token(string), token URL(string))

Description

Creates an OAuth2 token for securely accessing data across different web APIs.

Arguments (Required)

user The user name, email, or personal identifier for the account being accessed.
client ID The public identifier that acts as an API key.
client secret The private identifier that corresponds to Client ID.
refresh token A token used to get access tokens.
token URL The URL that access tokens are received from. Unique to every service and accessible through their API or OAuth page.

Arguments (Authorization Code Grant)

redirect URL( "https://app.getpostman.com/oauth2/callback" ) The URL that an access code is sent back to. Unless your company or the service provides one, we recommended that you create a free Postman account and use this redirect.
client secret( "1aB893cdDeFf2D" ) The private identifier that corresponds to Client ID.
request auth( ... ) Extra parameters indicating that you’ll use an Authorization Code flow. Requires Auth URL(). Some services require scope. You can add custom fields with Fields.
scope( "spreadsheets email docs" ) A space-separated list of scopes. Unique to every service, and accessible through their API or OAuth page. Only usable in Request Auth().

auth URL( "https://www.example.com/oauth2/v1/authorize" ) The URL for requesting authorization. Unique to every service, and accessible through their API or OAuth page. Only usable in Request Auth().

**Arguments (Implicit Grant)**

redirect URL( "https://app.getpostman.com/oauth2/callback" ) The URL that an access code is sent back to. Unless your company or the service provides one, it’s recommended to create a free Postman account and use this redirect.

**Arguments (Resource Owner)**

password( "wordpass123" ) The password that corresponds to the username.

client secret( "1aB893cdDeFf2D" ) The private identifier that corresponds to Client ID.

**Arguments (Custom Data)**

fields( fields ) Custom fields that are equivalent to HTTP Request’s Form( fields ). Can be specified both in New OAuth2 Token() and in Request Auth(). Only necessary if the service requires information that is not defined in the OAuth 2.0 standard.

headers( headers ) Custom headers that are equivalent to HTTP Request’s Headers( headers ). Can only be specified in New OAuth2 Token(). Only necessary if the service requires information not defined in the OAuth 2.0 standard.

**Example**

token = New OAuth 2 Token (  
  User( "yourgoogleaccount@gmail.com" ),  
  Refresh Token( "1a2b3c4e5F" ),  
  Token URL( "https://www.example.com/oauth2/token" ),  
  Client ID( "12ab" ),  
  Client Secret( "3456dEfG" )  
);

**See Also**

See your API documentation for more information about how to get values such as the client secret and token URL.

---

Open Datafeed()

Datafeed()

**Description**

Creates a Datafeed object and window.

**Returns**

A reference to the Datafeed object.
Arguments
No arguments are required. You usually set up the basic operation of the data feed within the `Open Datafeed()` command, however.

Open Help("Help"|"Statistics Index"|"Scripting Index", ...)

Description
Opens the specified help window.

Parse XML(`string`, On Element("tagname", Start Tag(expr), End Tag(expr), Text))

Description
Parses an XML expression using the On Element expressions for the specified XML tags.

Example
XMLData =
""
  <Book name='Foods'>All you want to know
    <Chapter num='1'>Fruit
      <kind>Apple</kind>
      <kind>Cherry</kind>
      <ps>I love dessert!</ps>
    </Chapter>
    <Chapter num='2'>Bread
      <kind>Wheat</kind>
      <kind>Corn</kind>
      <ps>I love sandwiches!</ps>
    </Chapter>
    <Chapter num='3'>Veggy
      <kind>Squash</kind>
      <kind>Cabbage</kind>
      <ps>I love anything else!</ps>
    </Chapter>
  </Book>
and more.

// variables are initialized so text can be concatenated
title = "";
subtitle = "";
chap = "";
chapnum = "";
ps = "";
Parse XML( XMLData,
On Element( "Book",
    // capture the name attribute during the start of the Book
    Start Tag( title = XML Attr( "name" ) ),
    /* this book has split the subtitle and needs to join the text;
       the joined text will be used by endTag.
       Text(...) supplies the JSL.*/
    Text( subtitle = subtitle || " -- " || Trim( XML Text() ) ),
    /* after endTag processes the variables, set them back
       to their initial state, just in case there is a second book
       to process in the same XML. */
    endTag( Write( "!n", title, " ", subtitle ); title = ""; subtitle
    = ""; )
    ),
On Element( "Chapter",
    // capture the chapter number during the start of the Chapter
    Start Tag( chapnum = XML Attr( "num" ) ),
    /* the chapter text is joined together, newlines
       and extra space is trimmed, and a single space is used to
       separate the separated texts. The <kind> tag is ignored by
       this ParseXML specification. The <kind> text is processed
       by this Text(...) because it wasn't consumed by any other
       On Element. */
    Text( chap = chap || Trim( XML Text() ) || " ",
    /* after endTag processes the variables, set them back to
       their initial state, because there is another chapter
       that needs to start with a clean slate. */
    endTag( Write( "!n", chapnum, " ", chap, " ps: ", ps ); chapnum = "";
    chap = ""; ps = ""; )
    ),
On Element( "ps", End Tag( ps = XML Text() ) )
);

1 Fruit Apple Cherry ps: I love dessert!
2 Bread Wheat Corn ps: I love sandwiches!
3 Veggy Squash Cabbage ps: I love anything else!
Foods -- All you want to know -- and more.

Platform Preferences(platform(option(value)), ...)
Platform Preference(platform(option(value)), ...)
Set Platform Preferences(platform(option(value)), ...)
Set Platform Preference(platform(option(value)), ...)

Description
Sets and resets values for platform options and turns the options on and off.

Arguments
platform Specifies the platform of the preference.
**JSL Syntax Reference Utility Functions**

**option** Specifies the preference name.

**value** Specifies the preference value.

**Notes**

Table 2.4 describes the syntax for setting platform preferences.

**Table 2.4 Platform Preferences() Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Preferences( &lt;&lt;Default )</td>
<td>Resets all platform preferences to their default values.</td>
</tr>
<tr>
<td>Platform Preferences( &lt;&lt;Factory Default )</td>
<td>Resets the specified platform preferences to their default values.</td>
</tr>
<tr>
<td>Platform Preferences( Default )</td>
<td>Resets the specified platform preference to its default value.</td>
</tr>
<tr>
<td>Platform Preferences( Platform( option( &lt;&lt;Default ) ) )</td>
<td>Resets the specified platform option to its default value.</td>
</tr>
<tr>
<td>Platform Preferences( Platform( option( &lt;&lt;Factory Default ) ) )</td>
<td>Sets the value of the specified platform option and turns it on.</td>
</tr>
<tr>
<td>Platform Preferences( Platform( option( value, &lt;&lt;On ) ) )</td>
<td>Sets the value of the specified platform option and turns it off.</td>
</tr>
<tr>
<td>Platform Preferences( Platform( option( value, &lt;&lt;Off ) ) )</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

The following expression selects (or turns on) Set Bin Width in the Distribution platform preferences and sets the value to 2:

```
Platform Preferences( Distribution( Set Bin Width( 2 ) ) );
```

The following expression changes the Set Bin Width value and turns the option off:

```
Platform Preferences( Distribution( Set Bin Width( 2, <<Off ) ) );
```

The following expression resets the default Set Bin Width value and deselects the preference:

```
Platform Preferences( Distribution( Set Bin Width( <<Default ) ) );
```
Polytope Uniform Random(samples, A, b, L, U, neq, nle, nge, <nwarm=200>, <nstride=25>)

**Description**
Generates random uniform points over a convex polytope.

**Arguments**
- **Samples** The number of random points to be generated.
- **A** The constraint coefficient matrix.
- **B** The right hand side values of constraints.
- **L, U** The lower and upper bounds for the variables.
- **neq** The number of equality constraints.
- **nle** The number of less than or equal inequalities.
- **nge** The number of greater than or equal inequalities.
- **nwarm** (Optional) The number of warm-up repetitions before points are written to the output matrix.
- **nstride** (Optional) The number of repetitions between each point that is written to the output matrix.

**Notes**
The constraints must be listed as equalities first, less than or equal inequalities next, and greater than or equal inequalities last.

Preferences(pref1(value1), ...)
Preference(pref1(value1), ...)
Pref(pref1(value1), ...)
Prefs(pref1(value1), ...)
Set Preferences(pref1(value1), ...)
Set Preference(pref1(value1), ...)

**Description**
Sets preferences for JMP.

**Arguments**
- **Add Files Opened by Scripts to the Recent Files List(Boolean)** Determines whether a file that is opened by a script is added to the Home Window's Recent Files list.
- **Analysis Destination(window)** Specifies where to route new analyses.
- **Annotation Font("font", size, "style")** Font choice for annotations in reports.
- **Axis Font("font", size, "style")** Font choice for axis labels.
- **Axis Title Font("font", size, "style")** Font choice for axis titles.
Background Color( {R, G, B} | <color> ) Sets the background color for windows.
Calculator Boxing(Boolean) Turns on boxing to show hierarchy of expressions.
Conditional Formatting Rules Creates rules for conditionally formatting text in
reports. See “Examples” on page 357.
Data Table Font("font", size, "style") Font choice for data tables.
Data Table Title on Output(Boolean) Titles reports with name of data table.
Date Title on Output(Boolean) Titles reports with current date.
Evaluate OnOpen Scripts("always"|"never"|"prompt") Determines whether an On
Open table script is run after the user opens the data table. By default, the user is
prompted. Their choice is remembered each time they open the data table in the current
JMP session. Scripts that execute other programs are never run.
Excel Has Labels(Boolean) When on, forces JMP to interpret the first row of data as
column headings.
Excel Selection(Boolean) When on, the user is prompted for which non-blank Excel
worksheets should be imported from an Excel workbook.
File Location Settings(<Directory Type>("<path>"<,"initial directory">))
Valid directory types are:
  Data Files Directory Sets the default location for data files.
  Help Files Directory Sets the default location for help files.
  Installation Directory By default, this location is set to the JMP installation folder
  on Windows:
    "C:/Program Files/SAS/JMP/16" or "C:/Program Files/SAS/JMPPro/16"
  License File Path Sets the default location for JMP license file.
  Preferences File Directory Sets the default location for the preferences settings
  file.
  Save As Directory Sets the default location for Save As file operations.
Foreground Color(color) Sets the foreground color for windows.
Formula Font("font", size, "style") Font choice for the formula editor.
Graph Background Color(color) Sets the color for the background area inside the
graph frame.
Graph Marker Size(size) Default size for drawing markers.
Heading Font("font", size, "style") Font choice for table column headings in
reports.
Initial JMP Starter Window(Boolean) Specifies whether the JMP Starter window is
shown at launch.
Initial Splash Window(Boolean) Enables you to show or suppress the initial splash
screen.
Maximum JMP Call Depth(size) Sets the default for the maximum call depth (or stack size) for JMP in which JSL built-in functions, user-defined functions, or `Recurse()` function calls can be made. By default, the maximum call depth is set to 256KB. Each thread that JMP creates has a 2MB stack by default. Increasing the maximum call depth can cause a physical runtime stack overflow, so incrementally increase this preference in small amounts until you find the best value that works for your JSL script.

Marker Font("font", size, "style") Font choice for markers used in plots.

Monospaced Font("font", size, "style") Font choice for monospaced text.

ODBC Suppress Internal Quoting(Boolean) Prevents internal quoting in SQL statements that contain table and variable names with mixed case and spaces.

Outline Connecting Lines(Boolean) Draws lines between titles for same-level outline nodes.

Print Settings(option(value), ...) Changes print options on the Page Setup window:

Margins(<n>, <n>, <n>, <n>) sets the left, top, right, and bottom margins. Margins are in inches.

Margins(<n>) sets all margins to the same value in inches.

Orientation("portrait" | "landscape") changes the page’s print orientation.

Headers(<"char">, <"char">, <"char">) specifies text that appears in the left, middle, and right header.

Headers(<"char">) specifies the only text in the header.

Footers(<"char">, <"char">, <"char">) specifies text that appears in the left, middle, and right footer.

Footers(<"char">) specifies the only text in the footer.

Scale(<n>) decreases or increases the percentage at which the content prints.

Show Explanations(Boolean) Some analyses have optional text that explains the output.

Show Menu Tips(Boolean) Turns menu tips on or off.

Show Status Bar(Boolean) Turns display of the status bar on or off.

Small Font("font", size, "style") Font choice for small text.

Text Font("font", size, "style") Font choice for general text in reports.

Thin Postscript Lines(Boolean) macOS only. Specifies that line widths drawn to a Postscript printer be narrower than otherwise.

Title Font("font", size, "style") Font choice for titles. Arguments are name of font (for example, "Times"), size in points, and style ("bold", "plain", "underline", "italic").
Use Triple-S Labels as Headings(Boolean) When on, this argument forces JMP to interpret label names as column headings. Example: Pref(Name("Use Triple-S Labels as Headings")(0)); turns off the preference.

Examples
The following expressions reset all preferences to their default values.
Preferences("Default");
Preferences("Factory Default");
The following script creates conditions for formatting text in reports.
Preferences(
  Conditional Formatting Rules(
    RuleSet(
      RuleName("Warning"),
      // if the value is not equal to 0, format the text as 80% gray
      NotEqualTo(Value(0), Format(TextAlpha(0.8)))
    )
  )
);

Notes
The preferences for the following areas are not accessible in JSL: Text Data Files, Windows Specific, Mac OS Settings, Fonts, Communications, Script Editor, and JMP Updates.

See Also
"Platform Preferences(platform(option(value), ...)” on page 352

Register Addin("unique_id", "home_folder", <named_arguments>)

Description
Register a JMP Add-In and load the add-in if it registers successfully.

Returns
If successful, returns a scriptable object representing the registered add-in. If unsuccessful, returns Empty.

Arguments
unique_id A quoted string that contains the unique identifier for the add-in. The string can contain up to 64 characters. The string must begin with a letter and contain only letters, numbers, periods, and underscores. Reverse-DNS names are recommended to increase the likelihood of uniqueness.

home_folder A quoted string that contains the filepath for the folder containing the add-in files. The filepath must conform to the valid pathname requirement for the host operating system.
DisplayName( "name" ) An optional, quoted string that contains a name that can be displayed in the JMP user interface wherever add-in names are displayed, instead of the unique ID.

JMPVersion("version") An optional string that contains a specific version of JMP. The default value is "All", which enables the add-in to be loaded and run in any version of JMP that supports add-ins. "Current" restricts the use of the add-in to only the current version. Any quoted version number (for example, "7" or "9") restricts the add-in to a single specific version of JMP.

LoadsAtStartup(Boolean) An optional Boolean. The default value is True (1), which causes the add-in to be loaded when JMP is started. If the value is False (0), the add-in is not loaded automatically.

LoadNow(Boolean) Loads the add-in immediately.

Notes

If a file named addin.def is found in the specified home folder, values from that file are used for any optional arguments that are not included in the Register Addin() function.

Example

In the following example, the first argument is the unique identifier. The second argument identifies where the add-in is installed. The third argument is the name that appears where add-in names are displayed (for example, the View > Add-Ins menu on Windows).

Register Addin("com.company.lee.dan.MyAddIn","$DOCUMENTS/myaddin", displayname( "Calculator Addin" ));

The second argument becomes the $ADDIN_HOME path variable definition. When you refer to the add-in scripts, be sure to include a trailing slash after the path variable.

Include("$ADDIN_HOME(com.jmp.jperk.texttocols)/texttocols.jsl");

Revert Menu()

Description

Resets your JMP menus to factory defaults.

Run Program(Executable("path/filename.exe"), Options({"/a", "/b", "..."}), Read Function(expression), Write Function(expression), Parameter(expression))

Description

Runs the external program specified by the Executable argument, with the command line arguments specified by the Options argument.

Results

Returns either a quoted string, a blob, or a Run Program object as controlled by the Read Function argument.
Arguments

Executable  The path to the executable. On macOS, type the full path to the executable.
Options  Command line arguments for the executable.

Read Function  If Read Function( "text" ) is specified, a quoted string is returned. If Read Function( "blob" ) is specified, a blob is returned. The script waits until the external program closes its stdout. Run Program then returns all data that the external program has written to its stdout as a quoted string or a blob.

If Read Function is not specified, a Run Program object is returned.

Write Function  Optional argument that accepts a function as its value; it does not accept "text" or "blob".

Parameter  Optional argument to read and write the expression in Read Function.

Notes:

• Use global variables when Run Program() is inside a function.

• The Run Program object, which is returned if Read Function is not specified, accepts the following messages to read data from the external program’s stdout:
  – <<Read: reads any available data as a quoted string. If no data is available, an empty string is returned.
  – <<Can Read: returns true if there is data available to be read.
  – <<Is ReadEOF: returns true when the external program has completed and all its data has been read.

You can use these messages to poll for data and process the data as it is produced by the external program.

• A Run Program object accepts the following messages to write data to the external program’s stdin:
  – <<Write( "text" ): sends data to the external program’s stdin.
  – <<Can Write: returns true if the external program will accept data immediately; otherwise, calling <<Write causes your script to block.
  – <<WriteEOF: signals to the external program that you are done sending data to it.

• Instead of sending messages to the returned Run Program object, you can specify the Read Function argument as an inline function. RP is the Run Program object.

RP = Run Program(
   Executable( ... ),
   Read Function(
      Function( {RP},
         <your code here>
         RP << Read
      )
   )
)
The `Parameter(optParm)` argument is optional in `Read Function`. If specified, the functions defined for `Read Function` and `Write Function` can receive a second argument, which is the value of `optParm`.

**Examples**

The following script is an example of the `Write Function` argument. `RP` is the Run Program object. In this context, it accepts the `<Write` and `<WriteEOF` messages.

```javascript
RP = Run Program(
    Executable( ... ),
    Write Function(
        Function( {RP},
            <your code here>
            RP << Write( "Program finished." )
        )
    )
);
```

The following script shows an example of `Parameter(optParm)` argument:

```javascript
RP = Run Program(
    Executable( ... ),
    Parameter( x ),
    Read Function( Function( {RP, optParm},... ) )
);
```

Within the `Read Function`, `optParm` contains the value of `x`. Do not attempt to access the `optParm` argument in your function if you have not specified a `Parameter` argument.

---

**Schedule(n, script)**

**Description**

Queues an event to run the `script` after `n` seconds.

---

**Set Clipboard(string)**

**Description**

Evaluates the quoted `string` argument looking for a character result, and then places the string on the clipboard.

**Example**

```javascript
Set Clipboard( "copy me" );
```
SetJVMOption( Version("<version number>") )

**Description**
Sets the Java Runtime Environment (JRE) version that you want JMP to use (rather than the version installed with JMP). This script must be run before JMP connects to the JRE.

**Argument**
version (Windows only) In the Windows registry, there are two requirements for the JavaSoft/Java Runtime Environment key: the key must include a quoted string called “RuntimeLib” that points to a valid jvm.dll. And the Java Runtime Environment key must include a key named after the quoted JVM version number.

Set Platform Preference()
Set Platform Preferences()
See “Platform Preferences(platform(option(value)), ...)” on page 352.

Set Preference()
Set Preferences()
See “Preferences(pref1(value1), ...)” on page 354.

Set Toolbar Visibility( "toolbar name" | default | all, window type | all, "true" | "false" )

**Description**
On Windows, shows or hides a toolbar based on the window type or for all windows.

**Arguments**
toolbar name | default | all The internal name of the toolbar (see the View > Toolbars list in JMP), the default toolbar for the specified window type, or all toolbars. Include quotes around "toolbar name".
window type | all Data table, script, report, journal, or all windows.
true | false A quoted string that shows or hides the toolbar.
Shortest Edit Script( A, B )

Shortest Edit Script( strings( A, B, <matrix( 0|1 )>, <limit( number )> ) )

Shortest Edit Script( lines( A, B, <matrix( 0|1 )>, <limit( number )>,
<separators( characters )>, <ignore( characters )|ignore white space( )> ) )

Shortest Edit Script( sequences( nA, nB, Function( {iA, iB}, adata[iA] == bdata[ib] ) ) )

Description

Compares two quoted strings, lines, or sequences.

Returns

Returns a list or a matrix of edit commands. The simplest form returns a list. quoted
strings and lines return a matrix (if set to 1) or a list. sequences returns a matrix.

There are three possible commands: common data in both quoted strings, delete data from
the first string, and keep data from the second string.

Optional Arguments

matrix Indicates whether the returned value is a matrix.

limit Stops the evaluation when the edit list exceeds the specified number of inserted or
deleted items. Two quoted random strings have a lot of common characters in a lot of
distinct sections. The function runs for a long time trying to find a best match. limit
stops the function sooner.

Optional Lines Arguments

matrix Indicates whether the returned value is a matrix.

limit Stops the evaluation when the edit list exceeds the specified number of inserted or
deleted items. Two quoted random strings have a lot of common characters in a lot of
distinct sections. The function runs for a long time trying to find a best match. limit
stops the function sooner.

separators A character that separates words.

ignore Ignores the specified spaces or characters in a line.

ignore white space Ignores white space in a line.

Optional Sequences Argument

Function A user-defined function.

Examples

The following example compares two quoted strings with three common sequences of
characters between them.

Shortest Edit Script( "abcdef", "abdezgh" );

{"Common", "ab"}, {"Remove", "c"}, {"Common", "de"}, {"Insert", "zgh"},
{"Remove", "f"}

The following example examines each line in quoted string aa and bb:

aa = "this is
a test of shortest edit script lines with several words;

bb = "this is a test 2 of shortest edit ?., script lines with several words";

Shortest Edit Script( lines( aa, bb, separators( "\n" ),

    // quote and newline separators
    ignore( "?., " ) ); // ignore these characters and spaces

    {{"Common", "this is // lines in aa and bb contain "this is"
        ""}, {{"Remove", "a test of // only on line 2 of aa
        ""}, {{"Insert", "a test 2 of // only on line 2 of bb
        ""},
        {{"Common", "shortest edit script lines with several words"}}

    // lines in aa and bb contain "shortest", "edit script", and "lines with several words"

Show Addin Builder Dialog()

Description

Opens a window in which you can make custom add-ins.

Show Addins Dialog()

Description

Opens the Add-In Status window (View > Add-Ins).

Arguments

None.

Show Commands()

Description

Lists scriptable objects and operators. Arguments are All, DisplayBoxes, Scriptables, Scriptable Objects, StatTerms, Translations.
Show Preferences(<"all">)

**Description**
Shows current preferences. If no argument is specified, preferences that have been changed are shown. If "all" is given as the argument, all preferences are shown.

Show Properties(object)

**Description**
Shows the messages that the given object can interpret, along with some basic syntax information.

Sobol Quasi Random Sequence(nDim, nRow)

**Description**
Generates a sequence of space-filling quasi random numbers using the Sobol sequence in up to 4000 dimensions.

Socket(<STREAM | DGRAM>)

**Description**
Creates a socket.

**Returns**
The socket that was created.

**Arguments**
STREAM | DGRAM Optional argument to specify whether the socket is a stream or datagram socket. If no argument is supplied, a stream socket is created.

Speak(text, <wait(Boolean)>)

**Description**
Calls system’s speech facilities to read aloud the text. If Wait is turned on, script execution pauses until speaking is done.

Status Msg("message")

**Description**
Writes the quoted message string to the status bar.
Subtract(a, b)

Description
Subtracts the values of the listed arguments, left to right. No arguments are changed.

Returns
The difference.

Arguments
Two or more variables, numbers, or matrices.

Notes
Two or more arguments are permitted.

Unregister Addin("unique_id")

Description
Unregisters (removes) a previously registered add-in.

Argument
unique_id A quoted string that contains the unique identifier for the add-in to unregister.

Web(string, <JMP Window>)

Description
Opens the URL stored in the quoted string in the default web browser.

Examples
url = "www.jmp.com"; // open the URL in the default web browser
Web( url );

Web( "www.jmp.com" ); // open the URL in the default web browser

Web( "www.jmp.com", JMP Window ); // open the URL in the JMP browser window

XML Attr("attr name")

Description
Extracts the quoted string value of an xml argument in the context of evaluating a Parse XML command
XML Decode("xml")

**Description**
Decodes symbols in XML to ordinary text. For example, `&amp;` becomes `&`, and `&lt;` becomes `<.

**Argument**
xml A quoted string containing XML.

XML Encode("text")

**Description**
Prepares text for embedding in XML. For example, `&` becomes `&amp;`, and `<` becomes `&lt;`.

**Argument**
xml A quoted string containing plain text.

XML Text()

**Description**
Extracts the quoted string text of the body of an XML tag in the context of evaluating a `Parse XML` command.
This topic provides abbreviated descriptions for many of JMP’s general object messages. For complete information about object messages, see the JMP Scripting Index. In JMP, select Help > Scripting Index.

For information about platform messages, see Scripting Guide.

Alpha Shape

For the following messages, `ashape` stands for an alpha shape or a reference to one.

**ashape <<Get Alpha**

Returns the current alpha value.

**ashape <<Set Alpha(alpha)**

Sets the current `alpha` value and recomputes the triangulation.

**ashape <<Get Tri Alpha**

Returns the alpha values for each triangle.

Associative Arrays

For the following messages, `map` stands for an associative array or a reference to one.

**map<<First**

Returns the first key within `map`, or `Empty()` if `map` has no keys. Note that keys are returned in lexicographical order.

**map<<Get Contents**

Returns a list of all key-value pairs within `map`.

**map<<Get Keys**

Returns a list of all the keys within `map`.

**map<<Get Default Value()**

Returns the implicit value of all absent keys, or `Empty()` if none has been set.

**map<<Get Value(key)**

Returns the value for the `key` within `map`. 
map<<Get Values(<{keyList}>)

If no argument is provided, a list of all values within map is returned.
If a list of keys is provided, a list of the values corresponding to only those keys is returned.

map<<Insert(key, value)

Inserts the key into map and assigns value to it. If key already exists in map, its value is replaced by the new value given. This message is equivalent to the function Insert Into.

map<<Next(key)

Returns the key following the given key within the map, or Empty() if map has no keys. Note that keys are returned in lexicographical order.

map<<Remove(key)

Removes the key and value from map. This message is equivalent to the function Remove From.

map<<Set Default Value(v)

Sets the implicit value of all absent keys. Any key added without a value is assigned this value by default.

Classes

obj<<Clone

Returns a reference to a new class object that is a copy of the obj class object.

obj<<Contains(quoted string)

Returns 1 if the obj class object contains the specified quoted string expression, and 0 otherwise.

obj<<Delete Class

Deletes the obj class object.
obj<<Equal(classref)

Returns 1 if the classref class object is equal to the obj class object, and 0 otherwise.

obj<<First

Returns the quoted string representation of the name of the first member (item) in the obj class object. The members (items) in the class object are sorted in alphabetical order.

obj<<Get Contents

Returns a list of members (items) in the obj class object. Each element in the list is a two-item list that contains a key and an associated value.

obj<<Get Keys

Returns a list of keys within the obj class. Each key is a quoted string representation of the name of a member (item) in the obj class object.

obj<<Get Name

Returns a quoted string representation of the name of the obj class object.

obj<<Get Value(key quoted string)

Returns the value of the specified member (item) within the obj class object. The quoted key quoted string argument specifies the key to the member (item).

obj<<Get Values

Returns a list of values of the members (items) in the obj class object. Each element in the list is the expression that represents the value of each member (item) in the class.

obj<<Insert(quoted string, value)

Inserts a member (item) into the obj class object. The quoted string argument is the name of the member (item), and the value argument is the expression value of the member (item).

obj<<Lock Class(<quoted string>{quoted stringList}>)

Locks the obj class object, or locks specific members (items) within the obj class object. When a class object is locked, members (items) cannot be added, changed, or removed. The quoted string or quoted stringlist arguments specify a member (item) to lock. You can also specify a list of quoted strings to lock multiple members (items).
obj<<N Items
Returns the number of members (items) in the obj class object.

obj<<Next(quoted string)
Returns the quoted string representation of the name of the member (item) in the obj class object that follows the member (item) specified by the quoted string. The members (items) in the class object are sorted in alphabetical order.

obj<<Remove(<string|{stringList}>)
Removes the member (item) specified by the quoted string or quoted stringlist from the obj class. You can remove multiple members (items) using a list of quoted strings.

obj<<Show Contents
Shows the contents of the obj class object in the log window.

obj<<Unlock Class(<quoted string|{stringList}>)
Unlocks the obj class object, or unlocks specific members (items) within the obj class object. When a class object is unlocked, members (items) can be added, changed, or removed. The quoted string or quoted stringlist specify a member (item) to unlock. You can also specify a list of quoted strings to unlock multiple members (items).

Data Tables

dt<<Add Column Properties(property argument, ...)
Adds the specified properties (such as Value Order and Missing Value Codes) to the selected column.

dt<<Add Multiple Columns(column prefix, n, "Before First"|"After Last"|After(column), "Character"|"Numeric"|"Row State", <Field Width(n)>)

Description
Adds n columns to dt at the position indicated.

Required Arguments
column prefix The prefix to add to the new columns names.
n The number of columns to add.
Character A new character column.
Numeric A new numeric column.
Row State A new row state column.

Optional Arguments
Before First Adds the columns before the first column.
After Last Adds the columns after the last column.
After(column) Adds the columns after the specified column.
Field Width(n) Specifies the width of the columns.

Notes
If you omit arguments, or the arguments are incorrectly specified, the Add Multiple Columns window appears.

```
\texttt{dt<<Add Rows(<n>, \{"At Start" | "At End" | After(row number)\}|\{column name=value pairs\})}
```

Description
Adds rows at the start, at the end, or after a specified row in the data table. The message can also add rows based on the specified column name and value pairs. Those rows are added to the end of the data table.

Notes
If you omit arguments, or the arguments are incorrectly specified, the Add Rows window appears.

```
\texttt{dt<<Add Scripts to Table(script, ...)}
\texttt{dt<<Add Properties to Table(script, ...)}
```

Adds the specified scripts to the data table.

```
\texttt{dt<<Anonymize(<Columns column list(s)>), <Output Table Name(name)>};
```

Removes unique identifiers from data, some column properties, and table scripts. Applies to a data table or the specified list of columns. The new data table has the name that is specified by the quoted \texttt{name} argument.

```
\texttt{dt<<Begin Data Update}
```

Holds off display updating to allow for quick updating of data table cells. Use \texttt{End Data Update} in conjunction with this command to turn display updating back on.

Notes
\texttt{Begin Data Update} does not affect the data refresh due to some other table manipulations. For example, when you delete or add columns, the data table is updated and then the data update begins.
**dt<<Clear Column Selection**
Deselects all selected columns.

**dt<<Clear Edit Lock(</"Modify Cells">, </"Add Rows">, </"Add Columns">, </"Delete Rows">, </"Delete Columns">)**

**Description**
Allows the specified data table operation again.

**Notes**
If no arguments are specified, all locks are cleared.

**dt<<Clear Row States**
Cancels any row states in effect.

**dt<<Clear Select**
Turns off the current selection.

**dt<<Clone Formula Column(column, n, Substitute Column Reference(column1, \{list\}))**
Creates \(n\) new formula columns, substituting references to \(column1\) with columns from the \(list\) into the formula from the original \(column\).

**dt<<Close Data Grid(Boolean)**
If true, closes the data table grid.

**dt<<Close Side Panels(Boolean)**
If true, closes the side panel in a data table.

**dt<<Color or Mark by Column(column, <named arguments>)**
**dt<<Color by Column(column, <named arguments>)**
**dt<<Marker By Column(column, <named arguments>);**

**Description**
Assigns colors or markers according to the values of a data table column. If no optional arguments are provided, colors are assigned according to the default color theme.

**Required Argument**
- \(column\) The column to color or mark.
Optional Named Arguments

Color(n) Uses the specified JMP color.
Add Marker(Boolean) Shows or hides the marker in the data table.
Color Theme(color theme) Uses the specified quoted color theme.
Marker Theme(marker theme) Uses the specified quoted marker theme:
  "Standard", "Hollow", "Paired", "Classic", or "Alphanumeric".
Continuous Scale|Continuous Scale(Boolean) Assigns colors in a chromatic sequential fashion based on the values in the highlighted column.
Reverse Scale|Reverse Reverses the color scheme in use.
Excluded Rows(Boolean) If true, applies the row states to excluded columns.
"Make Window with Legend" Creates a separate window with a legend.

```
dt<<Color Rows by Row State
Colors the rows in the data table grid using the color assignments by row states. Send the message again to turn off the row colors.
```

```

dt<<Combine Columns(Delimiter("delim"), Columns(column1, column2, etc.), Column Name(quoted string))

Combines several columns into a single column. Each source columns' values are separated by the delimiter specified as the quoted delim argument.
```

Examples

```
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
dt << Combine Columns(
  Delimiter( "," ),
  Columns(
    :Brush After Waking Up,
    :Brush After Meal,
    :Brush Before Sleep,
    :Brush Another Time
  ),
  Column Name( "When to Brush")
);
```

```

dt<<Compress File When Saved(Boolean)
Compresses the file when the data table is saved.
```

```

dt<<Compress Selected Columns({column1, ...})
Compresses the listed columns into the most compact form that is possible. Columns with character data are compressed to 1 byte if there are fewer than 255 levels. Columns with numeric data are compressed to 1 byte if the integers are between -127 and 127.
```
dt<<Concatenate(dt2|Data Table(name)|Multiple Data Table(name) arguments, (<"Private"|"Invisible">), <Output Table Name(name)>|"Append to First Table">, <"Keep Formulas">, <"Create Source Column">)

Description
Creates a new table (name) from the rows of dt and dt2. By default, Concatenate creates a new data table and appends the rows of each data table that is specified.

Returns
A reference to the concatenated data table.

Required Arguments
dt2|Data Table(name)|Multiple Data Table(name) A data table reference or the names of the data table or data tables that you would like to combine.

Optional Arguments
"Private" A quoted keyword that opens the data table without displaying it in a data table window.
"Invisible" A quoted keyword that hides the data table. Use this argument to keep the data table hidden but use it in a subsequent expression. The data table is displayed in the Home Window’s Window List and the Window > Unhide list.
Output Table name(name) The name of the final data table. If you do not enter a name, JMP names the data table Untitled # (for example, Untitled 1).
"Append to First Table" Appends rows to the first data table reference or data table name in the first argument. This option is an alternative to creating a new data table.
"Keep Formulas" Includes formulas in the final data table.
"Create Source Column" Adds a column called Source Table to the new data table.

Notes
"Private" and "Invisible" only apply if not using "Append to First Table".

dt<<Copy Column Properties
Copies all of the column properties for the selected columns into a list of separate lists of properties. Optionally, you can specify a list of source columns instead of preselecting them in the data table.

Example
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Select Columns( :MODULUS, :ELONG );
dt << Copy Column Properties;
New Window( "Script", Script Box( "//Try paste here" ) );
or
dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Copy Column Properties( {:MODULUS, :ELONG} );
New Window( "Script", Script Box( "//Try paste here" ) );

dt<<Copy Selected Properties

Description
Copies the selected table properties to the clipboard.

Example
  dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
  dt << Select Properties( {"Distribution", "Oneway"} );
  proplist = dt << Copy Selected Properties();
  New Window( "Script", Script Box( "//Try pasting here" ) );

dt<<Copy Table Script("No Data")

Copies the script to recreate the data table onto the clipboard so that it can be pasted somewhere else. Add the "No Data" argument to omit the data.

dt<<Copy Table Scripts
dt<<Copy Selected Properties

Description
Copies the selected scripts to the clipboard.

Example
  dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
  dt << Select Properties( {"Distribution", "Oneway"} );
  proplist = dt << Copy Table Scripts();
  New Window( "Script", Script Box( "//Try pasting here" ) );

dt<<Data Filter(<Location(x, y), <"Close Outline">, <"Local">,
  <Inverse(Boolean)>, <Show Columns Selector(Boolean)>, <Title(quoted string)>, <Save and Restore Current Row States(Boolean)>,
  <Conditional(Boolean)>, <Auto Clear(Boolean)>, <Group By AND(Boolean)>, <Show Histograms and Bars(Boolean)>, <Count Excluded Rows(Boolean)>, <Mode(...)>), <Add Filter((cols(...), <Where(...)>,
  <Display(...)>, <Select Missing(cols)>, <Order By Count(cols)>)>,
  <Favorites(...)>), <Animation(...)>)

Constructs a data filter. If no arguments are specified, the Add Filter Columns window appears.

Optional Arguments
  Location(x, y) Moves the data filter window to the specified location. x and y are measured in pixels. 0,0 is the top left of the monitor.
  "Close Outline" Closes the data filter outline.
"Local" Enables the filter to be embedded in reports to filter one or more platforms without affecting other reports.

Inverse(Boolean) Selects all but the specified rows for all filters.

Show Columns Selector(Boolean) If true, a column list is shown that adds a new column to the filter.

Title(quoted string) The title that is displayed on the outline.

Save and Restore Current Row States(Boolean) Restores your current row states when the Data Filter window is closed.

Conditional(Boolean) Limits the categories displayed for the selected filter column.

Auto Clear(Boolean) If you have more than one nominal or ordinal column selected in the Data Filter, this option clears any other selections before making a new selection.

Group By AND(Boolean) Enables you to create a filter group, specify OR, and add one or more filters to create a second filter group. If you specify Grouped By And, the behavior is reversed and grouped by AND instead.

Show Histograms and Bars(Boolean) Shows or hides the histogram and bars in the data filter.

Count Excluded Rows(Boolean) Shows or hides the number of excluded rows.

Mode The three modes of filtering: Select(Boolean) shows or hides the selected rows in the data table in a highlighted state; Show(Boolean) shows or includes the unselected rows and shows the Hide icon; Include(Boolean) shows or includes the unselected rows and shows the Exclude icon.

The global data filter default is Select(), Show(0), and Include(0). The local data filter default is Show(1), Include(1), Select() is not a valid option.

Add Filter Creates the data filter. Arguments include Columns(), Where(), Display(), Select Missing(cols), and Order By Count(cols). Columns() takes one or more column names separated by commas. You can add one or more Where clauses to define the filter.

Where Defines a Where clause by which the data is filtered.

Display(column, size, display type) Sets how the specified categorical column levels are displayed in the filter. The arguments are Blocks Display, List Display, Single Category Display, Check Box Display, Radio Box Display. In categorical columns, you can include the Find(Set Text(quoted string)) argument to include and initialize the search field. Display can also be included for a continuous column and can contain a size argument.

Select Missing Cols(cols) Selects missing values in continuous columns.

Order by Count(cols) For a categorical column, this option sorts the values in decreasing order by count.

Favorites Saves the current data filter criteria as a favorite.

Animation Cycles through the sorted values of the specified column, selecting and deselecting rows. Optional arguments include Animate Column(col), Animate
Rate(number), and "Forward"|"Backward"|"Bounce" highlights values from first to last. "Backward" highlights values from last to first. "Bounce" highlights forward and then backward repeatedly.

```plaintext
dt<<Get Header Height

Returns the column header’s display height (in pixels).
```

```plaintext
dt<<Data View(<named arguments>)

Description

Duplicates the data table in a new window. If you specify one of the following quoted arguments, the new data table includes only the corresponding rows.

Returns

A reference to the data view.

Optional Named Arguments

- Excluded: The new data table includes only the rows that are marked as excluded in the original data table.
- Labeled|Labelled: The new data table includes only the rows that are marked as labeled in the original data table.
- Hidden: The new data table includes only the rows that are marked as hidden in the original data table.
- Selected: The new data table includes only the rows that are selected in the original data table.
```

```plaintext
dt<<Delete Columns(column1, column2, ...)

dt<<Delete Column

Description

Deletes one or more columns from the data table dt. Specify which column or columns to delete. Without an argument, deletes the selected columns, if any.
**dt<<Delete Rows(<n>)**

**Description**
Deletes the currently selected rows or rows specified. Returns the number of rows that were deleted.

**dt<<Delete Scripts(table script name|{table script1, table script2, ...})**

**Description**
Deletes the specified data table script or scripts with the quoted name or names, or deletes a list of data table scripts.

**Notes**
In JMP versions prior to 14, use Delete Table Property to delete a table script.

**dt<<Delete Table Property(name|{property1, property2, ...})**

Deletes a table property (for example, a script or variable) with the quoted name.

**dt<<Delete Table Variable(name)**
Deletes a table variable with the quoted name.

**dt<<Disable Undo(Boolean)**
If true, disables undo operations in the data table.

**dt<<End Data Update**
Resumes display updating after a Begin Data Update message. These commands are used for quick updates of the data table when many changes have to be made. Speed is gained by turning off display updating.

**dt<<Exclude**
**dt<<Unexclude**
Toggles selected rows in dt from excluded to unexcluded or vice versa.
\textbf{dt<<Get All Columns As Matrix}

Returns the values from all columns of \textit{dt} in a matrix. Character columns are numbered according to the levels, starting at 1.

\textbf{dt<<Get As Matrix(\{list of columns by name\}|\{list of columns by number\},<column range>)}

Returns values from the numeric columns of \textit{dt} in a matrix. The default output is all numeric columns.

\textbf{Examples}

\begin{verbatim}
dt1 = Open( "$SAMPLE_DATA/Big Class.jmp" );
cols = dt1 << Get As Matrix(); // returns all numeric columns
Show( cols );
    cols =
        [ 12 59 95,
          12 61 123,
          12 55 74,... ]
colnums = dt1 << Get As Matrix( \{4, 5\} ); // returns columns four and five
Show( colnums );
    colnums = [ 59 95, 61 123, 55 74, 66 145, 52 64, 60 84, 61 128, ... ]
\end{verbatim}

\begin{verbatim}
dt2 = Open( "$SAMPLE_DATA/Probe.jmp" );
colrange = dt2 << Get As Matrix( 10::22); // returns columns 10 through 22
Show( colrange );
    colrange =
        [ -0.08818069845438 0.711340010166168 1.85904002189636 0.396923005580902
          4.50656986236572 7.86504983901978 1.53891003131866 -2.76178002357483
          0.0711032971739769 5.75577020645142 -3.62023997306824 -0.071698999404907
         -0.0525696985423565, ... ]
\end{verbatim}

\textbf{dt<<Get As Report}

Returns the data table as a report. If rows and columns are selected in the data table, only those rows and columns are in the report.

\textbf{Example}

The following script returns \texttt{Big Class.jmp} as a report and displays it and a distribution in one window.

\begin{verbatim}
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dtRpt = dt << Get As Report;
distRpt = V List Box(
    dt << Distribution(
        Continuous Distribution( Column( :weight ) ),
        Nominal Distribution( Column( :age ) )
    ));
New Window( "Example", H List Box( dtRpt, distRpt ) );
\end{verbatim}
dt<<Get Cell Height

Returns the data table cell height in pixels.

dt<<Get Column Names(quoted string, <modeling type>, <data type>)

**Description**

Returns a list of column names in a data table. The quoted string returns a list of quoted strings rather than a list of column references.

**Required Argument**

*quoted string* Returns a list of quoted strings rather than a list of column references.

**Optional Arguments**

*modeling type* The quoted modeling type. The options are "Continuous", "Ordinal", "Nominal", "Multiple Response", "Unstructured Text", "None", and "Vector".

*data type* The quoted data type. The options are "Numeric", "Character", "Row State", and "Expression".

**Notes**

The data types and the modeling types get only the specified types of columns. More than one of each type can be specified.

dt<<Get Column Reference({list of column names}|[matrix of column numbers])

dt<<Get Column References({list of column names}|[matrix of column numbers])

Returns the column references of the quoted strings in the list or matrix. If no list or matrix is used, JMP returns a list of references to all columns.

dt<<Get Display Width

Returns the column display width in pixels.

dt<<Get Edit Lock

Returns the disallowed operations on the data table (if cells cannot be edited; rows cannot be added or deleted; and columns cannot be added or deleted).

dt<<Get Excluded Columns

Returns the currently excluded columns in the data table.
dt<<Get Excluded Rows

Returns the rows that are excluded in the data table.

dt<<Get Hidden Columns

Returns the columns that are hidden in the data table.

dt<<Get Hidden Rows

Returns the currently hidden rows in the data table.

dt<<Get Journal

Returns a quoted string that contains journal source for the display box.

Example

dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( Y( :weight ), X( :height ) );
rbiv = biv << Report;
Print( rbiv << Get Journal );

dt<<Get Label Columns

dt<<Get Labeled Columns

dt<<Get Labelled Columns

Returns the currently labeled columns in the data table.

Example

In PopAgeGroup.jmp, the Country and Year columns are labeled. The following script returns a list of the labeled column names.

dt = Open( "$SAMPLE_DATA/PopAgeGroup.jmp" );
dt << Get Labeled Columns;
{:Country, :Year}

dt<<Get Labeled Rows

dt<<Get Labelled Rows

Returns the currently labeled rows in the data table.

dt<<Get Name

Returns the name of the data table.
dt<<Get Path

Returns the absolute path for the JMP data table. Note that this function is not for imported data that is not saved yet.

dt<<Get Property(name)

Returns the script from the quoted property name.

dt<<Get Row Change Function

Returns the expression that is evaluated when a row is selected.

dt<<Get Row ID Width

Returns the row ID display width in pixels.

dt<<Get Row States

Returns a vector containing the row state for every row in the data table or data filter.

dt<<Get Rows Where(where clause)

Returns the rows in the data table that match the specified Where criteria. Here are some examples:

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Get Rows Where( :sex == "M" );
dt << Get Rows Where( :sex == "M" & :age < 15 );
```

dt<<Get Script(<script name>)

Returns the script specified by the quoted script name. If the script name is omitted, Get Script returns a text representation of the data table and all scripts in the table.

dt<<Get Script Group(<group name>)

Description

Returns the list of table scripts in the quoted group name. If no group name is specified, a list of all table scripts in all groups is returned.

dt<<Get Script Group Names

Description

Returns the list of names of table script groups.
dt<<Get Scroll Locked Columns

Returns a list of columns that are locked from scrolling.

dt<<Get Selected Columns(<quoted string>)

Description

Returns a list of selected columns as column references. Include the quoted string argument to return the selected column names as a list of strings.

dt<<Get Selected Properties(<{list of properties}>)

Description

Returns the selected table properties in a list.

Optional Argument

list of properties Specifies the properties to get.

Example

dt = Open("$SAMPLE_DATA/Big Class.jmp");
dt << Select Properties( {2, 4} );
proplist = dt << Get Selected Properties();
// returns the second and fourth table scripts and highlights them
// in the data table

dt<<Get Selected Rows()

Returns the selected rows.

dt<<Get Table Script Names()

Returns a list of the names of all the scripts and properties in the data table.

dt<<Get Table Variable(name)

Returns the value of the quoted name variable.

dt<<Get Table Variable Names

Returns a list of the names of all the variables in the data table.

dt<<Go To Row(n)

Locates and selects row number n in dt.
\texttt{dt<<Group Columns({\texttt{column1}, \texttt{column2}, ...})}
\texttt{dt<<Group Columns(\texttt{group name, column, n})}
\texttt{dt<<Group Columns(\texttt{first column, n})}

**Description**
Groups the columns under the specified quoted \texttt{group name}. You can provide either a list of columns to group, or a column name and the number of columns to group. In the latter case, the number \texttt{n} specifies to group the column given with the \texttt{n-1} columns that follow.

\texttt{dt<<Group Scripts({\texttt{script1, script2, ...}})}

**Description**
Groups a list of table scripts in the data table.

\texttt{dt<<Hide}
\texttt{dt<<Unhide}

Toggles selected rows in \texttt{dt} from hidden to unhidden or \textit{vice versa}.

\texttt{dt<<Hide and Exclude}

Hides the selected rows from graphs and excludes them from contributing to calculations.

\texttt{dt<<Invert Column Selection(\{list of columns\})}

**Description**
Selects any column that is currently deselected and deselects any column that is currently selected. If the \texttt{list of columns} is specified, the columns that are not in the list are selected.

\texttt{dt<<Invert Row Selection}

Selects any row that is currently deselected and deselects any row currently selected.

\texttt{dt<<Is Dirty}

Returns 1 if the table has been modified from its saved state. Otherwise, returns 0.

\texttt{dt<<Join(With(Data Table(name)), (<"Private">|"Invisible"), Select(columns), Select With(columns), (By Matching Columns(column1=column2, ...)|"Cartesian"|"By Row Number"), <"Merge Same Name Columns">, <"Match Flag">, <Copy Formula(Boolean)>, <Suppress Formula Evaluation(Boolean)>, <"Update">, <Drop}
Multiples(Boolean, Boolean>, <Include Non Matches(Boolean, Boolean)>, <"Preserve Main Table Order">, <Output Table Name(name)>)

Description
Combines data tables $dt$ and $Data\ Table$ side to side.

Returns
A data table.

Required Arguments

**With(Data Table(name))** Specifies the data table to join with the active table.

"Private" Specifies a quoted keyword that opens the data table without displaying it in a data table window.

"Invisible" Specifies a quoted keyword that hides the data table. Use this argument to keep the data table hidden but use it in a subsequent expression. The data table is displayed in the Home Window’s Window List and the Window > Unhide list.

**Select(columns)** Selects the data table to join with the active table.

**Select With(columns)**

**By Matching Columns(column1=column2)** Selects columns in both tables whose values and data types match.

"Cartesian" Joins two tables using a Cartesian fashion, where it forms a new data table consisting of all possible combinations of the rows from two original data tables. JMP crosses the data in the first table with the data in the second to display all combinations of the values in each set.

"By Row Number" Joins the two tables side by side.

"Merge Same Name Columns" Data from the second table replaces the data of the same name columns in the original table. Note that missing values in the first table are replaced by nonmissing values in the second.

"Match Flag" Determines whether the Match Flag column is created when you are matching by column.

**Copy Formula(Boolean)** Includes formulas from the main table and/or the second table in the output columns.

**Suppress Formula Evaluation(Boolean)** Prevents JMP from evaluating columns’ formulas during the creation of the new table.

"Update" Column data from the second table change the data of the same name columns in the original table. The results are displayed in a new data table. Note the following: JMP does not replace data with missing values; the output table uses the same columns as the original table. Thus, when you use "Update", Select Columns, the "Update" option is available only when joining by row number or by matching columns.

**Drop Multiples(Boolean, Boolean)** Specifies that you want the new table to contain only one row for each name. Applies only when matching by columns.

**Include Non Matches(Boolean, Boolean)** Includes non-matching columns in the main table and new data table. Applies only when matching by columns.
"Preserve Main Table Order" Maintains the order of the original data table in the joined table, instead of sorting by the matching columns.

**Output Table Name** (*name*) Specifies the name of the joined table. If you do not specify a name, JMP names the data table *Untitled* # (for example, *Untitled 1*).

```jsl
dt<<Journal
```

Makes a journal from the data table. Only the data grid is included, not notes, variables, or scripts.

**Notes**

- Journals that are created in JMP 14 or later might contain compressed matrix data for large matrices. If you have JSL scripts that open journals and extract data from them, you might need to use the `Get Journal` message (which does not compress the matrices) rather than saving the journal to disk with the `Journal` message.

**See Also**

See “`dt<<Get Journal`” on page 384

```jsl
dt<<Journal Link(<Save(<path>)|Embed(), <Button Name(<name>)>))
```

Adds a link to the data table in the current journal. If a journal does not exist, a new one is created.

**Optional Arguments**

- `path` Specifies the quoted *path* where the table is saved. If omitted, the data table should already have a disk location (previously saved or loaded), otherwise the journal link is incomplete and will not reload the table.
- `Embed` Embeds a JSL script to recreate the data table.
- `Button Name(name)` Specifies the name that is displayed on the button. The *name* argument is quoted. If the button name is not specified, the button is named after the data table.

```jsl
dt<<Label
```

```jsl
dt<<Unlabel
```

Toggles selected rows in *dt* from labeled to unlabeled or *vice versa*.

```jsl
dt<<Last Modified
```

Returns the date on which the data table was last saved.

```jsl
dt<<Layout
```

`Layout` is deprecated and will be removed in a future release. Use `Journal` instead.
dt<<Lock Data Table

**Description**

Locks the data table so that data and column properties cannot be added or changed.

**See Also**

“dt <<Set Edit Lock("Modify Cells"), "Add Rows", "Add Columns", "Delete Rows", "Delete Columns")” on page 397

---

dt<<Make Indicator Columns(<Append Column Name(Boolean)>, <Include Missing(Boolean)>)

Creates indicator columns of 0 and 1 values for the specified categorical columns.

**Example**

The following example creates indicator columns for the `sex` column. `Append Column Name` creates columns named `sex_F` and `sex_M`. Otherwise, the columns are named after each level (F and M). `Include Missing` includes missing values.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Make Indicator Columns(
    Columns( :sex ),
    Append Column Name( 1 ),
    Include Missing( 1 )
);
```

---

dt<<Make RowState Handler

Creates a row state handler function. The argument of the function holds the rows whose row states get changed.

---

dt<<Make SAS Data Step

Returns the data table as a SAS Data Step.

---

dt<<Make SAS Data Step Window

Returns the data table as a SAS Data Step and places it in a SAS script window.

---

dt<<Make Validation Column

Creates a column that is used to divide the data into training and validation sets.

---

dt<<Marker by Column(column)

**Description**

Assigns markers according to the values of the specified data table `column`. 
See Also

\[ \texttt{dt<<Marker By Column(column, <named arguments>);} \]

\[ \texttt{dt<<Markers(} n \texttt{)} \]

Assigns marker \( n \) to the selected rows.

\[ \texttt{dt<<Maximize Display} \]

Deprecated. Use \texttt{Optimize Display} instead.

Forces the data table to remeasure all of its columns and zoom to the best-sized window.

\[ \texttt{dt<<Move Script Group(group name, "To First"|"To Last"|After(table script name)|After(group))} \]

Description

Rearranges the table script groups that are specified by the quoted \texttt{group name}.

\[ \texttt{dt<<Move Selected Column(name(s), "To First"|"To Last"|After(name))} \]
\[ \texttt{dt<<Move Selected Columns(name(s), "To First"|"To Last"|After(name))} \]

Description

Moves the selected column or columns in the data table to the specified position. The \texttt{name} argument is quoted.

Example

The following example moves the \texttt{age} column to the last column in Big Class.jmp:
\[ \texttt{dt = Open( "$SAMPLE_DATA/Big Class.jmp" );} \]
\[ \texttt{dt << Go To( :age );} \]
\[ \texttt{dt << Move Selected Columns( "To Last" );} \]

You may also use a list to specify the column names.
\[ \texttt{dt = Open( "$SAMPLE_DATA/Big Class.jmp" );} \]
\[ \texttt{list = \{"name", "sex"\};} \]
\[ \texttt{dt << Move Selected Columns( list, To Last );} \]

\[ \texttt{dt<<Move Rows("At Start"|"At End"|After(n))} \]

Moves the selected rows in the data table to the specified position. \( n \) represents a row number.
dt<<New Column(name, <data type>, <modeling type>, <Format(format, width), <Formula()>, <Set Values({...}, ...), <Set Property(properties)>)

Description

Adds a new column titled with the quoted name after the last column in dt. Unless otherwise specified, columns are numeric, continuous, and 12 characters wide.

Returns

A column reference.

Required Argument

name  The name of the new column.

Optional Arguments

data type  A quoted string that specifies the data type. The options are "Numeric", "Character", "Row State", or "Expression".

modeling type  A quoted string that describes the modeling type ("Continuous", "Nominal", "Ordinal", "Multiple Response", "Unstructured Text", "None", or "Vector").

Format(format, width)>  Sets the format type and column width.

Set Values({})  Specifies the data in the column.

Formula  Specifies the column formula.

Set Property(properties)  Specifies any messages that data table columns support. Action arguments are found in the Column Properties menu in the New Column window. Axis and Link Reference are action argument.

See Also

For examples of setting other numeric format properties, see “col<<Format(<width>, <decimal places>, <"Use Thousands Separator">)” on page 405.

dt<<New Data Box()

Makes a data table view in a display box tree. Useful for displaying the data table and report in one window. A data browser box is created when you send the New Data Box message to the data table object.

Example

The following script creates a data table view and report in one window. The data table is placed in a data browser box. The width of that box is set to 800 pixels. Because auto stretch is turned off, the data table view remains 800 pixels wide even if you stretch the right border of the window.

dtA = Open( "$SAMPLE_DATA/Semiconductor Capability.jmp", invisible );
nw = New Window( "Example",
H List Box(
    V List Box( dtbox = dtA << New Data Box() ),
### dtA << Distribution

```plaintext
Continuous Distribution( Column( :NPN1 ) ),
Continuous Distribution( Column( :PNP1 ) )
```

### dtbox << Set Stretch( "Off", "Off" ) << Set Width( 800 )

---

### dt<<New Data View

Opens a duplicate of the data table. The second data table is identical to and linked to the original data table, so that any changes made in one are reflected in the other. Closing either data table also closes the other and all references to the data tables are deleted.

This can be useful to show an invisible data table.

---

### dt<<New Script(name, script)

dt<<Set Property(name, script)

Creates a new table property (also called a *table script*) using the quoted `name` that stores the specified `script`.

Use `New Script()` or `Set Property()` rather than the deprecated `New Property()` and `New Table Property()`.

**Example**

```plaintext
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Set Property( "Bivariate Example", Bivariate( Y( :weight ), X( :height ), Fit Line ) );
```

---

### dt<<New Table Variable(name, number)

dt<<Set Table Variable(name, number)

Creates a new table variable with the quoted `name` and the `number`.

---

### dt<<Next Selected

Scrolls data table down to show the next selected row that is not already in view.

---

### dt<<Optimize Display

Forces the data table to remeasure all of its columns and zoom to the best-sized window.

---

### dt<<Original Order

Restores saved order of columns in `dt`.
dt<<Paste Column Properties

Pastes multiple lists of column properties to multiple columns. Optionally, you can specify a list of target columns instead of selecting them in the data table.

Example

dt = Open( "$SAMPLE_DATA/Tiretread.jmp" );
dt << Copy Column Properties( {:MODULUS, :ELONG} );
dt2 = New Table( "test it",
    New Column( "T1", numeric, continuous ),
    New Column( "T2", numeric, continuous ),
    New Column( "T3", numeric, continuous ),
    Add Rows( 10 )
);
dt2 << Paste Column Properties( {:T1, :T3} );
// pastes the column properties from MODULUS and ELONG to T1 and T3

dt<<Predictor Screening
dt<<Screen Predictors

Description

Used to identify strong predictors.

Example

dt = Open( "$SAMPLE_DATA/Boston Housing.jmp" );
obj = dt << Predictor Screening(
    Y( :mvalue ),
);

dt<<Previous Selected

Scrolls data table up to show the previous selected row that is not already in view.

dt<<Print Window(<"Show Dialog">)

Prints the window. If the optional named argument "Show Dialog" is specified, the print window is displayed. Otherwise, the window is printed to the default printer using the current settings, and no print window is displayed.

dt<<Rename Script Group(old name, new name)

Description

Renames the table script group.

Example

dt << Rename Script Group( "Maps", "Street Maps" );

\texttt{dt<<Reorder By Data Type}

Reorders columns in \textit{dt}, row state first, then character, then numeric.

\texttt{dt<<Reorder By Modeling Type}

Reorders columns in \textit{dt} to continuous, then ordinal, then nominal.

\texttt{dt<<Reorder By Name}

Reorders columns in \textit{dt} to alphanumerical order by name.

\texttt{dt<<Rerun Formulas}

Recalculates all formula-based data table variables. Recalculations are performed in the proper dependency order.

\texttt{dt<<Reverse Order}

Reverses columns in \textit{dt} from current order.

\texttt{dt<<Revert}

Reverts to the most recently saved version of \textit{dt}.

\texttt{dt<<Row Selection(Select Where(condition), <current selection("Extend"|"Restrict"|"Clear")> <Dialog("Keep Dialog Open")>)

Description

Selects all rows that meet the specified condition.

Required Argument

Select Where(condition) Specifies the condition by which the rows are selected.

Optional Arguments

current selection("Extend"|"Restrict"|"Clear") Extends, restricts, or clears the existing selections. Clear is the default value.

Dialog("Keep Dialog Open") Shows the dialog so that the user can edit the options.

\texttt{dt<<Run Formulas}

Performs all pending formula evaluations, including evaluations that are pending as a result of evaluating other formulas.
dt<<Run Script(name)

Finds the table property with the quoted name and runs it as a JSL script.

dt<<Save(path)
dt<<Save As(path)

Description
Saves the table in the specified quoted path.

dt<<Save Database(connection information, table name, "Replace")

Saves the data table to the database named using the quoted connection information and quoted table name. The "Replace" option replaces the existing database with the current database.

dt<<Save Script to Script Window

Saves a script to reproduce the data table in a script editor window. Appends the script to any script that currently appears in the script editor.

dt<<Select All Rows

Selects all rows in the data table.

dt<<Select Columns(<column1>, <column2>,...|"All")

Selects the specified columns (or all columns) in the data table.

dt<<Select Duplicate Rows

Description
Selects the second and subsequent duplicate rows. If columns are selected, duplicate values are found in the rows of those columns. The duplicate values are case sensitive.

dt<<Select Excluded

Selects only those rows in the data table that are currently excluded.

dt<<Select Hidden

Selects only those rows in the data table that are currently hidden.
**dt<<Select Labeled**

Selects only those rows in the data table that are currently labeled.

**dt<<Select Randomly(n|p|Sample Size(n)|Sampling Rate(p))**

Randomly selects the given percentage $p$ of the rows in the data table, or the number of rows $n$. If you specify an argument with a keyword, numbers between 0 and 1 represent a percentage, and numbers larger than 1 represent a number of rows.

**dt<<Select Rows([row1, row2, ...])**

Selects the rows given in the list of row numbers.

**dt<<Select Script Group(<group name>{group1, group2, ...}>)**

Selects the table script group specified as a quoted `group name` or a list of quoted strings. If no argument is provided, all groups are selected.

**dt<<Select Where(condition, <Current Selection(“Extend”|“Restrict”|“Clear”)>)**

**Description**

Selects the rows in $dt$ where the condition evaluates as true.

**dt<<Set Dirty(Boolean)**

Marks the data table as changed, even if no changes have been made.

**Description**

Prevents cells from being modified; rows from being added or deleted; and columns from being added or deleted.

**dt <<Set Cell Height(n)**

Sets the cell height to the specified number of pixels.

**dt<<Set Header Height(n)**

Sets the column header’s height to the specified number of pixels.

**JSL Messages**

Chapter 3

Data Tables

JSL Syntax Reference

---

**dt<<Set Label Columns(column1, columns2, ...)**

Assigns the specified columns as label columns.

**dt<<Set Matrix([matrix])**

Inserts the specified matrix into a data table, adding new columns and rows as necessary.

**dt<<Set Name(name)**

**Description**

Specifies a name for the table. The *name* argument is quoted.

**Returns**

The data table name as a quoted string.

**Notes**

A change was made to the **Set Name** message so that now the new table name is returned as a quoted string. In previous releases, **Set Name** returned a scriptable data table object. As a result of this change, JMP scripts might need to be updated for the desired result to be returned. For example, rewrite the following script:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" ) << Set Name( "Test" );
```

Separate the messages so that *dt* represents the data table instead of “Test”:

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
dt << Set Name( "Test" );
```

The result is the same as in previous releases but will run successfully in both earlier and newer versions of JMP.

**dt<<Set Property(name, script)**

See “**dt<<New Script(name, script)**” on page 393.

**dt<<Set Label Columns(column(s), ...)**

**dt<<Set Label Columns**

Turns on the Label attribute for the specified columns. If no columns are listed, it turns the Label attribute off.

**dt<<Set Row ID Width(n)**

Sets the row ID display width to the specified number of pixels. If *n* is set to zero, the row ID display width automatically resizes.
dt<<Set Row States([matrix])

Sets the row states for all rows in the data table.

dt<<Set Scroll Lock Columns(column name, ...)

Locks scrolling for the columns specified as quotes quoted strings. If no columns are listed, unlocks scrolling.

dt<<Set Table Variable(name, value)

See “dt<<New Table Variable(name, number)” on page 393.

dt<<Sort("Private" | "Invisible", "Replace Table", By(columns), Order("Descending" | "Ascending"), <Output Table Name(name)>)

Description

Creates a new table (named after the quoted name) by rearranging the rows of dt according to the values of one or more columns.

Returns

A reference to the sorted table.

dt<<Split(Split(columns), Split By(column), <Group(column)>, "Private" | "Invisible", Remaining Columns("Keep All" | "Drop All" | Keep(columns) | Drop(columns)), <Copy Formula(Boolean)>, <Suppress Formula Evaluation(Boolean)>, <Sort by Column Property>, <Output Table (name)>)

Description

Unstacks multiple rows for each Split column into multiple columns as identified by the Split by column. The Split and Split by arguments are required.

Returns

A reference to the split data table.

Required Arguments

Split(columns) The column to split.
Split By(column) The column to split by.

Optional Arguments

Group Splits data within the specified groups.
Remaining Columns("Keep All" | "Drop All" | Keep(columns) | Drop(columns)) Specifies what to do with the remaining columns in the resulting table. Keep All is the default setting.
Note: Keep All includes all columns in the output data table. However, the values of every column are not included. Because multiple rows are collapsed to a single row in the output data table, some values of the kept columns are dropped.

Copy Formula(Boolean) Includes column formulas from the source table in the resulting table.
Suppress Formula Evaluation(Boolean) Stops any copied formulas from being evaluated. True is the default setting.
Sort by Column Property Sorts the order of the output columns by the sort column property that is defined for the Split by column.
Output Table(name) Generates the output to the specified table name.

dt<<Stack(<"Private">|<"Invisible">, Columns(columns), <Source Label Column(quoted string)>, <Stacked Data Column(quoted string)>, <Copy Formula(Boolean)>, <Suppress Formula Evaluation(Boolean)>, <Drop All Other Columns(Boolean)|Name(non-stacked columns) (Keep(column1, column2, ...))|Name(non-stacked columns) (Drop(column1, column2, ...))>, <Output Table(name)>>), <Number of Series(n)>, <"Contiguous">

Description
Creates a new table by combining the values from several columns in dt into one column.

Returns
A reference to the stacked data table.

Description
Subscribes to a data table to get messages regarding changes in the data table.

Returns
The keyname.

Arguments
"keyname"(<client>) Specifies the subscription name so that it can be referenced. The quoted client triggers a close confirmation when a close is attempted on the data table, warning that other open windows depend on the data table.
On Delete Columns(<function>|<script>) Returns the keyname when columns are deleted.
On Add Columns(<function>|<script>) Returns the keyname when columns are added.
On Add Rows(<function>|<script>) Returns the keyname when rows are added.
On Delete Rows(<function>|<script>) Returns the keyname when rows are deleted.
On Rename Column(<function>|<script>) Returns the keyname when columns are renamed.
On Close(<function>|<script>) Returns the keyname when the data table is closed.
    Takes one argument, a function. The function requires only one argument, the data table name.
On Save(<function>|<script>) Returns the keyname when the data table is saved.
On Rename(<function>|<script>) Returns the keyname when a rename is attempted on the data table. The function can be either the name of a previously defined function or the function itself.

Notes
Each subscription option remains in effect until you unsubscribe.

dt<<Subset("Private"|"Invisible", "Selected Columns",<Columns(\text{column list})","Selected Rows","Rows([\text{number, number, ...}])", <By(\text{column list})>, <Sampling Rate(\text{fraction})>, <Sample Size(\text{integer})>, <Stratify(\text{column list})>, <Link to Original Data Table(\text{Boolean})>, <Copy Formula(\text{Boolean})>, <Suppress Formula Evaluation(\text{Boolean})>, "Keep by Columns"))

Description

Creates a new table from the rows and columns that you specify in $dt$.

Returns

A reference to the subset data table.

dt<<Summary("Private"|"Invisible", <Group(\text{column})>,<Subgroup(\text{column})>, <N(\text{column})>, <Mean(\text{column})>, <Std Dev(\text{column})>, <Min(\text{column})>, <Max(\text{column})>, <Range(\text{column})>, <Sum(\text{column})>, <CV(\text{column})>, <Freq(\text{column})>, <Weight(\text{column})>, "Include Marginal Statistics", <Link to Original Data Table(\text{Boolean})>, <Statistics Column Name Format(\text{Stat(\text{column})|Column|Stat of Column|Column Stat})>)

Description

Creates a new table of summary statistics for the column that you specify, according to groups and subgroups. Statistics Column Name Format values are quoted.

Returns

A reference to the summary data table.
dt<<Suppress Formula Eval(Boolean)

Turns off automatic calculation of formulas for data table dt.

dt<<Text to Columns(Delimiters(<separator>, <"Tab">, <"Newline">), Columns(column1, column2...))

Makes a set of text columns or indicator columns from a delimited text column. "newline" includes the three forms: \r, \n, and \r\n. The separator is quoted.

Example
dt = Open( "$SAMPLE_DATA/Consumer Preferences.jmp" );
dt << Text To Columns(
delimiter( "," ),
columns( :Brush Delimited )
);

dt<<Transpose(Columns(columns), Rows([matrix]), Output Table Name(name))

Description

Creates a new table (named after the quoted name) from the rows and columns that you specify.

Returns

A reference to the transposed data table.

dt<<Ungroup Columns({column1, column2, ...})

Ungroups the columns defined in the list argument.

dt<<Ungroup Scripts(Name of Script Group|{script1, script2,...})

Description

Removes the specified table scripts or group from the group. The Name of Script Group argument is quoted.

dt<<Unsubscribe(keyname, "On Delete Columns"|"On Add Columns"|"On Add Rows"|"On Delete Rows"|"On Close"|"On Col Rename"|"All")

Releases any previous subscriptions to the data table dt. The keyname argument is quoted.

dt<<Update from Database

Updates the data in the table dt with data reimported from the database.
Columns

col<<Add Column Properties(name, expression)

Adds the quoted column property name with the expression given. You can add any standard column property by name or a user-specified property.

col<<Add From Row States

Updates a row state column with any currently used row state changes that are not the default state.

col<<Add To Row States

Copies all row state values in a column that are not the default state to the currently used row state in the data table.

col<<Color Cells(color)

Description
Colors the cells of the column within the data table grid. Use any quoted named color or 0 to clear the color.

col<<Color Cell by Value(Boolean)

Description
Colors the cells of the column in the data table grid using the value color property.

col<<Copy Column Properties

Copies the column properties into the buffer.

col<<Copy From Row States

Copies all row state values currently used in the data table to a column.

col<<Copy to Row States

Copies all row state values in the column to the currently used row state in the data table.
**col<<Data Type**

```
col<<Data Type(type, <Format(format quoted string)>, <Input Format(format quoted string)>, <width>)
```

**Description**

Sets the data type to `col`.

**Required Argument**

*type* Specifies the "Numeric", "Character", "Row State", or "Expression" data type.

**Optional Arguments**

*Format(format quoted string)* Specifies the way the data are displayed, such as `h:m` for hours and minutes. The *format quoted string* argument is quoted.

*Input Format(format quoted string)* Specifies the way the data are input. The *format quoted string* argument is quoted.

*width* (Optional for numeric data) Specifies 1, 2, or 4 (the number of bytes in the column).

---

**col<<Delete Formula**

Deletes the formula from a column.

---

**col<<Delete Property(name)**

**col<<Delete Column Property(name)**

Deletes the quoted property name from a column.

---

**col<<Eval Formula**

Forces the formula to evaluate (perhaps again). If formula suppression is enabled, the evaluation is not performed.

---

**col<<Exclude(Boolean)**

Turns the excluded or unexcluded state on, depending on the Boolean argument.
col<<Format(<width>, <decimal places>, <"Use Thousands Separator">)
col<<Format("Best", <width>, <"Use Thousands Separator">)
col<<Format(("Fixed Dec"|"Percent"), <width>, <decimal places>, <"Use Thousands Separator">)
col<<Format("Pvalue", <width>)
col<<Format(("Scientific"|"Engineering"|"Engineering SI"), <width>, <decimal places>)
col<<Format("Precision", <width>, <decimal places>, <"Use Thousands Separator">, <"Keep Trailing Zeros">, <"Keep All Whole Digits">)
col<<Format("Currency", <"Currency Code">, <width>, <decimal places>, <"Use Thousands Separator">)
col<<Format("Datetime", <width>, <input format>)
col<<Format(("Latitude DDD"|"Latitude DDM"|"Latitude DMS"|"Longitude DDD"|"Longitude DDM"|"Longitude DMM"), <width>, <decimal places>, ("PUN"|"DIR"|"PUNDIR"))
col<<Format("Custom", Formula(...), <width>, <input format>)

Description
Sets the numeric display specified format.

Arguments
See Using JMP for more information about the arguments.

Examples
col<<Format( 10, 2, "Use thousands separator");
col<<Format( "Currency", "EUR", 20 );
col<<Format( "m/d/y", 10 );
col<<Format( "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole digits" );
col<<Format( "Latitude DDD", "PUNDIR" ); // "PUN" for punctuation, "DIR" for direction, PUNDIR for both
col<<Format( "Custom", Formula( Abs( value ) ), 15 );

col<<Formula(expression)
col<<Set Formula(expression)
Sets the formula for the variable and evaluates it.

col<<Get Column Field Width
Returns the field width used for displaying data in the column.
col<<Get Data Type
Returns the data type of `col`.

col<<Get Data Type Length
Returns the data type and length of the data column. Only the data type is returned if the data length is not fixed, as with character columns.

col<<Get Format
Returns the format of the column.

col<<Get Formula
Returns the formula.

col<<Get Hidden
Returns 1 if the column is hidden.

col<<Get Input Format
Returns the format used for input and storing of data for the column.

col<<Get Labeled
Returns 1 if the column is labeled.

col<<Get List Check
Returns the list check definition. If list check is not defined for the column, a message is sent to the log stating so.

col<<Get Lock
Returns the current Lock setting.

col<<Get Modeling Type
Returns the modeling type of the column.

col<<Get Name
Returns the name of the column.
col<<Get Property("property name")
   Returns the specified property definition. If the specified property is not defined for the column, a message is sent to the log stating so.

col<<Get Range Check
   Returns the range check definition. If range check is not defined for the column, a message is sent to the log stating so.

col<<Get Role
   Returns the preselected role of col.

col<<Get Script
   Returns the script to reproduce the column.

col<<Get Scroll Locked
   Returns 1 if the column is scroll locked.

col<<Get Selected
   Returns 1 if the column is selected, or 0 otherwise.

col<<Get Stored Values
   Returns the values in the columns without considering the Missing Value Codes column property.

col<<Get Value Labels
   Returns the value labels definition. If value labels is not defined for the column, a message is sent to the log stating so.

col<<Get Use Value Labels
   Returns 1 if the value labels are set to be used for the column, or 0 otherwise.

col<<Get Values
   Returns the values in the column.
**col<<Hide(Boolean)**

Turns the Hide attribute on or off according to the Boolean argument given.

---

**col<<Ignore Errors**

Ignores formula evaluation errors in a column, and sets the cell value to missing when a formula error occurs.

---

**col<<Input Format(format)**

Sets the quoted format used for input and storage for the column. The argument is the name of any JMP format (for example, "ddmmyyyy" for a date column).

---

**date_col<<Is Transformed On SAS Export**

Returns true if the data in the resulting SAS data set for the date column will be changed when it is exported to SAS.

---

**col<<Label(Boolean)**

Turns the Label attribute on or off according to the Boolean argument given.

---

**col<<Lock(Boolean)**

**col<<Set Lock(Boolean)**

Turns the Lock attribute on or off according to the Boolean argument given.

---

**col<<Preselect Role(role)**

Preselects the specified role for the column. Choices are "Y", "X", "Weight", "Freq", and "None", or "No Role".

---

**col<<Reset Transform**

Removes the cached data for the transform column. Accessing column data rebuilds the caches. Use this option to reduce memory or to allow recalculation if the formula depends on external information.

---

**col<<Set Display Width(n)**

Sets the column display width to the n in pixels. If n is set to zero, the column display width automatically resizes.
**col<<Set Each Value(n)**

Sets all the values in the column to \( n \).

**col<<Set Excluded**

Excludes the column.

**col<<Set Field Width(n)**

Sets the field width for the column to \( n \).

**col<<Set Hidden**

Hides the column.

**col<<Set Labeled**

**col<<Set Labelled**

Uses the column’s data values for labels.

**col<<Set Modeling Type(type)**

Sets the modeling type for the variable. Choices are "Continuous", "Ordinal", "Nominal", "None", "Row State", "Unstructured", "Multiple Response", or "Vector".

**col<<Set Name(name)**

Sets the name for the column. The \textit{name} argument is quoted.

**col<<Set Property(name, expression)**

Sets the quoted property name to the \textit{expression} given. You can set any standard column property by name or a user-specified property.

**Examples**

The following example adds the Value Colors column property to the \textit{sex} column, with pink for females and blue for males.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "sex" ) << Set Property( "Value Colors", {"F" = 78, "M" = 69} );
```

The following example adds a custom column property named \textit{Date recorded} to the \textit{height} column.

```julia
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Column( "height" ) << Set Property( "Date recorded", 05Jan1990 );
```
See Also
   
   Scripting Guide
   Using JMP

---

`col<<Set Scroll Locked(Boolean)`
   
   Turns the Scroll Lock attribute on or off according to the Boolean argument given.

---

`col<<Set Selected(Boolean)`
   
   Sets the column to be selected or not selected.

---

`col<<Set Use for Marker`

`col<<Use for Marker`
   
   Uses the values in the column as markers in graphs. Designed to use with expression columns and character columns that have IDs. In the `Big Class Families.jmp` sample data table, the `picture` column is specified to use as markers in graphs. Not supported in Bubble Plot.

---

`col<<Set Values([matrix] or {list})`

`col<<Values([matrix] or {list})`
   
   Sets values for the matrix (for numeric variables) or list (for character variables).

---

`col<<Suppress Eval(Boolean)`
   
   Turns off automatic calculation of formulas for the column.

---

`col<<Use For Marker(Boolean)`
   
   Uses the values in the column as markers in graphs or turns off the option. Designed to use with expression columns and character columns that have IDs. In the `Big Class Families.jmp` sample data table, the `picture` column is specified to use as markers in graphs.

---

Rows

---

`row<<Colors(n)`
   
   Assigns the color \(n\) to the selected rows.
row<<Exclude(Boolean)
row<<Unexclude(Boolean)

Turns the excluded or unexcluded state on for the selected rows according to the Boolean argument given. Omit the argument to toggle the row state.

row<<Hide(Boolean)
row<<Unhide(Boolean)

Turns the Hide attribute on or off according to the Boolean argument given. Omit the argument to toggle the row state.

row<<Hide and Exclude

Shows or hides the selected rows from appearing on graphs, and excludes or unexcludes them from contributing to calculations.

row<<Label(Boolean)
row<<Unlabel(Boolean)

Turns the Label attribute on or off according to the Boolean argument given. Omit the argument to toggle the row state.

row<<Markers(marker)

Assigns the quoted "marker" to the selected rows.

row<<Next Selected

Causes the next selected row in the data table to blink.

row<<Previous Selected

Causes the previous selected row in the data table to blink.

row<<Row Editor

Opens the Row Editor window for the selected rows.
Data Filter

```julia
df<<Add Favorites("name")
```

**Description**

Associates the current filter selection with the quoted "name" and saves it in the Favorites list.

**Returns**

The favorite as a quoted string.

**Example**

```julia
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Add Filter(
        Columns( :age, :sex, :height, :weight ),
        Where( :sex == "F" ),
        Where( :height >= 55 & :height <= 65 )
    ),
    Mode( Select(1) )
);
Wait(1); // for demonstration purposes
fav1 = df << Add Favorites( "Female Average Ht" );
```

```julia
dtf<<Add Filter(Columns("column1", "column2"), "Where(clause)")
```

Add one or more filter columns in a new OR group.

```julia
dtf<<Auto Clear(Boolean)
```

Clears all currently selected rows before setting a new selection.

```julia
dtf<<Clear
```

Clears the currently selected rows.

```julia
dtf<<Close
```

Closes the data filter window.

```julia
dtf<<Columns("column1", "column2", ...)
```

Sets the columns to use in the data filter.

```julia
dtf<<Data Table Window
```

Shows the data table that the data filter window is using.
**JSL Syntax Reference Data Tables**

- `dtf<<Delete All`
  
  Removes all filters that are set.

- `dtf<<Delete(column1, column2, ...)`
  
  Removes the specified columns from the data filter.

- `dtf<<Display(column, <Size(x, y)>, "Blocks Display"|"List Display"|"Single Category Display"|"Checkbox Display")`
  
  Sets how the specified categorical column levels are displayed in the filter.

- `dtf<<Get Script`
  
  Returns the data filter script as text in the log.

**Example**

```
dt = Open( "SAMPLE_DATA/Big Class.jmp" );
df = dt << Data Filter(
    Add Filter( Columns( :age, :sex ), Where( :age == 12 ) )
);
txt = df << Get Script;
Show( txt );
```

- `dtf<<Local Data Filter`
  
  Embeds the data filter in the specified window. See Scripting Guide for more information about local data filters.

- `dtf<<Location(x, y)`
  
  Moves the data filter window to the specified location. `x` and `y` are measured in pixels. 0,0 is the top left of the monitor.

- `dtf<<Make Filter Change Handler(function)`
  
  Creates a data filter handler to handle notification that the filter has changed. The number of rows filtered is returned in the argument to the function.

**Example**

```
dt = Open( "SAMPLE_DATA/PopAgeGroupSubset.jmp" );
dist = Distribution( Automatic Recalc( 1 ), Continuous Distribution( Column( :POP ) ) );
filter = dist << Local Data Filter( Add Filter( Columns( :Region ) ) );
f = Function( {a}, Print( a ) );
rs = filter << Make Filter Change Handler( f );
```
dtf<<Make Subset

Creates a new subset data table that contains the rows that are selected in the data filter.

dtf<<Match(Filter Columns(column1, column2, ...), Where(clause))

Sets the filter conditions for each column. The Where clause is used for all the columns listed. To use different Where clauses for different columns, send the Match message separately for each column.

dtf<<Mode(Select(Boolean)|Show(Boolean)|Include(Boolean))

Sets the action, or mode, that is used when rows are selected using the data filter.

dtf<<Save and Restore Current Row States

Saves the current row states for the data table, and then restores those states when the data filter is closed.

dtf<<Show Columns Selector(Boolean)

Displays or hides the column selector after completing a filter.

dtf<<To Clipboard

Creates a Where clause from the current state of the data filter and places it on the clipboard, where it can be pasted elsewhere.

dtf<<To Data Table

Creates a Where clause from the current state of the data filter and saves it as a property to the data table.

dtf<<To Journal

Creates a Where clause from the current state of the data filter and appends it to the current journal. If there is no current journal, a new journal is opened and the Where clause is added to it.

dtf<<To Row State Column

Creates a row state column whose formula is the Where clause.
**dtf<<To Script Window**

Creates a Where clause from the current state of the data filter and appends it to the current script window. If there is no current script window, a new script window is opened and the Where clause is added to it.

**dtf<<Use Floating Window** *(Boolean)*

Sets whether the data filter window floats on top of its associated data table or behaves as a normal window.

**dtf<<Where** *(clause)*

Sets a condition for selecting rows.

---

**Data Feed (Windows Only)**

**feed<<Close**

Closes the data feed object and its window.

**feed<<Connect** *(port settings)*

Sets up port settings for the connection to the device.

**feed<<Disconnect**

Disconnects the device from the data feed queue but leaves the data feed object active.

**feed<<EOL** *("CR", "LF", "CRLF")*

Sets the line ending value used as a separator when parsing incoming lines of data. The value is also used as the terminator in outgoing lines of data.

- "CR": ASCII character 13 (carriage return)
- "LF": ASCII character 10 (line feed)
- "CRLF": Uses both CR and LF in sequence.

**feed<<Get Line**

Returns and removes one line from the data feed queue.
feed<<Get Lines

Returns as a list and removes all lines from the data feed queue.

feed<<Print Queue

Prints the internal queue of messages to the log window.

feed<<Queue Line(quoted string)

Sends one quoted string (or line) to the end of the data feed queue. Queue Line is primarily useful for testing your script without requiring it to be attached to a device. You can essentially simulate the data coming from the device to make sure the rest of your code handles the values properly when it's really attached to a working device.

feed<<Restart

Restarts processing queued lines.

feed<<Set Script(script)

Assigns the script that is run each time a line of data is received.

feed<<Stop

Stops processing queued lines.

feed<<Write(quoted string)

Description

Sends a quoted string to the data feed device.

Example

exfeed = Open Datafeed(  
    Connect( Port( "com1" ), Baud rate( 4800 ), Parity( "even" ), DataBits( 8 ) ),  
    Set Script(  
        ex = exfeed << Get Line;  
        Show( ex );  
    )  
);  
exfeed << Write( "Ready" );  
/* Example - send a message to external device over the serial port to trigger data messages. This can be used to send control messages to a sensor or other attached device.*/
feed<<Write Line(quoted string)

Description

Sends a quoted string to the data feed device. If EOL has been set for the data feed, the quoted strings are terminated by the specified EOL value. If EOL has not been set, the line is terminated with CRLF.

Example

```julia
exfeed = Open Datafeed(
    Connect( Port( "com1" ), Baud rate( 4800 ), Parity( "even" ), DataBits( 8 ) ),
    Set Script(
        ex = exfeed << Get Line;
        Show( ex );
    )
);
exfeed << Write Line( "Ready" );
/* Example - send a message to external device over the serial port to trigger data messages. This can be used to send control messages to a sensor or other attached device.*/
```

feed<<Write Lines({quoted string1, quoted string2, quoted string3})

Description

Sends a list of quoted strings to the data feed device. If EOL has been set for the data feed, the quoted strings are terminated by the specified EOL value. If EOL has not been set, the line is terminated with CRLF.

Example

```julia
exfeed = Open Datafeed(
    Connect( Port( "com1" ), Baud rate( 4800 ), Parity( "even" ), DataBits( 8 ) ),
    Set Script(
        ex = exfeed << Get Line;
        Show( ex );
    )
);
exfeed << Write Lines( {"Ready", "Set", "Go"} );
/* Example - send a message to external device over the serial port to trigger data messages. This can be used to send control messages to a sensor or other attached device.*/
```

Display Boxes

For additional examples, see the JMP Scripting Index.
All Display Boxes

\texttt{db<<Add Text Annotation\,(Text(\textit{quoted\ string}),\ Text\ Box(\langle x1,\ y1,\ x2,\ y2\rangle))}

Draws a text annotation box at the specified pixel location that contains the quoted \textit{string}. The \texttt{Text Box} argument controls where the text annotation box is drawn in the window, from the upper left corner to the lower right corner.

Note that \texttt{x1, y1, x2, y2} are not graph axis values but the specific pixel locations in the window. Exactly where the text box appears depends on the user’s window size, display resolution, and so on.

\texttt{db<<Append\,(db2)}

Add \texttt{db2} as the last child of the \texttt{db}.

\texttt{db<<Child}

Returns the child of the box.

\texttt{db<<Class Name}

Returns the name of the display class for the box.

\texttt{db<<Clone Box}

Makes a new copy of the display box.

\texttt{db<<Close Window}

Closes the containing window.

\texttt{db<<Copy Picture}

Puts a picture of the box on the clipboard.

\texttt{db<<Delete}

Deletes the display box.

\texttt{db<<Enable\,(Boolean)}

Controls the ability to interact with the display box. 0 disables the display box. 1 enables the display box.
db<<Get HTML

Returns a quoted string containing HTML source for the box.

db<<Get Journal

Returns a quoted string containing journal source for the box.

db<<Get Menu Item State(index)

Returns the popup menu item state of the index menu item. The state can be normal (0), checked (1), or disabled (-1).

db<<Get Menu Items

Description

Returns the menu items used for popup menu when the button is clicked. Menu items are returned in a list.

See Also

For submenus see “db<<Get Submenu(index)” on page 420.

db<<Get Menu Script

Returns the menu script attached to the calling object.

db<<Get Page Setup()

Returns the page setup settings.

Example

The example below creates a new window and returns the page setup configuration.

w = New Window( "Window",
   Text Box( "Page Setup Test" )
);

w << Get Page Setup();

The results of the message:

{Margins( {0.75, 0.75, 0.75, 0.75} ), Scale( 1 ), Portrait( 1 ),
   Paper Size( "Letter" )}

db<<Get Picture( <Scale(n)> )

Captures db as a picture object. The Scale(n) argument is a factor of the original picture size. For example, Scale(2) makes the picture object twice as large.
JSL Messages
Display Boxes

db<<Get RTF

Returns a quoted string containing RTF source for the box.

db<<Get Script

Returns the script for recreating the display box.

db<<Get Size

Returns either \{ x, y \} or \{ h, v \} in pixels:

\[ xy = \text{DisplayBox} \ll \text{Get Size}; \]

Returns x and y in pixels:

\[ \{ x, y \} = \text{DisplayBox} \ll \text{Get Size}; \]

db<<Get Submenu(index)

Returns the number of submenu items under the given menu item.

Example

The example below creates a menu containing "A", "B", and "C" with "A" having a submenu "A1" and "A2", and "B" having a submenu "B1", "B2", and "B3". db<<Get Submenu(inc) returns the number of submenu items under each indexed menu item.

```
New Window( "Title", 
obj = Outline Box( "title" ) );
submenus = { };
obj << Set Menu Script(
    "B", ",", "B1", Print( "B1" ), "B2", Print( "B2" ), "B3", Print( "B3" ),
    "C", Print( "C" )}
);
obj << Set Submenu( 1, 2 ); // menu A with 2 items in submenu A1 and A2
obj << Set Submenu( 4, 3 ); // menu B with 3 items in submenu B1, B2, and B3
For( inc = 1, inc <= N Items( Words( obj << Get Menu Script, "," ) )/2, inc++,
    Insert Into( submenus, obj << Get Submenu( inc ) );
);
submenus;
{2, 0, 0, 3, 0, 0, 0, 0}
```

The log output indicates that index(1) contains two submenu items and index(3) contains three submenu items.

db<<Get Text

Returns a quoted string containing the text of the box.
**db<<Horizontal Alignment(position)**

Aligns a child display box inside the display parent box according to the specified `position`. The default value is "Left", or you can specify "Center", or "Right".

**Example**

```jscript
New Window( "Example",
  Outline Box( "Parent display box",
    Button Box( "OK", db<<Horizontal Alignment( "Center" ) )
  )
);
```

---

**db<<Inval**

Invalidates the display box area in the window. The window is updated the next time the operating system has an opportunity to update windows (for example, when the user resizes the display box).

**Notes**

Consider including the message `<<Update Window` rather than including `Wait(0)`. The problem with using `Wait(n)` is knowing how large `n` should be.

Many display box messages, such as `<<Set Text`, automatically mark the box as invalid, so the `<<Inval` message is usually unnecessary. Some interactive scripts that use sliders with JSL callbacks might need `<<Update Window` to keep various parts of the display synchronized with the slider.

---

**db<<Is Enabled**

Returns the enabled state of the control. The message is supported in `Busy Light Box()`, `Button Box()`, `Calendar Box()`, `Check Box()`, `Col List Box()`, `Combo Box()`, `Completion Box()`, `Filter Col Selector()`, `gtext()`, `List Box()`, `Number Edit Box()`, `Popup Box()`, `Radio Box()`, `Range Slider Box()`, `Slider Box()`, `Spin Box()`, `Text Edit Box()`, `Tree Box()`, `Tree Map Box()`, and `Tree Map Seg()`.

---

**db<<Journal**

Appends the box to the journal.

---

**db<<Journal Window**

Appends the containing window of the display box to the journal; compare with `Journal`.

---

**db<<Move Window(x, y)**

Moves the window to the `(x, y)` location on your screen.
### JSL Messages

**Chapter 3**

**Display Boxes**

**JSL Syntax Reference**

---

**db<<Page Break**

Inserts a page break before the box.

---

**db<<Parent**

Returns the parent of this display box.

---

**db<<Prepend(db2)**

Add `db2` to the display tree before `db`.

---

**db<<Prev Sib**

Returns the previous sibling of the display box.

---

**db<<Reshow**

Invalidates the display box's area in the window and immediate removes invalid areas from the window.

---

**db<<Save Capture(<path>, <format>, <Add Sibling(n)>)**

Saves the display box as a graphic to the specified quoted `path` in the specified quoted `format`. The optional `Add Sibling` argument adds the number of sibling display boxes to include in the capture. The default value is 1, which captures only the specified display box. Note that the specified portion of the report is not guaranteed to be scrolled into view or unobstructed by other windows. If the display box is not visible, the saved graphic will not contain the contents that you expect.

If you omit the path, you are prompted to name and save the file when running the path.

---

**db<<Save HTML(<path>, <format>)**

Saves the HTML source and folder of graphics to the quoted `path` and in the quoted `format`. If you omit the `path` argument, you are prompted to name and save the file when running the script.

---

**db<<Save Interactive HTML(<path>, "Is Static")**

Saves the display box as a web page (that includes interactive HTML features) in the quoted `path`. Non-JMP users can then explore the data. Note that the data is embedded in the web page.

**Arguments**

- `path` A optional quoted `path` that specifies the location where the web page will be saved.
"Is Static" Omits the data from the web page and saves a static version of the web page.

Examples

do = Open( "SAMPLE_DATA/Big Class.jmp" );
biv = do << Bivariate( y( weight ), x( height ) );
riv = (biv << Report);
riv << Save Interactive HTML( "DOCUMENTS/MyInteractiveHTML.htm" );

db<<Save Journal(<path>)

Saves the journal source for the box in the quoted path. If you omit the argument, you are prompted to name and specify the graphic type.

db<<Save MSWord(<path>)

(Windows Only) Saves the display box as a Microsoft Word document in the quoted path. If you omit the path argument, you are prompted to name and save the file when running the script.

db<<Save PDF(<path>, <Show Page Setup(Boolean)>, <Portrait(Boolean)>)

Description

Saves a PDF of the display box in the quoted path.

Optional Arguments

- path Saves the file in the quoted path. If you omit the argument, you are prompted to name and save the file when running the script.
- Show Page Setup(Boolean) (Windows only) Displays the Page Setup window, where you can specify page orientation, headers and footers, margins, page scale, and paper size.
- Portrait(Boolean) Displays the content in portrait or landscape orientation.

Notes

- The PDF file contains headers and footers. Use Save Picture to omit these components.

db<<Save Picture(<path>, <format>)

Description

Saves a picture of the display box in the quoted path and with the specified quoted format.

Notes

- If you omit the quoted path argument, you are prompted to name and save the file when running the script.
• Valid file formats include "PDF", "PNG", "GIF", "JPG" or "JPEG", "EPS", "SVG", and "EMF".

• On Windows, the Windows Specific preferences determine the resolution (or DPI), or you can run the following script:

```javascript
Pref( Save Image DPI( number ) );
```

• On macOS, the operating system determines the DPI.

• Use Save Picture to export a report as a PDF file with no headers or footers. Use Save PDF to include these components.

```javascript
db<<Save Presentation(<path>, <Template(path)>, <Insert("Begin"|"End"|n)|Replace("Begin"|"End"|n)|Append>, <Outline Titles(title location)>, <format>)
```

Saves display boxes in a Microsoft PowerPoint presentation. You can open the file in any presentation software program.

**Optional Arguments**

- **path** Saves the file in the quoted path. You must include the .pptx extension in the filename. If you omit the path argument, you are prompted to name and save the file when running the script.

- **Template(path)** Specifies the quoted path of a custom PowerPoint template. Without this argument, JMP uses the default template located in the pptx folder of the installation directory.

  Include a simple table in your template, or a default table format is applied to report tables. For an example on Windows, see /pptx/JMPExportTemplate.pptx in the JMP installation folder.

- **Insert** Determines where the slides are inserted in an existing presentation.
  - n inserts the slides as the nth slide number.
  - "Begin" inserts the slides at the beginning of the presentation.
  - "End" inserts the slides at the end of the presentation.

- **Replace** Determines which slides are replaced in an existing presentation. The arguments are n, "Begin", and "End" as described for Insert.

- **Append** The slides are inserted at the end of an existing presentation.

- **Outline Titles** The location of the outline title and any parent outline titles on the slide.
  - "None" omits the slide title above the graphic and the outline titles.
  - "Hide" omits the outline titles.
  - "TopLeft", "TopRight", "BottomLeft", "BottomRight" determine the position of any of the parent outline titles on the slide.
format  The format of the embedded graphics. Options are "Native", "EMF", "PNG", "JPG", "BMP", "GIF", "TIF". On Windows, the native format is EMF. On macOS, the native format is PDF. See “Notes” for compatibility issues. Without this argument, JMP applies the “Image Format for PowerPoint” General preference.

Notes
Windows does not support the native PDF graphics produced on macOS. macOS does not support the native EMF graphics produced on Windows. For cross-platform compatibility, specify "PNG", "JPG", "GIF", or "TIF".

If no arguments are provided, the user is prompted to name and save the file.

```
db<<Save RTF(<path>, format)
```

Saves the file in the specified quoted `path` and with the quoted `format`. If you omit the `path` argument, you are prompted to name and save the file when running the script.

```
db<<Save Text(<path>, format)
```

Saves a file containing the text of the box in the quoted `path` and with the specified quoted `format`. If you omit the `path` argument, you are prompted to name and save the file when running the script.

```
db<<Scroll Window(Display Box|relative-vertical-pixels|relative-horizontal-pixels, relative-vertical-pixels|{absolute-vertical-pixels, absolute-horizontal-pixels})
```

Scrolls the containing window.

```
db<<Select
db<<Deselect
```

Selects (highlights) or deselects the box.

```
db<<Set Menu Item State(index, 0|1|-1)
```

Sets the popup menu item at `index` to be normal (0), selected (1), or disabled (-1).

```
{left, right, top, bottom}>, <Scale(s)>, <Portrait(Boolean)>, <Paper Size(paper size)>)
```

Sets the page settings. Margins are set in inches. Scale variable `s` is a number in the range of 10 (for 1000%) to 0.2 (for 20%) with the default as 1 (for 100%). If `Portrait` is True the page
is oriented for portrait, otherwise the page is landscape. Paper Size is a quoted string specifying the paper size, for example, "Letter" or "Legal".

Example
The example below creates a new window and configures the page setup.

```julia
w = New Window( "Window",
    Text Box( "Page Setup Test"
    )
); 
w << Set page setup( 
    margins( 1, 1, 1, 1 ), 
    scale( 1 ), 
    portrait( 1 ), 
    paper size( "Letter"
    )
);
```

db<<Set Print Headers(_left header, center header, right header)_

Description
Sets the left, center, and right header for print output.

Example
```julia
w = New Window( "Window", Text Box( "Header Example"
    )
); 
w << Set Print Headers( 
    "Today is: &d;", // left 
    "&wt;", // center 
    "Page &pn; of &pc;" // right 
    );
w << Print Window;
```

db<<Set Print Footers(_left footer, center footer, right footer)_

Description
Sets the left, center, and right footer for print output.

Example
```julia
w = New Window( "Window", Text Box( "Footer Example"
    )
); 
w << Set Print Footers( 
    "Today is: &d;", // left 
    "&wt;", // center 
    "Page &pn; of &pc;" // right 
    );
w << Print Window;
```
db<<Set Submenu (index, submenu count)

Description
Sets the submenu items for the item (specified by index number) by specifying the number of items in the submenu.

Example
The example below creates a menu containing “A”, “B”, and “C” with “A” having a submenu “A1” and “A2” and “B” having a submenu “B1”, “B2”, and “B3”.

```
New Window( "title", ob = Outline Box( "title" ) );
ob << Set Menu Script(
    "B", "", "B1", Print( "B1" ), "B2", Print( "B2" ), "B3", Print( "B3" ),
    "C", Print( "C" )}
);
ob << Set Submenu(1, 2); // menu A with 2 items in submenu A1 and A2
ob << Set Submenu(4, 3); // menu B with 3 items in submenu B1, B2, and B3
```

db<<Set Report Title(title)
Sets a new title. The title is quoted.

Show Properties(db)
Shows the messages a given display box can interpret.

db<<Sib
Returns the sibling of the display box.

db<<Sib Append(db2)
Appends a display as a sibling to this one. The argument must evaluate to a display box owner or reference.

db<<Size Window(x, y)
Resizes the containing window.

db<<Update Window
Updates the window that holds the display box (and possibly other windows as well, depending on the operating system) if there are invalidated regions. Previously invalidated box areas are redrawn with their new content.
Notes

In some interactive JSL scripts that combine sliders with JSL callbacks, you might need to use `<<Update Window` to keep parts of the display synchronized with the slider.

---

db<<Zoom Window

Resizes the window to be large enough to show all of its contents.

### Axis Boxes

**Axis Box<<Axis Settings(<named arguments>)**

Opens the Axis Specification window or specifies axis settings, such as tick marks and axis labels.

If no arguments are included, the axis specification window appears.

Otherwise, specify named arguments for each axis.

- Specify the Y axis as `Axis Box(1)`.
- Specify the X axis as `Axis Box(2)`.

#### Optional Named Arguments

**Scale("Linear"|"Log"|"Power"|"Geodesic"|"Geodesic US"|"Custom Scale"|"Normal Probability|Weibull Probability|Frechet Probability|Logistic Probability|Exponential Probability|Gamma Probability|Beta Probability|Mixture of 2 Normals Probabilities|Mixture of 3 Normals Probabilities)**

Specifies the scale of the axis. If the type is `Custom Scale`, this message expects two additional named arguments: `Scale to Internal(expr)` and `Scale to External(expr)`.

**Min(n)** Changes the minimum value on the axis.

**Max(n)** Changes the maximum value on the axis.

**Reverse Order(Boolean)** Reverses the axes by reversing the minimum and maximum values.

**Inc(n)** Shows the numbers at the specified increments.

**Set Font(font)** Specifies the quoted `font` that is applied to the numbers. The JMP Font preferences determine the default font.

**Set Font Size(points)** Specifies the size of the font that is applied to the numbers. The JMP Font preferences determine the default font.

**Set Font Style("Strikeout"|"Underline")** Specifies the quoted style that is applied to the numbers.
Automatic Font Size(\textit{Boolean}) JMP attempts to decrease the font size (down to a certain minimum) if all of the labels cannot fit at the default size. If 0, the font size is not decreased.

Automatic Tick Marks(\textit{Boolean}) Turns on tick marks only if one or more labels are hidden (due to insufficient space).

Label Orientation(  
"Automatic"|"Horizontal"|"Vertical"|"Perpendicular"|"Parallel"|"Angled ") Rotates the axis label. The default value is "Automatic", which is based on the width of the labels.

Lower Frame(\textit{Boolean}) Shows a frame below the labels. The default value is off.

Value Labels Displays the label that you specify instead of the data value.

Inside Ticks(\textit{Boolean}) Shows tick marks inside or outside of the axis.

Add Ref Line({Label Row Nesting(\textit{n}), begin range, \textless end range>,  
<"Solid"|"Dotted"|"Dashed"|"DashDot"|"DashDotDot">, \textless \textit{color}\textgreater, \textless \textit{label}\textgreater,  
<width(\textit{n})>, <opacity(\%)}>}) Defines the reference line range, line pattern, color, label, width, and opacity. A solid, black, 1-pixel line is the default setting. 

Label Row Nesting(\textit{n}) specifies the number of nested rows on the axis. The \textit{color} and \textit{label} arguments are quoted.

Categorical Axes

Wrap Lines(\textit{n}) Wraps long labels across multiple lines (\textit{n}).

Numeric Axes

Format(\textit{arguments}) Specifies the format of the numeric axis data. See the Format list in a numeric column’s column properties for arguments. If you specify the a datetime format, also include the Interval argument: "Numeric", "Year", "Quarter", "Month", "Week", "Day", "Hour", "Minute", or "Second".

Minor Ticks(\textit{number}) Specifies the \textit{number} of minor tick marks between major tick marks.

Tick Offset(\textit{number}) Specifies the starting point of the tick marks.

Major Ticks(\textit{Boolean}) Shows or hides a major tick mark between each number.

Minor Ticks(\textit{Boolean}) Shows or hides a minor tick mark between each number.

Show Major Grid(\textit{Boolean}) Shows or hides a grid line at each major tick mark.

Show Minor Grid(\textit{Boolean}) Shows or hides a grid line at each minor tick mark.

Major Grid Line Color(\textit{color}) Sets the color for the major grid (if enabled) using the quoted \textit{color}.

Minor Grid Line Color(\textit{color}) Specifies the color of the grid line at each minor tick mark.
Example

The following example creates a bivariate plot and defines basic settings for the X and Y axes.
```
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
biv = dt << Bivariate( X( :height ), Y( :weight ), FitLine );
rbiv = biv << Report;
xaxis = rbiv[Axis Box( 2 )];
yaxis = rbiv[Axis Box( 1 )];
xaxis << Axis Settings( Show Major Grid( 1 ) );
yaxis << Axis Settings( Decimal( 10, 3 ) );
```

Axis Box<<Add Axis Label(*quoted string*)

Adds an axis label with the specified quoted string.

Axis Box<<Add Ref Line(*number*, *linestyle*, *<color>* , *<label>* , *<width>* )

Adds a reference line at *number* in the specified *linestyle* ("Solid"|"Dashed"|"Double"), *color* (using the quoted *color*), quoted *label*, and *width* (in pixels).

Axis Box<<Decimal(*width*, *decimal places*)

Changes the numeric format for axis values.

Axis Box<<Format(*name*)

Changes to the numeric format given by the quoted *name*.

Axis Box<<Get Inc(*n*)

Gets the increment value of the axis.

Axis Box<<Inc(*n*)

Sets the increment between ticks.

Axis Box<<Interval(*format*)

Specifies the units used for Inc() with date/time formats: "Numeric", "Year", "Quarter", "Month", "Week", "Day", "Hour", "Minute", or "Second".
Axis Box<<Label Orientation(format)
    Rotates the axis label to one of the following formats: "Automatic" (the default setting based on the width of the label), "Horizontal", "Vertical", "Perpendicular", "Parallel", and "Angled".

Axis Box<<Major Grid Line Color(color)
    Sets the color for the major grid (if enabled) using the quoted color.

Axis Box<<Max(maximum)
    Changes the maximum value on the axis.

Axis Box<<Minor Grid Line Color(color)
    Sets the color for the minor grid (if enabled) using the quoted color.

Axis Box<<Min(minimum)
    Changes the minimum value on the axis.

Axis Box<<Minor Ticks(number)
    Specifies the number of minor tick marks between major tick marks.

Axis Box<<Remove Axis Label
    Removes any label added with Add Axis Label.

Axis Box<<Reverse Scale(Boolean)
    Reverses the normal scale direction so that the highest value is on the left or bottom (that is, closest to the origin).

Axis Box<<Revert Axis
    Restores the axis’ original settings (from time of creation).

Axis Box<<Scale(type)
    Changes the scale of the axis to type ("Linear"|"Log"|"Exp Prob"|"Weibull Prob"|"Logistic Prob"|"Frechet Prob"|"Normal"|"Cube Root"|"Johnson Su Scale")
"Geodesic"|"Geodesic US"|"Custom Scale"|"Power"|"Gamma Prob"|"Beta
Prob"|"Mixture of 2 Normals Prob"|"Mixture of 3 Normals Prob").

If the type is Custom Scale, this message expects two additional named arguments:
Scale to Internal(expr) and Scale to External(expr).

Axis Box<<Tick Font(name, <size>, <style/style style...>, <angle>)

Sets the font name (quoted), size, and quoted properties for tick marks. To specify more
than one style, include a space between each style and place them in quotes.

Axis Box<<Show Labels(Boolean)

Shows or hides labels for the axis values.

Axis Box<<Show Major Grid(Boolean)

Adds or removes grid lines at the major tick values.

Axis Box<<Show Major Ticks(Boolean)

Shows or hides major tick marks.

Axis Box<<Show Minor Grid(Boolean)

Adds or removes grid lines at the minor tick values.

Axis Box<<Show Minor Ticks(Boolean)

Shows or hides minor tick marks.

Axis Box<<Tick Label List(<i>, {text1, text2, ...},<{n1, n2, ...}>)

Sets the values and positions of the axis tick labels.

**Note:** Major tick increments are automatically set to 1.0 if the tick labels are not specified.

**Required Arguments**

{text1, text2, ...} Specifies the quoted string titles for your labels.

**Optional Arguments**

i Specifies the label row index. Leaving it out clears any existing label rows and creates
one new one as specified. Including it allows you to override any particular label row;
using an index higher than the current number of label rows adds a new label row on to
the end.

{n1, n2, ...} Specifies the values corresponding to each label. If the value list is
omitted, the labels will be on integer increments starting with 1.
Border Boxes

**Note:** Border boxes support only one display box argument.

---

**Border Box**<Set Background Color({r, g, b}|<color>)

Sets the background color for a border box. Specify an optional quoted list of RGB values or color. For example:

border box<<Set Background Color("red");

or

border box<<Set Background Color( {255, 192, 3} );

---

**Border Box**<Set Color({r, g, b}|<color>)

Sets the border color for a border box. Specify a list of RGB values or a quoted color. For example:

border box<<Set Color("red");

---

**Border Box**<Get Color

Gets the border color for a border box.

---

**Border Box**<Set Style(style)

Sets the border style for a border box. Specify the style as one of the following numbers or keywords: 0 ("Solid"), 1 ("Dotted"), 2 ("Dashed"), 3 ("DashDot"), or 4 ("DashDotDot"). For example:

border box<<Set Style("Dotted");

---

**Border Box**<Get Style

Gets the border style for a border box.

---

Data Browser Boxes

**dbb**<Set Data Table(<data table>)

Sets the data table for the data browser box.
Data Filter Source Boxes

\texttt{dfsbi\textless Set Row States}(dt, rs)\texttt{)}

Sets the row states for the given data table within the filter. Selections made in this row state will not be linked with the data table, but will be included in the reports linked to the selection filter.

Frame Boxes

\texttt{Frame Box\textless Add Graphics Script}(<order>, <description>, <script>)\texttt{)}

\textbf{Description}

Adds a script to draw graphics in the frame box.

\textbf{Optional Arguments}

- \texttt{order} Specifies the order in which the graphics elements are drawn. The value can be the keyword "Back" or "Forward" or an integer that specifies the drawing order for a number of graphics element. 1 means the object is drawn first.
- \texttt{description} A quoted string that appears in the Customize Graph window next to the graphics script. The \texttt{description} argument is quoted.
- \texttt{script} A JSL script.

\textbf{Example}

In the following example, the graphics script draws the line first and then draws the other graphics elements: the grid lines, references lines, and markers that create the bivariate plot. Without the 1 order argument, the line is drawn last and covers up the markers.

\begin{verbatim}
dt = Open( "\$SAMPLE_DATA/Big Class.jmp" );
obj = dt << Bivariate( Y( :weight ), X( :height ) );
Report( obj )[FrameBox( 1 )] <<
Add Graphics Script( 1, // draws the line first
Description( "Pen Script" ),
Pen Color( "red" );
Pen Size( 5 );
Y Function( 60 + 120 / 2 * (1 + Sine( (2 * Pi() * (x - 50)) / 22.5 )), x );
);
\end{verbatim}

\texttt{Frame Box\textless Append Seg}

Adds a display seg to the specified Frame Box.
Frame Box<<Background Color({RGB values}|<color>)
Changes the background color. Specify a list of RGB values or a quoted color.

Frame Box<<Child Seg
Returns the display seg child of the Frame Box.

Frame Box<<Edit Graphics Script
Brings up a dialog box to view, edit, or delete the current graphics scripts.

Frame Box<<Find Seg
Returns a display seg with the specified argument (for example, the name of a seg).

Frame Box<<Frame Size(x, y)
Resets the size of the frame, in pixel units.

Frame Box<<Make Table of Graphs Like This
Creates a data table of graphs.

Frame Box<<Marker Size(size)
Changes the marker size. The values are 0 (dot), 1 (small), 2 (medium), and so on.

Frame Box<<Row Colors(color) Frame Box<<Row Markers(marker)
Frame Box<<Row Exclude(Boolean)
Frame Box<<Row Hide(Boolean)
Frame Box<<Row Label(Boolean)
Forwards commands to the data table associated with the report, so that the row states of selected rows can be manipulated. For Row Exclude, Row Hide, and Row Label, omitting the argument toggles the option. If the option is off, the message turns it on. If the option is on, the message turns it off.

frame box<<Set Background Fill(Boolean)
Enables or disables filling the background with the background color. Use this option when you want to paste a graph and make the background transparent.

Example

dt = Open("$SAMPLE_DATA/Big Class.jmp");
biv = Bivariate( y( weight ), x( height ) );
rbiv = biv << Report;
framebox = rbiv[Frame Box( 1 )];
// set background color
framebox << Background Color( "red" );
// for demonstration purposes: wait to see the color change
Wait( 1 );
// turn off background fill color
framebox << Set Background Fill( 0 );

framebox<<X Axis(<Min(minimum)>, <Max(maximum)>, <Inc(n)>, <named arguments>)
Scales the X coordinate system.

framebox<<Y Axis(<Min(min)>, <Max(max)>, <Inc(n)>, <named arguments>)
Scales the Y coordinate system.

Display 3D Boxes

Graph 3D Box()
Sends display commands to the 3D plot.

Excerpt Boxes

Excerpt Box(rptnum, lstSubscripts)
Returns a display box containing the excerpt designated by the report held at number rptnum and the list of display subscripts lstSubscripts. The subscripts reflect the current state of the report after previous excerpts have been removed.

Filter Col Selector

Filter Col Selector(<Data Table(name)>, <width(pixels)>, <nLines(n)>, <script>, <onChange(expr)>)
Returns a display box that contains a list of items. The control supports column filtering.
Global Boxes

\[
\text{Global Box}(\text{value})
\]

Creates a display box that shows the value of a global variable.

Hier Boxes

\[
\text{Hier Box}(\text{title}, \text{Hier Box}(\ldots), \text{Hier Box}(\ldots), \ldots)
\]

Returns a display box with the \textit{title} (quoted) that contains a hierarchy of quoted strings.

Matrix Boxes

\[
\text{Matrix Box}<<\text{Get}
\]

Returns the matrix contents.

\[
\text{Matrix Box}<<\text{Make Into Data Table}(\langle\text{Invisible(\text{Boolean})|Private(\text{Boolean})}\rangle)
\]

**Description**

Turns the matrix into a new data table. \texttt{Invisible(1)} hides the data table from view. An invisible data table can be open from the JMP Home Window or the Window menu. \texttt{Private(1)} opens the data table without displaying it in a data table window. A private data table is generally for scripts that want better control of the data table by not exposing it to general use.

**Returns**

A reference to the new data table.

\[
\text{Matrix Box}<<\text{Set Format}(\langle\text{width}, \langle\text{decimal places}\rangle, \langle\text{"Use Thousands Separator"}\rangle)\rangle)
\]

**Description**

Sets the numeric format for matrix elements.

**Arguments**

A number of other formats can be set on matrix boxes. See “\texttt{Number Col Box}<<\text{Set Format}(\langle\text{width}\rangle|\langle\text{width, decimal places}\rangle, \langle\text{"Use Thousands Separator"}\rangle)” on page 440 for more information about the syntax.
Matrix Box<<Sort(column number, ascending)

Sorts the rows of the matrix based on the column number specified by column_num. The default sort order is ascending.

If column number is 0, the sort is removed.

ascending is a Boolean value. If ascending is "True", the sort is performed in ascending order. If ascending is "False", the sort is in descending order.

Nom Axis Boxes

Nom Axis Box<<Divider Lines(Boolean)

Adds or removes divider lines between labels in the axis box.

Nom Axis Box<<Lower Frame(Boolean)

Adds or removes a lower frame around the axis.

Nom Axis Box<<Rotated Tick Labels(Boolean)

Rotates or unrotates the labels at each tick value.

Number Col Boxes

Number Col Box<<Add Element(item)

Adds the item to the Number Col Box. item can be a single number, a list of numbers, or a matrix.

Number Col Box<<Bootstrap(nsample, Random Seed(number), Fractional Weights(Boolean), Split Selected Column(Boolean), Discard Stacked Table if Split Works(Boolean)

Description

Bootstraps the analysis, repeating it many times with different resampling weights and collecting tables as selected.

Arguments

tnsample Sets the number of times that you want to resample the data and compute the statistics. A larger number results in more precise estimates of the statistics’ properties. By default, the number of bootstrap samples is set to 2,500.

Random Seed(number) Sets a random seed that you can re-enter in subsequent runs of the bootstrap analysis to duplicate your current results. By default, no seed is set.
Fractional Weights(\textit{Boolean}) Performs a Bayesian bootstrap analysis. In each bootstrap iteration, each observation is assigned a weight that is calculated as described in \textit{Basic Analysis}. The weighted observations are used in computing the statistics of interest. By default, the fractional weights option is not selected and a simple bootstrap analysis is conducted.

\textbf{Split Selected Column(\textit{Boolean})} Places bootstrap results for each statistic in the column that you selected for bootstrapping into a separate column in the Bootstrap Results table. Each row of the Bootstrap Results table (other than the first) corresponds to a single bootstrap sample.

If you exclude this option, a Stacked Bootstrap Results table appears. For each bootstrap iteration, this table contains results for the entire report table that contains the column that you selected for bootstrapping. Results for each row of the report table appear as rows in the Stacked Bootstrap Results table. Each column in the report table defines a column in the Stacked Bootstrap Results table.

\textbf{Discard Stacked Table if Split Works(\textit{Boolean})} (Applicable only if the Split Selected Column option is included.) Determines the number of results tables produced by Bootstrap. If the Discard Stacked Table if Split Works option is not selected, then two Bootstrap tables are shown. The Stacked Bootstrap Results table, which contains bootstrap results for each row of the table containing the column that you selected for bootstrapping, gives bootstrap results for every statistic in the report, where each column is defined by a statistic. The unstacked Bootstrap Results table, which is obtained by splitting the stacked table, provides results only for the column that is selected in the original report.

\begin{itemize}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Get}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Get(} \textit{i} \textbf{)}
    \begin{itemize}
      \item Gets the values in a list, or the \textit{i}th value.
    \end{itemize}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Get As Matrix}
    \begin{itemize}
      \item Gets the values in a matrix, specifically a column vector.
    \end{itemize}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Get Format}
    \begin{itemize}
      \item Returns the current format.
    \end{itemize}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Get Heading}
    \begin{itemize}
      \item Returns the column heading text.
    \end{itemize}
  \item \textbf{Number Col Box}\textless\textasciitilde\textbf{Remove Element(} \textit{row number} \textbf{)}
    \begin{itemize}
      \item Removes an element from the column at the specified position.
    \end{itemize}
\end{itemize}
Number Col Box<<Set Format(<width>|<width, decimal places>, <"Use Thousands Separator">)

Number Col Box<<Set Format("Best", <width>, <"Use Thousands Separator">)

Number Col Box<<Set Format("Fixed Dec"|"Percent"), <width>|<width, decimal places>, <"Use Thousands Separator">)

Number Col Box<<Set Format("Scientific"|"Engineering"|"Engineering SI"), <width>|<width, decimal places>)

Number Col Box<<Set Format("Precision", <width>|<width, decimal places>, <"Use Thousands Separator">, <"Keep Trailing Zeroes">, <"Keep All Whole Digits">)

Number Col Box<<Set Format("Currency", <currency code>, <width>|<width, decimal places>, <"Use Thousands Separator">)

Number Col Box<<Set Format(datetime, <width>, <input format>)

Number Col Box<<Set Format("Latitude DDD"|"Latitude DDM"|"Latitude DMS"|"Longitude DDD"|"Longitude DDM"|"Longitude DMS"), <width>|<width, decimal places>, (<"PUN"|"DIR"|"PUNDIR"))

Number Col Box<<Set Format("Custom", Formula(...), <width>, <input format>)

Description
Sets the column format.

Arguments
Using JMP describes the arguments. Note that Matrix Box(), Number Col Box(), Number Col Edit Box(), Number Edit Box() have the same Set Format syntax.

Examples
<<Set Format( 10, 2, "Use thousands separator");
<<Set Format( "Currency", "EUR", 20, );
<<Set Format( "m/d/y", 10 );
<<Set Format( "Precision", 10, 2, "Keep trailing zeroes", "Keep all whole digits" );
<<Set Format( "Latitude DDD", "PUNDIR"); // "PUN" for punctuation, "DIR" for direction, PUNDIR for both
<<Set Format( "Custom", Formula( Abs( value ) ), 15 );

Notes
• For a list of currency codes, see Scripting Guide. The currency code is based on the locale if the code is omitted.
• If you don’t specify the format, set the decimal places to greater than 100 for datetime values and to 97 for p-values.
• You must always precede the number of decimal places with the width.
• Options can be defined in a list or a variable, or they can be in a Function() that is evaluated.
  ncbFunc = Function({}, {"Fixed", 12, 5});

  number col box<<Set Heading(quoted string)
  Changes the column heading text.

**Number Col Edit Boxes**

**Number Col Edit Box<<Set Format(\textless width\textgreater, \textless decimal places\textgreater, \text{"Use Thousands Separator"}\textmid\textless other options\textgreater)**

**Description**
Sets the column format.

**Arguments**
A number of other formats can be set on number col edit boxes.

**See Also**
“Number Col Box<<Set Format(\textless width\textgreater|\textless width, decimal places\textgreater, \text{"Use Thousands Separator"})” on page 440

**Number Col Edit Box<<Remove Element(x position, y position, i)**
Removes an element from the column at the specified position.

**Number Edit Box**

**Number Edit Box<<Set Format(\textless width\textgreater, \textless decimal places\textgreater, \text{"Use Thousands Separator"}\textmid\textless other options\textgreater)**

**Description**
Sets the column format.

**Arguments**
A number of other formats can be set on number edit boxes.

**See Also**
“Number Col Box<<Set Format(\textless width\textgreater|\textless width, decimal places\textgreater, \text{"Use Thousands Separator"})” on page 440
Outline Boxes

Outline Box<<Close(Boolean)
Closes the outline box.

Outline Box<<Close All Below
Closes all the node’s child nodes.

Outline Box<<Close All Like This
Closes all nodes similar to this outline box.

Outline Box<<Close Where No Outlines
Closes all nodes that do not have children.

Outline Box<<Get Title
Gets the title of the outline box.

Outline Box<<Horizontal(Boolean)
Horizontally aligns the node’s children.

Outline Box<<Open All Below
Opens all the node’s child nodes.

Outline Box<<Open All Like This
Opens all nodes similar to this outline box.

Outline Box<<Set Menu Script({quoted string1, script1, quoted string2, script2, ...})
Adds an entry to the menu when the red triangle on an outline box is selected.

Outline Box<<Set Title(title)
Specifies the quoted title of the outline box.
Panel Boxes

Panel Box<<Get Title
Gets the title of the panel box.

Panel Box<<Set Title(title)
Specifies the title (quoted) of the panel box.

Plot Col Boxes

Plot Col Box<<Get As Matrix
Gets the values in a matrix, specifically a column vector.

Plot Col Box<<Get Labels
Gets the labels for each row.

Plot Col Box<<Remove Element(row number)
Removes an element from the column at the specified position.

Plot Col Box<<Set Labels({list})
Sets the labels for each row.

Plot Col Box<<Set Scale(minimum, maximum, "format", width, decimal places, "Use Thousands Separator")
Description
Specifies the minimum and maximum values of the horizontal axis.

Arguments
The format arguments specify a format that is used when the first two arguments are 0 and 1. A number of formats can be set on plot col boxes. See “Number Col Box<<Set Format(width|width, decimal places, "Use Thousands Separator")” on page 440 for more information about the syntax.

Plot Col Box<<Set Values([matrix] or {list})
Sets values for the matrix (for numeric variables) or list (for character variables).
Slider Boxes and Range Slider Boxes

Slider Box<<Get(<index>)
Range Slider Box<<Get Lower(<index>)
Range Slider Box<<Get Upper(<index>)

Returns the current value of the slider.

Slider Box<<Get Max()

Returns the maximum value possible for the range slider and slider.

Slider Box<<Get Min()

Returns the minimum value possible for the range slider and slider.

Slider Box<<Get Var
Range Slider Box<<Get Lower Var
Range Slider Box<<Get Upper Var

Returns the variable name associated with the slider.

Slider Box<<Set(float, <index>, <Run Script(Boolean)>)
Range Slider Box<<Set Lower(float, <index>, <Run Script(Boolean)>)
Range Slider Box<<Set Upper(float, <index>, <Run Script(Boolean)>)

Sets the value of the slider. Run Script(Boolean) controls whether an on-change script runs after the Set, Set Lower, or Set Upper message.

Slider Box<<Set Max(float, <index>)

Sets the maximum value possible for the range slider and slider.

Slider Box<<Set Min(float, <index>)

Sets the minimum value possible for the range slider and slider.

Slider Box<<Set Script(<script>)

Sets a script to be run when the range sliders and slider is updated.
Slider Box<<Set Var(slider variable)
Range Slider Box<<Set Lower Var(slider variable)
Range Slider Box<<Set Upper Var(slider variable)
Sets the variable name associated with the slider.

\textbf{quoted string Col Boxes}

\textbf{quoted string Col Box<<Add Element(item)}
Adds the item to the quoted string Col Box. Item can be a single quoted string or a list of quoted strings.

\textbf{quoted string Col Box<<Get}
\textbf{quoted string Col Box<<Get(i)}
Gets the values in a list or the \(i\)th value.

\textbf{quoted string Col Box<<Get Heading}
Returns the column heading text.

\textbf{quoted string Col Box<<Remove Element(row number)}
Removes an element from the column at the specified position.

\textbf{quoted string Col Box<<Set Allow Text Search(Boolean)}
\textbf{Description}
In table boxes with selectable rows, allows a quoted string column that has focus to respond to keyboard input to change the selected row.

\textbf{Example}
\begin{verbatim}
// Run the example.
// Select K2.
// Type the letter g. Notice the last row is selected.
// Type the letters ki. Notice the third row is selected.
New Window( "Mountains",
    tb = Table Box(
        sb =
            quoted string Col Box( "Mountain",
                {"K2", "Delphi", "Kilimanjaro",
                    "Grand Teton"}
            ),
        )
    ),
\end{verbatim}
Number Col Box( "Elevation (meters)",
{8611, 681, 5895, 4199}
),
Plot Col Box( "", {8611, 681, 5895, 4199} )
);
tb << Set Selectable Rows( 1 );
sb << Set Allow Text Search( 1 );

quoted string Col Box<<Set Heading(title)
Changes the column heading specified in the quoted title.

quoted string Col Box<<Set Justify(Justification)
Specifies the alignment of the contents in the quoted string col box to "Right", "Left", or "Center".

Tab Boxes

Tab Box<<Get Tab Margin()
Returns a list of the current margins in pixels for the tab box in this order: Left, Top, Right, and Bottom.

Tab Box<<Set Style("Tab"|"Combo" |"Outline"|"Vertical Spread"|"Horizontal Spread"|"Minimize Size")
Changes the appearance of the tab box from a tab to a combo box or outline node.
"Vertical Spread" and "Horizontal Spread" change the orientation of the tab title.
"Minimize Size" bases the tab style on the width of the tab title.

Tab Box<<Set Tab Margin(n|{...})
Sets the tab margin for the tab box. If a single number is specified, all four margins are set to that number of pixels. If a list of two numbers is specified, the left and right margins are set to the first number, and the top and bottom margins are set to the second number. If a list of four numbers is specified, the margins are set in this order: {left, top, right, bottom}.
Tab Box<<Show Tabs(Boolean)

Shows or hides the tabs for tab boxes. If you hide the tabs, you need to provide another way to select and show tabs. For example, a list box that contains a list of references to the tabs. The default value is 1.

Table Boxes

Table Box<<Bootstrap(nsampale, Random Seed(number), Fractional Weights(Boolean), Split Selected Column(Boolean), Discard Stacked Table if Split Works(Boolean)

Description

Bootstraps the analysis, repeating it many times with different resampling weights and collecting tables as selected.

See Also

“Number Col Boxes” on page 438

Table Box<<Get

Gets the entries of the table in list form.

Table Box<<Get As Matrix(<"Visible">)

Gets the numeric entries of the table in matrix form. "Visible" means that only visible columns will be included.

Table Box<<Get Click Sort

Returns 1 if the table can be sorted by clicking a column header and 0 otherwise.

Table Box<<Get Locked Columns

Returns the number of columns that cannot be dragged with the cursor or have any columns dropped before them.

Table Box<<Get Row Change Function

Returns the expression that is evaluated when a row is selected.

Table Box<<Get Selectable Rows

Returns True if the table box currently allows row selection.
Table Box<<Get Selected Row Color

Returns the index number of the background color of the selected rows in the table box.

Table Box<<Make Combined Data Table

Returns a reference to the data table. Same as Make Data Table, but also searches the report for report tables with the same columns and combines all of these into the new data table.

Table Box<<Make Data Table(name)

Returns a reference to the data table. Turns the table entries into a new data table with the quoted name argument.

Table Box<<Reorder Columns(from column index, to column index)

Puts the column specified with from column index in the place of the column specified with to column index. The indexes are 0-based. For example, indicate the first column with “0”, and indicate the second column with “1”.

Table Box<<Set Cell Changed Function(Function({this, col box, row},<script>))

Description

Sets a function that is called whenever the user edits a cell in a column in a table.

Example

This example prints the new values for the changed cell to the log.

```julia
New Window( "Mountains",
    tb = Table Box( 
        quoted string Col Edit Box( 
            "Mountain",
            {"K2", "Delphi", "Kilimanjaro", 
                "Grand Teton"}
        ),
        Number Col Edit Box( 
            "Elevation (meters)",
            {8611, 681, 5895, 4199}
        ),
        Plot Col Box( "", {8611, 681, 5895, 4199} )
    );
    tb << 
    Set Cell Changed Function(
        Function( {this, col, row},
```
Print(
  (col << Get Heading) || " row:" ||
  Char(3) || " is now " ||
  Char(col << Get(row))
)
);

Table Box<<Set Click Sort(Boolean)
   Specifies if the table can be sorted by clicking a column header.

Table Box<<Set Column Borders(Boolean)
   Draws a line on each side of the column.

Table Box<<Set Heading Column Borders(Boolean)
   Draws a line on each side of the column headings.

Table Box<<Set Locked Columns(n)
   Locks the first n columns. You cannot drag the locked columns or drag columns before them.

Table Box<<Set Row Borders(Boolean)
   Draws a line above and below each row.

Table Box<<Set Row Change Function(function)
   Sets the expression that is evaluated when a row is selected.

Table Box<<Set Selectable Rows(Boolean)
   Makes the rows of the table box selectable or not.

Table Box<<Set Selected Row Color(color)
   If the rows of the table box are selectable (Set Selectable Rows(True)), sets the background color (specified in the quoted color argument) for the selected rows.

Table Box<<Set Shade Cells(Boolean)
   Shades the background of every cell in the table.
Table Box<<Set Shade Alternate Rows(Boolean)
Shades the background of every other row in the table.

Table Box<<Set Shade Heading(Boolean)
Shades the background in column headings.

Table Box<<Set Underline Headings(Boolean)
Draws a line underneath the column headings.

Table Box<<Sort By Column(<column number|column title>, <Ascending(Boolean)>)
Sorts all rows based on the values in the specific column number or quoted column title. The default order sorting is descending.

Text Boxes

Text Box<<Font Color(n)
Sets the color for Text quoted strings.

Text Box<<Get Hidden State
Returns the current state of a text box.

Text Box<<Get Text
Returns the quoted string content of the box.

Text Box<<Get Tip
Returns the tooltip for the text box (or a text edit box).

Text Box<<Markup
Returns text formatted with the specified HTML tags. The HTML must be well-formed; make sure you close nested tags correctly.

The following example returns text formatted in bold, italic, and underlined.

w = New Window( "Formatted Text",
    Text Box( "This is <b>b</b>old</b> text. This is <b><i>i</i>b</b>old italic</i> text. This is <u>u</u>nderlined</u> text.",
    <<Markup) );
**TextBox**<<**Rotate Text**(*direction*)

Rotates the text 90 degrees "Left" or "Right", or returns it to horizontal.

**TextBox**<<**Set Font**(*name*, *<size>*[, *<style|style style...>*[, *<angle>*]])

Sets the font specified in the quoted *name* argument and the properties for text quoted strings. To specify more than one style, include a space between each *style* and place them in quotes.

**TextBox**<<**Set Font Size**(*n*)

Sets the font size in points for text quoted strings.

**TextBox**<<**Set Script**(*script*)

Associate a script with a text box. The script executes when the user presses Enter (or the text edit box otherwise loses focus).

**TextBox**<<**Set Text**(*quoted string*)

Sets the text in the box as specified in the quoted *string* argument.

**TextBox**<<**Set Tip**(*quoted string*)

Sets the tooltip for the text box (or a text edit box) as specified in the quoted *string* argument.

**TextBox**<<**Set Wrap**(*n*)

Set the wrap point, in pixels, in pixels (*n*).

---

**Tree Node and Tree Box**

For the following messages, *node* stands for a tree node or a reference to one and *root* stands for a tree box or a reference to one.

**Caution:** If you send a root node that contains one or more nodes with the **Set Node Select Script** defining a collapse message, then macOS runs the script twice. Windows doesn’t run the script. This behavior on macOS doesn’t just affect increments. Any script runs twice. It will print to the log twice, create a column twice, try to delete something twice, and so on.

**node**<<**Append**(*<node>*)

Inserts a referenced tree node after this node’s children.
node<<Collapse

Closes the node. The behavior is not guaranteed if the node has a collapsed parent.

node<<Expand

Opens the node. The behavior is not guaranteed if the node has a collapsed parent.

node<<Get Dimmed(<node>)

Gets the option to dim text (decrease the opacity) for the node.

node<<Get Font Style(<node>)

Gets the font style for the node.

node<<Get Tip

Returns the tooltip for the node.

node<<Prepend(<node>)

Inserts a tree node before this node's children.

node<<Remove

Removes the given tree node and all its children from the tree display box.

node<<Set Dimmed(Boolean)

Sets the option to dim text (decrease the opacity) for the node.

node<<Set Font Style("Plain"|"Bold")

Specifies the font style for the node.

node<<Set Selected(<node>)

Selects the node. The behavior is not guaranteed if the node has a collapsed parent.

node<<Set Tip(tooltip)

Sets a tooltip for the node. The tooltip argument is quoted.

root<<Collapse(<node>)

Collapses the given tree node.
root<<Expand(<node>)

Expands the given tree node.

root<<Get Selected(<node>)

Gets the currently selected tree node.
- In a single-item tree, the currently selected tree node or Empty is returned.
- Table 3.1 shows the results for a Tree Box() that contains the MultiSelect argument.

Table 3.1 Multi-Select Tree Results

<table>
<thead>
<tr>
<th>Items Selected in Tree</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>no items selected</td>
<td>empty</td>
</tr>
<tr>
<td>single item selected</td>
<td>list of one tree node</td>
</tr>
<tr>
<td>multiple items selected</td>
<td>list of selected tree nodes</td>
</tr>
</tbody>
</table>

root<<Is Multiselect

Returns 1 for a MultiSelect tree and 0 for a single-select tree.

root<<Set Selected(node|{nodes}, <Boolean>)

Selects the given tree node in the tree display box. In list of tree nodes, all nodes in the list are selected for MultiSelect trees. Otherwise, the first node in the list is selected. Specify the Boolean argument to indicate whether the node or nodes should be selected or unselected. The default value is 1, which selects the nodes.

Notes:
- On Windows, the Set Selected message expands all nodes between the selected node or nodes and the root of the tree; items that are selected deep within the tree are shown. The expansion state does not change for nodes that were previously selected.
- On macOS, the Set Selected message does not change the tree expansion state.

Triangulation

For the following messages, tri stands for a triangulation or a reference to one.

tri<<Get N Points

Returns the number of unique points in the triangulation.
tri<<Get Points
   Returns the coordinates of the unique points in the triangulation.

tri<<Get Y
   Returns the Y values of the unique points in the triangulation.

tri<<Get N Hull Points
   Returns the number of points on the boundary of the triangulation.

tri<<Get Hull Points
   Returns the indices of the points on the boundary of the triangulation.

tri<<Get N Hull Edges
   Returns the number of edges on the boundary of the triangulation.

tri<<Get Hull Edges
   Returns the indices of the edges on the boundary of the triangulation.

tri<<Get Hull Path
   Returns the boundary of the triangulation as a path.

tri<<Get N Triangles
   Returns the number of triangles.

tri<<Get Triangles
   Returns the indices of the triangles in the form of an Nx3 matrix.

tri<<Get N Edges
   Returns the number of edges in the triangulation.

tri<<Get Edges
   Returns the indices of the edges in the form of an Nx2 matrix.

tri<<Subset({indices})
   Returns a triangulation resulting from the given subset of points.
tri<<Peel

Peel the boundary layer of a triangulation, returning a new triangulation.

Windows

window<<Bring Window to Front

Brings the window to the front.

window<<Close Window(<nosave>)

Closes the window. If the optional argument nosave is specified, the window (journal, report, and so forth) is closed without saving or prompting.

window<<Get Content Size

Returns the size of the window’s contents.

window<<Get Window Icon

Returns the name of the window’s icon.

window<<Get Window Position

Returns the position of the window.

window<<Get Window Size

Returns the size of the window.

window<<Get Window Title

Returns the title of the window.

window<<Inval

Invalidate the display box. The window updates either when the <<Update Window message is sent or when the operating system has time for the update. See “window<<Reshow” on page 456 for another method.

window<<Maximize Display

Maximizes the window. Deprecated.
window<<Maximize Window(Boolean)
   Maximizes the window. Deprecated.

window<<Minimize Window(Boolean)
   Minimizes the window.

window<<Move Window(x, y)
   Moves the window to the specified position.

window<<On Close(script)
   Runs the script when the window is closed.

window<<Pad Window(Boolean)
   Turns padding around a window’s contents on (1) or off (0). The default value is off.

window<<Print Window
   Prints the window to the default printer. Note that the Print window is not opened and user input is not required.

window<<Reshow
   Invalidates the display box and updates the window with the new content. See <<Inval and <<Update Window messages if more control over timing of the update is required.

window<<Save Window to Report(pathname, <Embed Data(Boolean)>)
   Saves the current report window to a JMP report file (.jrp).

window<<Set Main Window
   Sets the specified window as the default window that appears when JMP is run.

window<<Set Window Icon(icon name)
   Sets the window’s icon as specified in the quoted icon name argument.

window<<Set Window Size(x, y)
   Resizes the window.
window<<Show Window(Boolean)

1 shows the window (only if the window is not currently open). 0 hides the window. If the window is also minimized (on Windows) or docked (on macOS), showing the window restores it to the normal state and brings it to the front.

window<<Size Window(x, y)

Resizes the window.

window<<Update Window

Updates or refreshes the window holding the display box if there are invalidated regions. See “window<<Inval” on page 455 and “window<<Reshow” on page 456 for additional methods.

window<<Window Class Name

Returns the name of the window class for the display box. Valid responses include: DataTable, FormulaEditor, Starter, Journal, Launcher, Report, Dialog, DialogWithMenu, ModalDialog, FindReplace, User, Generic, ToolWindow, FindReplace, AppBuilder, and Debugger.

window<<Zoom Window

Resizes the window to be large enough to show all of its contents.

Dynamic Link Libraries (DLLs)

dll object<<Call DLL(function name, signature, arguments)

Calls the specified function in the DLL with the specified signature and arguments.

dll object<<Declare Function(name, <named arguments>)

Description

Declares the return type and argument types for the specified function so that it can be successfully invoked. You can use one of the named arguments for Convention: "STDCALL" or "PASCAL", or "CDECL". The type argument for Returns takes the same named arguments as Arg. The name argument is quoted.

Optional Named Arguments

Alias(name) Specifies a quoted name that you can include if you don’t like the name encoded in the DLL.
Arg(<type>, <description>, <access mode>, <array>) Arg can appear multiple times, once for each argument to be sent to the function.

type is one of these keywords that specifies the argument type: "Int8", "UInt8", "Int16", "UInt16", "Int32", "UInt32", "Int64", "UInt64", "Float", "Double", "Ansiquoted string", "Unicodequoted string", "Struct", "IntPtr", "UIntPtr", or "ObjPtr".

description is a quoted string that describes the argument for reference.

access mode is an optional keyword that specifies how the argument is passed. "input" specifies that the argument is passed by value. "output" specifies that the argument is passed by address with the initial value undefined. "update" specifies that the argument is passed by reference and the value of the JSL variable is set as the initial value. The default value is "input".

array is an optional keyword. It is valid only if the type is specified as "Double" and the access mode is specified as either "input" or "update". Specifies that the exported function expects an array of doubles.

Convention(calling convention) Specifies the calling convention: "STDCALL" or "PASCAL", or "CDECL". The default value is "STDCALL". STDCALL and PASCAL are equivalent.

MaxArgs(n) Specifies the maximum number of arguments that can be supplied.

MinArgs(n) Specifies the minimum number of arguments that can be supplied.

Returns(type) Specifies the data type that the function returns: "Int8", "UInt8", "Int16", "UInt16", "Int32", "UInt32", "Int64", "UInt64", "Float", "Double", "Ansiquoted string", "Unicodequoted string", "Struct", "IntPtr", "UIntPtr", or "ObjPtr".

StackOrder(order) Specifies the order in which arguments are placed on the stack when calling the function. Valid values are "L2R" (left-to-right) and "R2L" (right-to-left). The default value is "R2L".

StackPop(pop) Specifies how the exported function expects the stack to be cleared after the function returns. Valid values are "CALLER" and "CALLEE". The default value is "CALLEE".

StructArg(Arg(...), <Arg(...>), ..., <access mode>, <pack mode>, <description>) Can appear multiple times. If an exported DLL function requires that a structure argument be passed in as an argument, use StructArg to declare the structure members. The Arg arguments use the same syntax as for Arg arguments to Declare Function (one for each structure member), an access mode indicator and a pack mode indicator.

access mode is an optional keyword that indicates whether the struct argument should be passed by value (input) or by reference (update).

pack mode is an optional integer that determines how the structure is packed. Valid values are 1, 2, 4, 8, and 16. The default value is 8.
description is an optional, quoted string that contains a description of the structure for reference.

dll object<<Get Declaration JSL
    Sends the declaration JSL from the DLL object to log.

dll object<<Load DLL(path, <AutoDeclare(Boolean|"Quiet"|"Verbose")>)
dll object<<Load DLL(path, <"Quiet"|"Verbose">)

Description
    Loads the DLL from the specified path.

Required Argument
    path  A quoted path that specifies where to load the DLL.

Optional Named Arguments
    AutoDeclare(Boolean|"Quiet"|"Verbose")  AutoDeclare(1) and AutoDeclare("Verbose") write verbose messages to the log. AutoDeclare("Quiet") turns off log window messages. If you omit this option, verbose messages are written to the log.
    Quiet|Verbose  When you use Declare Function, this option turns off log window messaging ("Quiet") or turns on log window messaging ("Verbose").

dll object<<Show Functions
    Sends the declared functions for the DLL object to the log.

dll object<<Unload DLL
    Unloads the DLL.

HTML 5

Web Report

webreport<<Publish(<Add Image(...)>, <Add Report(...)>, <Add Reports(...)>, <Public(Boolean)>, <Index(...)>, <User Name(...)>, <Password(...)|password function>),
<Prompt("IfNeeded"|"Always"|"Never")>, <URL(...)], <Publish Data(Boolean), Replace([id], Prompt("IfNeeded"|"Always"|"Never"))>

Description

Publishes the web report to the JMP server.

Returns

On success, the URL of the published report is returned.

Optional Arguments

Add Image Inserts an image at the top of the index page. Valid formats are "png", "bmp", "jpeg", "jpg", "tiff", and "tif". Title and Description are optional. Title appears above the image. Description appears below the image. Use File(filepath) or just a quoted string. Here is an example:

webrpt << Add Image( File( "C:\Users\Public\JMP\Projects\WebJMP\atlas.jpg" ), Title( "Atlas" ), Description( "Holding up the world as always." ) ) ;

Add Report Adds a report to publish within the web report.

Public(Boolean) Specifies whether the public has access to the report. By default, the report is private.

Index The name of the index page for multiple reports. You can also specify the description.

UserName Specifies the user name registered on the JMP server.

Password Specifies the user’s password. You can also define a password function.

Prompt Displays a window in which the user types the server URL, user name, and password.

URL The location that you are publishing to.

Publish Data(Boolean) Includes the data in the HTML. Reports contains static rather than interactive images. In a public report, you might not want to share the data.

Replace Replaces the report. Get the URL from the address field in the browser where the page is displayed.

Images

The Scripting Index provides examples for processing images. In JMP, select Help > Scripting Index to view this interactive resource.

Additional resources are available from the JMP File Exchange at https://community.jmp.com/community/file-exchange.

img<<Crop(Left(pix), Right(pix), Top(pix), Bottom(pix))

Creates a new image from an existing image to the specified dimensions (in pixels).
**img<<Filter(name, <n>)**

Filters the image based on the specified algorithm. Filtering is useful for cleaning up noise in the image.

**Note:** All of the JMP image filters are supported at the operating system level. Images that are processed on Windows might differ from images processed on macOS.

**Argument**

- **name** Specifies the quoted name of a JMP image filter. The following filters are available:
  - "Despeckle" removes defects (that is, speckles) from a scanned or captured image (for example, scratches, dust, etc.).
  - "Edge" identifies pixels in an image where the brightness changes sharply and darkens pixels with no sharp change. Edge detection is used to detect changes in surface, depth, material, and lighting.
  - "Enhance" reduces the contrast between pixels in a noisy image.
  - "Median" reduces noise (that is, the random variation) and smooths an image by comparing each pixel’s brightness with its neighbors’ and, if the value is very different, replaces it with the average of the neighbors’ values.
  - "Negate" creates the negative of the color or gray-scale image by changing each pixel color to its complementary color.
  - "Normalize" changes a color image’s pixels to use the full range of the file format’s number system. Normalization will make the image’s colors more intense.
  - "Sharpen" reduces blur by sharpening edges of an image.
  - "Contrast", $n$ brightens or darkens an image. A higher number ($>0.0$) brightens an image; a lower number ($<0.0$) darkens an image.
  - "Gamma", $n$ corrects the image visual display (brightness and intensity) to account for differences in monitor hardware. A higher number ($>1.0$) lightens the image; a lower number ($<1.0$) darkens the image.
  - "Reduce Noise", $n$ reduces the random variation (or noise) that occurs with higher ISO sensitivity or longer exposure times.
  - "Gaussian Blur", $\text{radius}$, $\text{sigma}$ reduces image noise and detail creating a smoother image. Radius is equal to the blur radius around each pixel and sigma is the standard deviation of the Gaussian distribution. Gaussian blur is commonly used when resizing or performing edge detection.

**img<<Flip Both**

Flips the image from left to right and top to bottom.
**img<<Flip Horizontal**

Flips the image from left to right.

**img<<Flip Vertical**

Flips the image from top to bottom.

**img<<Get EXIF**

Returns EXIF data from the image (such as the shutter speed and aperture value) in an associative array.

**img<<Get N Frames**

**Description**

Returns the number of frames in a multi-frame TIF or animated GIF file, where the number of frames begins with frame 0.

**Example**

The following example places a four-frame TIF file in a new window and shows the image that is in the first frame.

```julia
img = New Image( "$DOWNLOADS/Multiframe.tif" );
nframes = img << Get N Frames(); // return 4
img << Set Current Frame( 1 ); // show image 1
win = New Window( "Multi-Frame TIFF", img );
```

**img<<Get Size**

**img<<Size**

Returns a list containing the width and height (in pixels) of the image.

**img<<Rotate(degrees)**

Rotates the image by the specified number of degrees.

**img<<Save Image(path)**

Saves the image to the quoted path.

**img<<Scale(scale/xscale, yscale)**

Resizes the image by the specified dimensions. Provide one argument to resize both the width and height. Provide two arguments to resize the width and height separately.
Examples

```javascript
img = New Image( "$SAMPLE_IMAGES/tile.jpg" );
xs = 2;
img << Scale( xs );
New Window( "Tilex 2", img );

img = New Image( "$SAMPLE_IMAGES/tile.jpg" );
img << Scale( 2, 0.5 ); // scale image width by 2 and height by 1/2
New Window( "Tile squished", img );
```

Notes

Using `Scale` is an alternative to getting the size of the image, multiplying by the scale factor, and then setting the size.

```javascript
img<<Set Current Frame
```

Description

Sets the frame that shows in a multi-frame TIFF or animated GIF file. Specify 0 through the number of frames minus 1. For example, with four frames, you can specify frame 0 through frame 3.

See Also

“`img<<Get N Frames`” on page 462

```javascript
img<<Set Size(width, height)
```

Resizes the image to the specified dimensions (in pixels). To scale the image proportionally, specify a width and height that correspond to the aspect ratio in the original image.

```javascript
img<<Transparency(fraction)
```

Sets the transparency for the image where the fraction is between 0.0 (full transparency) to 1.0 (no transparency).

JMP Applications

The JMP Application Builder and JMP Dashboard Builder use the same infrastructure to design and execute applications and dashboards. Because a dashboard is a special form of an application, this section uses the term `application` to describe how both dashboard and application objects use scripting.

See the Scripting Index in the JMP Help menu for examples.
**JMP App**

The **JMP App** object is the main controller for JMP applications built by Application Builder or Dashboard Builder. Scripts both inside and outside of a JMP application can use a **JMP App** object.

A JMP application can have one of three states: initial (with no editor, and the application is not running), running, or editing. A **JMP App** object only exists in one state at a time; if you are editing a JMP Application and choose to run it, a copy of the JMP application is created before it is run.

```julia
app<<Combine Windows({reports or data tables})
```

**Description**

Combines the given list of platform reports or data tables into a new module. The application should be in the initial state when this message is sent.

```julia
app<<Debug
```

Invokes the JSL Debugger on a JMP application. The application script will run first. The Debugger then breaks as each module is created, invoking the module scripts. In the Debugger, set breakpoints to debug the scripts that are associated with the application or modules.

```julia
app<<Edit
```

Starts Application Builder on a JMP application that is in the initial state. There is no editor, and the application is not running.

```julia
app<<Get Modules
```

Gets the list of modules associated with an application. In Application Builder, each module corresponds to a tab in the workspace, which describes the layout and behavior for one type of window in the application.

```julia
app<<Get Namespace
```

The **JMP App()** object automatically creates an anonymous namespace for the variables created within the application script. Use this message to get a handle to this namespace to inspect or modify variables. There is a default symbol in this namespace called **thisApplication**, which holds a reference to the application itself.
app<<Get Windows

Gets a list of all windows created as instances of JMP app modules. Some modules might create more than one instance. All windows might not exist at the same time, so the number of windows might vary and might differ from the number of modules.

app<<Open File(path)

Resets the state of an existing application from a the .jmpapp or .jmappsource file. path is quoted.

app<<Relaunch Analysis

Creates a new copy of a running application and runs the new instance.

app<<Run

Runs the application. The application script runs first, and depending on settings, one or more JMP app module instance objects might be created automatically.

app<<Save Script to Add-In
app<<Save Script to Data Table
app<<Save Script to Journal
app<<Save Script to Script Window

Saves the script for the application to the given destination. An application script consists of a JMP App() object that contains the definition for the application. Scripts saved to an add-in, data table, or journal include a Run message to run the application. A script saved to the script window includes an Edit message to open Application Builder.

JMP App Module

A JMP application module is a definition of the display box layout and behavior for a single component in a JMP application or dashboard. Depending on the module type, the component might represent a window in the application or just part of a window.

module<<Create Instance

Use Create Instance within a JMP App() or JMP App Module() script to create an instance of a JMP app module. By default, one instance of each JMP application module is created when an application is run. For more complex applications with multiple windows, such as a launcher and report combination, it might be necessary to change the default settings and control how the module instance is created.
module<<Get Instance

Returns a handle to the application that owns a module.

JMP App Module Instance

The JMP application module instance is a running realization of a JMP app module, a window on the screen, or a collection of display box elements that can be inserted into another window.

inst<<Create Objects

Appears in the default template for a JMP app module script. This message controls the point at which the display and window for a module instance are created. The message appears in the script so that the script writer can choose to do certain setup before the objects are created. One example of this setup is for a parameterized application.

inst<<Get Box

Returns a handle to the top-most display box associated with a module instance. This might be useful to issue display or window commands, such as the Save to PDF or Close Window messages.

inst<<Get Namespace

Like JMP App(), each JMP application module instance also creates an anonymous namespace for all variables created in the module script. The namespace also includes all the variables that represent the display boxes in the module. This namespace contains a default symbol named thisModuleInstance that refers to itself.

inst<<Get User Data

inst<<Set User Data

Stores and retrieves a JSL value in the JMP application module instance. The value could be a number, quoted string, list, associative array, or other JSL type that is returned with the Type() function.

MATLAB

The MATLAB interfaces are scriptable using a MATLAB connection object. Use the MATLAB Connect() JSL function to obtain a scriptable MATLAB connection object.
mlconn<<Control(<Echo(Boolean)>, <Visible(Boolean)>)

Controls the execution of MATLAB.

**Returns**

None.

**Optional Global Arguments**

Echo(Boolean)  Echo MATLAB source lines to the JMP Log window.
Visible(Boolean)  Determine whether to show or hide the active MATLAB workspace.

mlconn<<Disconnect()

**Description**

Disconnects this MATLAB integration interface connection.

mlconn<<Execute({list of inputs}, {list of outputs}, mCode, <Expand(Boolean)>, <Echo(Boolean)>)

Submits MATLAB code to the active global MATLAB integration interface connection given a list of inputs and upon completion a list of outputs are retrieved.

**Returns**

0 if successful, otherwise nonzero.

**Required Arguments**

{list of inputs}  Positional, name list. List of JMP variable names to be sent to MATLAB as inputs.
{list of outputs}  Positional, name list. List of JMP variable names to be retrieved from MATLAB as outputs.
mCode  Positional, quoted string. The MATLAB code to submit.

**Optional Named Arguments**

Expand(Boolean)  Performs an Eval Insert on the MATLAB code prior to submission.
Echo(Boolean)  Echos MATLAB source lines to the JMP Log window. Default is true.

mlconn<<Get Graphics(format)

Gets the last graphic object written to the MATLAB graph display window. The graphic object can be returned in several graphic formats.

**Returns**

JMP Picture object.

**Optional Argument**

format  Positional. The quoted format the MATLAB graph display window contents are to be converted to. Valid formats are "png", "bmp", "jpeg", "jpg", "tiff", and "tif".
mlconn<<Get Version()

Gets the current version of the installed MATLAB.

Returns
Matrix, returns a vector of length 3 containing the MATLAB version number.

mlconn<<Get(name)

Description
Gets a named variable from MATLAB to JMP.

Returns
Value of named variable.

Required Argument
name Positional. The name of a JMP variable to be retrieved from MATLAB.

mlconn<<Is Connected()

Description
Determines whether connection is active.

Returns
1 if connected, otherwise 0.

mlconn<<JMP Name To MATLAB Name(jmp name)

Description
Maps a JMP variable name to its corresponding MATLAB variable name using MATLAB variable name naming rules.

Returns
A quoted string, a mapped MATLAB name.

Required Argument
jmp name Positional. The name of a JMP variable to be sent to MATLAB.

mlconn<<Send(name, <named arguments>)

Description
Sends the named variable from JMP to MATLAB.

Returns
0 if successful, otherwise nonzero.

Required Argument
name Positional. The name of a JMP variable to be sent to MATLAB.
Named Arguments

The following arguments are for data tables only:

- **Selected(Boolean)** Send selected rows from the referenced data table to MATLAB.
- **Excluded(Boolean)** Send only excluded rows from the referenced data table to MATLAB.
- **Labeled(Boolean)** Send only labeled rows from the referenced data table to MATLAB.
- **Hidden(Boolean)** Send only hidden rows from the referenced data table to MATLAB.
- **Colored(Boolean)** Send only colored rows from the referenced data table to MATLAB.
- **Markered(Boolean)** Send only markered rows from the referenced data table to MATLAB.

**Row States (Boolean, <named arguments>)** Send row states from referenced data table to MATLAB by adding an additional data column named “RowState”. Create multiple selections by adding together individual settings. The row state consists of individual settings with the following values:

- Selected = 1
- Excluded = 2
- Labeled = 4
- Hidden = 8
- Colored = 16
- Markered = 32

Row State Optional Named Arguments

The following optional, named Row States arguments are supported:

- **Colors(Boolean)** Send row colors. Adds additional data column named “RowStateColor”.
- **Markers(Boolean)** Send row markers. Adds additional data column named “RowStateMarker”.

`mlconn<<Submit(mCode, <named arguments>)`

**Description**

Submits MATLAB code to the active global MATLAB integration interface connection.

**Returns**

0 if successful, otherwise nonzero.

**Required Argument**

- **mCode** Positional quoted string. The MATLAB code to submit.

**Named Arguments**

- **Expand(Boolean)** Perform an Eval Insert on the MATLAB code prior to submission.
- **Echo(Boolean)** Echo MATLAB source lines to the JMP log. The default is true.
mlconn<<Submit File(path)

Description
Submits statements to MATLAB using a quoted path.

Returns
0 if successful, otherwise nonzero.

Arguments
path Positional quoted string. The path to a file containing the MATLAB source lines to be executed.

Namespaces

ns<<Contains(string)
Returns 1 or 0, depending on whether the specified quoted string exists within the namespace.

ns<<Delete Namespace
Removes this namespace from the internal global list.
To delete variables in the namespace, use the Remove(variable name) message.

ns<<First
Returns a quoted string that contains the first variable name used within the namespace.

ns<<Get Contents
Returns a list of key-value pairs, which are each enclosed in a list. Each key is a quoted string that contains a variable name, and each value is the unevaluated expression that the variable contains.

ns<<Get Keys
Returns a list of variable names.

ns<<Get Name
Returns the name of this namespace.
\texttt{ns<<Get Value(\textit{variable name});}

Returns the unevaluated expression that the quoted \textit{variable name} contains in this namespace.

\texttt{ns<<Get Values}

Returns a list of unevaluated expressions that each variable in the namespace contains.

\texttt{ns<<Get Values(\{\textit{variable name1, variable name2, ... }\});}

Returns a list of unevaluated expressions that each quoted variable in the namespace specified in the list argument contains. If a requested variable name is not found, an error is returned.

\texttt{ns<<Insert(\textit{variable name, expr});}

Inserts into this namespace a quoted variable named \textit{variable name} that holds the expression \textit{expr}.

\texttt{ns<<Lock Namespace(<\textit{variable name, ...}>)}

Locks all specified variables in the namespace and prevents quotes variables from being added or removed. If no variables are specified, all variables in the namespace are locked.

\texttt{ns<<N Items}

Returns the number of variables contained in the namespace.

\texttt{ns<<New Namespace(\textit{name, \{list of expressions\}})}

Creates a namespace where all functions and variables created are defined only within the optional quoted \textit{name} argument.

\texttt{ns<<Next(\textit{variable name})}

Returns the name of the variable that follows the specified quoted variable.

\texttt{ns<<Remove(\textit{variable name, ...})}

Removes the specified quoted variable or list of variables.

\texttt{ns<<Show Contents}

Shows the contents of a namespace in the log.
ns<<Unlock Namespace(variable name, ...);

Unlocks the specified quoted variables in the namespace. If no variables are specified, all variables are unlocked.

## Platforms

### obj<<Action

Evaluates expressions. Useful for quoted stringing together multiple platforms interrupted by user input.

### obj<<Automatic Recalc

Redoes the analysis automatically for exclude and data changes. If automatic recalc is on, you should use Wait(0) commands to let the triggers take effect and do the recalculation.

**Note:** Not supported on all platforms.

### obj<<Bring Window To Front

Brings the current window to the front.

### obj<<Close Window

Closes window identified by *obj*, typically a platform surface.

### obj<<Column Switcher(default column, {column1, column2, ...})

Adds a control panel to a platform for switching variables.

### obj<<Copy ByGroup Script

Creates a script to produce this analysis containing By variables and place it on the clipboard.

### obj<<Copy Script

Creates a script to produce this analysis and place it on the clipboard.

### obj<<Data Table Window

Makes the associated data table window active (front-most).
obj<<Get Data Table

Returns a reference to the data table.

obj<<Get Script

Returns script to reproduce the analysis as an expression in the log.

obj<<Get Script With Data Table

Creates a script to reproduce the analysis, specifically referencing the source data table, and returns it as an expression in the log.

obj<<Get Timing

Times the launch of the platform and returns it in the log.

obj<<Get Web Support

Returns the score for the display tree that is about to be saved as interactive HTML. Possible values are -1 (unsupported), 0 (supported), and 1 (supported). If the score does not equal -1, interactive HTML is supported and the Save Interactive HTML message can be used.

obj<<Get Window Position

Gets the position of the window. Returns an ordered pair.

obj<<Get Window Size

Gets the window size, in pixels. Returns an ordered pair.

obj<<Ignore Platform Preferences(Boolean)

Ignores the current settings of the platform’s preferences. The message is ignored when sent to the platform after creation.

obj<<Journal Window

Appends the contents of the window to the journal.

obj<<Local Data Filter

Filters data to specific groups or ranges, but stays local to the platform.
obj<<Maximize Window

Maximizes the window. Equivalent to pushing the maximize button in the corner of the window. This message takes an optional Boolean argument:

// maximize the window:
obj<<Maximize Window(1)
// restore the window:
obj<<Maximize Window(0)

obj<<Minimize Window

Minimizes the window. Equivalent to pushing the minimize button in the corner of the window. This message takes an optional Boolean argument:

// minimize the window
obj<<Minimize Window(1)
// restore the window
obj<<Minimize Window(0)

obj<<Move Window(x, y)

Moves the window to the (x, y) location on your screen.

obj<<Print Window

Sends the selected window to the printer.

obj<<Redo Analysis

Reruns the analysis with the same options.

obj<<Redo ByGroup Analysis

Reruns the same analysis involving By groups.

obj<<Relaunch Analysis

Returns to the launch window for this analysis.

obj<<Relaunch ByGroup

Returns to the launch window for this analysis involving By groups.

obj<<Remove Column Switcher

Removes all Column Switchers that were added to the platform.
**obj<<Remove Local Data Filter**

Removes all Local Data Filters that were added to the platform.

**obj<<Report**

Report(obj)

Returns a display box reference for the report in the platform window.

**obj<<Report View**

Determines the level of detail visible in a platform report. Full shows all detail and Summary shows only select content, dependent upon the specific platform. For customized behavior, use the Set Summary Behavior message with display boxes.

**obj<<Save ByGroup Script to Data Table(<name>, <Append Suffix(Boolean)>, <Prompt(Boolean)>, <Replace(Boolean)>)**

**Description**

Creates a table script to produce the analysis involving By variables and saves it as a table script in the data table.

**Optional Arguments**

- **name** The name of the script. *name* is quoted. If omitted, the platform names the script. For example, in Tabulate, the script is named “Tabulate”. In Bivariate, the script might be named “Bivariate of height by weight” to reflect the platform and column names.
- **Append Suffix(Boolean)** If true, appends a numerical suffix to the script name. This suffix differentiates the script from an existing script with the same name.
- **Prompt(Boolean)** If true, prompts the user to specify a script name.
- **Replace(Boolean)** If true, replaces an existing script with the same name.

**obj<<Save ByGroup Script to Journal**

Creates a table script to produce the analysis involving By variables and adds a button to the journal containing this script.

**obj<<Save ByGroup Script to Script Window**

Creates a script to produce the analysis involving By variables and appends it to the current Script window.

**obj<<Save Script for All Objects**

Saves script to reproduce all analyses found within the object’s window in the Script Journal window.
**obj<<Save Script for All Objects to Data Table**

Saves a script for all report objects to the current data table. The script is named after the platform unless you specify the script name in quotes.

`obj << Save Script for All Objects To Data Table("My Script")`

**obj<<Save Script to Data Table**

Saves script to reproduce analysis as a property in the associated data table.

**obj<<Save Script to Journal**

Creates a script to produce the analysis and adds a button to the journal containing this script.

**obj<<Save Script to Report**

Saves script to reproduce analysis as a text box at the top of the report.

**obj<<Save Script to Script Window**

Saves a script to reproduce analysis in the Script Journal.

**obj<<Scroll Window(x, y)**

**obj<<Scroll Window({x, y})**

Scrolls the window `x` pixels to the right and `y` pixels down from the current position. Negative coordinates go left and up. If the coordinates are a list in braces `{}`, they are absolute coordinates. The window scrolls to the point `x` pixels from the left and `y` pixels from the top.

**obj<<SendToReport**

Used with the Dispatch function to customize the appearance of a report.

**obj<<SendToByGroup**

Sends messages to open platforms or turn on platform features to each level of a by-group.

**obj<<Show Window(Boolean)**

1 shows the window (brings it to the front). 0 hides the window. If the window is also minimized (on Windows) or docked (on macOS), showing the window restores it to the normal state and brings it to the front.
**obj<<Size Window(x, y)**

Resizes the window to x pixels wide by y pixels high.

**obj<<Title(new title)**

Sets the quoted title of the platform.

**obj<<Top Report**

Returns a reference to the top display box in the report. Useful for By groups or other cases when several platform reports are in one window.

**obj<<View Web XML**

Returns the XML used to create the interactive HTML report. The XML code appears in the log.

**obj<<Zoom Window**

Resizes the window to be large enough to show all of its contents.

---

**Bubble Plot**

**bp<<Set Shape("Circle"|"Triangle"|"Square"|"Diamond"|"Arrow"|"Custom")**

**Description**

Sets the shape for the bubble. When specifying a custom shape, use the Set Custom Path message to specify the path for the bubbles.

**See Also**

“bp<<Set Custom Path(path matrix|path text)” on page 477.

**bp<<Set Custom Path(path matrix|path text)**

Sets a path for custom bubbles.

**Arguments**

- **path matrix** An Nx3 matrix.
- **path text** A quoted string that contains SVG code.

**See Also**

“bp<<Set Shape("Circle"|"Triangle"|"Square"|"Diamond"|"Arrow"|"Custom")” on page 477.
DOE

obj<<Get Prediction Variances

Description
Returns a vector of the MC variances used for the FDS plot.

Example
dt = Open( "$SAMPLE_DATA/Design Experiment/Bounce Data.jmp" );
d = DOE( Evaluate Design, X( :Silica, :Sulfur, :Silane ), Y( :Stretch ) );
d << Get Prediction Variances;

obj<<Set Number of FDS Points()

Description
Enables you to specify the number of runs used to generate an FDS plot.

Example
dt = Open( "$SAMPLE_DATA/Design Experiment/Bounce Data.jmp" );
d = DOE( Evaluate Design, X( :Silica, :Sulfur, :Silane ), Y( :Stretch ) );
d << Set Number of FDS Points( 20000 );

Partition

obj<<Initial Splits(condition, {left}, {right})

Description
Describes the splits that are performed.

Example
dt = Open( "$SAMPLE_DATA/Car Poll.jmp" );
obj = Partition(
  Y( :country ),
  X( :sex, :marital status, :age, :type, :size ),
  Method( "Decision Tree" ),
  Initial Splits( :size == {"Large"}, {}, {:size == {"Medium"}} )
);

Notes
The condition is for the left side and is either [name compareoperator value] or [name == list of values]. The left is an empty list if the right has splits. Omit the right side if there are no splits. The left and right continue recursively in this format.
Response Screening

obj<<Get PValues
   Returns a reference to a PValues table.

obj<<Save PValues
   Stores the $p$-values in an output data table.

obj<<Save Compare Means
   Stores the means comparisons in an output data table.

obj<<Save Mean
   Stores the means in an output data table.

obj<<Save Outlier Indicator
   Saves Outlier Indicator for each fit.

obj<<Save Std Residuals
   Saves the residual formula for each fit.

obj<<Select Columns
   Select columns in the original table corresponding to selected rows in this table.

Tabulate

obj<<Display Column Width(<Data Column(Column Table(n), <column name path>), Row Label(Row Table(n), <column name path>)), <width>)
   Returns or sets the display pixel width of a column in a Tabulate table.

Required Argument
   Row Label Use Row Table and heading for columns in the row labels area.

Optional Arguments
   Data Column Use Column Table and column references to define columns in the main body of the table.
   column name path Specifies the Column Table or Row Table (both quoted), and the series of column headings that traces the path of the column. Note: Column Table or Row Table can be omitted if the table referenced is the first table.
width  Specifies the pixel width of the column.

Examples

```julia
dt = Open( "SAMPLE_DATA/Car Poll.jmp" );
obj = dt << Tabulate(
   Add Table(
      Column Table(
         Grouping Columns( :sex, :marital status ),
         Analysis Columns( :age ),
         Statistics( Sum, "% of Total" )
      ),
      Row Table( Grouping Columns( :type ) ),
      Row Table( Grouping Columns( :country, :size ) )
   )
);
Wait( 3 ); // for demonstration purposes
obj << Display Column Width( Row Label( Row Table( 2 ), "country" ), 150 );
Wait( 3 ); // for demonstration purposes
obj << Display Column Width(
   Data Column(
      Column Table( 1 ),
      "sex",
      "Female",
      "marital status",
      "Married",
      "age",
      "Sum"
   ),
   150
);
```

**Python Integration Messages**

The Python interfaces are also scriptable using a Python connection object. A scriptable Python connection object can be obtained using the `Python Connect()` function. See “Python Connect(<Echo(Boolean)>, <Path(path)>, <Use Python Version(string)>, <Python System Path(list)>)” on page 259 in the “JSL Functions” chapter.

```julia
pythconn<<Control(<Interactive(Boolean)>|<Echo(Boolean)>)
```

**Description**

Controls the execution of Python.
Optional Named Arguments

Interactive (Boolean) Enables interactive mode in the Python matplotlib package. Determines whether the graphics window is released or closed when graphics rendering is complete.

Echo (Boolean) Global argument. Prints the Python source lines to the JMP log. The default value is true.

```pythconn<<Disconnect```

Disconnects the Python integration interface connection.

```pythconn<<Execute([list of inputs], [list of outputs], Python code, <named arguments>)```

Description

Submits Python code to the active global Python integration interface connection given a list of inputs. On completion, returns a list of outputs.

Returns

Returns 0 if successful and 1 otherwise. The results are returned using the list of outputs. Given each element of the JMP output list, the corresponding Python variable value is returned.

Positional Arguments

{list of inputs} A list of JMP variable names to be sent to Python as inputs.

{list of outputs} A list of JMP variable names to be retrieved from Python as outputs.

Python code The quoted Python code to submit.

Optional Named Arguments

See “pythconn<<Submit(Python code, <Expand (Boolean)>, <Echo (Boolean)>)” on page 483.

```pythconn<<Get(name)```

Description

Gets a named variable from Python.

Returns

Returns the value of the named variable.

Argument

name The name of the JMP variable to be received from Python. The argument can represent any of the following Python data types: numeric, quoted string, matrix, list, or data frame.
**pythconn<<Get Graphics**(format)

**Description**
Gets the last graphics object written to the Python graph display window in the specified graphics format. The graphics object can be returned in several different graphic formats.

**Returns**
Returns a JMP picture object.

**Argument**
- **format** The format that the Python graph display window contents are to be converted to. Valid formats are PNG, BMP, JPEG, JPG, TIFF, and TIF.

---

**pythconn<<Get Version**

**Description**
Gets the current version of the Python installation.

**Returns**
Returns a list of length 5 that contains the five components of the version number: major, minor, micro, releaselevel, and serial. The releaselevel value is a quoted string.

---

**pythconn<<Is Connected**

**Description**
Determines if the connection is active.

**Returns**
Returns 1 if connected and 0 otherwise.

---

**pythconn<<JMP Name to Python Name**(name)

**Description**
Maps a JMP variable name to its corresponding Python variable name using Python variable name naming rules.

**Argument**
- **name** The name of the JMP variable to be sent to Python. Some variable names allowed by JMP are not allowed by Python. When you send using these variables from JMP to Python (the **Send** message), their names get changed. Use **JMP Name to Python Name** to determine what the variable name was changed to.

---

**pythconn<<Send**(name)

**Description**
Sends a named variable from JMP to Python.
Returns

Returns 0 if successful and non-zero otherwise.

Argument

name The name of the JMP variable to be sent to Python.

```
pythconn<<Submit(Python code, <Expand(Boolean)>, <Echo(Boolean)>)
```

Description

Submits Python code to the active global Python integration interface connection.

Returns

Returns 0 if successful and 1 otherwise.

Required Arguments

Python code The quoted Python code to submit.

Optional Arguments

Expand(Boolean) Performs an Eval Insert() on the Python code before submission.
Echo(Boolean) Prints the Python source lines to the JMP log. The default value is true.

```
pythconn<<Submit File(path)
```

Description

Submits statements to Python using the quoted path name.

Argument

path The quoted path to the file that contains the Python source lines to be executed.

R Integration Messages

The R interfaces are also scriptable using an R connection object. A scriptable R connection object can be obtained using the R Connect() function.

```
rconn<<Control(Interrupt|Async(Boolean)|Echo(Boolean))
```

Changes the control options for R. If Async is set to true (1) for R Submit(), this message immediately stops the execution of the R code that was submitted.

```
rconn<<Disconnect()
```

Disconnects this R connection.

```
rconn<<Is Connected()
```

Returns 1 if the R connection is active, 0 otherwise.
rconn<<Send File(name, <named arguments>)

Send the specified JMP variable to R.

Returns
0 if successful, nonzero otherwise.

Required Argument
name A quoted string contains the name of a JMP variable to send to R.

Optional Named Arguments for Data Tables
Selected(Boolean) If true, sends only the selected rows from the referenced data table to R.
Excluded(Boolean) If true, sends only the excluded rows from the referenced data table to R.
Labeled(Boolean) If true, sends only labeled rows from the referenced data table to R.
Hidden(Boolean) If true, sends only hidden rows from the referenced data table to R.
Colored(Boolean) If true, sends only colored rows from the referenced data table to R.
Markered(Boolean) If true, sends only markered rows from the referenced data table to R.
Row States(Boolean, <named arguments>) Includes a Boolean argument and optional named arguments. Sends row state information from the referenced data table to R by adding an additional data column named “RowState”. The row state value consists of individual settings with the values shown in Table 3.2.

Table 3.2 Row States

<table>
<thead>
<tr>
<th>Multiple row states are created by adding together individual settings.</th>
<th>Selected = 1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Excluded = 2</td>
</tr>
<tr>
<td></td>
<td>Labeled = 4</td>
</tr>
<tr>
<td></td>
<td>Hidden = 8</td>
</tr>
<tr>
<td></td>
<td>Colored = 16</td>
</tr>
<tr>
<td></td>
<td>Markered = 32</td>
</tr>
</tbody>
</table>

Arguments
Colors(Boolean) (Optional) If true, sends row colors and adds an additional data column named “RowStateColor”.
Markers(Boolean) (Optional) If true, sends row markers and adds an additional data column named “RowStateMarker”.
rconn<<Send(name, <R Name(name)>)

Sends the quoted JMP data file to R. The name argument can represent any of the following data types: numeric, quoted string, matrix, list, or data table.

rconn<<Get(name)

Returns data from R. The name argument can represent any of the following data types: numeric, quoted string, matrix, list, or data table.

Returns
The value of the specified variable.

Arguments
name Specifies the quoted name of a JMP variable to be retrieved from R.

rconn<<Get Graphics(type)

Gets the last graphics object written to the R graph display window. The graphics object can be returned in different graphic formats.

Returns
A JMP picture object.

Required Argument
type The format the R graph display window contents are converted to. Valid formats are "png", "bmp", "jpeg", "jpg", "tiff", and "tif".

rconn<<Submit(R code, Expand(Boolean), Echo(Boolean))

Submits the quoted R code.

Returns
0 if successful, nonzero otherwise.

Required Argument
code Specifies the quoted R code to submit.

Optional Named Arguments
Expand(Boolean) Performs an Eval Insert() on the R code before submitting the code.
Echo(Boolean) Echoes the R source lines to the JMP log. The default value is true.

Rconn<<Submit File(path)

Submits statements to R using the file in the quoted path.

Arguments
path Specifies the quoted path to the file that contains R code to be executed.
rconn<<Execute({list of inputs}, {list of outputs}, R code, <named arguments>)

Submits the quoted R code to the R connection using the list of inputs. Upon completion, a
list of outputs is returned.

Returns

0 if successful, nonzero otherwise.

Required Arguments

R code Specifies the quoted R code to submit.
{list of inputs} List of JMP variable names to be sent to R as inputs.
{list of outputs} List of JMP variable names to be retrieved from R as outputs.

Optional Named Arguments

See rconn<<Submit(R code, Expand(Boolean), Echo(Boolean)) on page 485.

rconn<<Control(<Echo(Boolean)>)

Controls the execution of R.

Returns

Void.

Optional Named Argument

Echo(Boolean) Echoes the R source lines to the JMP log.

rconn<<Get Version()

Gets the current version of R that is installed.

Returns

A vector of length 3 containing the R version number.

rconn<<JMP Name To R Name(name)

Maps a quoted JMP Name to its corresponding R Name using R variable name naming rules.

Returns

A quoted string that contains the quoted R name.

Arguments

name A quoted string that specifies the name of a JMP variable to be sent to R.
SAS Integration Messages

Metadata Server Objects

metaserver<<Disconnect()

Description
Disconnects the metadata server.

Returns
Void.

metaserver<<Get Display Name()

Description
Gets the display name of the metadata server.

Returns
A quoted string.

metaserver<<Get Host Name()

Description
Gets the host (machine) name of the metadata server.

Returns
A quoted string.

metaserver<<Get Port()

Description
Gets the port used for the metadata server connection.

Returns
An integer.

metaserver<<Get User Identity()

Description
Gets the identity of the connected user as defined in metadata.

Returns
A quoted string.
metaserver<<Get User Name()

Description
Gets the user name (login ID) that was used for the metadata server connection.

Returns
A quoted string.

SAS Server Objects

sasconn<<Assign Libref(libref, path, engine, engine options)

Description
Assign a SAS libref on this SAS server connection.

Returns
Void.

Arguments
See “SAS Assign Lib Refs("libref", "path", <"engine">, <"engine options">)” on page 295 in the “JSL Functions” chapter.

sasconn<<Cancel Submit()

Description
Cancels the currently running SAS Submit for this server that is presumably running asynchronously.

Returns
1 if a running submit was found and canceled; 0 otherwise.

sasconn<<Clear Log History()

Description
Clears the SAS Log history for this server.

Returns
Void.

sasconn<<Clear Output History()

Clears the SAS Output history for this server.
sasconn<<Connect(<User Name(name)>, <Password(password)>,<Prompt("Always"|"Never"|"IfNeeded")>)

Description
Attempt to reconnect a SAS server connection object that has become disconnected.

Returns
1 if the connection was successful, 0 otherwise.

Optional Named Arguments
User Name(name) Specifies the quoted user name for the connection.
Password(password) Specifies the quoted password for the connection.
Prompt A quoted keyword. "Always" means always prompt before attempt to connect.
"Never" means never prompt even if the connection attempt fails (just fail with an error
message going to the log), and "IfNeeded" (the default) means prompt if the attempt to
connect with the given arguments fails (or is not possible with the information given).

sasconn<<Deassign Libref(libref)

Description
De-assign the quoted SAS libref on this SAS server connection.

Returns
Void.

Arguments
libref Specifies the quoted library reference.

sasconn<<Disconnect()

Description
Disconnect this SAS server connection.

Returns
Void.

sasconn<Does Module Exist(module name)

Description
Determines whether the specified SAS module exists in the SAS installation represented
by the SAS connection. This can be helpful in determining whether certain SAS products
are installed. The SAS DATA Step function MODEXIST is used to determine module existence.

Returns
1 if the specified module is found to exist, 0 if it does not exist.
Argument

module name Specifies the quoted SAS module, the existence of which should be checked. Do not include any extension.

sasconn<<Export Data(\textit{dt, library, dataset, <named arguments>})

Description

Exports a JMP data table to the specified SAS data set in the specified library on the active SAS server connection.

Returns

1 if the data table was exported successfully; 0 otherwise.

Optional Named Arguments

See “SAS Export Data(\textit{dt, "library", "dataset", <named_arguments>})” on page 298 in the “JSL Functions” chapter.

sasconn<<Get Data Sets(\textit{libref})

Description

Returns a list of the data sets defined in a SAS library on this SAS server connection.

Returns

A list of quoted strings.

Arguments

\textit{libref} Specifies the quoted SAS libref or friendly library name associated with the library for which the list of defined SAS data sets will be returned.

sasconn<<Get Error Count()

Description

Gets the count of the number of errors encountered in the previous SAS Submit.

Returns

An integer.

sasconn<<Get File(\textit{source, dest})

Description

Downloads a file from this SAS server connection.

Returns

Void.
Arguments

See “SAS Get File("source", "dest", "encoding")” on page 299 in the “JSL Functions” chapter.

sasconn<<Get File Names(fileref)

Description

Gets a list of filenames found in the quoted fileref on this SAS server connection.

Returns

A list of quoted strings.

Arguments

fileref  A quoted string that contains the name of fileref from which to retrieve filenames.

sasconn<<Get File Names In Path(path)

Description

Gets a list of filenames found in the quoted path on the current SAS server connection.

Returns

A list of quoted strings.

Arguments

path  The quoted directory path on the server from which to retrieve filenames.

sasconn<<Get File Refs()

Description

Gets a list of the currently defined SAS filerefs on this SAS server connection.

Returns

A list of quoted strings.

sasconn<<Get Librefs(<named arguments>)

Description

Gets a list of the currently defined SAS librefs on this SAS server connection.

Returns

A list of quoted strings.

Optional Named Arguments

See “SAS Get Lib Refs(<named arguments>)” on page 300 in the “JSL Functions” chapter.
sasconn<<Get Log()

**Description**

Retrieves the SAS Log from the last SAS Submit from this SAS server connection.

**Returns**

A quoted string.

sasconn<<Get Option Name()

**Description**

Queries SAS for the value of a SAS option variable.

**Returns**

A quoted string.

**Example**

The following script iterates through the define variables and prints out the values:

```javascript
option_names = sasconn << Get Option Names();
For(i=1, i <= N Items(option_names), i++,
    option_value = sasconn << Get Option Value (option_names[i]);
    output = option_names[i] || "=" || char(option_value) || "/n";
    Write(output);
);
```

sasconn<<Get Output()

**Description**

Retrieves the listing output from the last submission of SAS code to this SASServer object.

**Returns**

A quoted string.

sasconn<<Get Results()

**Description**

Retrieves the results of the previous SAS Submit as a scriptable object, which allows significant flexibility in what to do with the results.

**Returns**

A SAS Results Scriptable Object.

sasconn<<Get Submit Status()

**Description**

Gets the current status of a SAS Submit for this server that is presumably running asynchronously.
Returns
1 if the submit has not started; 2 if the submit is running; 3 if the submit has been canceled; 10 if the submit has completed successfully; 11 if the submit has completed with errors.

```
sasconn<<Get Var Info(libref, dataset, <Password(password)>)
```

Description
Returns information about the variables the specified SAS data set.

Required Arguments
- `libref` The library name.
- `dataset` The quoted name of the data set from which to retrieve variable names.

Optional Argument
- `Password(password)` The quoted `password` for the connection.

```
sasconn<<Get Var Names(libref, dataset, <named arguments>)
```

Description
Retrieves the variable names contained in the specified data set on this SAS server connection.

Returns
A list of quoted strings.

Arguments
See “SAS Get Var Names(string, "dataset"); <password("password")>” on page 301 in the “JSL Functions” chapter.

```
sasconn<<Get Version(<"Long">)
```

Description
Returns the SAS version as a quoted string such as “9.3” or “9.4”.

Returns
A quoted string that contains the SAS version.

Optional Argument
- `Long` A quoted keyword that specifies to return the long SAS version, which corresponds to the SYSVLONG SAS macro (for example, "9.02.02M0P01152009").

```
sasconn<<Get Work Folder()
```

Description
Returns the full path of the folder corresponding to the WORK library for this server.
Returns
A quoted string that specifies the work folder path.

\texttt{sasconn}<<\texttt{Import Data}(\textit{library, dataset, <named arguments>})

Description
Imports a SAS data set from this SAS server connection into a JMP table.

Returns
A JMP Data Table object.

Arguments
See “\texttt{SAS Import Data(string, "dataset"}, <named arguments>)” on page 302 in the “JSL Functions” chapter.

\texttt{sasconn}<<\texttt{Import Query}(\textit{sqlquery, <named arguments>})

Description
Executes the requested SQL query on this SAS server connection, importing the results into a JMP data table.

Returns
A JMP data table object.

Arguments
See “\texttt{SAS Import Query("sqlquery", <named arguments>)” on page 304 in the “JSL Functions” chapter.

\texttt{sasconn}<<\texttt{Is Connected()}

Description
Determines whether this SAS Server object is currently connected to SAS.

Returns
1 if \texttt{sasconn} is connect, 0 otherwise.

\texttt{sasconn}<<\texttt{Is Product Available}(\textit{product name})

Description
Determines whether the quoted SAS product is both licensed and installed in the session represented by the SAS connection. The SAS DATA Step functions SYSPROD and MODEXIST are used to determine the licensed and installed status of the product.

Returns
1 if the specified product is licensed, 0 if the product is not licensed, or -1 if the specified product is not recognized by SAS. This function throws an exception if the requested product is not one for which JMP knows how to check the installed status.
**Required Argument**

`product name` The quoted SAS product for which licensing should be checked. The product name can be specified with or without the “SAS/” prefix.

---

`sasconn<<Is Product Licensed(product name)`

**Description**

Determines whether the quoted SAS product is licensed in the session represented by the SAS connection. The SAS DATA Step function `SYSPROD` is used to determine the licensing status of the product.

**Returns**

1 if the specified product is licensed, 0 if the product is not licensed, or -1 if the specified product is not recognized by SAS.

---

**Required Argument**

`product name` The quoted SAS product for which licensing should be checked. The product name can be specified with or without the “SAS/” prefix.

---

`sasconn<<Kill Session(<n>)`  

**Description**

If no argument is provided, the SAS connection is immediately terminated.

**Returns**

Void.

**Arguments**

`n` An optional number. The system waits n seconds for a normal shut-down before immediately terminating the SAS connection.

---

`sasconn<<Load Text File(path, <named arguments>)`  

**Description**

Downloads the file specified in the quoted `path` from the active SAS server connection and retrieve its contents as a quoted string.

**Returns**

A quoted string.

**Arguments**

See “SAS Load Text File("path")” on page 305 in the “JSL Functions” chapter.

---

`sasconn<<Open Log Window()`  

**Description**

Opens (or brings to the front) the SAS Log window for this server.
Returns
Void.

```javascript
sasconn<<Open Output Window()
```

Description
Opens (or brings to the front) the SAS Output window for this server.

Returns
Void.

```javascript
sasconn<<Open SAS Results()
```

Description
Opens the results from the previous SAS Submit. Intended to be used with asynchronous SAS submits or the use of the OnSubmitComplete option to SAS Submit to give the JSL author a way to conditionally open the results of a submit.

Returns
Void.

```javascript
sasconn<<Open Submit Results()
```

Description
Opens all the results from the last SAS Submit command.

Returns
Void.

```javascript
sasconn<<Send File(source, dest)
```

Description
Uploads a file to this SAS server connection.

Returns
Void.

Arguments
See “SAS Send File("source", "dest", "encoding")” on page 306 in the “JSL Functions” chapter.

```javascript
sasconn<<Submit(sas code, <named arguments>)
```

Description
Submits quoted SAS code to this SAS server connection.
Returns
Void.

Arguments

sasconn<<Submit File(filename, <named arguments>)

Description
Submits a SAS code file to this SAS server connection.

Returns
Void.

Arguments
See “SAS Submit File("filename", <named arguments>)” on page 308 in the “JSL Functions” chapter.

Stored Processes

stp<<Begin Run(<named arguments>)

Description
Starts this stored process executing in the background. This message is paired with End Run, which should also be called at some point after Begin Run to wait for the stored process to complete.

Returns
-1 = execution failed.
1 = not started.
2 = running.
3 = canceled.
10 = completed successfully.
11 = completed with errors.

Optional Named Arguments
Same as Run, except AutoOpenResults and NoAlerts are not supported. They are available on EndRun.

AutoResume(<filename>) If specified with no argument, it specifies that the stored process results should be auto-opened when the stored process completes. If a quoted filename is specified, filename is opened rather than all results of the stored process being auto-opened.
AutoResumeScript(script) Specifies that after stored process execution completes, the quoted script should be evaluated. If the script is a function taking at least one argument, the function is evaluated with the scriptable stored process object passed as the first (and only) argument. AutoResume and AutoResumeScript are mutually exclusive.

stp<<Delete Results(<named arguments>)

Description

Deletes all results from the execution of this stored process.

Returns

1 if deletion is successful, 0 otherwise (error message to JMP log).

Optional Named Arguments

NoAlerts(Boolean) If True, the user is not prompted for confirmation before the attempt is made to delete results.

DeleteDirectory(Boolean) If true, deletes the directory containing the stored process results along with the result files themselves. The default value is true.

stp<<Edit Param Values()

Description

Opens the stored process window for interactively setting parameter values.

Returns

1 if the user clicks OK to dismiss the window, 0 if the user clicks Cancel.

stp<<End Run(<named arguments>)

Description

Waits a specified amount of time (or forever) for a stored process started with Begin Run to complete. If the stored process is complete, retrieves the results, and opens them.

Returns

-1 = execution failed.
1 = not started.
2 = running.
3 = canceled.
10 = completed successfully.
11 = completed with errors.

Optional Named Arguments

AutoOpenResults(Boolean) Optional, Boolean. If True, results are automatically opened if the stored process completes in the time specified by MaxWait. If False,
results are not automatically opened, and can be manually opened via the object returned by the `Get Results` message. Default is `True`.

`MaxWait(milliseconds)`  An integer that specifies the maximum amount of time in milliseconds to wait for the stored process to complete. If `MaxWait` is not specified, `End Run` waits forever for the stored process to complete.

`NoAlerts(Boolean)`  If `True`, error messages are sent to the JMP log rather than message boxes. The default value is `False`.

---

stp<<Get Metadata Id()

**Description**

Returns the metadata ID of the stored process.

**Returns**

A quoted string.

stp<<Get Metadata Path()

**Description**

Returns the full metadata path of the stored process.

**Returns**

A quoted string.

---

stp<<Get Name()

**Description**

Returns the name of the stored process.

**Returns**

A quoted string.

---

stp<<Get Param Enum Labels(name)

**Description**

Gets the enumeration labels specified by the quoted `name` for a parameter.

**Returns**

A list of quoted strings.

**Arguments**

`name`  Specifies the quoted name of the parameter whose enumeration labels to retrieve.
stp<<Get Param Enum Values(name)

Description
Gets the possible enumerated values for a parameter.

Returns
A list of quoted strings.

Arguments
name  Specifies the quoted name of the parameter whose possible enumerated values to retrieve.

stp<<Get Param Names(<named arguments>)

Description
Gets a list of parameter names for this stored process of specific types.

Returns
A list of quoted strings.

Optional Named Arguments
Visible(Boolean)  If true, gets only visible parameters. If False, gets only non-visible parameters. If not specified, gets both visible and non-visible parameters.
Modifiable(Boolean)  If true, gets only modifiable parameters. If False, gets only non-modifiable parameters. If not specified, gets both modifiable and non-modifiable parameters.
Required(Boolean)  If true, gets only required parameters. If False, gets only non-required parameters. If not specified, gets both required and non-required parameters.
Expert(Boolean)  If true, gets only expert parameters. If False, gets only non-expert parameters. If not specified, gets both expert and non-expert parameters.

stp<<Get Param Value(name)

Description
Gets the current value of the specified parameter.

Returns
A quoted string.

Required Argument
name  Specifies the name of the parameter whose value to retrieve.

stp<<Get Results()

Description
Gets the results generated by the execution of this stored process as a scriptable object.
Returns
A SAS Results scriptable object.

stp<<Get Status()

Description
Gets the execution status of the stored process.

Returns
-1 = execution failed.
1 = not started.
2 = running.
3 = canceled.
10 = completed successfully.
11 = completed with errors.

stp<<Get Status Message()

Description
Gets the message associated with the failure of the stored process, if any.

Returns
A quoted string.

stp<<Reset Param Values()

Description
Resets all parameter values to their metadata-defined default values.

Returns
Void.

stp<<Run(<named arguments>)

Description
Executes this stored process object in the foreground.

Returns
-1 = execution failed.
1 = not started.
2 = running.
3 = canceled.
10 = completed successfully.
11 = completed with errors.

**Optional Named Arguments**

- **AutoOpenResults** *(Boolean)* If True, results are automatically opened when the stored process completes. If False, results are not auto-opened, and can be manually opened via the object returned by the *GetResults* message. The default value is *True*.
- **UserName** *(username)* Specifies the quoted *username* under which to run the stored process.
- **Password** *(password)* Specifies the quoted *password* for *UserName*.
- **AuthDomain** *(authDomain)* Specifies the quoted authentication domain of the credentials *(username, password)* given.
- **ODSDest** *(dest)* Specifies the quoted ODS destination *("HTML", "PDF", "tagsets.SASReport12")* for any ODS-generated results from the stored process. This requires the stored process SAS code to call %STPBEGIN. The default value is "HTML".
- **GraphicsDevice** *(device)* Specifies the quoted SAS graphics device to use when generating graphics in ODS results. This requires the stored process SAS code to call %STPBEGIN. The default value is "GIF".
- **ODSStyle** *(style name)* Specifies the quoted ODS style to apply to the results. This requires the stored process SAS code to call %STPBEGIN. There is no default value.
- **ODSStyleSheet** *(path)* Specifies the quoted *path* to a CSS file on the client machine that is to be applied to generated ODS results. This requires the stored process SAS code to call %STPBEGIN. There is no default value.
- **NoAlerts** *(Boolean)* If True, error messages are sent to the JMP log rather than message boxes. The default value is *False*.

```js
stp<<Set Param Value(name, value)
```

**Description**

Sets the value of the specified stored process parameter to the specified value.

**Returns**

1 if successful, 0 otherwise (value can violate the parameter’s constraints).

**Arguments**

- **name** Specifies the quoted name of the parameter whose value to set.
- **value** Specifies the quoted string that you want to set the parameter to.

```js
stp<<Set Results Directory(path)
```

**Description**

Sets the quoted *path* on the client machine where stored process results are placed.

**Returns**

A quoted string.
Arguments

path  Specifies the full quoted path of the directory where results of the stored process execution should be placed. The directory must exist or be creatable. If the results directory is not set, a temporary location appropriate for the operating system will be used, and that directory can be retrieved from the stored process Results scriptable object after the stored process executes.

SAS Results

results<<Delete All Result Files()

Description

Deletes all files created by the SAS Submit or Stored Process execution. Note that any result files that are still in use are not deleted.

Returns

1 if the deletion was successful; 0 if some of the files could not be deleted.

results<<Get Directory()

Description

Gets the directory where the results generated by the stored process or SAS submit are located.

Returns

A quoted string.

results<<Get Log()

Description

Get the SAS Log from the execution of the stored process or SAS submit.

Returns

A quoted string.

results<<Get Main Result File Name(<Fullpath(Boolean)>)

Description

Gets the full path of the main result file generated by the stored process or SAS submit.

Returns

A quoted string.

Optional Named Argument

Fullpath(Boolean)  If true, the main result filename is returned as a full path. The default value is false.
results<<Get Output()

**Description**

Gets the SAS Listing output from the execution of the stored process or SAS submit.

**Returns**

A quoted string.

results<<Get Output Datasets()

**Description**

Get a list of output data set generated by the SAS Submit that created this SAS Results object.

**Returns**

A list of data set names in the form “libname.membername”.

results<<Get Result File Info(<Mimetype(mime-type)>,
<Fullpath(Boolean)>)

**Description**

Get information about result files that were generated by the execution of the stored process or SAS submit.

**Returns**

List of two lists of quoted strings. The first list is filenames, and the second list is the MIME-type of the corresponding file from the first list.

**Optional Arguments**

- `Mimetype(mime_type)` Restricts the set of files for which information is returned to only those files with the specified quoted MIME-type. If not specified, information about all generated files is returned.
- `Fullpath(Boolean)` If true, the filename returned for each result file is returned as a full path; if false, only the name of the file is returned. The default value is false.

results<<Make JMP Report()

**Description**

Parses the ODS XML results and creates a JMP report.

**Returns**

The display box for the report.
results<<Open All Results()

Description
Opens all results generated by the execution of the stored process or SAS submit.

Returns
Void.

results<<Open Result File(filename, <Run Script(Boolean)>)

Description
Attempts to open the result file with the given name.

Returns
JMP Data Table if one was opened.

Required Argument
filename Specifies the quoted name of the file from the generated results to open.
filename should just be the name of the file, not the full path. If filename is a filename
with no extension, both JMP data tables and JSL scripts in the results are searched for a
match, and if both exist, both are opened.

Optional Argument
Run Script(Boolean) If true, and if filename is a JSL script, the script is executed. If
false, filename is just opened, even if it is a JSL script.

results<<Run Script(filename)

Description
Looks for the JSL file in the results with the given filename and runs it if it finds it.

Returns
Void.

Argument
"filename" Specifies the quoted name of the JSL file from the generated results to open.
The filename argument should just be the name of the file, not the full path, and it
does not need to include the .jsl extension.

Schedule

See also “Schedule(n, script)” on page 360 in the “JSL Functions” chapter.

sch<<Clear Schedule()
Cancels all scheduled events.
sch<<Close()
  Closes the scheduler.

sch<<Restart()
  Restarts the scheduler after it was stopped from running all scheduled events.

sch<<Show Schedule()
  Shows a list of all scheduled events.

sch<<Stop()
  Stops the scheduler from running all scheduled events.

Segments

Pie Seg(<style>, {x, y}, radius, [values])

Description
  Creates a pie seg at the specified origin, with the specified radius, based on given values.

Required Arguments
  {x, y}  Specifies the x and y coordinates at which the pie seg is displayed.
  radius  Specifies the radius.
  values  Specifies the values specified in matrix format.

Optional Argument
  style  A quoted string that specifies the style: "Pie" (traditional pie chart with each slice sized by the Summary Statistic), "Ring" (each variable or level of a stratifying variable is represented by a concentric ring), or "Coxcomb" (the central angles for all slices are equal).

Sockets

skt<<Accept(<callback, timeout>)

Description
  Tells the server socket to accept a connection and return a new connected socket.
Returns
A list of up to four items. The first is a quoted string that echoes the command ("accept"). The second is a quoted string, either "ok" or an error. The third is a quoted string that specifies the name of the machine that just connected. The fourth is a reference to the socket that you can send more messages.

Optional Arguments

\textit{callback}  Specifies the name of a function to receive the data.

\textit{timeout}  If you use a \textit{callback}, \textit{timeout} specifies how long the function should wait for an answer. For a server socket, 0 is an acceptable value because a server should not shut down because no one has connected to it recently.

\begin{verbatim}
      skt<<bind(\textit{localhost}, \textit{port})
\end{verbatim}

Description
Associates a port on the local machine with the socket.

Returns
A list of two quoted strings. The first string is the command name ("bind") and the second is “ok” if successful or an error.

Required Arguments

\textit{localhost}  Specifies the quoted local machine. You cannot bind to another machine.

\textit{port}  Specifies the port that should be used.

\begin{verbatim}
      skt<<Close()
\end{verbatim}

Description
Closes a socket.

Returns
A list of two quoted strings. The first string is the command name ("close") and the second is “ok” if successful.

\begin{verbatim}
      skt<<Connect(\textit{socketname}, \textit{port})
\end{verbatim}

Description
Connects to a listening socket.

Returns
A list of two quoted strings. The first string is the command name ("connect") and the second is “ok” for a successful connection or an error sent back by the other socket.

Arguments

\textit{socketname}  Specifies the name of the other socket. If you are connecting to a web server, this is the web address (the name is preferred to the IP address).
port  Specifies the port of the other socket to connect through.

skt<<GetPeerName()

Description
Retrieves the address and port of the socket at the other end of the connection.

Returns
A list of four quoted strings. The first echoes the command ("getpeername"). The second is either “ok” or an error. The third and fourth are the address and the port.

skt<<Get Sock Name()

Description
Retrieves the address and port of the socket at this end of the connection.

Returns
A list of four quoted strings. The first echoes the command ("getsockname"). The second is either “ok” or an error. The third and fourth are the address and the port.

skt<<ioctl(FIONBIO, Boolean)

Description
Controls the socket’s blocking behavior.

Returns
A list of two quoted strings. The first string is the command name ("ioctl") and the second is “ok” if successful or an error.

Arguments
FIONBIO, 1 FIONBIO means Non-Blocking I/O. If true, turns on the behavior and the argument.

skt<<Listen()

Description
Tells the server socket to listen for connections.

Returns
A list of two quoted strings. The first echoes the command ("listen") and the second is "ok" or an error message.
skt<<recv(n, <callback, timeout>)

Description
Receives either a stream message (recv) or a datagram message (recvfrom) from the other socket. If the two optional arguments are used, the data is not received immediately. Instead, the data is received when the function callback is called.

Returns
A list of three quoted strings. The first string is the command name ("recv" or "recvfrom"). The second is "ok" if successful or an error message if not. The third string is the data that was received. If a callback function is used, a fourth element is the socket that was used in the original recv or recvfrom message.

Required Argument
n Specifies the number of bytes to receive from the other socket.

Optional Arguments
callback Specifies the name of a function to receive the data.
timeout If you use a callback, timeout specifies how long the function should wait for an answer.

skt<<Send(stream)

Description
Sends the data in the argument to the other socket. Send sends a stream and sendto sends a datagram.

Returns
A list of three quoted strings. The first string is the command name ("send" or "sendto"). The second is "ok" if successful or an error message if not. The third string is any portion of the stream that could not be sent, or empty if all the data was sent correctly.

Arguments
stream Specifies the command to send to the other socket.
dgram Specifies the command to send to the other socket.

Notes
Either argument might need to contain binary data. JMP represents non-printable ASCII characters with a tilde (~) followed by the hexadecimal number. For example,
skt<<send(("GET / HTTP/1.0~0d~0a~0d~0a");
sends a "get request" to an HTTP server.
obj<<Custom SQL(sql)

**Description**

Changes the query to a custom SQL query and sets the SQL.

**Required Argument**

*sql*  The quoted SQL query.

obj<<Generate SQL

Returns the SQL that the query generates when you run it.

obj<<Modify

Opens the query in Query Builder.

obj<<PostQueryScript(script as text)

Sets a JSL script that runs after the query finishes executing. *script as text* is quoted JSL code.

obj<<Query Name(<new name>)

Gets (without the *new name* argument) or sets (with the *new name* argument) the name of the query. The name of the query is used as the name of the data table that results from running the query.

obj<<Run("Private" | "Invisible"), <Update Table(table)>, <OnRunComplete(script)>, <OnRunCanceled(script)>, <OnError(script)>)

**Description**

Runs the SQL query in the background or foreground depending on the Query Builder preference “Run queries in the background when possible”.

**Returns**

Null (if the query runs in the background) or a data table (if the query runs in the foreground).

**Optional Named Arguments**

"Private"  A quoted keyword that opens the data table that the query produces without displaying it in a data table window. "Private" is available only if OnRunComplete is included in the script.
"Invisible" A quoted keyword that hides the data table that the query produces. Use this argument to keep the query result hidden but use it in a subsequent query. The data table is displayed in the Home Window’s Window List and the Window > Unhide list.

Update Table Updates the specified data table. Runs the query in the foreground.

OnRunComplete Specifies a script to run after the query is complete. To get the resulting data table, include OnRunComplete. The OnRunComplete script needs to be defined in the global namespace, as indicated by the double colons in this example:

Names Default To Here( 1 );
::onComplete = Function( {dt},
  {default local},
  Write(
    "\!NQuery is complete! Result name: \!"",
    dt << Get Name,
    "\!", Number of rows: ",
    N Rows( dt )
  )
);

query = Include( "rentals_fam_romcom.jmpquery" );
query << Run Background( On Run Complete( ::onComplete ) );

OnRunCanceled Specifies a script to run after the user cancels the query.

OnError Specifies a script to run if an error occurs.

Notes

If you want the data table that results from the background query, use the OnRunComplete optional argument. You can include a script that runs when the query completes and then assigns a data table reference to the resulting data table. Or you might pass the name of a function that accepts a data table as its first argument. That function is called when the query completes.

Examples

The following example opens a query that you previously saved from Query Builder. The query opens privately, that is, without opening Query Builder. The query runs, and the resulting data table opens.
query = Open( "c:/My Data/Movies.jmpquery", "Private" );
dt = query << Run();

You can include a .jmpquery file in a script and run the query in the background using the <<Run Background message.
query = Include( "C:/Queries/movies.jmpquery" );
query << Run Background();

The following example queries the database, opens the resulting data table, and prints the number of data table rows to the log.
confirmation = Function( {dtResult},
    Write( "\!NNumber of rows in query result: ", N Rows( dtResult ) )
);
query = New SQL Query(
    Connection( "ODBC:DSN=SQL Databases;APP=MYAPP;TrustedConnection=yes;WSID=D79255;DATABASE=SQB;" ),
    QueryName( "movies_to_update" ),
    Select( Column( "YearMade", "t1" ), Column( "Rating", "t1" ) ),
    From( Table( "g6_Movies", Schema( "SQB" ), Alias( "t1" ) ) ),
);
query << Run( OnRunComplete( confirmation ) );

Run Background(<OnRunComplete(script), <"Private"|"Invisible">>, <OnRunCanceled(script)>, <OnError(script)>)

Description
Runs the SQL query in the background. The running query is not displayed.

Returns
Null (or the data table object, if OnRunComplete is included).

Optional Named Arguments
OnRunComplete(script) Specifies a script to run after the query is complete. To get the resulting data table, include OnRunComplete. The OnRunComplete script needs to be defined in the global namespace, as indicated by the double colons in this example:
Names Default To Here( 1 );
::onComplete = Function( {dt},
    {default local},
    Write( "\!NQuery is complete!  Result name: \!"",
        dt << Get Name,
        "\!", Number of rows: ",
        N Rows( dt )
    )
);
query = Include( "rentals_fam_romcom.jmpquery" );
query << Run Background( On Run Complete( ::onComplete ) );

"Private" Does not open the resulting data table. Specify only with OnRunComplete. If you include private in a background query, JMP opens the data table as invisible instead.
"Invisible" Hides the data table. Use this argument to keep the query result hidden but use it in a subsequent query. The data table is displayed in the Home Window’s Window List and the Window > Unhide list.

**OnRunCanceled** Specifies a script to run after the user cancels the query.

**OnError** Specifies a script to run if an error occurs.

**Notes**

All queries except for SAS queries run in the background based on the Query Builder preference “Run the queries in the background when possible”, which is selected by default. For SAS queries, `Run Background()` is ignored.

You can include a `.jmpquery` file in a script and run the query in the background using the `Run Background` message.

```julia
query = Include( "C:/Queries/movies.jmpquery" );
query <<Run Background();
```

**Run Foreground**(`<OnRunComplete(script), <"Private"|"Invisible">>, <OnRunCanceled(script)>, <OnError(script)>`)  

**Description**  
Runs the SQL query in the foreground.

**Returns**  
A data table that opens when the query is finished.

**See Also**  
“`Run Background(<OnRunComplete(script), <"Private"|"Invisible">>, <OnRunCanceled(script)>, <OnError(script)>)`” on page 512

**obj«`Save`**  
Saves the query to its associated file. The save fails if the query does not yet have an associated file.

**obj«`Save As(path, <Replace Existing(Boolean)>)`**  
Saves the query to the specified file. If the file already exists, the save fails unless `Replace Existing` is true.
Other Objects

Zip Archives

```julia
list = za<<Dir
```

Returns a list of member names.

```julia
data = za<<Read(member name, <Format("blob")>)
```

Returns a quoted string that contains the entire quoted `member name`. A zip file consists of filenames, also called “member names”.

**Notes**

For remote files, JMP copies the URL data to the local disk. When the zip archive is no longer accessible, the local data file is deleted.

```julia
actualname = za<<Write(member name, member data, <"replace">)
```

Writes a quoted string or quoted blob to a zip archive member file. If the quoted `member name` isn't in the current zip file, the returned `actualname` is the same as `member name`. This member name will be changed to prevent overwriting an existing member; the name actually used is returned. The quoted `member data` argument is the data to write into the zip file’s member of that name. `replace` creates the file with a temporary name, deletes the old file, and renames the temporary file to the existing name.

Journals

```julia
jnl<<Save HTML(<path>, <format>)
```

Saves the journal as HTML.

**Optional Arguments**

"path" Specifies the quoted path for the saved HTML file (for example, "c:/myFile.html").

`format` Specifies the quoted graphic file format. JPG, PNG, and TIFF formats are supported. The graphics are saved in a subdirectory named `gfx`.

```julia
jnl<<Save RTF(<path>, <format>)
```

Saves the journal as an RTF file.

**Optional Arguments**

"path" Specifies the quoted path for the saved RTF file (for example, "c:/myFile.rtf").
"format" Specifies the quoted file format for the embedded graphics. "JPG", "PNG", and "EMF" formats are supported on Windows. All journals are saved as PDF files by default on macOS.

Notes
If no path or format are provided, you are prompted to name the file and specify the format on Windows. On macOS, you are prompted to name the file. The file is saved as a PDF file by default.

jnl<<Save PDF(<path>, <Show Page Setup(BOOLEAN)>, <Portrait(BOOLEAN)>)
Saves the journal as a PDF file.

Optional Arguments
"path" The quoted path for the saved PDF file (for example, "c:/myFile.pdf").
Show Page Setup If set to true, opens the Page Setup window to let the user change the margin, magnification level, and other page layout options.
Portrait Determines whether the page orientation is portrait or landscape. Overrides the user’s selection in the Show Page Setup window.
The Query() JSL function performs a SQL query on selected tables and exports the data to a data table. The following example first assigns the t1 alias to Big Class.jmp. name, age greater than 13, and height are then selected from the t1 table.

```javascript
dt = Open( "$SAMPLE_DATA/Big Class.jmp" );
Query( Table( dt, "t1" ),
      "SELECT t1.name, t1.age, t1.height FROM t1
       WHERE t1.age > 13" );
```

You can use SQL functions in a query. For example, SELECT CURRENT_TIMESTAMP returns the current UTC/GMT time stamp as a SQLite time string:

```javascript
Query( Scalar, "SELECT CURRENT_TIMESTAMP;" );
```

This appendix lists the numeric, date-time, string, system SQL, and aggregate functions that you can use in SQL queries. “Yes” in the SQLite column indicates native SQLite functions. See the Online SQLite documentation at https://www.sqlite.org/lang.html.

# Numeric SQL Functions

The numeric SQL functions are described here.

<table>
<thead>
<tr>
<th>Numeric Function</th>
<th>Native SQLite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ABS( number )</strong></td>
<td></td>
<td>Returns the absolute value of the specified number.</td>
</tr>
<tr>
<td><strong>ACOS( cosine )</strong></td>
<td></td>
<td>Returns the angle in radians for the specified cosine.</td>
</tr>
<tr>
<td><strong>ASIN( sin )</strong></td>
<td></td>
<td>Returns the angle in radians for the specified sine.</td>
</tr>
<tr>
<td><strong>ATAN( tangent )</strong></td>
<td></td>
<td>Returns the angle in radians for the specified tangent.</td>
</tr>
<tr>
<td><strong>ATAN2( x, y )</strong></td>
<td></td>
<td>Two-argument arctangent function.</td>
</tr>
<tr>
<td><strong>CEILING( number )</strong></td>
<td></td>
<td>Returns the smallest integer larger than the specified number.</td>
</tr>
<tr>
<td><strong>CEIL( number )</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>COS( radians )</strong></td>
<td></td>
<td>Returns the cosine of the specified angle in radians.</td>
</tr>
<tr>
<td><strong>COT( radians )</strong></td>
<td></td>
<td>Returns the cotangent of the specified angle in radians.</td>
</tr>
<tr>
<td><strong>DEGREES( radians )</strong></td>
<td></td>
<td>Converts an angle in radians to an angle in degrees.</td>
</tr>
<tr>
<td><strong>EXP( number )</strong></td>
<td></td>
<td>Returns the constant $e$ raised to the specified power.</td>
</tr>
<tr>
<td><strong>FLOOR( number )</strong></td>
<td></td>
<td>Returns the largest integer smaller than the specified number.</td>
</tr>
<tr>
<td><strong>LN( number )</strong></td>
<td></td>
<td>Returns the natural logarithm of the specified number.</td>
</tr>
<tr>
<td><strong>LOG( number )</strong></td>
<td></td>
<td>Returns the common logarithm of the specified number.</td>
</tr>
<tr>
<td><strong>LOG10( number )</strong></td>
<td></td>
<td>Returns the common logarithm of the specified number.</td>
</tr>
<tr>
<td><strong>MAX( n1, n2, ... )</strong></td>
<td>Yes</td>
<td>Returns the largest of the specified numbers. A minimum of two numbers must be specified.</td>
</tr>
<tr>
<td><strong>MIN( n1, n2, ... )</strong></td>
<td>Yes</td>
<td>Returns the smallest of the specified numbers. A minimum of two numbers must be specified.</td>
</tr>
<tr>
<td><strong>MOD( dividend, divisor )</strong></td>
<td></td>
<td>Returns the remainder when <strong>dividend</strong> is divided by <strong>divisor</strong>. Floating-point values are truncated to integers before the modulus operation is performed.</td>
</tr>
<tr>
<td><strong>PI()</strong></td>
<td></td>
<td>Returns the value of the constant pi ($\pi$).</td>
</tr>
<tr>
<td><strong>POWER( number, power )</strong></td>
<td></td>
<td>Raises <strong>number</strong> to the specified <strong>power</strong>.</td>
</tr>
<tr>
<td><strong>POW( number, power )</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Numeric Function</td>
<td>Native SQLite</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RADIANS( degrees )</td>
<td></td>
<td>Converts an angle in degrees to an angle in radians.</td>
</tr>
<tr>
<td>RANDOM()</td>
<td></td>
<td>Returns a random number. RANDOM() returns a number between 0 and 1. RANDOM( max ) returns a number between 0 and max. RANDOM( min, max ) returns a number between min and max. This function is equivalent to the Random Uniform() JSL function, and its seed can be controlled using the Random Reset() JSL function. RANDOM can be shortened to RAND.</td>
</tr>
<tr>
<td>RANDOMBLOB( length )</td>
<td>Yes</td>
<td>Returns an N-byte blob that contains pseudo-random bytes. See the SQLite Online documentation at <a href="https://www.sqlite.org/lang.html">https://www.sqlite.org/lang.html</a>.</td>
</tr>
<tr>
<td>ROUND( number, &lt;precision&gt; )</td>
<td></td>
<td>Rounds number to the number of decimal places given by &lt;precision&gt;. The default value of &lt;precision&gt; is 0, and &lt;precision&gt; can be negative.</td>
</tr>
<tr>
<td>SIGN( number )</td>
<td></td>
<td>Returns 1 if number is positive, -1 if number is negative, or 0 if number is zero.</td>
</tr>
<tr>
<td>SIN( radians )</td>
<td></td>
<td>Returns the sin of the specified angle in radians.</td>
</tr>
<tr>
<td>SQRT( number )</td>
<td></td>
<td>Returns the square root of number.</td>
</tr>
<tr>
<td>TAN( radians )</td>
<td></td>
<td>Returns the tangent of the specified angle in radians.</td>
</tr>
<tr>
<td>TRUNCATE( number, &lt;precision&gt; )</td>
<td></td>
<td>Truncates number at the number of decimal places given by &lt;precision&gt;. The default value of &lt;precision&gt; is 0, and &lt;precision&gt; can be negative. TRUNCATE() can be shortened to TRUNC().</td>
</tr>
</tbody>
</table>

**Date-Time SQL Functions**

Using date-time functions in JMP queries is complicated by the fact that the SQL engine that handles JMP queries (SQLite) uses different formats for storing dates than JMP does. SQLite stores date-times as strings. However, JMP stores date-times as the number of seconds since January 1, 1904. When you have columns in your table that contain date-times, the conversions are handled automatically. However, when you use functions that return date-times, you might need to let JMP know when a conversion is required.
Consider the CURRENT_TIMESTAMP function. CURRENT_TIMESTAMP is a built-in SQLite function that returns the current UTC/GMT time stamp as a SQLite time string:

```
Query( Scalar, "SELECT CURRENT_TIMESTAMP;" );
```

returns:

"2016-02-16 15:44:42"

The string could perhaps be parsed as a date to return it as a JMP date. To prevent the need to do so, wrap the CURRENT_TIMESTAMP function in the JMPDATE() function:

```
Query( Scalar, "SELECT JMPDATE( CURRENT_TIMESTAMP );" );
```

returns:

3538482531

The string is an unformatted JMP date. However, if you pass a SQLite time string to another SQL date-time function, you do not need to use JMPDate(); the value will be converted to a JMP date automatically. Here is an example:

```
Query( Scalar, "SELECT EXTRACT('YEAR', CURRENT_TIMESTAMP);" );
```

Using native SQLite date-time functions (date(), time(), datetime(), julianday(), strftime()) in JMP queries is not recommended because JMP date-time values are not compatible with those functions.

<table>
<thead>
<tr>
<th>Date-Time Function</th>
<th>Naive SQLite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_DATE</td>
<td>Yes</td>
<td>Returns the current date (UTC/GMT) as a SQLite time string.</td>
</tr>
<tr>
<td>CURRENT_TIME</td>
<td>Yes</td>
<td>Returns the current time (UTC/GMT) as a SQLite time string.</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP</td>
<td>Yes</td>
<td>Returns the current date and time (UTC/GMT) as a SQLite time string.</td>
</tr>
<tr>
<td>DATEDIFF( date1, date2, interval, &lt;alignment = &quot;Start&quot;&gt; )</td>
<td></td>
<td>Computes the difference between two dates in units specified by interval, based on alignment. This function works the same as the Date Difference() JSL function. Valid values for interval are: “Year”, “Quarter”, “Month”, “Week”, “Day”, “Hour”, “Minute” and “Second”. Valid values for alignment are “Start”, “Actual” and “Fractional”. If alignment is not specified, “Start” is used.</td>
</tr>
<tr>
<td>Date-Time Function</td>
<td>Naive SQLite</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>EXTRACT( <em>datepart</em>, <em>datetime</em>, <em>&lt;use_locale = 1&gt;</em> )</td>
<td></td>
<td>Extracts a specific part of a date or date-time value. <em>Datet ime</em> is a JMP date-time value or a SQLite time string. <em>Use_locale</em> is optional and applies only to date name parts such as &quot;MonthName&quot; and &quot;DayName&quot; and determines whether values from the current language or English are returned. The following values of <em>datepart</em> are supported:</td>
</tr>
<tr>
<td>&quot;Year&quot;</td>
<td>Returns the year as a number.</td>
<td></td>
</tr>
<tr>
<td>&quot;Month&quot;</td>
<td>Returns the numeric month (1-12).</td>
<td></td>
</tr>
<tr>
<td>&quot;MonthName&quot;</td>
<td>Returns the full name of the month in the current language (<em>use_locale = 1</em>) or English (<em>use_locale = 0</em>).</td>
<td></td>
</tr>
<tr>
<td>&quot;Mon&quot;, &quot;MMM&quot;</td>
<td>Returns the abbreviated name of the month.</td>
<td></td>
</tr>
<tr>
<td>&quot;Day&quot;</td>
<td>Returns the day of the month (1-31).</td>
<td></td>
</tr>
<tr>
<td>&quot;DayName&quot;</td>
<td>Returns the name of the day of the week.</td>
<td></td>
</tr>
<tr>
<td>&quot;DayOfWeek&quot;</td>
<td>Returns the numeric day of the week (1-7).</td>
<td></td>
</tr>
<tr>
<td>&quot;DayOfYear&quot;</td>
<td>Returns the numeric day of the year (1-366).</td>
<td></td>
</tr>
<tr>
<td>&quot;Quarter&quot;</td>
<td>Returns the numeric quarter (1-4).</td>
<td></td>
</tr>
<tr>
<td>&quot;Hour&quot;</td>
<td>Returns the hour (0-23).</td>
<td></td>
</tr>
<tr>
<td>&quot;Minute&quot;</td>
<td>Returns the minute (0-59).</td>
<td></td>
</tr>
<tr>
<td>&quot;Second&quot;</td>
<td>Returns the seconds, including any fractional part.</td>
<td></td>
</tr>
<tr>
<td>&quot;Date&quot;</td>
<td>Returns just the date portion of a date-time value as a JMP date-time value.</td>
<td></td>
</tr>
<tr>
<td>&quot;Time&quot;</td>
<td>Returns just the time portion of a date-time value as a JMP date-time value.</td>
<td></td>
</tr>
<tr>
<td>JMPDATE( <em>SQLite time string</em> )</td>
<td></td>
<td>Converts a SQLite time string to the equivalent JMP date-time value.</td>
</tr>
<tr>
<td>NOW()</td>
<td>A synonym for TODAY().</td>
<td></td>
</tr>
<tr>
<td>TODAY()</td>
<td>Returns the JMP date-time value of the current moment in local time, which matches the JMP Today() function.</td>
<td></td>
</tr>
</tbody>
</table>
## String SQL Functions

The string SQL functions are described here.

<table>
<thead>
<tr>
<th>Function</th>
<th>Native SQLite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>HEX( binary )</code></td>
<td>Yes</td>
<td>SQLite built-in function that converts a BLOB to a string of hexadecimal characters. Useful when paired with the <code>RANDOMBLOB()</code> function.</td>
</tr>
<tr>
<td><code>JLEFT( string, len, &lt;pad&gt; )</code></td>
<td></td>
<td>Like the JSL <code>Left()</code> function. Returns <code>len</code> characters from the beginning of <code>string</code>. If <code>pad</code> is specified and fewer than <code>len</code> characters are present in <code>string</code>, the result is padded with <code>pad</code> out to length <code>len</code>.</td>
</tr>
<tr>
<td><code>JRIGHT( string, len, &lt;pad&gt; )</code></td>
<td></td>
<td>Like the JSL <code>Right()</code> function. Returns <code>len</code> characters from the end of <code>string</code>. If <code>pad</code> is specified and fewer than <code>len</code> characters are present in <code>string</code>, the result is padded with <code>pad</code> at the front out to length <code>len</code>.</td>
</tr>
<tr>
<td><code>LENGTH( string )</code></td>
<td>Yes</td>
<td>SQLite equivalent of the ANSI standard <code>CHAR_LENGTH()</code> function. Returns the length of its string argument in characters.</td>
</tr>
<tr>
<td><code>LOCATE( string1, string2 )</code></td>
<td>Position( string1, string2 )</td>
<td>Returns the (1-based) starting position of <code>string1</code> within <code>string2</code>, returning 0 if <code>string1</code> is not found within <code>string2</code>.</td>
</tr>
<tr>
<td><code>LOWER( string )</code></td>
<td></td>
<td>Returns a copy of <code>string</code> with all uppercase characters converted to lowercase.</td>
</tr>
<tr>
<td><code>LTRIM( string, &lt;trimchars&gt; )</code></td>
<td>Yes</td>
<td>Trims any characters contained in <code>trimchars</code> from the beginning of <code>string</code> and returns the result. If <code>trimchars</code> is omitted, spaces are trimmed.</td>
</tr>
<tr>
<td><code>PRINTF( format, &lt;arg1, ..., argN&gt; )</code></td>
<td>Yes</td>
<td>Allows constructing strings using placeholders and arguments. See the SQLite Online documentation at <a href="https://www.sqlite.org/lang.html">https://www.sqlite.org/lang.html</a>.</td>
</tr>
<tr>
<td><code>REPLACE( string, find, replace )</code></td>
<td>Yes</td>
<td>Replaces all instances of <code>find</code> in <code>string</code> with <code>replace</code> and returns the result. If <code>replace</code> is numeric, it is converted to a string.</td>
</tr>
<tr>
<td><code>REVERSE( string )</code></td>
<td></td>
<td>Returns a copy of <code>string</code> with the order of the characters reversed.</td>
</tr>
</tbody>
</table>
Aggregate SQL Functions

When passing a single argument to an aggregate function, that argument can be preceded by the keyword DISTINCT, which filters out duplicate values.

For all aggregations other than \( \text{COUNT}(\,\ast\,\)\), NULL and missing values are ignored.

---

### System SQL Functions

The system SQL functions are described here.

<table>
<thead>
<tr>
<th>Function</th>
<th>SQLite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COALESCE( ( \text{arg}_1,\ldots,\text{arg}_N ) )</td>
<td>Yes</td>
<td>Returns the first argument passed to it that is non-NULL. Returns NULL if all arguments are NULL. Requires at least two arguments.</td>
</tr>
<tr>
<td>IFNULL( ( \text{arg}_1, \text{arg}_2 ) )</td>
<td>Yes</td>
<td>Returns ( \text{arg}_1 ) if not NULL, otherwise ( \text{arg}_2 ). Basically, IFNULL is a two-argument version of COALESCE().</td>
</tr>
<tr>
<td>NULLIF( ( \text{arg}_1, \text{arg}_2 ) )</td>
<td>Yes</td>
<td>Returns ( \text{arg}_1 ) if ( \text{arg}_1 ) and ( \text{arg}_2 ) are different and returns NULL if the arguments are equal. Used when you have non-NULL values in your database that you want to treat as NULL.</td>
</tr>
</tbody>
</table>

---

### Aggregate SQL Functions

Trims any characters contained in \( \text{trimchars} \) from the end of \( \text{string} \) and returns the result. If \( \text{trimchars} \) is omitted, spaces are trimmed.

Returns a string consisting of \( \text{length} \) space characters.

Returns the substring of \( \text{string} \) starting at \( \text{start} \) (1-based) that is \( \text{length} \) characters long. If \( \text{length} \) is omitted, the substring starting at \( \text{start} \) and continuing to the end of \( \text{string} \) is returned.

Trims any characters contained in \( \text{trimchars} \) from the end of \( \text{string} \) and returns the result. If \( \text{trimchars} \) is omitted, spaces are trimmed.

Returns a copy of \( \text{string} \) with all lowercase characters converted to uppercase.
### Aggregate SQL Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>SQLite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AVG( num_expr )</strong></td>
<td></td>
<td>Computes the average of num_expr for the rows in the group. Num_expr must be numeric.</td>
</tr>
<tr>
<td><strong>COUNT( expr )</strong></td>
<td></td>
<td>Counts the number of times expr is not NULL in the group. COUNT( * ) returns the total number of rows in the group.</td>
</tr>
<tr>
<td><strong>COUNT( * )</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>GROUP_CONCAT( expr, &lt;separator = ',','&gt; )</strong></td>
<td>Yes</td>
<td>Concatenates all non-NULL values of expr and returns them as a string. Numeric values of expr are converted to character. If separator is present, it is placed between the values. The default separator is a comma. DISTINCT can be used only with GROUP_CONCAT() if separator is not specified.</td>
</tr>
<tr>
<td><strong>MAX( expr )</strong></td>
<td></td>
<td>Returns the maximum value of expr in the group. Expr can be character or numeric.</td>
</tr>
<tr>
<td><strong>MIN( expr )</strong></td>
<td></td>
<td>Returns the minimum value of expr in the group. Expr can be character or numeric.</td>
</tr>
<tr>
<td><strong>STDDEV_POP( num_expr )</strong></td>
<td></td>
<td>Computes the population standard deviation of num_expr for the group.</td>
</tr>
<tr>
<td><strong>STDDEV_SAMP( num_expr )</strong></td>
<td></td>
<td>Computes the sample standard deviation of all num_expr for the group.</td>
</tr>
<tr>
<td><strong>SUM( num_expr )</strong></td>
<td></td>
<td>Returns the sum of num_expr for the group. If no non-NULL values are found, SUM() returns NULL.</td>
</tr>
<tr>
<td><strong>TOTAL( num_expr )</strong></td>
<td>Yes</td>
<td>Same as SUM( num_expr ), except TOTAL() returns 0.0 if no non-NULL values are found.</td>
</tr>
<tr>
<td><strong>VAR_POP( num_expr )</strong></td>
<td></td>
<td>Computes the population variance of num_expr for the group.</td>
</tr>
<tr>
<td><strong>VAR_SAMP( num_expr )</strong></td>
<td></td>
<td>Computes the sample variance of num_expr for the group.</td>
</tr>
</tbody>
</table>

You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
– You must give any other recipients of the Work or Derivative Works a copy of this License; and

– You must cause any modified files to carry prominent notices stating that You changed the files; and

– You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

– If the Work includes a “NOTICE” text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

– You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.
